Abstract

Background: Artificial intelligence is experiencing rapid growth, with continual innovation and advancements in the health care field.

Objective: This study aims to evaluate the application of artificial intelligence technologies across various domains of respiratory care.

XSL•FO
RenderX

Methods: We conducted a narrative review to examine the latest advancements in the use of artificial intelligence in the field of respiratory care. The search was independently conducted by respiratory care experts, each focusing on their respective scope of practice and area of interest.

Results: This review illuminates the diverse applications of artificial intelligence, highlighting its use in areas associated with respiratory care. Artificial intelligence is harnessed across various areas in this field, including pulmonary diagnostics, respiratory care research, critical care or mechanical ventilation, pulmonary rehabilitation, telehealth, public health or health promotion, sleep clinics, home care, smoking or vaping behavior, and neonates and pediatrics. With its multifaceted utility, artificial intelligence can enhance the field of respiratory care, potentially leading to superior health outcomes for individuals under this extensive umbrella.

Conclusions: As artificial intelligence advances, elevating academic standards in the respiratory care profession becomes imperative, allowing practitioners to contribute to research and understand artificial intelligence's impact on respiratory care. The permanent integration of artificial intelligence into respiratory care creates the need for respiratory therapists to positively influence its progression. By participating in artificial intelligence development, respiratory therapists can augment their clinical capabilities, knowledge, and patient outcomes.

Introduction

Background

Artificial intelligence is a sophisticated branch of computer science and engineering endowed with the capability to perform intricate data analysis, demonstrating a computational understanding of intelligent behavior [1]. Alan Turing first introduced the concept of simulating intelligent behavior with computers in 1950, including a test to assess whether machines can imitate human intelligence. Later, John McCarthy defined "artificial intelligence" as creating intelligent machines [2]. Artificial intelligence has evolved from simple rules to complex algorithms similar to human intelligence, with various specializations such as machine learning (ML), which uses patterns for decision-making and can be applied dynamically to customize patient care. Moreover, ML has progressed into a more complex form known as deep learning (DL), which uses algorithms to construct artificial neural networks (ANNs) [2]. These ANNs can independently learn and make decisions, emulating human brain functionality. On the other hand, computer vision enables a computer to interpret and comprehend data from images or videos [2]. It is notable that avoidable medical errors are the third leading cause of death in the United States, causing >400,000 deaths annually [3]. Therefore, integrating the use of artificial intelligence into the health care field may have strong positive outcomes [4].

Artificial intelligence pertains to computer systems that have the ability to carry out tasks that are typically exclusive to human intelligence, including visual and speech recognition, decision-making, and language translation [5]. Artificial intelligence systems use techniques such as ML and DL to learn from multiple layers of digital data. ML is a subset of artificial intelligence that involves teaching computer algorithms to acquire knowledge from information and make forecasts or choices without being directly programmed [5]. DL is a subset of ML, which involves training deep neural networks to learn from large datasets that consist of >3 layers and has been particularly successful in tasks such as image and speech

recognition [5]. Supervised learning, or supervised ML, involves teaching an algorithm how to map inputs to outputs based on labeled training data, whereas unsupervised learning involves discovering patterns and relationships from unlabeled data [4,6]. Reinforcement learning, where an agent learns by making decisions based on feedback from its environment, has been applied in video game playing or robotics [5,7]. Similar applications can be drawn or applied to the field of medicine [4].

In fact, various artificial intelligence methods, including fuzzy expert systems, Bayesian networks, ANNs, and combined intelligent systems, have been implemented across various medical environments in health care. Specifically, artificial intelligence applications are crucial in health care as they assist clinicians in delivering comprehensive health care services to diverse patient populations with various health conditions [4,8].

In this paper, we conduct a narrative review and provide an in-depth summary of the latest advancements in artificial intelligence as it applies to various scopes of practice within the field of respiratory care. Furthermore, we provide a detailed discussion about the substantial benefits that accompany the implementation and integration of such tools within respiratory care methodologies for clinical purposes. Within this context, we evaluate the progression and application of artificial intelligence, highlighting its relevance across various areas within the field of respiratory care. Experts from various disciplines, based on their areas of expertise and research backgrounds, provided insights and summaries regarding the recent emergence and potential use of artificial intelligence in different aspects of respiratory care: pulmonary diagnostics, respiratory care research, critical care and mechanical ventilation, pulmonary rehabilitation, telehealth, public health and health promotion, sleep clinics, home care, smoking or vaping behavior, and neonates and pediatrics.

Objectives

The primary aim of this review was to synthesize existing research and expert opinions to assess the current and potential

impacts of artificial intelligence technologies on respiratory care practices.

Methods

This is a narrative review aimed at capturing the broad spectrum of artificial intelligence applications within respiratory care. The focus was on identifying artificial intelligence's contributions across several key areas (eg, pulmonary diagnostics, respiratory care research, and critical care or mechanical ventilation).

To ensure comprehensive coverage, each domain was independently explored, with the MEDLINE database serving as the primary source of literature; a narrative literature search was performed in MEDLINE and Embase databases via the Ovid portal to select studies that met the inclusion criteria. We included studies that were published in English with full text available, without restrictions on publication date. This review focused on articles discussing the application of artificial intelligence in key respiratory care areas as indicated in their titles or abstracts. Multimedia Appendix 1 provides more information regarding the search terms.

Results

This review identified key artificial intelligence applications in respiratory care. Each of the following sections highlights artificial intelligence's role and potential advancements in these aspects of respiratory care.

Artificial Intelligence in Pulmonary Diagnostics

Advanced technologies such as artificial intelligence, precise ML, and DL have been proposed and harnessed for an array of clinical applications in respiratory care, notably in the realms of pulmonary imaging and pulmonary function tests (PFTs) [9-11]. In addition, certain clinical, ethical, and usability challenges are inherently associated with the implementation of artificial intelligence in the sphere of respiratory care [12].

Artificial Intelligence Applications in Chest Imaging

Artificial intelligence applications are frequently used in conjunction with chest x-rays, computed tomography (CT), and magnetic resonance imaging. By leveraging artificial intelligence, we can analyze specific regions in these images, calculate volumes, and extract features with remarkable speed and accuracy. When integrated with ML models, artificial intelligence can assist greatly in quantifying and categorizing image characteristics. For respiratory care practitioners (RCPs), chest x-rays are an essential tool commonly used in critical settings to screen for and interpret pulmonary pathologies. ML models have been used to evaluate chest x-rays, particularly in the diagnosis of COVID-19. For instance, a previous review reported that ML models were used to predict the prognosis of patients with COVID-19 based on chest x-ray analysis [13]. In addition, another ML model demonstrated commendable performance, with a sensitivity of 78% (95% CI 74%-81%) and a specificity of 82% (95% CI 78%-85%) [14]. This highlights the tremendous potential of artificial intelligence in assessing

x-rays, enabling clinicians to make evidence-based decisions, and offering a cost-effective solution.

Artificial Intelligence Applications in PFTs

PFTs represents one of the crucial responsibilities of RCPs, requiring appropriate training to yield reliable results. Indeed, effective coaching for RCPs is necessary to proficiently administer standard PFTs and derive key indicators, such as the forced vital capacity (FVC), forced expiratory volume in the first second, and forced expiratory volume in the first second/FVC ratio. Moreover, these indexes are evaluated and reported using percentage predicted values, with abnormalities defined by fixed cutoff values. It is important to note that these values have been reported to be influenced by variables such as age and height [15]. Consequently, as PFTs can be reported numerically and reference values are widely available for numerous testing methodologies, ML models could serve as effective tools for evaluating lung function tests. This assertion is supported by a previous multicenter study, which compared a trained ML model with pulmonologists. The ML model was found to outperform pulmonologists in detecting physiological patterns and diagnosing pulmonary diseases [16]. This exemplifies a compelling application of ML to assist clinicians in optimizing diagnostic accuracy through the use of ML-trained data. In addition, ML models have been used to detect poor FVC maneuvers [17]. This could significantly aid practitioners in smaller, rural, or nonspecialist clinics by enabling them to evaluate the maneuver before interpreting the results. Notably, it has been previously highlighted that spirometry maneuvers in general practitioners' clinics tend to be inaccurate [18].

Despite the availability of robust reference ranges for various ethnic and age groups, spirometry remains underused [19,20]. This deficiency may also be attributed to a lack of trained RCPs to administer this test. By using ML models trained to identify pulmonary pathologies, a cost-effective health care model for pulmonary care can be established, thus aiding in evidence-based clinical decision-making. Indeed, objective physiological pulmonary tests were reported to be underused in advanced health care services [20].

Artificial Intelligence Applications in Pulmonary Disease Management

Artificial intelligence and innovative technology offer various ways to enhance personal adherence to therapy, with smart inhalers being a prime example [21,22], and allow for early detection of worsening in chronic pulmonary disease [23,24]. Furthermore, wearable biomedical sensors, for example, can measure physiological parameters and assist in identifying cases of asthma exacerbations and symptoms of worsening chronic obstructive pulmonary disease (COPD) episodes [23,25]. Wearable sensors can also identify environmental parameters, which can be used to create air quality maps, benefiting patients with atopic asthma [26]. Moreover, in the case of COPD, scattered data from PFTs and other medical investigations have enabled the generation of accurate COPD diagnoses and minimized misdiagnoses of asthma as both conditions share symptoms, such as airflow limitations [27,28]. These examples highlight personalized care that focuses on individualized traits

to enhance respiratory disease management and alleviate its burden.

In summary, artificial intelligence offers significant potential in pulmonary diagnostics, enhancing accuracy in chest imaging and PFTs. While it improves decision-making and efficiency, challenges such as ethical concerns and the need for trained practitioners remain.

Artificial Intelligence in Respiratory Care Research

Overview

The field of artificial intelligence is rapidly evolving, driven by continuous innovation and research advancements. As a result, the applications of artificial intelligence and ML have expanded to include diverse areas, such as statistical analysis, literature searches, and manuscript preparation for publication [29,30]. In this context, we compiled and analyzed evidence pertaining to artificial intelligence applications in respiratory care research.

Applications of Artificial Intelligence in Respiratory Care Research

Artificial intelligence is used to gather, store, access, and analyze data, including large and complex datasets [31,32]. It has proven effective in analyzing data that might otherwise be too time-consuming or require hiring external experts and analysts to evaluate [31]. Furthermore, researchers continue to develop new ML techniques for various applications in scientific research. These techniques help convert raw data into valuable insights, make predictions, categorize information, and enable highly informed decision-making through innovative approaches [33]. Researchers have also adopted novel technologies such as blockchain to support artificial intelligence research, particularly in critical fields such as medicine [34]. Finally, the rapid growth of artificial intelligence and ML in respiratory care research makes it challenging to provide a comprehensive overview of these evolving technologies.

Functions of Artificial Intelligence in Respiratory Care Research

Analysis

Artificial intelligence enables faster data analysis compared to traditional methods, which typically rely on human-driven sequential procedures for data checking, cleaning, and analysis. Artificial intelligence also enhances the efficiency of filtering and extracting information from datasets [31]. Moreover, artificial intelligence can provide highly accurate results, increasing the reliability of the data and the overall rigor of the research. These technologies are less prone to human errors, resulting in a lower margin of error than human analysis [31].

Rapid Advancements

ML software, applications, and techniques gather information and adjust their operations to improve performance on a given task. For example, search engines use user interactions and search histories to deliver results tailored to the user's specific interests. These ML techniques allow artificial intelligence to continuously improve at an accelerated pace [2].

Data Handling

This is a crucial aspect of the research process. Effective data gathering, storage, and accessibility are invaluable tools for researchers. The researchers recognize the importance of cleaning the data before conducting analysis. Artificial intelligence uses various tools and approaches to safeguard collected data from unauthorized access and ensure their long-term storage without accidental tampering, preserving them for future use [31].

Role of Artificial Intelligence in Respiratory Care Research

Decision-Making

Artificial intelligence is a unique and exciting field within ML that seeks to bridge the gap between humans and machines. This technology focuses on improving how artificial intelligence clearly explains and translates information to users, enabling them to make more informed decisions [35]. Advancements in this technology enable machines to more easily predict the outcomes of actions and decisions for users. Consequently, researchers may use artificial intelligence to assess parameters before making decisions, ultimately enhancing the quality of their research.

Imaging

Artificial intelligence has improved the capture and analysis of different types of images [36]. This can further identify pathologies and remarks of various respiratory disease by providing accurate and consistent information. These images can be used for clinical and research purposes.

Diagnosis

Researchers have validated the high accuracy of artificial intelligence in diagnosing various respiratory conditions and diseases [37]. These technologies can reduce health care providers' workloads without compromising the quality of care. Such achievements are acknowledged by the scientific community for enhancing the incorporation of artificial intelligence within the health care sector.

In summary, artificial intelligence represents the next frontier in respiratory care and medical research. While artificial intelligence has already made significant progress, its future promises even greater potential, particularly in areas such as generalization, understanding, data efficiency, transparency, ethical decision-making, emotional intelligence, robustness, and real-time learning. These developments will continue to enhance research and problem-solving across various fields.

Artificial Intelligence in Critical Care or Mechanical Ventilation

The field of critical care medicine is experiencing significant transformations with the integration of artificial intelligence technologies. Artificial intelligence has proven effective in predicting various clinical outcomes, such as sepsis [38], circulatory failure [39], and mortality rates [40]. Since the 1970s, artificial intelligence and ML have played a pivotal role in mechanical ventilation. An early application, the ventilator manager monitoring system [41], assists clinicians by

summarizing the patient's physiological status, detecting adverse events, suggesting corrective actions, and recommending adjustments to ventilatory therapy based on long-term assessments. It also identifies measurement errors and helps maintain patient-specific goals for ongoing evaluation. Another example, the VQ-ATTENDING system [42], evaluates and provides feedback on ventilator settings to ensure their appropriateness. Furthermore, Ganzert et al [43] emphasized that ML and data-mining techniques provide an objective means to analyze the pressure-volume loop obtained through various methods, enhancing clinical decision-making in critical care environments.

Many mechanical ventilation modes do not strictly use artificial intelligence or traditional ML. Instead, they are primarily closed-loop ventilation modes, such as automated ventilation, that use advanced feedback control systems. These systems automatically adjust ventilator settings based on the patient's pulmonary mechanics, using complex mathematical models to optimize respiratory support [44]. A detailed summary of these automated ventilation algorithms is presented in Table 1 [45]. The significant advancements in software and the power of multi-microprocessors have facilitated an increase in the variety and complexity of ventilation modes [44,45]. Currently, there are almost 500 different names for commercial modes derived from 55 distinct ventilators. However, a taxonomy classification reveals that only 74 of these modes are truly unique [46]. Recent data [44] demonstrate that, in patients with moderate to severe acute respiratory distress, the closed-loop ventilation mode, specifically INTELLiVENT–adaptive support ventilation (ASV), resulted in lower transpulmonary driving pressures, inspiratory pressures, and respiratory rates while increasing tidal volume compared to conventional ventilation. INTELLiVENT-ASV automatically sets and adjusts tidal volume, respiratory rate, positive end-expiratory pressure, and the fraction of inspired oxygen to minimize the work and force of breathing. This mode operates based on measured physiological parameters such as end-tidal carbon dioxide and oxygenation saturation, as well as user-defined maximum limits (eg, maximum pressure limit) [45]. Another randomized controlled trial by De Bie et al [47] indicated that, in patients undergoing cardiac surgery, INTELLiVENT-ASV led to 30% more time spent using optimal ventilation settings, 2.5% less exposure time to injurious ventilation, significantly reduced risk of severe hypoxemia (risk ratio=0.26, 95% CI 0.22-0.31), and faster assumption of spontaneous breathing (hazard ratio=1.38, 95% CI 1.05-1.83) compared to conventional ventilation.

Artificial intelligence has the potential to facilitate individualized mechanical ventilation by using comprehensive patient and population data alongside continuous monitoring. A recent systematic review exploring artificial intelligence applications in mechanical ventilation identified its most prevalent uses: predicting weaning success, initiating mechanical ventilation, detecting ventilation complications, and recognizing patient-ventilator asynchrony. However, most of the studies in this review exhibited significant bias, and as they were retrospective single-center studies, they suffered from limited external validity [48]. Moreover, extensive research has used computational modeling to provide a mechanistic understanding of respiratory pathophysiology [49,50] and optimize ventilator settings [51-53]. These studies underscore the depth and range of analytical strategies that can enhance the efficacy and personalization of mechanical ventilation.

The Better Care system is not a ventilation mode but a closed-loop monitoring system that uses an algorithm to continuously assess a patient's respiratory effort. It detects and quantifies ineffective efforts, providing real-time feedback to clinicians. The system's effectiveness has been validated for accuracy against experienced clinicians, showing high sensitivity and specificity in detecting ineffective respiratory efforts [54]. The implications of these capabilities are significant for patient outcomes. For instance, a study highlighted that desynchronization during mechanical ventilation is common and is associated with increased mortality [55]. In addition, an innovative detection tool within the system has been developed to automatically identify and quantify reverse triggering events, a prevalent issue. This algorithm demonstrated high sensitivity and specificity in comparison to manual detection by 3 experienced clinicians [56].

Despite the potential benefits of artificial intelligence, several limitations warrant careful consideration. One major limitation is the need for large volumes of high-quality data to effectively train artificial intelligence algorithms. In respiratory care, data collection is often time-consuming, and variability in data collection and recording practices can pose significant challenges. Another critical issue is the potential for bias within artificial intelligence algorithms, which can lead to inaccurate predictions or recommendations, as highlighted by Obermeyer et al [57]. It is essential to ensure that the deployment of artificial intelligence technologies adheres to ethical standards and responsible practices to mitigate potential harms or negative consequences. This includes promoting transparency and accountability in artificial intelligence development and use, addressing concerns such as bias and discrimination, protecting individual privacy and security, and ensuring that artificial intelligence technologies contribute positively to humanity [57,58]. Furthermore, it is crucial that respiratory therapists (RTs) are equipped with the necessary skills, training, and knowledge to effectively interact with and interpret the outputs of artificial intelligence algorithms. This training will enable them to integrate artificial intelligence insights into clinical decision-making processes effectively. In brief, the potential of artificial intelligence in mechanical ventilation relies on overcoming challenges such as data quality and algorithmic bias and on ensuring ethical use.

Table 1. A summary of some of the currently available algorithms for intensive care unit mechanical ventilators [45].

Algorithm	Description	Benefits	Limitations	Year introduced
PAV+[a] by Medtronic	Delivers inspiratory assistance proportional to patient effort.	Improves patient-ventilator synchrony, may reduce sedation requirements, and better matches patients' respiratory drive.	• Requires additional monitoring. • May not be suitable for patients with unstable respiratory drive, dynamic hyperinflation, or air leak.	1992
ASV[b] by Hamilton	Automatically regulates tidal volume and respiratory rate based on the set minute ventilation and lung mechanics.	Simplifies ventilator management, improves patient-ventilator synchrony, and reduces time on a ventilator.	• May not be suitable for patients with severe lung injury or increased airway resistance.	1998
NAVA[c] by Maquet	Delivers assistance proportional to patients' diaphragmatic electrical activity.	Improves patient-ventilator synchrony, may reduce sedation requirements, and allows for more precise and personalized ventilation.	• Requires specialized equipment and training. • May not be suitable for patients with certain neurological or neuromuscular conditions.	2002
VTV[d], available from many manufactures	Targets a specific tidal volume via titrating the inspiratory pressure.	Prevents lung injury and simplifies ventilator management.	• May not be suitable for patients with unstable lung mechanics, leaks, or varying respiratory demand.	__e
Auto-release feature in APRV[f] by Dräger	The duration of the lower pressure is automatically adjusted to terminate expiration at a certain percentage of peak expiratory flow set by the user.	Creates appropriate intrinsic PEEP[g] to prevent lung derecruitment, leading to improved oxygenation and reduced VQ mismatch.	• May require frequent adjustments and monitoring. • More studies are needed to determine its long-term efficacy and safety.	—
Auto-Trak by Philips	NIV[h] advanced algorithm to optimize patient-ventilator synchrony	Accurate detection of inspiratory efforts while a leak is present, dynamic adaptation to changing patterns, and adjustment of pressure support effectively	• Effectiveness varies with patients. • May require fine-tuning. • Requires skilled health care professional supervision. Influenced by sensor integrity. • Not for invasive ventilation.	—
INTELLiVENT-ASV by Hamilton	Automatically adjusts V_T[i], RR[j], PEEP, and FiO_2[k] aiming to lower the work and force of breathing.	Personalized and protective ventilation, reduced clinician workload, and a faster weaning process	• Complexity, limited data inputs, restricted human judgment, and limited validation in certain populations	2011

[a]PAV+: proportional assist ventilation.

[b]ASV: adaptive support ventilation.

[c]NAVA: neurally adjusted ventilatory assist.

[d]VTV: volume-targeted ventilation.

[e]Not reported.

[f]APRV: airway pressure release ventilation.

[g]PEEP: positive end-expiratory pressure.

[h]NIV: non-invasive ventilation.

[i]V_T: tidal volume.

[j]RR: respiratory rate.

[k]FiO_2: fraction of inspired oxygen.

Artificial Intelligence in Pulmonary Rehabilitation

The advent of technology has ushered in a new era in which DL and ML are increasingly recognized as vital tools for enhancing the accuracy and quality of health care delivery [59]. These technologies have found multiple applications in the medical field, ranging from speech recognition for detecting changes in breathing patterns to the diagnosis of post–COVID-19 condition, cancer, and COPD [60-63]. Moreover, artificial intelligence has been instrumental in developing tailored exercise programs for sports and weightlifting based on extensive data analysis of tracked vitals, exercise patterns, intensity, and physical limitations [64,65]. Exercise is a critical component of rehabilitation in respiratory

health care, as noted by Jones et al [66]. The integration of web-based exercise programs has made rehabilitation more accessible, allowing therapists and patients to engage more efficiently [67]. Pulmonary rehabilitation for patients with muscular impairments and injuries or COPD includes using methods such as neuromuscular stimulation of different muscles for exercises and inspiratory muscle training to improve the physical state [68]. These exercises adhere to established standards that guide clinicians in delivering electrical stimulation as part of conventional care. However, artificial intelligence has the potential to transform this domain by offering more precise rehabilitation programs tailored to individual needs after discharge or for those requiring specific respiratory or neuromuscular stimulations. Adjusting pulse amplitude and frequency through artificial intelligence can enable clinicians to prescribe these interventions with reduced effort and ensure uniformity in treatment parameters [69,70].

Nevertheless, artificial intelligence's role in rehabilitation extends to integrating programs that control neuromuscular stimulation delivery and provide the necessary parameters. This integration could aid in enhancing strength and tolerance through individualized breathing exercises tailored to each patient's condition. In addition, the care regimen includes both invasive and noninvasive mechanical ventilation to support and manage breathing for patients who are critically ill or chronically dependent, requiring continuous monitoring and adjustments as needed. Deep ML holds significant promise in intensive care units, wards, and outpatient clinics. It can be used to conduct tests (eg, of pulmonary function) to monitor breathing patterns, analyze captured wave data, and recommend or adjust the delivery mode and settings optimally for various situations. This ensures precision and proper interpretation and aims for a more personalized treatment approach, facilitating the rehabilitation process [16,71]. For these reasons, rehabilitation is a crucial phase in any patient's recovery and management of their condition, significantly influencing their physical, emotional, and social engagement with family, friends, and society [72].

Hence, using artificial intelligence can facilitate access to tailored respiratory or physical exercises devised through the automated analysis of various health markers. These exercises can be personalized using data collected at home via portable devices, smartphones, or wearables, which capture live data and store them in a cloud. This setup allows both practitioners and patients to access the information remotely. Artificial intelligence can also be leveraged to determine the optimal times for medication intake, relaxation, and sleep through continuous monitoring—all crucial for enhancing patient outcomes and

improving overall health care delivery. Another promising application of artificial intelligence is the external recording and automated analysis of breathing patterns. This technology can assess breathing variability, adding a vital metric for diagnosing diseases by tracking improvements or deteriorations in respiratory function [73].

In summary, the integration of artificial intelligence into pulmonary rehabilitation represents a significant advancement in health care. Through the use of artificial intelligence for tasks such as neuromuscular stimulation and respiratory function monitoring, this technology has the potential to improve patient outcomes and personalize treatment, setting a new standard for health care and quality of life.

Artificial Intelligence in Telehealth

Artificial intelligence represents an approach that falls under the broader category of telehealth, yet it transcends mere use of information and communications technology in supporting health care [74,75]. ML and DL are 2 processes that underpin artificial intelligence, as depicted in Figure 1. Their application in health care is becoming increasingly prominent, enhancing learning, justifying reasoning, and supporting decision-making processes [76,77] Current evidence showcases promising results from the application of artificial intelligence in driving health care innovations [78,79].

Furthermore, a recent systematic review and meta-analysis indicated that this new eHealth approach has gained considerable acceptance among users, proving beneficial in enhancing disease management and quality of life [80,81]. In addition, the ability to detect deterioration and exacerbations in patients with COPD before they occur has been shown to reduce hospital admissions and health care costs [82,83]. In idiopathic pulmonary fibrosis, artificial intelligence has been instrumental in screening radiologic data and simulating accurate diagnoses, thereby saving resources and supporting medical decisions [84,85]. Interpreting results such as cough symptoms through positron emission tomography and CT represents another promising area for artificial intelligence application [86].

In cough analysis, researchers have developed algorithms capable of detecting cough signals, although human input is still essential for refining data and verifying the presence of these events [87,88]. This progress necessitates an enhancement of academic standards for RCPs, enabling them to effectively analyze these signals. Additional applications of artificial intelligence in health care include symptom screening, location detection, infection zone alerts, and the use of robotic surgeons to assist in operations [79,89].

Figure 1. The Telehealth Umbrella Includes Artificial Intelligence, Machine Learning, Deep Learning, and Traditional Data Analysis.
Despite the feasibility and benefits achieved by the application of artificial intelligence in health care, crucial determinants for its operation and sustained use must be identified. Factors such as familiarity with the technology, internet access, data availability, and patient privacy are essential in the ongoing operation and sustainability of artificial intelligence in health care [75,90]. In addition, there is an urgent need to base artificial intelligence applications in health care on a theoretical model that links artificial intelligence content, mechanisms, and outcomes. Addressing current barriers such as lack of knowledge, training, and time requires further research based on real-time clinical data, not just general perceptions about using these telehealth applications [91]. While artificial intelligence may partially or completely transform the health care discipline, standardization and human factors are still necessary for optimal functionality. Artificial intelligence in the clinical setting was initially developed to support health care services and physicians and not intended to replace them. However, as artificial intelligence applications rapidly integrate into health care services, this scenario may change in the coming years. Current efforts should be monitored to minimize errors and establish excellent and sustainable health care services.

Artificial Intelligence in Public Health and Health Promotion

Due to the explosive growth in health-related data, artificial intelligence, including subfields such as ML, now holds promising potential to enhance public health. Artificial intelligence provides unprecedented insights into social, behavioral, and environmental health determinants. These insights can guide health policy formulation, prioritize focus areas, and foster health improvements across entire populations [92-96]. The substantial advancements in informatics and biotechnology have catalyzed the modernization of various fields, including public health. Precision public health, a contemporary version of public health, uses routinely collected data and artificial intelligence to reinforce existing evidence-based methodologies. The aim is to foster an agile, responsive, and data-driven health care system [97-99].

Artificial intelligence serves as a robust tool for big data analysis in biostatistics and epidemiology. Artificial intelligence algorithms facilitate the detection of intricate patterns in data, which may be challenging for human analysts to discern. These include the identification of disease-specific biomarkers, the prediction of patient outcomes, and the analysis of gene expression data [100,101]. Furthermore, leveraging artificial intelligence in big data analysis not only enhances the explained variance in models but also addresses the shortcomings associated with reliance on a single data source [102].

Moreover, in the realm of health policy and management, artificial intelligence can aid in intricate decision-making and handle complex logistical tasks through real-time information provision. It has been used to tackle health-related challenges, including overcoming the limitations of low- and middle-income countries in achieving the United Nations' Sustainable Development Goals [103]. Artificial intelligence has also been used in surveillance to visually represent health events geographically and temporally, leveraging public data sources [104], allocation of resources [105], and staffing requirements [106]. In environmental health science, artificial intelligence enhances our understanding of environmental health, analyzes ecological data, and examines the association between environmental factors and health outcomes [107]. In addition, artificial intelligence is extensively used in social and behavioral sciences to deepen our understanding of human behavior through extensive data modeling and investigate correlations among social factors, behavioral factors, and health outcomes. For instance, some studies analyze social media posts to determine the relationship between mental health and social media use, whereas others create models to predict drug use based on a person's social media activity [108].

Moreover, artificial intelligence can be instrumental in determining the most effective strategies to promote positive

health behaviors. This application of artificial intelligence can potentially enable early interventions and lead to improved outcomes in mental health care [109] and chronic disease management and prevention [110]. In addition, artificial intelligence offers innovative ways to facilitate health behavior changes. For instance, it can support smoking cessation programs by using sentiment analysis of X, formerly known as Twitter, data to identify and target individuals most likely to be responsive. This approach leverages artificial intelligence's capability to analyze vast quantities of data, customizing health interventions to increase their effectiveness [111].

Given the prevalence of respiratory health threats, incorporating artificial intelligence into public health measures for respiratory diseases can lead to more targeted, timely, and population-specific interventions. An example of this is BlueDot, an artificial intelligence–driven algorithm that successfully predicted the early spread of respiratory infections during the initial stages of the COVID-19 outbreak in Wuhan and the Zika virus spread in South Florida. Such applications of artificial intelligence demonstrate significant potential for pre-emptively managing future respiratory health threats [112-114]. Beyond disease prediction, artificial intelligence has numerous other applications in respiratory health. These include developing sophisticated methods for analyzing medical images such as x-rays or CT scans, which can enhance diagnostic accuracy. In addition, artificial intelligence is used to predict disease progression and patient outcomes, providing valuable insights that can guide treatment plans and improve patient care [9,11,84,115,116].

In summary, integrating artificial intelligence into public health and health promotion efforts can significantly enhance respiratory care. By enabling personalized interventions, facilitating early detection of exacerbations, and implementing data-driven strategies, artificial intelligence substantially improves overall respiratory health outcomes from a public health perspective.

Artificial Intelligence in Sleep Clinics

Artificial intelligence, particularly ML, is increasingly prevalent in sleep medicine. The primary use of artificial intelligence in this field involves classifying sleep stages in polysomnography data capitalizing on ML's self-learning capabilities [117]. Furthermore, automated polysomnography scoring has been assessed for its potential to augment the efficiency of sleep technologists. By integrating manual reviews with specific computer-derived polysomnography attributes—such as automated sleep spindle detection, sleep depth, and delta duration—interrater reliability has improved. In addition, innovative measures of sleep depth have shown predictive abilities for subsequent arousal [118]. Research on the accuracy of computer-based sleep staging versus human-based scoring has been ongoing since the early 90s. Challenges such as limited sample sizes and the unavailability of sleep-scoring software have historically complicated accurate sleep stage scoring [119]. A study exploring obstacles to artificial intelligence use in sleep medicine identified barriers across technology, data, regulation, human resources, education, and culture, many of which are common to artificial intelligence implementations in various

medical diagnostic settings. Thus, addressing these barriers is crucial for enhancing future artificial intelligence applications in the field [120]. ML can significantly enrich polysomnography by unveiling patterns that traditional methods overlook. When combined with clinical and demographic data, it enhances diagnostics and patient care, offering more accurate and comprehensive subtyping of sleep disorders [121]. Although polysomnography is considered the standard screening tool, other questionnaires such as the Berlin Questionnaire, STOP-Bang questionnaire, and Epworth Sleepiness Scale are also widely used. Despite their cost-effectiveness and accessibility, the accuracy of these tools has been questioned [122]. Consequently, recent research has focused on the application of artificial intelligence models for automated scoring and respiratory event detection to enhance the diagnosis of respiratory disorders and more comprehensively capture sleep events [123]. One study assessed the efficacy of generalized regression neural networks in detecting sleep stages, respiratory events, and limb movement in patients with obstructive sleep apnea (OSA), finding that this neural network could predict OSA presence with 98.9% sensitivity and 80% specificity. The aim was to explore whether neural networks could reduce the need for polysomnography in patients without OSA and guide patients with OSA toward treatment rather than diagnostic studies [124]. Another approach used a different neural network with 4 readily available inputs—sex, age, BMI, and snoring status—to demonstrate how an ANN could predict OSA in a clinical setting without the need for oximetry or polysomnography, achieving an accuracy of 86.6% [125]. In addition, a study developed an artificial intelligence–based model using easily accessible questionnaire information to predict sleep apnea, outperforming logistic regression with a sensitivity of 81.8% to 88% and a specificity of 95% to 97% [126].

In summary, artificial intelligence systems could significantly enhance the landscape of sleep diagnostics by addressing traditional limitations, streamlining the diagnostic process, and providing more accurate results, ultimately benefiting patients across various sleep disorders.

Artificial Intelligence in Home Care

Artificial intelligence has emerged as a crucial technology that enhances the quality of both short- and long-term medical care services, including home care [127,128]. Furthermore, the application of artificial intelligence and ML is anticipated to improve the effectiveness and cost-efficiency of home care as well as enhance patient care overall [129].

An example of artificial intelligence application in home care is the myAirCoach system, which has been effective in managing asthma and improving quality of life among patients with asthma [130]. A study has demonstrated the system's efficacy in monitoring patients with asthma, leading to reduced severity of asthma exacerbations. However, further research is necessary to fully understand its impact on patient outcomes [130]. The Care Robot represents another artificial intelligence application used to track medication adherence among long-term patients. It alerts caregivers when a patient refuses their medication [131].

The use of artificial intelligence in home care settings is expanding, including the development of an artificial intelligence system designed to assist in assessing and detecting the progression of Parkinson disease (PD) using nocturnal breathing signals during sleep [132]. The application of artificial intelligence in PD evaluation entails multiple benefits. It can reduce the duration and cost of clinical trials; facilitate drug development; and, most importantly, enhance early assessment of PD [132].

Artificial intelligence can be transformative in home care settings, particularly for rehabilitation and palliative care. A study examining home-based rehabilitation using smartwatch and smartphone apps with an ML algorithm for patients requiring physical therapy found that an artificial intelligence–driven home system could enhance outcomes and offer a cost-effective solution for individuals with chronic stroke [133]. In addition, artificial intelligence and ML have been applied for patients with cancer receiving palliative care. Systems designed to assess and monitor medical demands have proven pivotal in managing hospitalization needs. One such system helps palliative care units predict the number of patients requiring hospital admission, thereby improving patient management [134]. A comprehensive system has been developed to assess, monitor, and predict the medical needs and hospitalization requirements of patients with cancer. This artificial intelligence–enhanced system aids palliative care units in managing patient care more effectively by forecasting the need for hospital admissions [134].

In summary, the use of artificial intelligence and ML in home care settings is proving transformative. These technologies not only manage chronic diseases more efficiently but also significantly improve rehabilitation and palliative care processes. Artificial intelligence facilitates a cost-effective approach to enhancing patient outcomes through accurate monitoring and prediction of medical needs. Looking ahead, further advancements in artificial intelligence promise to expand its potential in home health care delivery even more.

Artificial Intelligence in Smoking or Vaping Behaviors

Both smoking and vaping, the latter involving electronic nicotine delivery systems, represent complex behaviors that pose significant public health threats [135]. Artificial intelligence applications are increasingly being used in the study of smoking and vaping behaviors. These applications use various approaches to predict outcomes related to behavioral factors, treatment efficacy, disease diagnosis, surveillance data, and policy implementation [136-165].

Supervised, unsupervised, and hybrid ML techniques, alongside DL and natural language processing, have demonstrated validity and precision in predicting smoking- or vaping-related outcomes. These advancements could pave the way for personalized care, enhanced cessation services, and more advanced tobacco control implementation and research [136-165].

Consequently, most artificial intelligence applications related to this topic have been deployed to predict smoking or vaping behaviors and their associated factors [136-146,165]. ML and

natural language processing are increasingly used to understand smoking or vaping behaviors from various perspectives, including behavioral perception, initiation, continuation, and dependence [137-140,146]. Similarly, various studies have used ML approaches to evaluate mobile apps for smoking or vaping cessation as well as adherence to nicotine replacement therapies [141-143]. In addition, the applicability and accuracy of physiological and wearable sensors in monitoring smoking behavior have been validated using a support vector ML approach [144-146].

It is noteworthy that numerous studies have used smoker data to aid in disease diagnosis and staging predictions. DL and data from chest radiographs and CTs have been effectively used for lung cancer screening. This method has successfully identified high-risk smokers and ascertained their disease stages, predicted prognoses, and estimated mortality rates [147-149]. In addition, gene expression studies involving smokers—which focus on lung cancer and COPD—have been conducted using ML, specifically using the support vector machine method [150,151]. Furthermore, the extreme gradient boosting method has been used to predict noncommunicable diseases induced by smoking through analyzing extensive self-reported datasets [152].

Several artificial intelligence approaches have been used to develop surveillance and registry systems for smokers, as well as to identify public health support and tobacco control threats on social media. Using natural language processing, numerous studies have mined electronic medical and dental records along with medication data to track tobacco use, assess documentation quality, and study longitudinal tobacco use and related health issues. This has significantly contributed to the establishment of tobacco use registries and surveillance systems [153-159]. In addition, through the use of DL and ML techniques, various studies have evaluated public health support for health messaging, assessed public health threats to tobacco control measures, processed images for tobacco point-of-sale advertising, and analyzed smoking locations and environments [111,160-165].

In summary, the application of artificial intelligence in assessing smoking or vaping outcomes has proven both innovative and effective. Given the complexity of these behaviors, sophisticated tools such as artificial intelligence provide a new lens for understanding, preventing, and treating them. The promising potential of artificial intelligence applications in this field warrants further investment, aiming ultimately to reduce the health complications associated with smoking and vaping.

Artificial Intelligence in Neonates and Pediatrics

The common practice of managing or detecting clinical deterioration in neonatal and pediatric settings primarily depends on the competency of health care providers and the experiences of parents. However, technological advancements in patient assessment and monitoring within these settings present significant opportunities for artificial intelligence application [166].

Pediatric and neonatal diseases often display less heterogeneous patterns and generally have more complete records compared to adult conditions, factors that significantly enhance the

potential of artificial intelligence applications in pediatric and neonatal health care [167]. In addition, the practice of admitting neonates from birth enables focused monitoring of physiological parameters and other clinical variables from the outset. Current research on artificial intelligence–based applications for pediatric respiratory conditions primarily focuses on 3 domains: breath sound analysis, chest imaging interpretation, and PFT analysis [168].

Unfortunately, pneumonia remains one of the leading causes of morbidity and mortality in the pediatric population [169]. CAD4Kids is a computer-aided diagnosis system specifically designed to assess childhood pneumonia using chest radiographs as a diagnostic tool [170]. Developed to classify chest x-rays into 3 categories—pneumonia, another infiltrate, or no infiltrate—the artificial intelligence algorithm achieved an impressive area under the curve (AUC) of 0.85, demonstrating a sensitivity of 76% and a specificity of 80% in correctly identifying radiographs with pneumonia [169,170].

In addition, a predictive algorithm using pediatric patients' temperature, respiratory rate, heart rate, and oxygen saturation has been used to diagnose pneumonia. This algorithm achieved an impressive AUC of 97.8% with a sensitivity of 96.6% and a specificity of 96.4%, showcasing the potential of artificial intelligence in providing accurate pneumonia diagnoses [171]. The simplicity of this algorithm makes it ideally suited for integration into smartphones or tablets, giving health care providers convenient access. This user-friendly approach has the potential to significantly enhance diagnostic capabilities and improve respiratory care for pediatric patients on a broader scale [171].

Croup, a pediatric condition known for its distinctive loud barking cough, has been the focus of a new algorithm developed to identify affected pediatric patients by analyzing the acoustic features of their coughs [172]. This algorithm demonstrated a sensitivity of 92% and specificity of 85%, proving effective in accurately diagnosing croup. In addition, a study focused on asthma control used nocturnal cough frequency as a valid marker, monitoring both audio data and abdominal movements [173]. The findings revealed a significant increase in cough count among children with asthma, underscoring the potential for developing a cough monitoring system. Such a system could assess the level of asthma control and facilitate the implementation of more effective management strategies [173].

In another advancement, a DL model has been trained to predict uncontrolled asthma a week in advance by leveraging a self-monitoring tool and incorporating patient demographics. This innovative approach promises to enhance asthma management by facilitating early intervention and personalized care [174]. The DL model achieved an AUC of 0.75, with a sensitivity of 73.8% and a specificity of 71.4%, effectively predicting uncontrolled asthma a week in advance by using a self-monitoring tool and patient demographics. The potential further development of this model promises to provide early warnings for deteriorating asthma control, enabling timely interventions and leading to improved respiratory health outcomes [174].

In neonatal settings, the abundance of data presents a significant opportunity for ML research [175]. A mature artificial intelligence model uses heart rate characteristic monitoring to enhance outcomes for infants with very low birth weight [176]. The study found that neonates monitored using heart rate characteristics showed improved survival rates and required fewer days on mechanical ventilators. This underscores the potential of artificial intelligence applications to optimize care and improve outcomes for vulnerable neonatal populations [176].

A notable example of ML model development for predicting bronchopulmonary dysplasia (BPD) incidence involves using patient clinical and genetic features, as seen in the BPD risk gene sets [177]. This study suggests that a model combining basic clinical risk factors with genetic data can effectively stratify BPD risk in preterm neonates. The field of predicting BPD has seen rapid growth over the last decade, highlighted by the identification of 26 BPD prediction models in 2012 [178]. However, most of these predictors have shown poor performance and limited promise, underscoring a vital need for further extensive research and clinical validation [178].

While artificial intelligence applications in pediatric and neonatal settings offer significant benefits, they also face various challenges that require careful consideration and resolution [179]. Ensuring the quality of the data used to train these systems is crucial, necessitating rigorous assessments to address issues such as small sample sizes, appropriate handling of missing values, and data heterogeneity [179].

In summary, while artificial intelligence promises significant advancements in pediatric and neonatal care, overcoming obstacles related to data quality and training is crucial for fully realizing its potential.

Discussion

Principal Findings

Our search was designed to encompass a broad spectrum of studies, reflecting the diverse applications of artificial intelligence technologies aimed at enhancing respiratory health outcomes and advancing the field of respiratory care. In this domain, artificial intelligence approaches have increasingly been deployed as tools for diagnosis, classification, and prediction of mortality outcomes [10]. Notably, artificial intelligence holds significant potential as a valuable asset in supporting RTs by enhancing care delivery and managing respiratory diseases more effectively. However, the successful integration of these technologies necessitates a robust understanding of digital interventions and artificial intelligence principles. It is equally important to promote collaboration with data specialists and computer scientists to address the challenges associated with implementing artificial intelligence in respiratory care [180]. From our review, it appears that artificial intelligence use and application can eventually elevate the overall quality of care by minimizing errors across the various areas that RTs work in.

The use of artificial intelligence in respiratory care involves the processing of large volumes of personal health information,

raising significant data privacy concerns. It is crucial to implement robust data protection measures that comply with regulations such as the General Data Protection Regulation and Health Insurance Portability and Accountability Act (HIPAA). These measures should ensure data anonymization and secure data storage and transmission [181]. Furthermore, informed consent is a cornerstone of ethical medical practice and is particularly pertinent in deploying artificial intelligence technologies. Patients must be adequately informed about how their data will be used, the role of artificial intelligence in their care, and any potential risks associated with artificial intelligence decision-making [182]. This process must be transparent and documented, allowing patients to make well-informed decisions about their care [182]. Furthermore, artificial intelligence systems can inadvertently perpetuate or amplify biases present in their training data, which could lead to unequal treatment outcomes across different demographics. It is imperative to assess and mitigate these biases by ensuring diverse and representative datasets. Moreover, continuous monitoring for biased outcomes and periodic model reassessment should be institutionalized to safeguard against discrimination [183]. Through these measures, we can explore the ethical complexities introduced by artificial intelligence in respiratory care, ensuring that these technologies augment health care delivery without compromising ethical standards or patient trust.

Implications for Future Work

Our study underscores the importance of integrating training and education for RTs and students on recent and relevant artificial intelligence technologies, ensuring their proficiency in using artificial intelligence tools and analyzing artificial intelligence–generated insights within clinical settings. It also highlights the necessity of encouraging interdisciplinary collaboration among RTs, data scientists, researchers, and artificial intelligence developers to enhance the development and implementation of pertinent artificial intelligence applications and research. These collaborations should aim to produce practical, effective, and user-friendly solutions that benefit patients and improve clinical research outcomes. In addition, it is clear that robust ethical guidelines and data protection measures are essential to ensure privacy and compliance with regulations such as the General Data Protection Regulation and HIPAA, safeguarding patient information. Furthermore, we recommend conducting research and validation studies on artificial intelligence applications in the respiratory care field to ensure that artificial intelligence–driven solutions are evidence based, accurate, reliable, and beneficial across various individuals receiving health care from RTs in different clinical settings.

Limitations

Our study has some limitations. For instance, the literature review conducted across various areas of respiratory care did not adhere to a standardized review process, such as systematic or scoping review, which may introduce potential biases. These biases could stem from selective inclusion of studies, nonsystematic search strategies, or subjective interpretation of findings. Therefore, it is imperative to adopt a well-standardized review methodology for future studies in each specific area of respiratory care to minimize these limitations and ensure more reliable and comprehensive conclusions.

Conclusions

Artificial intelligence applications should complement rather than replace the decision-making processes of RTs. By serving as a supportive tool, artificial intelligence enables RTs to enhance patient care, disease management, and respiratory health outcomes. As artificial intelligence continues to permeate medicine, it is imperative for RTs to engage actively in its evolution, ensuring that their involvement is central to artificial intelligence development, which is crucial for improving clinical decision-making. Moreover, as artificial intelligence technology advances, it is essential to elevate academic standards within the respiratory care profession, empowering practitioners to contribute effectively to research and grasp the implications of artificial intelligence on respiratory care. The integration of artificial intelligence into health care is irreversible and creates the need for RTs to positively influence its progression. Active participation in artificial intelligence development will enable RTs to expand their clinical capabilities and improve patient outcomes.

Abstract

Background: Mobile health (mHealth) technologies can be used for disease-specific self-management, and these technologies are experiencing rapid growth in the health care industry. They use mobile devices, specifically smartphone apps, to enhance and support medical and public health practices. In chronic disease management, the use of apps in the realm of mHealth holds the potential to improve health outcomes. This is also true for mHealth apps on osteoporosis, but the usage and patients' experiences with these apps are underexplored.

Objective: This prospective survey study aimed to investigate the eHealth literacy of Danish patients with osteoporosis, as well as the usability and acceptability of the app "My Bones."

Methods: Data on patient characteristics, disease knowledge, eHealth literacy, usability, and acceptability were collected using self-administered questionnaires at baseline, 2 months, and 6 months. The following validated questionnaires were used: eHealth Literacy Questionnaire, System Usability Scale, and Service User Technology Acceptability Questionnaire.

Results: Mean scores for eHealth literacy ranged from 2.6 to 3.1, with SD ranging from 0.5 to 0.6 across the 7 domains. The mean (SD) System Usability Scale score was 74.7 (14.4), and the mean (SD) scores for domains 1, 2, and 6 of the Service User Technology Acceptability Questionnaire were 3.4 (1.2), 4.5 (1.1), 4.1 (1.2), respectively.

Conclusions: Danish patients with osteoporosis are both motivated and capable of using digital health services. The app's usability was acceptable, and it has the potential to reduce visits to general practitioner clinics, enhance health outcomes, and serve as a valuable addition to regular health or social care services.

KEYWORDS

eHealth literacy; health literacy; mHealth; mobile health; eHealth; mobile health apps; self-management; osteoporosis; usability; acceptability

Introduction

Background

Osteoporosis ranks as the fourth most prevalent chronic disease globally, carrying substantial negative personal and economic consequences [1]. Osteoporosis affects approximately 40% of women and 17% of men aged 50 years or older. Despite its high prevalence, osteoporosis is significantly underdiagnosed [2]. Although osteoporosis may remain asymptomatic for many individuals, it presents significant risks such as fractures, chronic pain, reduced daily activity, compromised quality of life, and increased mortality [1]. Lack of disease-specific knowledge among patients with osteoporosis is a global issue [3]. It has been shown that improved support for patients to understand

osteoporosis upon diagnosis is required, along with support in self-management of the disease [4,5].

Mobile health (mHealth) technologies can be used for disease-specific self-management, and the technologies are experiencing rapid growth in the health care industry. These technologies use mobile devices, specifically smartphone apps, to enhance and support medical and public health practices [6]. Studies have demonstrated that, particularly in chronic disease management, the use of apps in the realm of mHealth holds the potential to enhance health outcomes [7]. Despite Slomian et al [8] addressing the potential of using mHealth apps to aid patients in self-managing osteoporosis in 2014, the implementation of such apps in the field of osteoporosis remains inadequate. A recently published systematic review and meta-analysis of digital health technologies for long-term self-management of osteoporosis identified 23 relevant apps for osteoporosis self-management and concluded that osteoporosis apps have the potential to support and improve the management of the disease. Furthermore, mHealth osteoporosis apps also appear to be valuable tools for patients and health care professionals. However, most of the identified apps that are currently available in the field of osteoporosis lack clinically validated evidence of their efficacy [9].

From 2015 to 2018, a team of researchers and health care professionals from Odense University Hospital, Denmark, developed and tested an mHealth app for women recently diagnosed with osteoporosis [10]. The development of the app was based on identified needs among patients and health care professionals [11,12]. The app evaluation revealed that patients perceived the app as providing confidence and reassurance, fostering equitable dialog during consultations, and offering readily accessible assistance for self-managing osteoporosis [13]. After the test period, the app was implemented at Odense University Hospital, Denmark. In 2019, the Danish Health Authority decided to support a nationwide rollout of the app, named "My Bones." A group of health care professionals with expertise in osteoporosis were engaged in the app's further development and testing. In September 2021, the app "My Bones" was launched as a freely available app on both the App Store and Google Play platforms. Visuals of the app are available in Multimedia Appendix 1.

After the app's launch, the Research Unit of the Medical Department at Zealand University Hospital, Denmark, initiated an evaluation of the app focusing on usability, acceptability, eHealth literacy, and self-perceived knowledge of osteoporosis. The Consumer Health Information System Adoption Model was used as a theoretical framework, as a basis for the choice of questionnaires used in this study. In this model, eHealth literacy of the user, usefulness, and usability are all determining factors for the adoption of consumer health information systems like the app "My Bones."

Objective

The aim of this study was to investigate the eHealth literacy of Danish patients with osteoporosis and to assess the usability and acceptability of the app "My Bones." Additionally, the aim was to assess the current level of disease knowledge within the patient group.

Methods

Study Design

This prospective survey study was conducted at Zealand University Hospital, Denmark, from January 2020 to February 2023. A total of 100 patients were recruited to test the app "My Bones." At the time of the study, the app was owned and operated by OSAIA Health. The app provided patients with comprehensive information about osteoporosis, its risk factors, available treatment options, the diagnostic procedure for osteoporosis, and the process of a dual-energy x-ray absorptiometry (DXA) scan. Alongside this general information, the app provided guidance on maintaining a bone-healthy lifestyle, dietary requirements including calcium and vitamin D supplements, and recommendations for physical activity. App users also gained access to basic and safe training exercises tailored to their individual fracture risk and functional level, enabling them to engage in a foundational level of physical activity. The app includes 2 interactive modules. One of these was a calcium calculator that assists patients in measuring their daily calcium intake and determining whether they require calcium supplements. The second module was an interactive DXA graph that gives patients the option to plot their T score values for the spine and hip from each DXA scan.

Three self-administered questionnaires were developed and internally pretested before distribution at baseline (Q0), at 2 months (Q2), and at 6 months (Q6). The questionnaires are described under the Measures section. The results from the baseline (Q0) and 2-month (Q2) questionnaires are presented here. However, the results from the 6-month (Q6) questionnaire are excluded because of technical issues preventing data analysis.

Sampling and Recruitment

Patients were recruited from the Outpatient Clinic of Endocrinology at Zealand University Hospital and through advertisements on the Danish Osteoporosis Association's homepage and a Facebook page.

The inclusion criteria include patients diagnosed with osteoporosis based on either the T score criterion ($T \leq -2.5$ at the lumbar spine, total hip, or hip neck) or a diagnostic osteoporotic fracture (fragility fracture of a vertebra with >20% compression or a hip fracture). Postmenopausal women or men over 45 years of age who can read and understand Danish and have access to, as well as the ability to use, a smartphone, tablet, or computer.

The exclusion criteria include patients with mental and cognitive conditions impairing their ability to use an app and read and understand questionnaire questions.

Procedures

Patients with osteoporosis interested in participating were provided with both written patient-oriented materials and oral information about the study. Informed consent was obtained from the patients by the data controller. The signed consent forms were stored in a secure location, only accessible by the data controller. After signing the informed consent, participants were asked to indicate their preferred method of receiving the

study questionnaires—either by email, through e-Boks (a digital postbox for communication between companies, public authorities, and private citizens), or in a printed copy. Detailed instructions on how to download the app from the App Store or Google Play were provided. If patients required assistance, the study staff aided in the process.

SurveyXact, a tool for creating electronic questionnaire-based surveys, was used to distribute the questionnaires to the patients and to establish a database. The data analyst gained access to the database only after all data had been collected and anonymized by way of a respondent key in the survey tool and transferred to the database. The survey tool is compliant with the European Union's General Data Protection Regulation.

In cases of nonresponse, electronic reminders were dispatched, followed by telephone follow-ups. If participants still did not complete the questionnaire despite these attempts, they were classified as dropouts.

Measures

Baseline Questionnaire (Q0)

Sociodemographic data include age, sex, education, occupation, time since diagnosis, and knowledge of the disease (self-reported T score of the spine and hip, medical treatment, and fracture history).

Data regarding education were initially reported on 6 levels and were subsequently consolidated into two levels for statistical analysis: (1) shorter education and (2) longer education. Longer education was defined as a bachelor's degree or higher. Data concerning occupation were reported across 8 levels and were later condensed into two levels for statistical analysis: (1) currently working and (2) not currently working. The various education and occupation levels can be found in Table 1.

The eHealth Literacy Questionnaire (eHLQ) consists of 35 items representing 7 scales covering the eHealth Literacy Framework dimensions. Each scale has 4 to 6 items with a 4-point response option. Mean scores are calculated from each scale with equal weighting [14].

The International Physical Activity Questionnaire measures the amount of time an individual spends physically active during a normal 7-day week [15].

Table 1. Participant characteristics (N=95).

Characteristics	Participants
Age (years), mean (SD)	66.3 (8.4)
Sex, n (%)	
Male	5 (5)
Female	90 (95)
Shorter education, n (%)	42 (44)

Two-Month Questionnaire (Q2)

The System Usability Scale (SUS) is a 10-item Likert scale questionnaire that offers a global perspective on subjective assessments of usability. The SUS generates a single number that represents a composite measure of the overall usability of the system under study, in this case, an app [16-18]. The questionnaire is validated in the Danish population.

The Service User Technology Acceptability Questionnaire (SUTAQ) is a questionnaire that consists of 22 items divided into 6 different subscales. For the purpose of this study, 3 of the 6 domains were included in the Q2 questionnaire. The included domains are (1) "Enhanced Care," (2) "Increased Accessibility," and (3) "Satisfaction." The sum of each subscale indicates the degree of average internal agreement with it [19]. The domains "Privacy and Discomfort," "Care Personnel Concerns," and "Kit as a Substitution" were excluded because of their irrelevance resulting from the lack of health monitoring and interaction between patients and health care professionals via the app. The questionnaire is validated in the Danish population.

Statistical Analysis

Statistical analysis was conducted using the SPSS statistical software (version 21; IBM Corp). Descriptive statistics were generated for participants' characteristics and other dependent variables, with calculation of mean values and SD for normally distributed data and median with range for data not normally distributed. Frequency data were calculated for categorical data.

The relation between each of the 7 eHLQ domains and the covariates age, education, and occupation was investigated using a backward stepwise linear regression analysis.

The correlation between the SUS questionnaire score and age was investigated using the Pearson 2-tailed correlation analysis.

All statistical outcomes were examined against a P value of .05 to determine statistical significance. The study was not an intervention study, and no power calculation was performed.

Ethical Considerations

The study was conducted in accordance with the principles of the Declaration of Helsinki. It received approval from the local Data Protection Authority (Reg-152-2020). Although the study did not meet the criteria that necessitate approval from the ethics committee, guidelines for obtaining informed consent were adhered to.

Results

Participant Characteristics

A total of 100 patients signed the informed consent. Of these, 95 responded to the entire or part of the baseline questionnaire (Q0), as shown in the flow diagram in Figure 1.

Of the 95 respondents, 90 were women and 5 were men. The mean (SD) age of the study population was 66.3 (8.4) years, and education levels were reported as shorter by 44% (42/95) of the participants and as longer by 56% (53/95) of the respondents. Regarding occupational status, 35% (33/95) stated a current connection to the labor market, while 65% (62/95) stated that they were either retired, unemployed, or on leave of absence (Table 1).

The mean time since the diagnosis of osteoporosis was 6 years (0-34 years). Among the 95 respondents, 52% (49/95) did not know the T score of the lumbar spine, and 68% (64/95) did not know the T score of the hip. Regarding self-reported osteoporosis status, 22% (21/95) and 4% (4/95) reported severe osteoporosis (T score<–3.0) in the spine region and the hip region, respectively (Table 2). Previous major osteoporotic fractures were reported by 49% (46/95) of the respondents (Table 2), while 67% (64/95) stated that they were currently undergoing medical treatment, the majority in treatment with bisphosphonate (Table 3).

Too much missing data hindered a meaningful analysis of the data from the International Physical Activity Questionnaire, and as a consequence, the results cannot be presented.

eHLQ, SUS, and SUTAQ

A total of 90 participants completed the eHLQ section of the Q0 questionnaire. Mean (SD) scores reported ranged from 2.6 (0.5) to 3.1 (0.6) across the 7 domains (Table 4). A definition of each domain can be found in Multimedia Appendix 1.

A total of 79 participants responded to the SUS questionnaire with a mean (SD) score of 74.7 (14.4), while 74 participants responded to the SUTAQ, with mean (SD) scores for domains 1, 2, and 6 being 3.4 (1.2), 4.5 (1.1), and 4.1 (1.2), respectively (Table 5). Answers to individual questions of the SUTAQ are presented in Table 6.

The covariate "occupation" had an effect on eHLQ domain 4 (P=.04) with an adjusted R^2 of 0.036 (Tables 7 and 8). No effects of the other covariates were found for the remaining domains of the eHLQ. No correlation was found between the SUS score and age (P=.37).

Table 4. eHealth Literacy Questionnaire (eHLQ, N=90).

Domain	Value, mean (SD)
eHLQ1: using technology to process health information	2.9 (0.6)
eHLQ2: understanding of health concepts and language	3.1 (0.5)
eHLQ3: ability to actively engage with digital services	3.0 (0.6)
eHLQ4: feel safe and in control	3.1 (0.5)
eHLQ5: motivated to engage with digital services	2.9 (0.6)
eHLQ6: access to digital services that work	2.9 (0.5)
eHLQ7: digital services that suit individual needs	2.6 (0.6)

Table 5. System Usability Score (SUS, n=80) and Service User Technology Acceptability Questionnaire (SUTAQ, n=73) scores at 2 months (Q2).

Discussion

Principal Results

Our analysis revealed eHLQ scores ranging between 2.6 and 3.1 across the 7 domains, with domain 7 "Digital services that suit individual needs" being the lowest-scoring domain and domains 2 "Understanding of health concepts and language" and 4 "Feel safe and in control" being the highest-scoring domains. These findings are comparable to those of another Danish study by Holt et al [20] on eHealth literacy conducted on 246 patients diagnosed with diabetes, other endocrine conditions, or gastrointestinal diseases. Holt et al [20] demonstrated eHLQ scores ranging between 2.6 and 3.1, with

slightly lower scores across the 7 domains. This suggests that our findings are representative of Danish patients with chronic diseases. A Spanish study investigating electronic health literacy in 166 primary care patients, with a median age of 65 (52-78) years, revealed somewhat lower eHLQ scores ranging from 1.7 to 2.8 across the 7 domains [21]. An Australian study of 525 patients at 3 primary care clinics, with a mean age of 56.7, showed eHLQ scores ranging from 2.4 to 3.0 [22]. In comparison with participants from other countries, Danish patients seem to score higher on the eHLQ. These elevated scores among Danish individuals could be attributed to the extensive digitization of public services in Denmark. According to the latest report on digitalization in Denmark (2022), 95% of citizens reported receiving messages from public services through the digital mailbox known as "e-Boks." Additionally, 74% of citizens aged 15 to 89 years use digital public services at least once a week, and 66% of citizens aged 16 to 74 years have booked a doctor's appointment via the web and accessed health information through online sources [23]. On examining the eHLQ scores in this study, high scores are observed in domains 1-6, suggesting that Danish patients with osteoporosis are both motivated and able to use digital services related to health. The lowest-scoring domain, domain 7, indicates the current state of technology regarding digital services and points to a potential for developing more individualized services designed to meet the needs of patients.

The statistical analysis revealed a significant but relatively small effect of the covariate "occupation" on the scores of eHealth literacy domain 4 "Feel safe and in control." This suggests that among the study sample, individuals who are currently working tend to feel safer and more in control when using electronic health services. However, given the small effect size within a limited sample, no definitive conclusions can be drawn. In the field of eHealth literacy, conflicting results have been reported regarding determinants of eHealth literacy scores. A recent systematic review demonstrated an association between eHealth literacy and age, sex, educational level, and family income [24]. Another study conducted by Arcury et al [25] failed to find a connection between eHealth literacy and sociodemographic factors. However, they did discover associations between eHealth literacy and the number of e-devices owned, as well as computer stress [25]. A related finding was reported by Richtering et al [26], who concluded that more time spent on the internet was associated with higher eHealth literacy among 453 patients with moderate to high cardiovascular risk. These findings suggest that factors other than sociodemographic variables play a role in eHealth literacy.

The app "My Bones" aims to assist patients in managing osteoporosis. To achieve this objective, it is crucial for the app to be both usable and well received by its users, prompting an investigation into its usability and acceptability. The analysis of the SUS questionnaire at the 2-month mark resulted in a mean (SD) score of 74.6 (15.3). According to Bangor et al [17], a score of approximately 70 indicates a user-friendliness rating of "Good." Conversely, scores around 35 and 50 correspond to ratings of "Poor" and "OK," respectively. On the other end of the spectrum, scores around 85 and 90 are associated with ratings of "Excellent" and "Best imaginable," respectively [17].

Based on the SUS score, the usability of the "My Bones" app is considered acceptable.

The statistical analysis showed no correlation with age, contradicting the finding by Bangor et al that indicated a slightly negative correlation between the SUS score and age [27]. This discrepancy could be attributed to both the small sample size and the higher average age of this study population.

Analyzing the data from the 3 SUTAQ domains revealed a mean (SD) score of 4.1 (1.2) for domain 1 "Enhanced care," which indicates a general agreement that the app "My Bones" can improve the care patients receive. The mean (SD) score of 4.5 (1.1) for domain 6 "Satisfaction" suggests acceptance and satisfaction with the app. However, the mean (SD) score of 3.4 (1.1) for domain 2 "Increased accessibility" indicates a lower level of agreement with beliefs that the app has facilitated the receipt of care from health care professionals.

In a Danish study involving 68 patients recruited from primary care and an outpatient clinic, the acceptability of a telehealth service was assessed using the SUTAQ. The scores obtained for domains 1, 2, and 6 were 5.0, 4.2, and 5.5, respectively [28]. Another Danish study focused on telehealth services for patients with chronic obstructive pulmonary disease, diabetes, and inflammatory bowel disease, and pregnant women with either diabetes or a need for enhanced care, demonstrated similar results. Scores for domain 1 ranged from 4.4 to 5.1, domain 2 from 3.8 to 4.7, and domain 6 from 5.2 to 5.6 [29]. Both studies exhibited higher scores across all 3 domains, indicating greater satisfaction and acceptance with the telehealth services compared with the "My Bones" app. One possible explanation for the lower scores in this study is that the SUTAQ was originally designed to assess the acceptability of telehealth services involving remote monitoring by health care professionals [19]. However, the app evaluated in our study does not function as a telehealth system, as it lacks monitoring, data collection by patients, and direct interaction with care personnel. Therefore, the applicability of SUTAQ results in describing the acceptability of the app among our study population may be limited. Certain statements within SUTAQ domains 1 and 2 are rendered irrelevant by the nature of the app. For instance, one statement in domain 2 referred to increased access to care through the received kit, which is not applicable because the app does not connect users with health care professionals. Similar issues were observed in other statements within these domains.

Nevertheless, it is worth noting that specific statements regarding the app's usefulness showed promising results. Among the 74 participants who answered the SUTAQ questions, 56% agreed that the app saved them a visit to the general practitioner clinic. In total 65% agreed that the app helped them improve their health, 54% agreed that the app made them less concerned about their health status, and 70% agreed that the app made them more involved in their own health. Furthermore, 84% of participants agreed that the app can be a valuable addition to regular health or social care.

In summary, our findings from both the SUS and SUTAQ questionnaires underscore a high level of satisfaction with the "My Bones" app. While the usefulness of SUTAQ scores may

be questionable, the responses to individual statements indicate that the app holds value for patients with osteoporosis.

Other Findings

We discovered that over half of the 95 patients with osteoporosis had a significant gap in their knowledge about their condition, as they were not aware of their T scores. The T score reflects the severity of bone loss and risk of fractures. Knowing the T score can empower patients to take preventive measures in their daily lives to avoid injuries. Osteoporosis is a silent disease that often exhibits no symptoms; thus, the T score becomes a crucial indicator for patients to manage their condition. The fact that half of the patients lack awareness of the T score suggests a communication issue within the Danish health care system. Lack of disease-specific knowledge among patients with osteoporosis is a global issue [3], which might be addressed by apps like "My Bones." However, because we did not inquire about the T score in our follow-up questionnaires, further research is needed to confirm whether the app can improve T score knowledge among patients with osteoporosis.

Perspectives

Based on our findings, it appears that the app "My Bones" has the potential to effectively support the self-management of osteoporosis in this population as a supplement to current health care services. Further investigation should be undertaken to fully assess the app's ability to enhance self-management among patients.

Limitations

This study is subject to several limitations. First, the small population size restricts the generalizability of our findings. Additionally, individuals who are already accustomed to using smartphones and health management apps on a daily basis may have been more likely to participate, potentially introducing a bias toward higher eHealth literacy, acceptability, and satisfaction with the app. Recruitment primarily occurred at a single outpatient clinic and through online advertisements on the patient organization's homepage and a Facebook page, introducing a sampling bias as most patients with osteoporosis in Denmark are typically treated at general practitioner clinics.

The use of questionnaires also presents limitations. Self-reported data on fractures, T scores, and medication are susceptible to response bias and may be less reliable than data obtained from registries. Conversely, the questions on T score and medication were specifically designed to provide insight into the patients' understanding of their disease.

Despite these limitations, our study provides valuable insights into the eHealth literacy of patients with osteoporosis and the acceptability and usability of the first publicly available osteoporosis management app in Denmark.

Conclusions

We uncovered a high level of eHealth literacy, indicating that Danish patients with osteoporosis possess both the motivation and ability to use mHealth services. The app demonstrated acceptable usability and garnered general satisfaction among users. These findings bolster the viability of an app for self-management of osteoporosis to support Danish patients. The app holds the potential to reduce visits to the general practitioner clinic, enhance health outcomes, and serve as a valuable addition to regular health or social care. However, further investigation is necessary to thoroughly evaluate its effectiveness in improving self-management of osteoporosis.

Conflicts of Interest

MGB has received speaker honorariums from Union Chimique Belge (UCB), Gedeon Richter, and Novo Nordisk. MFH has received grants from Amgen, UCB, and the Ellab-Foundation; received speaker honorariums from UCB and Amgen; and participated in advisory boards with UCB and Novo Nordic. BMTS and MR declare that they have no conflict of interest.

Abstract

Background: In comparison to the general population, prison inmates are at a higher risk for drug abuse and psychiatric, as well as infectious, diseases. Although intramural health care has to be equivalent to extramural services, prison inmates have less access to primary and secondary care. Furthermore, not every prison is constantly staffed with a physician. Since transportation to the nearest extramural medical facility is often resource-intensive, video consultations may offer cost-effective health care for prison inmates.

Objective: This study aims to quantify the need for referrals to secondary care services and hospital admissions when video consultations with family physicians and psychiatrists are offered in prison.

Methods: In 5 German prisons, a mixed methods evaluation study was conducted to assess feasibility, acceptance, and reasons for conducting video consultations with family physicians and psychiatrists. This analysis uses quantitative data from these consultations (June 2018 to February 2019) in addition to data from a sixth prison added in January 2019 focusing on referral and admission rates, as well as reasons for encounters.

Results: At the initiation of the project, 2499 prisoners were detained in the 6 prisons. A total of 435 video consultations were conducted by 12 physicians (3 female and 7 male family physicians, and 2 male psychiatrists during the study period). The majority were scheduled consultations (341/435, 78%). In 68% (n=294) of all encounters, the patient was asked to consult a physician again if symptoms persisted or got worse. In 26% (n=115), a follow-up appointment with either the video consultant or prison physician was scheduled. A referral to other specialties, most often psychiatry, was necessary in 4% (n=17) of the cases. Only in 2% (n=8) of the consultations, a hospital admission was needed. Usually, hospital admissions were the result of unscheduled consultations, and the videoconferencing system was the method of communication in 88% (n=7) of these cases, while 12% (n=1) were carried out over the phone. Reasons for admissions were severe abdominal pain, hypotension, unstable angina or suspected myocardial infarction, or a suspected schizophrenic episode.

Conclusions: Most scheduled and unscheduled consultations did not require subsequent patient transport to external health care providers. Using telemedicine services allowed a prompt patient-physician encounter with the possibility to refer patients to other specialties or to admit them to a hospital if necessary.

Introduction

In 2022 approximately 56,000 people were incarcerated in a total of 172 German prisons. While 19,339 (34%) out of 56,557 inmates face imprisonment of over 1 year to 4 years, 5340 (9%) out of 56,557 inmates serve prison sentences of 5 years or longer [1,2]. By law, these prisoners have the same right to access health care as patients with statutory health insurance outside the correctional system. However, caring for incarcerated patients is challenging. They are more likely to experience alcohol or drug abuse, mental illnesses, or communicable diseases, such as hepatitis C or HIV infections [3,4], and not every prison is constantly staffed with a physician on-site. Specialized (secondary care) services are less available to inmates since a resource-intensive transport to the next extramural facility has to be organized. Telemedicine offers the potential to close this gap and improve intramural health care [5]. In this context, the collective term telemedicine describes heterogeneous concepts that aim at providing medical diagnostics, therapy, and rehabilitation despite physical distance or time lag [6]. In many countries, it has been used to facilitate or enhance intramural care [7-10], but it has not been implemented on a broad scale in the German correctional system yet.

This study aims to assess the need and the reasons for referrals to secondary care services, as well as hospital admissions, when scheduled or unscheduled telemedicine consultations with family physicians and psychiatrists are offered in prison.

Methods

Overview

The pilot project to establish video consultations in German prisons was initiated by the Ministry of Justice Baden-Württemberg in cooperation with A+ Videoclinic (VC), a provider of telemedical services, and initially, involved 5 German prisons. Between June and December 2018, the pilot project was evaluated in terms of feasibility and acceptance of the video consultations, as well as consultation reasons by conducting a mixed methods evaluation study. Quantitative and qualitative data were collected through site visits in the prisons, questionnaires, semistructured interviews, and consultation documentation. Further details are reported elsewhere [11]. This analysis is a retrospective subanalysis using a quantitative VC data set that was generated during the evaluation study period containing the information depicted in Table 1, as well as additional data from a sixth prison, which was not part of the initial pilot project.

All 6 prisons were located in the federal state of Baden-Württemberg, Germany. Inmates were male and female (adults and adolescents) and 18 years of age and older. Participation in the pilot study was voluntary. Patients could choose either a video consultation or regular medical care. If the patient opted for a video consultation, he or she had to sign an informed consent form.

Consultations that were conducted between June 2018 and February 2019 were analyzed in this study. The videoconferencing system (VCS) was the preferred method of communication. The phone was used in case of any technical problems with the VCS. Consultations were carried out by a team of 12 physicians (3 female and 7 male family physicians, and 2 male psychiatrists) employed by the telemedicine provider. Scheduled encounters were conducted during fixed weekly timeslots—either with VC-family physicians or a VC psychiatrist. Outside of these consultation hours, prison nursing staff could reach the on-call VC-family physician 24 hours 7 days per week. These patient-physician-contacts outside of consultation hours were counted as unscheduled consultations. Depending on the time of contact, there was not always a trained nurse present in prison. If the on-call family physician required help regarding a psychiatric problem, he or she could contact a VC psychiatrist.

The VC provided the telemedical infrastructure for VC physicians and prisons. Physicians documented the consultations electronically with a VC laptop using a virtual private network to access the VC software called Videoclinic Portal (Videoclinic) developed by the Videoclinic. The participating prisons were also equipped with VC laptops to receive the documentation. No remote medical devices, such as stethoscopes, that would have allowed the physician to directly auscultate a patient were used during the pilot study. Either prison nursing staff or correctional officers were present during each encounter. Prison nursing staff could obtain the patient's vital signs (pulse, blood pressure, temperature, and oxygen saturation) and write an electrocardiogram if necessary and available. A total of 4 out of 6 prisons had an electrocardiogram on-site. Further details on the medical equipment available in the 5 prisons that were part of the initial pilot project can be found elsewhere [11].

For this study, an anonymized data set was exported from the VC software containing the variables depicted in Table 1. The data analysis for this study comprised descriptive statistical methods and was performed using Microsoft Excel 2016.

Table 1. Data provided by A+ Videoclinic.

Variable	Description
Date of consultation	• Date and time of the encounter
Prison	• Name of the prison
Physician	• Treating physician (pseudonymized number D1-12)
Medical specialty	• Family medicine • Psychiatry
Assessment	• Current assessment (free text)
Diagnosis	• Current diagnosis (free text and International Classification of Diseases, 10th revision code)
Plan	• Recommended treatment (free text)
Medication	• Current medication if any prescribed (free text)
Type of consultation	• Scheduled • Unscheduled
Method of communication	• Video • Phone
Interpreter	• Foreign language if interpreter was used
Follow-up	• No further treatment • Follow-up if symptoms persist or worsen • Planned follow-up appointment • Referral • Hospital admission

Ethics Approval

Ethics approval for the evaluation of the pilot project was obtained from the ethics committee of the Eberhard-Karls-University Tübingen (728/2018BO1) and the ethics committee of the State Medical Association Baden-Württemberg (F-2018-054) [11].

Results

Baseline Characteristics of the Participating Prisons

The ratio of prisoners to medical staff differed between the 6 prisons. Table 2 shows the sex and number of inmates of each prison at the initiation of the pilot study, as well as the number of physicians and nurses. Except for P4, prison staff comprised at least 1 physician. In P4, 2 external physicians offered scheduled consultation hours twice a week. Scheduled consultations with external physicians from other specialties (not family medicine) varied greatly. In most prisons, regular visits from a dentist were established. P2 offered appointments with a gynecologist and psychiatrist. In addition to dental care and the care provided by the prison physician, P6 offered consultations with a dermatologist and surgeon. Furthermore, nursing staff from P6 was able to contact an external psychiatrist if needed.

Table 2. Occupancy and staff per prison.

Prison	Characteristics	Number of prisoners (n=2499), n (%)	Number of physicians (n=12), n (%)	Number of nurses (n=69), n (%)
P1	Male adults	350 (14)	2 (17)	9 (13)
P2	Female adults or adolescents	350 (14)	1 (8)	6 (9)
P3	Male adolescents	395 (16)	4 (33)	9 (13)
P4	Male adults	52 (2)	0 (0)	3 (4)
P5	Male adults	772 (31)	4 (33)	22 (32)
P6	Male adults	580 (23)	1 (8)	20 (29)

Referrals Following Video Consultations

From June 2018 to February 2019, VC physicians conducted 435 consultations. Out of that, 78% (n=341) of all consultations were scheduled, and the remainder were unscheduled (94/435, 22%). In 68% (n=294), patients were asked to consult a physician again if symptoms persisted or got worse. In 26% (n=115) a follow-up appointment with the video consultant or prison physician was scheduled. A referral to other specialties was necessary in 4% (n=17). The VCS was the method of communication in all 17 cases during which a referral was necessary. A total of 3 of these encounters were unscheduled. Patient transport to an extramural facility was indicated in none of these cases since the secondary care physician could either be contacted via video consultation, was able to come to the prison, or was employed by the prison but off duty during the initial encounter (Table 3).

Due to the small number of necessary referrals, it is hard to rank specialties based on the frequency of necessary referrals. The data showed mixed results with psychiatry as the most common specialty referred to (3/17, 18%), followed by urology (2/17, 12%) and proctology (2/17, 12%). In 2 cases, patients were referred to an external psychiatrist; and 1 patient had a follow-up appointment with a prison psychiatrist. Referral diagnoses also varied between the cases (Table 3). A total of 5 out of the 12 VC physicians (4 family physicians and 1 psychiatrist) conducted the encounters resulting in a referral, however, the number of overall encounters per physician varied greatly ranging from 2 to 143. An interpreter was not needed in any of the 17 consultations that resulted in a referral.

Table 3. Overview of the referrals to other specialties (n=17).

Type of consultation	Medical specialty (physician number)	Diagnosis	Medical specialty referred to
Unscheduled	FM[a] (D7)	Drug abuse, opiate withdrawal	Psychiatry (coming to site)
Scheduled	PSY[b] (D8)	Adjustment disorder	Child and adolescent psychiatry
Unscheduled	FM (D9)	Acneiform dermatitis	Dermatology (video consultation)
Scheduled	FM (D5)	Nausea, suspected adverse reaction, suspected melena	Rheumatology
Scheduled	FM (D10)	(missing data)	(missing data)
Scheduled	FM (D10)	Presbyopia	Ophthalmology
Scheduled	FM (D10)	(missing data)	(missing data)
Scheduled	FM (D5)	Ankle sprain R	Physician licensed to treat work accidents (German: *Durchgangsarzt*)
Scheduled	FM (D10)	(missing data)	(missing data)
Scheduled	FM (D5)	Adverse drug reaction	Urology
Scheduled	FM (D10)	Toothache	Dentistry
Unscheduled	FM (D9)	Prison admission exam	Psychiatry or drug counseling (prison psychiatrist)
Scheduled	PSY (D8)	Chronic arm pain after car accident, insomnia[c]	Neurology
Scheduled	PSY (D8)	Liver cirrhosis, suspected ascites[c]	Gastroenterology
Scheduled	FM (D5)	Priapism	Urology
Scheduled	FM (D5)	First degree hemorrhoids	Proctology[d]
Scheduled	FM (D5)	First degree hemorrhoids	Proctology[d]

[a]FM: family medicine.

[b]PSY: psychiatry.

[c]No diagnosis coded—information taken from medical history.

[d]Referral only necessary if symptoms persist despite ordered treatment.

Hospital Admissions Following Video Consultations

In 2% (n=8) of the cases, a hospital admission was required. These cases were independent of the 17 cases that required a referral to another specialty in an ambulatory care setting. Hospital admission was usually the result of an unscheduled consultation (7/8, 88%), and the VCS was used in 88% (n=7). Gastrointestinal problems or pain were the most common reason for admission (4/8, 50%) and 6 VC physicians (5 family physicians and 1 psychiatrist) conducted the encounters (Table 4). An interpreter was not needed in any of these consultations.

Table 4. Overview of hospital admissions (n=8).

Type of consultation	Method of communication	Medical specialty (physician number)	Diagnosis
Unscheduled	Video	FM[a] (D1)	Suspected tuberculosis, hypotension
Unscheduled	Video	FM (D7)	Unstable angina
Unscheduled	Video	FM (D1)	Severe hypotension suspected due to antipsychotics
Unscheduled	Video	FM (D11)	Gastrointestinal hemorrhage
Unscheduled	Phone	FM (D2)	Abdominal pain, kidney stones
Unscheduled	Video	FM (D2)	Gallbladder disease
Unscheduled	Video	FM (D4)	Abdominal pain (differential diagnosis: myocardial infarction)
Scheduled	Video	PSY[b] (D8)	Suspected schizophrenia

[a]FM: family medicine.

[b]PSY: psychiatry.

Hospital Admission and Referrals per Prison and Physician

Almost half of the video consultations (194/435, 45%) were conducted in prison P2 (Table 5). It was the only prison with female inmates (adults and adolescents). At the time of the initial visit to the participating prisons in the framework of the pilot project (September 2018), the number of inmates was similar to P1 (male adults) and P3 (male adolescents; Table 2).

A referral following a video consultation was needed in all prisons apart from P1 and P6. P3 had the highest number of referrals, but less than 10% of video consultations were conducted there. A hospital admission following a video consultation was required in all prisons except P3 and P4.

VC physicians D1 and D8 conducted more than 60% of all encounters (Table 6). However, referrals and admissions were rather scattered among physicians—except for D5, who initiated 6 (35%) of the referrals.

Table 5. Video consultations, referrals, and hospital admissions per prison.

Prison	Video consultations per prison, (n=435), n (%)	Referrals per prison, (n=17), n (%)	Hospital admissions per prison, (n=8), n (%)
P1	41 (9)	0 (0)	2 (25)
P2	194 (45)	5 (29)	1 (13)
P3	41 (9)	6 (35)	0 (0)
P4	75 (17)	4 (24)	0 (0)
P5	68 (16)	2 (12)	4 (50)
P6	16 (4)	0 (0)	1 (13)

Table 6. Video consultations, referrals, and hospital admissions per physician.

Physician	Video consultations per physician, (n=435), n (%)	Referrals per physician, (n=17), n (%)	Hospital admissions, (n=8), n (%)

Discussion

Principal Findings

Most scheduled and unscheduled video consultations did not require a subsequent patient transport to an extramural health care provider or facility. A referral was only needed in 4% (n=17) of the cases and hospital admission was only required in 2% (n=2) of 435 cases.

Comparison to Prior Work

To our knowledge, this is the first study that focused on referral and hospital admission rates in intramural health care when video consultations with family physicians and psychiatrists are offered. Another study evaluated telemedicine consultations with an emergency room (ER) physician and found that 36% of the patients from a correctional facility required transport to the ER after a video encounter [12]. This rate was higher than the referral and hospital admission rate of this study. If prison physicians were given the possibility to refer patients to a telemedicine satellite facility for subspecialty consults, outpatient visits would increase by 40% in the 2 years after implementation. In contrast, ER visits decreased. The authors interpreted the effect as better access to care [13]. The same authors examined telemedicine programs in the juvenile justice system by measuring, for example, outpatient costs, ER costs, and transportation costs [14], which are parameters that are associated with referrals and admissions. Other studies focused on the treatment of single diseases, such as hepatitis C or diabetes, when telemedicine consultations were offered in prison [15,16].

Other studies have shown that outside of the correctional system home telemonitoring could reduce hospital admission rates in people with chronic obstructive pulmonary disease [17,18] and congestive heart failure [19,20]. Telemedicine consultations with an emergency physician led to reduced transfers from skilled nursing facilities to ERs and subsequently to lower hospital admission rates [21], and Rosner et al [22] showed that using telemedicine reduced readmissions after hip and knee arthroplasties. In contrast, a meta-analysis that evaluated different remote management strategies for patients with inflammatory bowel disease demonstrated a reduction in physician visits but no significant effect on relapse or hospital admission rates [23].

Regarding a reduction of referral rates, previous studies outside of the correctional system generally focused on electronic solutions for primary care providers to contact other specialists and have demonstrated mixed results. Liddy et al [24] reported that implementing an electronic consultation service in Canada that allowed family physicians to communicate with secondary care providers regarding a patient's care reduced referral rates between 36% and 53%, which was in line with prior findings of that group [25]. However, their randomized controlled trial with 2 study arms (primary care physicians with and without access to the electronic consultation service), showed a significant referral reduction in both arms [26]. Furthermore, according to an online survey among primary care physicians, a phone consultation with an HIV specialist reduced the perceived need to refer the patient to a secondary care provider,

although the authors acknowledged that actual referral rates had not been studied [27]. In another study, web-based consultation between primary care physicians and nephrologists did not affect referral rates [28].

In comparison to referral rates of (extramural) family medicine practices without the use of video consultations, a referral rate of 3.8% found in this study is at the lower end of the expected spectrum. Generally, referral rates to secondary care providers vary between practices. A recent study showed an average monthly rate of 20.3% with a range of 0.4%-67.1%. Outside of the correctional system, mental health services were the 10th most common specialty for referrals [29]. Older studies showed mean rates of 1.4% to 37% [30-33]. Variance can also be found regarding hospital admission rates of (extramural) family medicine practices. Mean rates of approximately 50-53 admissions per 1000 patients per year have been reported [34,35], which can only indirectly be compared with the data of this analysis (8 admissions per 435 encounters within 9 months).

International studies showed that telemedicine was able to deliver high-quality and timely primary care for adult and adolescent prison inmates [13,36], reduce costs [37], and facilitate mental health services [38,39]. Using telemedicine to improve access, cost, and quality of secondary care, for example, in the fields of ophthalmology [40,41], cardiology [42], and dentistry [10,43] has also been described before and is still under evaluation [44]. Especially, countries with remote regions outside of metropolitan areas, such as the United States or Australia, have reported the use of telemedicine in their correctional systems [45], but also more densely populated countries deemed the use as beneficial [10,46].

Strengths and Limitations

The pilot project was the first broad implementation of telemedicine in the German correctional system. But there are some limitations: first, a possible selection bias has to be considered: prison staff may have chosen to directly call an ambulance or organize a transport to an extramural facility instead of using video consultations for more severe medical cases. If only patients with less severe diseases were seen by VC physicians, the likelihood of required hospital admission was consequently decreased. Similarly, prison staff may have directly scheduled an appointment with a secondary care provider visiting the prison, which also might have reduced the likelihood of referrals. However, it was crucial that not only patients were given a choice to talk to a VC physician or receive usual care, but that prison staff was also free to choose whether or not to contact the VC—especially since 2 authors were VC founding members. Neither prison staff nor patients received incentives for contacting the VC. Second, there was no control group in this study, and therefore, referral and hospital admission rates cannot be compared with regular intramural care. Despite the low rates when using video consultations, a referral or an admission might not have been necessary if an in-person consultation had been done at that time. Third, only data from the VC portal was considered for this analysis. Fourth, it is unknown how many patients refused a video consultation. Fifth, at the beginning of the data collection, some VC physicians did

not complete the entire documentation template, therefore, some data were missing (the type of follow-up was not specified in 1 case, and in 2 cases, no diagnosis or reason for the referral was listed). The documentation improved throughout the project as physicians became more familiar with or received more training regarding the use of the VC portal. Finally, all consultations were carried out by a rather small group of physicians, and therefore, the influence of individual experience and working style cannot be excluded.

Implication for Practice and Research

The results show that a referral or admission was only required in a few cases after video consultations were offered in prison.

Compared with extramural family medicine practices, the referral rates found in this study were at the lower end of the expected spectrum and support that the implementation of telemedicine in intramural systems on a larger scale should not be postponed or revised due to concerns of high referral and admission rates. Further research, including controlled studies, is needed to explore whether institutional factors contribute to the effectiveness and safety, such as training of staff, use of remote medical devices, and acceptance of telemedicine by inmates, prison (nursing) staff, and physicians working on-site—especially in the light of the fact that the data were generated prior to the COVID-19 pandemic and video consultations became much more common since then.

Data Availability

The data sets generated or analyzed during this study are not publicly available due to privacy protection regulations but are available from the corresponding author on reasonable request.

Authors' Contributions

MS planned and acquired the project between the Ministry of Justice Baden-Württenberg and the A+ Videoclinic. MS and EEB monitored the telemedical processes and the quality management protocols. RK and MGC collected the data for the evaluation study of the pilot project. KS-B analyzed the data of this study. All authors helped to draft the manuscript and approved the final version.

Conflicts of Interest

MS is a founding member of the A+ Videoclinic and the head of the Medicine and Quality Committee. FV is the current chief executive officer. EEB is the acting medical head. JS represented the project to the Medical Association of Baden Württemberg as the medical leader. KS-B is a part-time employee of the A+ Videoclinic. RK and MGC declare no conflict of interest.

Abstract

Background: The significant impact of digital health emerged prominently during the COVID-19 pandemic. Despite this, there is a paucity of bibliometric analyses focusing on technologies within the field of digital health patents. Patents offer a wealth of insights into technologies, commercial prospects, and competitive landscapes, often undisclosed in other publications. Given the rapid evolution of the digital health industry, safeguarding algorithms, software, and advanced surgical devices through patent systems is imperative. The patent system simultaneously acts as a valuable repository of technological knowledge, accessible to researchers. This accessibility facilitates the enhancement of existing technologies and the advancement of medical equipment, ultimately contributing to public health improvement and meeting public demands.

Objective: The primary objective of this study is to gain a more profound understanding of technology hotspots and development trends within the field of digital health.

Methods: Using a bibliometric analysis methodology, we assessed the global technological output reflected in patents on digital health published between 2017 and 2021. Using Citespace5.1R8 and Excel 2016, we conducted bibliometric visualization and comparative analyses of key metrics, including national contributions, institutional affiliations, inventor profiles, and technology topics.

Results: A total of 15,763 digital health patents were identified as published between 2017 and 2021. The China National Intellectual Property Administration secured the top position with 7253 published patents, whereas Koninklijke Philips emerged as the leading institution with 329 patents. Notably, Assaf Govari emerged as the most prolific inventor. Technology hot spots encompassed categories such as "Medical Equipment and Information Systems," "Image Analysis," and "Electrical Diagnosis," classified by Derwent Manual Code. A patent related to the technique of receiving and transmitting data through microchips garnered the highest citation, attributed to the patentee Covidien LP.

Conclusions: The trajectory of digital health patents has been growing since 2017, primarily propelled by China, the United States, and Japan. Applications in health interventions and enhancements in surgical devices represent the predominant scenarios for digital health technology. Algorithms emerged as the pivotal technologies protected by patents, whereas techniques related to data transfer, storage, and exchange in the digital health domain are anticipated to be focal points in forthcoming basic research.

(Interact J Med Res 2024;13:e48259) doi:10.2196/48259

Introduction

Background

Over the past few decades, the intertwining of health care and digital technology has given rise to significant transformations in the production, alignment, and consumption of health care products [1]. This integration has contributed to the achievement of safer and more cost-effective health care outcomes. The conceptual emergence of terms such as "Digital Health," "Digital Medicine," and "Digital Therapeutics" is a direct consequence of this symbiotic relationship. The International Digital Therapeutics Alliance (DTA), founded in 2017 in the United States, stands as a nonprofit industry association comprising stakeholders committed to evidence-based therapeutic interventions aimed at preventing, managing, or treating diseases [2]. As per the DTA's classification, digital therapeutics represents a specific niche within digital health and digital medicine [3]. Notably, a range of digital therapeutics products is currently available for managing diabetes [4,5], treating patients with social anxiety disorder [6] or neurological disorders [7], addressing mental illness [8], and developing digital biomarkers designed to predict treatment response [9]. These products rely on real-world data, and clinical evidence is imperative to substantiate claims regarding risk, efficacy, and intended use [10].

Nielsen and Sahay [11] conducted a critical examination aimed at identifying gaps in the literature, approaching the analysis from an information systems perspective. Their study, based on the analysis of 342 articles published in interdisciplinary digital health research journals, revealed that these studies tended to deviate from the complexities inherent in real-life settings within health care organizations, particularly in relation to the characteristics of digital technologies and the context of their use. Notably, the literature on digital health primarily emphasized the processing power of digital technology and its potential effects [11]. In line with the observations from the study by Nielsen and Sahay [11], a bibliometric analysis conducted by Keng Yang et al [12] in 2022 spanning the period from 1998 to 2021 demonstrated a rapid expansion in the number of publications on digital health. The findings suggested that heightened awareness of digital health had the potential to improve health outcomes, bridge digital gaps, and reduce health disparities [12]. Supporting this perspective, Ahmadvand et al [13] used "digital health" as a keyword for their bibliometric analysis, covering articles published between January 2000 and August 2019 in JMIR Publications journals. Their study revealed a significant increase in the number of articles focusing on "digital health" over a 9-year period, with "mHealth" emerging as the most frequently used keyword within this domain [13]. In addition, Gupta et al [14] conducted a scientometric assessment of digital health research, examining 6981 global publications sourced from the Scopus database during the period 2007 to 2016. Their research underscored medicine as the dominant topic, constituting the largest publication share in digital health research at 54% [14].

Previous studies primarily focused on published papers, neglecting the distinctive value provided by patents as a special and unique source of knowledge, given that a significant amount of data and information contained in patents is not made available through alternative channels. The patent system, designed to stimulate innovation, concurrently ensures that the benefits of inventive efforts are made accessible to the public. In the field of digital health, considering the industry's rapid and iterative development, the patent system must leverage digital technology to safeguard algorithms, software, and advanced surgical instruments. Apart from furnishing information on digital health patents, the patent system serves an additional role by granting other researchers access to patent information, thereby facilitating enhancements in existing technologies.

Bibliometric analysis serves as a powerful tool for examining research trends, identifying prolific authors, understanding demographics, and exploring related information within specific fields [15]. CiteSpace5.1R8, a widely used scientific mapping software application, is adept at analyzing hot spots and trends, visually illustrating a systematic understanding of the past across various domains [16]. Bibliometrics, along with visual analysis, of patent landscapes in the fields of digital technology within public health is relatively scarce. Therefore, this study predominantly relies on this methodology to investigate granted patents related to digital technology in health care, shedding light on its technical status and prevailing tendencies.

Objectives

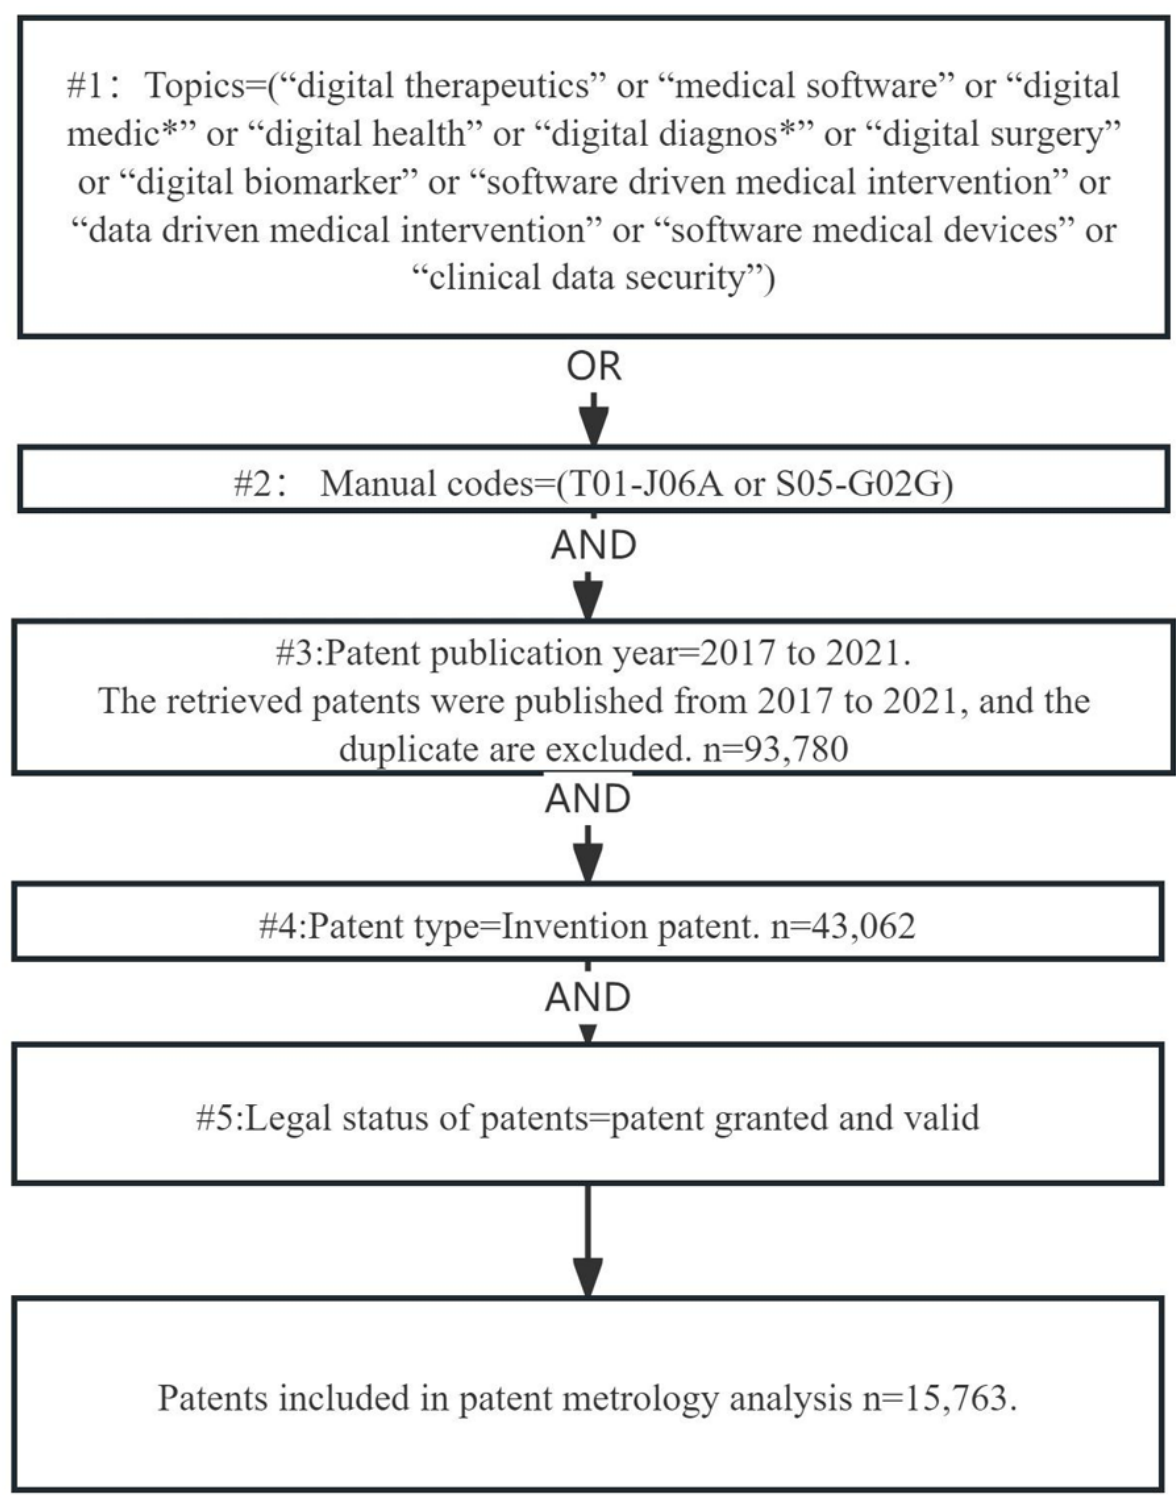
The research uses the bibliometric method to delve into the annual volume of patent applications and grants, scrutinizing information related to countries, inventors, patentees, cited patents, and Derwent Manual Code (DMC) classifications of digital technologies. The primary objective of this study is to gain a more profound understanding of technology hot spots and development trends within the field of digital health.

Methods

Data Collection

The data for this study were sourced from the Derwent Innovation Index, a database that amalgamates patent citations from the Derwent Patents Citation Index with additional patent data indexed from >50 patent issuing agencies in the Derwent World Patent Index (1963 to present). Adhering to the procedural guidelines by Chen [17], we retrieved patents associated with "digital health," "digital medicine," and "digital therapeutics," along with a selection of other pertinent topics. Our screening strategies incorporated DMC "T01-J06A," signifying "medical equipment and information systems," and "S05-G02G," representing "hospital equipment with medical IT systems," based on the categorization of DMC. DMC serves as a simplified classification system designed to categorize patent documents across all technologies. This coding system streamlines the categorization and indexing method used by

Derwent for all covered patents, ensuring efficiency [18,19]. Figure 1 illustrates our specific screening strategies in the flowchart for data collection.

Figure 1. The flowchart for data collection.


The patent retrieval process involved several steps to compile a comprehensive data set related to digital health. Initially, we extracted patents with topics relevant to digital health using the topic tag for string retrievals through titles and abstracts of patents in the Derwent Innovation Index. The first step (#1) used the following query: Topics=("digital therapeutics" OR "medical software" OR "digital medic*" OR "digital health" OR "digital diagnosis*" OR "digital surgery" OR "digital biomarker" OR "software-driven medical intervention" OR "data-driven medical intervention" OR "software medical devices" OR "clinical data security"). Subsequently, we retrieved patents using DMC. The query command for the second step (#2) was Manual Codes=(T01-J06A OR S05-G02G). In the third step, we combined the commands from

#1 OR #2 and limited the publication date of patents from 2017 to 2021. This timeframe was chosen because significant developments in digital health occurred in 2017, including the establishment of the International DTA, release of guidelines by the Chinese State Food and Drug Administration, publication of the World Health Organization recommendations on digital technologies for Tuberculosis care, and the US Food and Drug Administration approval of the first prescription digital therapy. We retrieved 93,780 published patents using this criterion. Subsequently, in the fourth step, we focused on invention patents, as they generally hold greater value in most countries, resulting in 43,062 invention patents included in the sample. As expired patents lack legal force, our analysis primarily considered patents in force to reflect the latest trends in digital technology in public health. We included patents from the previous step (#4) with a granted and valid legal status, resulting in a final data set of 15,763 patents included in our study sample. According to our search methods, patents from the African region have not been retrieved in this study.

As outlined in the introduction to the Derwent Innovation Index database, the earliest time stamp for data collection extended back to 1963. The initiation of patent retrieval for published patents began in 2017. Given that some patents published in 2017 might have been granted in 2022, the conclusion of the study period was set at the year 2022. The data retrieval process was completed on September 22, 2022.

Analysis Methodologies

In conducting this study, CiteSpace 5.1 R8 SE and Excel 2016 software were used. By configuring parameters such as time slicing and thresholds, diverse results could be obtained [20,21]. Furthermore, CiteSpace offered the capability to visualize the outcomes of the analysis [22], using linkages and nodes to illustrate the quality of various elements and their interrelationships [23]. The software also had the ability to cluster items using statistical techniques such as log-likelihood ratio and assess the burst of themes to identify DMCs with prolonged bursts and high strength [24]. CiteSpace contributes to enhanced clarity and interpretability of visualizations compared to other tools, thereby reducing cognitive load on users as they explore significant trends and turning points in a technological framework [25,26].

The chosen records were exported from the Derwent Innovation Index in plain text format and subsequently imported into CiteSpace for comprehensive analysis and visualization of cited patents, research hot spots, and frontiers. A total of 15,763 patent records, encompassed by the CiteSpace version, were retrieved based on their patent publishing timeframe spanning from 2017 to 2022. The data were segmented into 1-year time slices, and the top 50 most cited strings were extracted from each slice. The thematic analysis incorporated various fields from the plain texts, encompassing inventors, cited patents, patent assignees, cited authors, DMC, and International Patent Classification (IPC). Node types were specified as country, institution, author, and category, and the results were visualized in this specified order. This approach allowed for a detailed exploration of relationships and patterns within the data set, providing insights into the geographical, institutional, and authorship aspects of digital health patents.

The chosen records were exported from the Derwent Innovation Index in a table format and subsequently imported into Excel 2016 for thorough analysis. The study focused on examining the annual volume of applications, granted patents, the most productive countries, institutions, inventors, highly cited patents, and institutes. This approach in Excel allowed for a systematic exploration of quantitative aspects related to digital health patents, providing insights into the dynamics of patent activity over time and identifying key contributors and influential patents in the field.

Results

Applications and Granted Trends Across Diverse Sectors

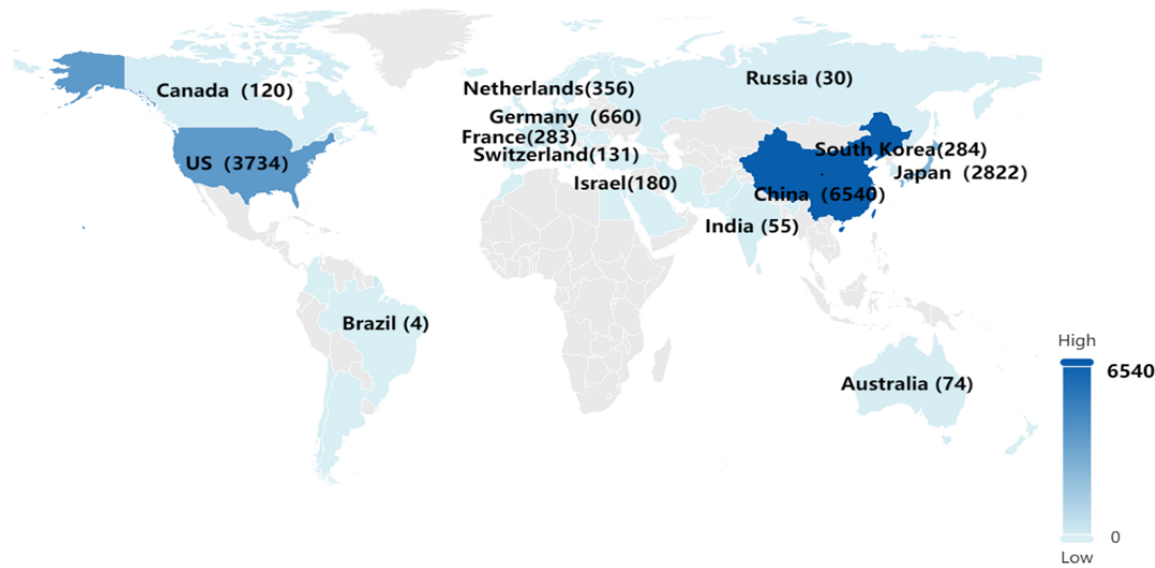
We conducted an analysis of all 15,763 granted patents related to digital health published between 2017 and 2021. In 2017, a total of 48 patents were granted, followed by a surge to 428 granted patents in 2018. As illustrated in Figure 2, the annual applications for patents in the digital health domain experienced a sharp increase from 2017 to 2019, followed by a slight stagnation in 2020. However, a renewed upward trend was observed from 2020 to 2021. A general upward trajectory was noted in granted patents from 2017 to 2022. The fluctuation in 2022 may be attributed to the timing of data retrieval, as patents published between 2017 and 2021 might not have been granted by September 22, 2022.

Figure 2. Applied and granted patents from 2017 to 2022.
Geographical Distribution

Applicants have the option to apply for patents through intellectual property offices (IPOs) in various countries or regions, thereby extending the scope of protection for their technological innovations in the field of digital health. Table 1 and Figure 3 present the top 10 IPOs for published patents and the top 10 patent applicant countries concerning patent publications. These insights offer a comprehensive view of the global landscape in terms of patent activities related to digital health, highlighting the key contributors and regions involved in the innovation and protection of digital health technologies.

Table 1. Top 10 intellectual property offices for published patents (N=15,763).

Intellectual property office	Published patents, n (%)
China National Intellectual Property Administration	7253 (46.01)
United States Patent and Trademark Office	4052 (25.71)
Japanese patent office	2174 (13.79)
European patent office	1242 (7.88)
IP Australia	244 (1.55)
Inspirations Property Institution	228 (1.45)
World Intellectual Property Organization	216 (1.37)
Deutsches Patent- und Markenamt	172 (1.09)
Canadian Intellectual Property Office	94 (0.6)
Spanish Patent and Trademark Office	46 (0.29)

Figure 3. Intellectual property office for published patents (marked according to the country where the intellectual property office is located).


A total of 99.73% (15,721/15,763) of the published patents originated from the top 10 IPOs, as detailed in Table 1. The China National Intellectual Property Administration (CNIPA) held the majority share, contributing 46% (n=15,763) published patents, surpassing other IPOs. The United States Patent and Trademark Office (USPTO) secured the second position with 25.71% (4052/15,763), followed by the Japanese patent office (JPO) at 13.79% (2174/15,763), the European Patent Office at 7.88% (1242/15,763), IP Australia at 1.55% (244/15,763), Inspirations Property Institution at 1.45% (228/15,763), and the World Intellectual Property Organization at 1.37% (216/15,763).

A total of 95.86% (15,110/15,763) of the published patents originated from the top 10 applicant countries, as illustrated in Figure 3. Among these, China emerged as the leading country, submitting the highest number of patents at 6540 (41.5%) of the total 15,763 publications. The United States secured the second position, contributing 23.69% (3734/15,763) of the publications, followed by Japan with 17.9% (2822/15,763).

The alignment of the top 3 IPOs with the leading patent applicant countries, namely, China, the United States, and Japan, underscores these regions as highly competitive in safeguarding technological innovations within the realm of digital health. This correlation suggests that institutions, enterprises, and individuals from these countries are at the forefront of technological innovation in the field of digital health. China, the United States, and Japan collectively stand out as leaders in driving advancements and securing intellectual property protection in the dynamic landscape of digital health technologies.

Multimedia Appendix 1 provides an overview of the nationality distribution of patent applicants within the top 3 IPOs.

Specifically, 92.72% (2001/2158) of patent applicants to the JPO were from Japan, with 4.45% (96/2158) and 0.65% (14/2158) of applicants originating from the United States and South Korea, respectively. For the CNIPA, 87.08% (6316/7253) of patent applicants were from China, whereas 3.38% (245/7253) and 3.25% (236/7253) were from Japan and the United States, respectively. In the case of the USPTO, 69.32% (2953/4260) of patent applicants were from the United States, with 6.1% (269/4260) and 3.87% (165/4260) from Japan and China, respectively. Notably, the JPO had the highest proportion of domestic applicants, closely followed by the CNIPA. Japanese patentees, who also held the second-largest share of granted patents in China and the United States, actively expanded their digital health patents globally. Chinese patentees, despite ranking third based on the nationality of patent applicants in JPO and USPTO, exhibited a notable gap in percentage compared to their American and Japanese counterparts.

Institution Distribution

A total of 671 institutions or individuals were identified as publishers of patents related to digital health. As detailed in Table 2, Koninklijke Philips emerged as the leading enterprise with 329 published patents, followed by Siemens Healthcare GmbH (252 publications), Shanghai United Imaging Healthcare (151 publications), Samsung Electronics (121 publications), and Canon Medical Systems (118 publications). Notably, all these published patents were granted, with Koninklijke Philips having the highest number of granted patents. The top 10 institution types were exclusively enterprises, with Japanese corporations leading the count at 339 published patents, followed by American companies with 211 published patents, as indicated in Table 2.

Table 2. Top 10 institutions with the most published patents (N=15,763).

Institution	Country of origin	Published patents, n (%)
Koninklijke Philips	The Netherlands	329 (2.09)
NV Siemens Healthcare GmbH	Germany	252 (1.6)
Shanghai United Imaging Healthcare	China	151 (0.96)
Samsung Electronics Co Ltd	South Korea	121 (0.77)
Canon Medical Systems Corp	Japan	118 (0.75)
Fujifilm Corp	Japan	115 (0.73)
Hitachi Ltd	Japan	106 (0.67)
International Business	United States	106 (0.67)
General Electric Company	United States	105 (0.67)
Biosense Webster (Israel) Ltd	Israel	97 (0.62)

Table 3 highlights the top 10 highly cited institutions, all of which are enterprises. Auris Health Inc and Masimo Corporation stand out with 849 and 983 citations globally, respectively, underscoring their substantial technological influence in the digital health field. It is noteworthy that Lepu (Beijing) Medical Equipment, founded in 1999, is the only Chinese company listed in Table 3.

Table 3. Top 10 highly cited institutes in the world.

Institute	Cited frequency, n	Patents, n	Proportion (cited frequency/patents)	Country
Auris Health Inc	849	19	44.68	United States
MASIMO corporation	983	28	35.11	United States
Ethicon Llc	700	24	29.17	United States
BERTEC Corporation	251	10	25.10	United States
VIGNET Incorporated	70	5	14.00	United States
Bardy Diagnostics Inc	60	5	12.00	United States
Lepu (Beijing)	149	13	11.46	China
Medical Hi LLC	69	7	9.86	United States
Amazon Technologies	74	8	9.25	United States
Heartflow Inc	43	6	7.17	United States

The analysis of coauthorship among institutions revealed noteworthy insights, as depicted in Figure 4. CiteSpace autonomously identified 215 institutions with 212 links, constructing a network illustrating institutional cooperation. The visual representation in Figure 4 incorporates color-coded circles denoting the publication year, node size representing the quantity of published patents, annual-ring width indicating the number of published patents in each year, and link thickness reflecting cooperation strength. Notably, Figure 4 highlights limited international cooperation in the field of digital health among institutions. However, the analysis identifies 2 notable enterprise alliances in Japan. The first alliance involves Fuji Film Corp, whereas the second features Panasonic Intellectual Property Management Corporation collaborating with both Fuji Film and Hitachi. Another noteworthy collaboration in Japan involves Canon, with Olympus maintaining a partnership, albeit with a lower link strength. These collaborative efforts signify strategic partnerships within the Japanese digital health landscape.

Figure 4. Institutional coauthorship network.

Conversely, there were relatively few local corporations collaborating with entities in the United States. General Electric Company exhibited robust research and development capabilities, evident by its limited linkages with other institutions, including universities.

In China, extensive collaboration was observed among hospitals, universities, and research institutions, providing substantial technological support to Shanghai United Imaging Healthcare. This collaborative landscape underscores the active engagement of various entities in China's digital health sector, fostering advancements through cooperative efforts. Multimedia Appendix 2 illustrates the collaboration direction between Shanghai United Imaging Healthcare, the sole Chinese company listed in Table 3, and Zhongshan Hospital, its primary joint patent application agency, depicted through a word cloud. The primary focus of collaboration between these 2 entities centered around medical imaging, particularly in the fields of tumors and the spine. This collaboration highlights the synergy between Shanghai United Imaging Healthcare, and Zhongshan Hospital in advancing medical imaging technologies, with a specific emphasis on tumor and spine-related applications.

Inventor Distribution

Table 4 outlines the top 10 most active inventors based on patent filings, featuring 7 Americans and 3 Chinese innovators. This compilation was conducted using Microsoft Excel 2016. Notably, Assaf Govari secured the top position with 43 (0.3%) patents of the total 15763. Frederick E published 31 (0.2%) patents of the total 15,763. Ammar Al Ali, Gary A, Jason L, Yong Wang, and Hairong Zheng collectively published 25 (0.2%) patents of the total 15,763, earning them the third spot in terms of publications. Among the top 10 inventors, 1 hailed from Zhejiang University, the remaining 9 were all affiliated with enterprises, highlighting the significant contributions of both academic and corporate entities in the realm of digital health innovation.

Table 4. Top 10 inventors with published patents.

The first inventor[a]	Nationality	Institution	Published patents, n
Assaf	Israel	Biosense Webster (Israel) Ltd	43
Frederick E	United States	Ethicon Llc	31
Ammar Al	United States	Masimo Corporation	25
Gary A	United States	Zoll Medical Corporation	25
Jason L	United States	Ethicon Llc	25
Yong Wang	China	Chison Medical Technologies Co Ltd	25
Hairong Zheng	China	Shenzhen National Res Institute of High-Performance Medical Devices Co Ltd	25
Gust H	United States	Bardy Diagnostics Inc	24
Avi	United States	Align Technology Inc	23
Tao Liu	China	Zhejiang University	20

[a]Inventors publishing the same number of patents were sorted alphabetically.

Assaf Govari, a prominent inventor, served as a fellow in research and development at Biosense Webster, a leading international company specializing in diagnosing and treating heart rhythm disorders [27]. A comprehensive search in the incoPat Patent Data System revealed 565 patent applications listing Assaf Govari as one of the inventors. Figure 5 depicts the analysis of technology themes using the patent 3D sandbox. This innovative visualization represents the competitive landscape of technologies in a 3D topographic map, where peaks signify technology-intensive areas and troughs represent technology gaps. Each dot represents a patent, and proximity indicates relevance. The most frequently mentioned technology theme was data point location tracking for analyzing magnetic resonance imaging data (176 patents). The second most frequent theme was electroporation technology used in ablation procedures during cardiac surgery (173 patents). The third most frequent theme involved an inflatable balloon (138 patents). These insights provide a glimpse into the diverse and impactful contributions of Assaf Govari in advancing technological frontiers in the field of digital health.

Figure 5. Top 10 technology topics of Assaf Govari.
Ammar Al Ali held a position as a fellow at Masimo Corporation, a global health care technology enterprise renowned for its research and development of cutting-edge noninvasive patient monitoring techniques. Masimo Corporation also secured the second position among the top 10 leading institutes globally, as indicated in Table 3. Frederick E and Jason L Harris were affiliated with Ethicon Llc, ranking third among the top 10 institutions. Ethicon Llc is widely recognized for its research and development in advanced tissue management. Gust H Bardy served as the founder and chief medical officer of Bardy Diagnostics, a company that held the sixth position among the top 10 institutes globally. Bardy Diagnostics specialized in the development of heart monitors and arrhythmia detection devices, emphasizing the delivery of diagnostically accurate and patient-friendly heart patches and other monitoring solutions. Gust H Bardy oversaw all clinical services related to ambulatory cardiac monitoring within the company.

Our analysis extended to coauthorship, using CiteSpace to scrutinize inventor networks. The software meticulously tallied all inventors in each patent, resulting in a coauthorship network of 168 inventors, 639 linkages, and a density of 0.05. Figure 6 visually represents this coauthorship network, with colors of circles denoting the publication year, node size indicating the quantity of published patents, annual-ring width reflecting the number of published patents in each year, and link thickness conveying cooperation strength. Figure 6 reveals that most inventors published patents in 2016 or 2017, and a decline is observed in the number of inventors contributing to technology innovation over subsequent years. This temporal trend offers

insights into the dynamics of inventor collaboration, emphasizing the early surge in collaborative efforts in the field

of digital health innovation.

Figure 6. Inventor coauthorship network.
Centrality serves as an indicator of a node's essentiality within a system. CiteSpace uses this metric to discern the relevance of authors or institutions, highlighting those with a centrality of at least 0.1 using a purple circle. In our analysis, Wang X emerged as a highlighted node, and we identified 142 published patents listing Wang X as the inventor.

Technological Topic and Patents With a High Citation Number

We conducted an investigation into the technological themes of digital health patents using the IPC Code and the DMC. Our searches and categorizations of patent materials were guided by hierarchical classification systems. The IPC, as the sole global classification system for patent documents, serves as a valuable tool for systematically organizing patents, establishing a foundation for the selective release of information, and providing a starting point for research into the state of the art in specific technological fields. The seventh edition of the IPC comprises 8 parts, divided into 120 classes, 628 subclasses, and approximately 69,000 groups [28]. Data for these research

categories were extracted from search results in the Derwent Innovation Index database system and the incoPat system.

Table 5 delineates the foremost 10 technology domains within the realm of digital health, as categorized by DMC and IPC numbers. It is noteworthy that a single patent may fall under multiple IPC and DMC classifications, thereby impacting the overall count of patents. Of particular significance in the classification system of DMC were "diagnostic devices" (9081/15,763, 57.61%) and "claimed software products" (3781/15,763, 23.99%), which emerged as the 2 paramount technology subjects in the landscape of digital health patents. In addition, "medical equipment and information systems" (14,579/15,763, 92.49%) played a pivotal role in the overall categorization. Within the spectrum of coding, T01-J (data processing system), P31-A (diagnosis or surgery apparatus), and S05-D (electrical diagnosis) predominated as the primary codes for the sample patents. Notably, the special code listed was B11-C11, denoting "general computing methods and apparatus," a prevalent technique within the realm of computer science. This underlines its ubiquity and relevance in the digital health patent landscape.

Table 5. Top 10 technology topics classified by Derwent Manual Code and International Patent Classification.

Content		Published patents, n
Derwent Manual Code		
T01-J06A	Medical equipment and information systems	14,579
P31-A05	Diagnostic devices	9081
T01-S03	Claimed software products	3781
T01-J10B2	Image analysis	2573
S05-D	Electrical diagnosis	1982
B11-C11	General computing methods and apparatus	1278
S05-D01	Measuring and recording systems	804
T01-J10B1	Image enhancement	1028
P34-A02	Syringes for removing and introducing fluids into the body	933
P31-A01	Surgical tools and instruments	894
S05-D07	Diagnostic displays and monitors	756
International Patent Classification number		
A61B5	Measurement for diagnostic purposes; human identification instruments used for radiation	5962
A61B6	Diagnosis combined with radiotherapy equipment	1769
G06T7	Image analysis	1523
G06K9	Method or device for pattern recognition	1214
A61B34	Manipulators or robots specially adapted to surgery; computer-assisted surgery	957
A61B8	Diagnosis with an ultrasonic, acoustic, or infrasonic waves input device used to convert the data to be processed into a form that can be processed by the computer	878
G06F3	Output device used to transfer data from the processor to the output device, for example, interface device equipment for testing eyes	696
A61B3	Instrument for checking eyes electrotherapy	690
A61N1	ICT[a] dedicated to arranging or managing health care resources or facilities	659
G16H40	ICT dedicated to operating medical equipment or devices	650

[a]ICT: information and communication technology.

From the perspective of the IPC number, pivotal metrics in the field of digital health were evident, with diagnostic and identification measurements (5962/15,763, 37.82%), instruments used for radiation diagnosis (1769/15,763, 11.22%), and image analysis (1532/15,763, 9.72%) emerging as the top 3 technology categories. Within the IPC classification, the sample patents displayed extensive distribution, notably within A61B (diagnosis, surgery, and identification) and G06 (computing and calculating or counting). A noteworthy inclusion in the coding spectrum was the special code G16H04, indicating that information and communication technology has been purposefully designed for the management or administration of health care facilities or resources or the operation of medical equipment and devices. This specialized code underscores the intentional convergence of technology and health care management within the digital health patent landscape.

CiteSpace served as the analytic tool to scrutinize category phrase bursts, facilitating a comprehensive exploration of temporal trends and hot spots within technological themes. Subject categories exhibiting robust burst strengths are indicative of heightened attention from the scientific community during specific periods. These subject categories, derived directly from the DMC of cited patents, encapsulate the primary areas of focus and exploration within a given field during a distinct timeframe. To map the landscape of subject categories, a cocitation network was constructed using the top 20 category themes identified each year. The extraction of the 20 most bursty category themes relied on CiteSpace's burstiness findings, cataloged in Table 6. The "Year" column denotes the year when a code first appeared, whereas "Strength" quantifies the citation burst intensity for the listed codes. The sorting of these categories is based on the inception year, indicating when a category first exhibited bursts, and is detailed in the fourth column. The "End" column signifies the concluding year of a bursting category, providing a temporal context to the identified trends.

Table 6. Top 10 patents according to number of citations.

Publication number	Institute	Year	Cited frequency, n	Client	Client-related product
US10420551B2	Covidien Lp	2019	80	Physicians	Maryland elbow closed cutting surgical instrument
US10980535B2	Ethicon Llc	2021	77	Physicians	Ottava laparoscopic surgery robot
US10464209B2	Auris Health Inc	2019	63	Physicians	Auris robotic endoscopy system
US10539478B2	Auris Health Inc	2020	54	Physicians	Monarch robot endoscope platform
US10416264B2	Hyperfine Research Inc	2019	54	Physicians	Swoop portable MRI[a]
US10426559B2	Auris Health Inc	2019	52	Physicians	Monarch robot endoscope platform
US10140544B1	12 Sigma Technologies	2018	50	Physicians	σ-Discover or Stroke CT[b]
US10070799B2	Pison Technology Inc	2018	49	Patients	Pison AI[c] neural insights
US10932729B2	Masimo Corporation	2021	47	Patients	Root platform
US10282914B1	Bao Tran; Ha Tran	2019	43	Physicians	VR[d]

[a]MRI: magnetic resonance imaging.

[b]CT: computed tomography.

[c]AI: artificial intelligence.

[d]VR: virtual reality.

As illustrated in Figure 7, the temporal evolution of digital health technology topics is graphically represented. The red line denotes the commencement year of each topic burst, whereas the subsequent timeline is delineated in green. Figure 7 showcases the top 20 DMC with the most robust burst strength in patents within the digital health domain, characterized by distinct thematic trajectories. The early phase of technological exploration predominantly encompassed topics such as "hospital equipment for patients' medical records" and "general diagnostic image processing." These themes garnered widespread citations from 2016 to 2017, exhibiting burst strengths of 33.171 and 24.483, respectively. This implies that patients' medical records served as a primary data source, and general diagnostic image processing emerged as a principal application scenario for digital health technology during this period.

Figure 7. Top 20 subject categories with the strongest citation bursts.

Subject categories	Year	Strength	Begin	End	2016-2022
HOSPITAL EQUIPMENT - PATIENT'S MEDICAL RECORDS	2016	33.1714	2016	2017	
GENERAL DIAGNOSTIC IMAGE PROCESSING	2016	24.4826	2016	2017	
RADIATION DIAGNOSIS USING X-RAYS - PROCESSING OF RECORDED IMAGE	2016	8.5003	2016	2018	
SIGNAL PATTERN RECOGNITION	2016	5.4597	2016	2017	
FORMING ELECTRONIC IMAGING	2016	10.7604	2017	2018	
PROGRAM SECRUIT MANAGEMENT	2016	22.5473	2018	2019	
MEDICAL IT[a] SYSTEMS	2016	53.7168	2019	2022	
KNOWLEGDE PROCESSING BY AI[b] WITH NEURAL NETWORK	2016	47.5348	2019	2022	
MEDICAL EQUIPMENT WITH MEDICAL SYSTEM	2016	40.8603	2019	2022	
MEDICAL INFORMATION SYSTEM FOR DATA PROCESS	2016	40.2373	2019	2022	
INFORMATION RETRIEVAL AND STORAGE	2016	37.8596	2019	2022	
ON-LINE MEDICAL INFORMATION SYSTEM	2016	35.8601	2019	2022	
NON VEHICLE NAVIGATION	2016	33.6554	2019	2022	
STERILIZATION AND DISINFECTION DEVICES	2016	30.6469	2020	2022	
ELECTRICAL DIAGNOSIS AND NEUROLOGICAL CURRENTS AND SIGNALS	2016	28.1068	2020	2022	
MEDICAL SIMULATION SYSTEMS	2016	23.2352	2020	2022	
COMPUTER CONTROL OF MANUFACTURING AND INDUSTRIAL MACHINES AND QUALITY CONTROL	2016	20.1284	2020	2022	
MEDICAL IT SYSTEM FOR DATA TRANSFER AND STORAGE METHODS AND APPARATUS	2016	13.8401	2020	2022	
DATA EXCHANGE WITH DISTANT STATIONS BY RADIO LINK	2016	8.4832	2020	2022	
SURGICAL TOOLS AND INSTRUMENTS	2016	3.2381	2020	2022	

A subsequent thematic surge in digital health technology research occurred from 2017 to 2019, with a focus on establishing electronic image and data security. The second burst peak materialized in 2019 with the emergence of "medical IT system," holding the strongest strength in the identified list, and its influence persisted until 2022. In addition, themes such as "knowledge processing by artificial intelligence with neural networks," "medical equipment with the medical system," and "medical information system for data processing" coincided with this burst period. Distinct trends unfolded from 2020 to 2022, with themes such as "sterilization and disinfection devices," "electrical diagnosis for neurological currents and signals," and "medical simulation systems" gaining prominence. The technology topics with the highest burst strength can be broadly categorized into 4 domains. First, the integration of medical equipment or apparatus with information technology systems, exemplified by themes such as "surgical tools," "sterilization and disinfection devices," "medical equipment with the medical system," and "hospital equipment for patients' medical records." Second, themes related to medical information systems, such as "general diagnostic image processing," "web-based medical information system," "medical simulation systems," "medical information technology system for data transfer or storage," and "medical information system for data

processing." The third category encompasses methods for processing medical data, including themes such as "signal pattern recognition," "forming electronic image," "knowledge processing by artificial intelligence with neural networks," "information retrieval and storage," and "data exchange with distant stations by radio link." The last category pertains to the specific application of digital health technology in medical fields, including themes such as "general diagnostic image processing," "processing of recording image of radiation diagnosis using x-rays," "electrical diagnosis for neurological currents and signals," and "nonvehicle navigation." Furthermore, key technology topics are intricately linked to data security and machine quality, as reflected in the themes of "program security management" and "computerized control of manufacturing of industrial machines and quality control."

Table 6 outlines the top 10 most cited patents in the digital health field, categorized by the intended users—physicians and patients. Key features of these highly cited patents include a predominant focus on technologies benefiting physicians, with most patentees representing US-based corporations. The granted technologies are primarily method patents, featuring algorithms for tasks such as capturing real-world anatomy, detecting

misalignment of robotic arms during surgery, and precise segmentation of medical digital images.

Among the top 10 patents, 4 (40%) prominently center around algorithmic technology. Notably, convolutional neural networks played a pivotal role in advancing the technological landscape. They significantly contributed to the development of image detection in the human brain through magnetic resonance [29] and played a key role in the accurate and efficient segmentation of medical images of human organs [30]. The patent US10426559B2, owned by Auris Health Inc, revealed a method for calibrating a medical instrument equipped with an articulable elongated shaft [31], showcasing advancements in instrument precision. In contrast, the patent titled "Systems and methods for computer-assisted operation" stood out as the sole patent applied by individuals. It unveiled a comprehensive technique for capturing real-world anatomy, implemented in 3D printing within the medical field [32].

Furthermore, 2 additional patents delve into the domain of robotic arms extensively used in surgical procedures. These patents are under the ownership of Auris Health Inc, a Subsidiary Corporation of Ethicon Llc. The patent US10464209B2 presents a system designed to control the position of manipulators both before and during medical procedures. It provides an illustrative example of this technology in action during a diagnostic "and" or "or" therapeutic bronchoscopy procedure [33]. Moreover, the patent addressing the "Detection of misalignment of robotic arms" unveils a system engineered for identifying undesirable forces on manipulators within a surgical machine system. This innovative technique is exemplified in the context of ureteroscopy and laparoscopic procedures [34].

In addition, 2 patents focus on technological advancements aimed at enhancing surgical instruments. The most widely cited patent describes a powered surgical instrument designed to enhance the reliability of communication between the disposable loading unit and the handle assembly. This patent, applied by Covidien Lp, a globally recognized enterprise in the development, production, and sales of health care products, was acquired by Medtronic in 2015 [35]. The patent with the identifier US10980535B2 introduces a surgical instrument tailored for use in endoscopic surgical cutting and fastening procedures [36]. Notably, this patent served to upgrade the Auris Robotic Endoscopy System, the first endoscopic robot developed by Auris Health Inc for the treatment of lung diseases. The system had successfully obtained approval from the US Food and Drug Administration in 2016. It is evident that these 2 highly cited techniques are product patents, conferring a broader scope of protected rights compared to method patents. This distinction underscores the significance of innovations in surgical instrument design and functionality within the realm of digital health.

Moreover, it is noteworthy that the technique titled "Detecting and using body tissue electrical signals," owned by Pison Technology Inc, holds a prominent position in Table 6 and finds widespread implementation in wearable devices. Pison Technology Inc has articulated the versatile application of this technique across industrial, business, medical, and military domains. Functionally, it is designed for monitoring, control, feedback, actuation, communication, and comprehensive data accumulation and analysis. This innovative technique has practical applications such as monitoring heart rate and electrocardiograph from the wrist or foot. In addition, it is instrumental in measuring or analyzing fitness parameters, including muscular strength and stamina. In the medical field, it plays a crucial role in observing the state and progression of neurological disorders such as amyotrophic lateral sclerosis and other neurodegenerative conditions. The technique's carrier is a wireless wrist-mounted user interface device, complemented by an app and a universal human-machine interface platform, as detailed in the patent [37]. This comprehensive approach reflects the broader impact and potential of digital health technologies, particularly in the realm of wearable devices and health monitoring.

The final patent to be highlighted is the one titled "Opioid overdose monitoring," owned by Masimo Corporation. This innovative technique comprises an oximeter designed to be compatible with a handheld monitor for physiological parameters. The system is specifically engineered for monitoring indications of opioid overdose and facilitating the delivery of therapeutic drugs [38].

Discussion

Principal Findings

It is crucial to acknowledge that a patent represents an exclusive right granted by a nation to an institution or individual for an invention characterized by innovation, a technical solution, and industrial applicability. Patent information encapsulates a wealth of technological, commercial, and competitor knowledge, with a substantial portion often remaining unpublished. Although bibliometric analyses have been traditionally drawn from articles in digital health–related journals, this study marks the first systematic analysis of digital health technologies using patent documents. This approach serves as a pioneering effort in scientific knowledge dissemination, aiming to identify key nations, inventors, and technological focal points within the realm of digital health. The insights derived from this analysis are intended to provide a valuable reference for researchers and inventors navigating the dynamic landscape of digital health innovation.

In this study, our analysis of patent layouts across different countries revealed Japan as the most active nation in terms of overseas patent distribution, as per statistics from CNIPA, JPO, and USPTO. Notably, we identified distinct cooperation models prevalent in major countries. During the developmental stages of digital health, China, in contrast to the United States and Japan, appeared to be in a startup phase and exhibited a preference for collaborations involving universities, hospitals, and enterprises. In Japan, where digital health industrialization has reached a relatively mature stage, an intercompany cooperation model was found to be more suitable. In the United States, being the most advanced country in digital health industrialization, the need for cooperation seemed less essential, given the presence of formidable companies such as General

Electric Company, equipped with robust technological development capabilities.

Furthermore, our examination of patents allowed us to delineate the top 20 subject categories exhibiting the strongest citation bursts. This analysis serves to illuminate the technological development paths within the field of digital health, offering valuable insights into the trajectory of innovation in this domain.

The comparison with the latest bibliometric analysis on digital technologies in health care by Sikandar et al [39], which focused on published articles from 2017 to 2021, reveals interesting disparities in findings. Sikandar et al [39] identified the United Kingdom as the most active country in the research field of digital technology in health care. Noteworthy themes from the sampled articles included "Digital health literacy," "Digital health for healthcare workers," "Digital health and covid 19," and "Applications of digital health" [39]. This comparison underscores a significant divergence in the hot spots and emphases between patents and articles within the digital health domain. While the United Kingdom emerged as the most active country in the article-centric analysis, our study, centered on patents, identified Japan as the most active nation. Furthermore, the themes that gained prominence in articles, such as "Digital health literacy," were notably absent or had limited mention in the patent landscape. This discrepancy highlights the varied perspectives and priorities of authors and inventors, suggesting that the focus of researchers, as reflected in published articles, may not entirely align with the areas of innovation and patent activity in the digital health field.

The analysis of digital health patents spanning from 2017 to 2021 reveals a notable increase in granted patents in 2018, driven by several key factors. First, supportive policies played a pivotal role in promoting the implementation of digital technology in the medical field. Initiatives such as the "Framework for FDA's Real World Evidence Program," "Regulatory decision making for medical devices supported by real-world evidence," and "Implementation of eHealth Records in Clinical Trial Guidance for Industry," launched by the US Food and Drug Administration in 2017 and 2018, provided a regulatory framework and impetus for digital health innovation. Furthermore, the Chinese government's strategic initiatives, as outlined in the "Guidance on Promoting and Regulating the Medical Data Applications" and "Regulations on promoting the development of online healthcare," released by the General Office of the Chinese State Council in 2016 and 2018, respectively, significantly contributed to the growth of digital health in China. The introduction of the General Data Protection Regulation by the European Union on May 25, 2018, marked a milestone in the formation of industry standards for digital health. This regulation, applicable to any entity handling personal data related to European Union member states, had a global impact on data protection practices. Moreover, the partial coverage of digital health costs by medical insurance in some countries, exemplified by the development of a digital formulary in the United States in 2017, enhanced accessibility and financial viability. This, in turn, stimulated innovation and contributed to the surge in granted patents. In summary, a convergence of regulatory support, strategic government initiatives, the establishment of industry standards, and advancements in

insurance coverage collectively fueled the remarkable increase in digital health patents in 2018.

There is no patent layout for digital health in Africa, and possible reasons are as follows. Policy guidance, technological innovation, and financial support are the foundation on which digital health is born and grows. Africa lacks the corresponding economic basis and talent reserve for the development of the digital health. Meanwhile, few corporation giants focusing on digital health are registered in this area because of the turbulent politics situation, poor economic foundation, and low education level, and this area also has no more mature commercial application for the digital health technology.

This study reveals the top countries, key inventors, and hot technologies in the patent landscape for digital therapies, which provides guidance for implementers who are applying for international patents on digital health. Innovation policies for digital health should be formulated and implemented in countries where patents are predominantly applied. The key inventors and hot technologies proposed by the study can be used as both a reference and as an inspiration for inventors to find cooperation partners and pioneer new research and development areas in the near future.

There is no established patent layout for digital health in Africa, and several factors contribute to this absence. The growth of digital health relies on a foundation of policy guidance, technological innovation, and financial support. Unfortunately, Africa lacks the corresponding economic basis and talent reserve necessary for the development of digital health. In addition, the turbulent political situation, poor economic foundation, and low education levels in the region deter major corporations from focusing on digital health, and there is a lack of mature commercial applications for digital health technology. In addition, it is possible that our search methods may impose limitations on the retrieval of patents from the African region.

This study not only underscores the challenges but also reveals key insights into the top countries, key inventors, and emerging technologies in the global patent landscape for digital therapies. These findings offer valuable guidance for international patent applicants in the field of digital health. Countries where patents are predominantly applied should consider formulating and implementing innovation policies for digital health. Moreover, the key inventors and emerging technologies identified in this study can serve as both a reference and an inspiration for inventors. They provide a road map for finding potential cooperation partners and exploring new research and development areas in the near future.

Limitations

Nevertheless, our study has certain limitations. First, we retrieved only a partial data set from the Derwent Innovations Index database, and some databases were not included. This omission may have resulted in overlooking certain frontier technologies. However, it is worth noting that the Derwent Innovations Index database, from which we collected most published patents, encompasses patents from >50 patent issuing authorities worldwide. Second, our analysis focused solely on granted and valid patents, emphasizing right stability. This

approach may overlook some significant patents in the initial application stage. Third, our study was dedicated to analyzing the technical construction of digital health patents through bibliometric analysis. We did not provide a detailed discussion on the content of patents. For a more comprehensive understanding, a systematic patent review in the future is essential. For future work, expanding the scope of patent searches by including searches on Google Scholar could enrich and fill gaps in patents that were not investigated in this study.

Conclusions

We conducted an analysis of the digital health technology trend from 2017 to 2021 using a data set of 15,763 published patents extracted from the Derwent Innovations Index database. The study not only identified the most productive countries, institutions, and inventors but also delineated the various stages of technology development, key technology categories, and the most cited patents within the digital health domain.

In terms of patent participation rates, China emerged as a frontrunner among the top 10 countries or regions, leading in both the number of patents and technological advancements. This dominance is attributed to China's concerted efforts in driving digital transformation across various sectors, particularly in medicine. In addition, the substantial patient populations in China contribute significantly to the wealth of data resources available for advancing digital health technologies.

Among the top 10 institutions with the highest number of published patents and the top 10 highly cited institutes globally, all were enterprises. This underscores the pivotal role that corporations play in shaping the patent landscape in the digital health sector. The active engagement of these enterprises is anticipated to yield considerable economic returns in the near future.

Examining the top 10 inventors featured in each patent list, 6 hailed from the United States. Furthermore, the patentees of the leading 10 patents, based on the number of citations, were all Americans. Overall, 90% (9/10) of the highly cited institutes globally also originated from the United States. Undoubtedly, the United States has been a frontrunner in the digital health technology domain. Illustrating a noteworthy collaboration model is Shanghai United Imaging Healthcare, a leader in advanced health care imaging techniques. The company closely collaborated with Zhongshan Hospital, a renowned health institution in the cardiovascular field in China, in the development of digital health solutions.

In our analysis of highly cited patents, we observed that health interventions and improvements in surgical devices were the primary application scenarios for digital health technology. Core to these advancements were algorithms, the focal point of patent-protected technologies. In addition, technologies related to data transfer, storage, and exchange, particularly in the context of telehealth, are anticipated to be hot spots in basic research in the near future.

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

WG contributed to formal analysis and original draft writing. JW contributed to formal analysis. SL and YZ handled image analysis. SL, ZA, and JL played a key role in conceptualization, funding acquisition, and both original draft writing, review, and editing. All authors reviewed and approved the final manuscript.

Abstract

Background: Hyperbaric oxygen (HBO_2) treatment is used across a range of medical specialties for a variety of applications, particularly where hypoxia and inflammation are important contributors. Because of its hypoxia-relieving and anti-inflammatory effects HBO_2 may be useful for new indications not currently approved by the Undersea and Hyperbaric Medical Society. Identifying these new applications for HBO_2 is difficult because individual centers may only treat a few cases and not track the outcomes consistently. The web-based International Multicenter Registry for Hyperbaric Oxygen Therapy captures prospective outcome data for patients treated with HBO_2 therapy. These data can then be used to identify new potential applications for HBO_2, which has relevance for a range of medical specialties.

Objective: Although hyperbaric medicine has established indications, new ones continue to emerge. One objective of this registry study was to identify cases where HBO_2 has been used for conditions falling outside of current Undersea and Hyperbaric Medical Society–approved indications and present outcome data for them.

Methods: This descriptive study used data from a web-based, multicenter, international registry of patients treated with HBO_2. Participating centers agree to collect data on all patients treated using standard outcome measures, and individual centers send deidentified data to the central registry. HBO_2 treatment programs in the United States, the United Kingdom, and Australia participate. Demographic, outcome, complication, and treatment data, including pre- and posttreatment quality of life questionnaires (EQ-5D-5L) were collected for individuals referred for HBO_2 treatment.

Results: Out of 9726 patient entries, 378 (3.89%) individuals were treated for 45 emerging indications. Post–COVID-19 condition (PCC; also known as postacute sequelae of COVID-19; 149/378, 39.4%), ulcerative colitis (47/378, 12.4%), and Crohn disease (40/378, 10.6%) accounted for 62.4% (n=236) of the total cases. Calciphylaxis (20/378, 5.3%), frostbite (18/378, 4.8%), and peripheral vascular disease–related wounds (12/378, 3.2%) accounted for a further 13.2% (n=50). Patients with PCC reported significant improvement on the Neurobehavioral Symptom Inventory (NSI score: pretreatment=30.6; posttreatment=14.4; *P*<.001). Patients with Crohn disease reported significantly improved quality of life (EQ-5D score: pretreatment=53.8; posttreatment=68.8), and 5 (13%) reported closing a fistula. Patients with ulcerative colitis and complete pre- and post-HBO_2 data reported improved quality of life and lower scores on a bowel questionnaire examining frequency, blood, pain, and urgency. A subset of patients with calciphylaxis and arterial ulcers also reported improvement.

XSL•FO
RenderX

Conclusions: HBO_2 is being used for a wide range of possible applications across various medical specialties for its hypoxia-relieving and anti-inflammatory effects. Results show statistically significant improvements in patient-reported outcomes for inflammatory bowel disease and PCC. HBO_2 is also being used for frostbite, pyoderma gangrenosum, pterygium, hypospadias repair, and facial filler procedures. Other indications show evidence for improvement, and the case series for all indications is growing in the registry.

Introduction

Background

Hypoxia and inflammation are part of the pathophysiology for various conditions across a range of medical subspecialties. One approach to relieving hypoxia and reducing inflammation is the use of hyperbaric oxygen (HBO_2). HBO_2 is 100% oxygen delivered at pressures >1.4 atmospheres absolute (ATA) within a pressurized chamber. Typically, pressures of ≥2.0 ATA are used. HBO_2 treatments greatly increase the amount of oxygen dissolved in plasma and tissue during the treatment and are very effective for relieving hypoxia. The high levels of oxygen in tissue lead to a variety of biochemical effects including reduced inflammation and the release of stem cells from the bone marrow [1,2], leading to its application in several conditions, often in cases when standard treatment is not effective.

Currently, the Undersea and Hyperbaric Medical Society (UHMS) has identified 15 conditions where HBO_2 can be considered an approved treatment [3]. These range from caisson disease (decompression illness), where the combination of increased pressure, relief of hypoxia, and reduced inflammation from HBO_2 help combat the impaired circulation and endothelial damage caused by bubbles [4], to radiation injury, where the pulses of oxygen promote angiogenesis and wound healing [3]. Because of HBO_2's effects on hypoxia and inflammation, more medical diagnoses likely exist that can benefit from HBO_2. However, HBO_2 is typically given in long courses (20-40 treatments), and most centers see only a limited number of patients. Therefore, gathering outcome data on HBO_2 treatment has been limited, and often, only case reports or small case series are available to support its use. In addition, practice patterns differ across centers, and some centers may use HBO_2 successfully for an indication that other centers may not consider it for. To gather more data on HBO_2 applications, outcome data from multiple centers need to be combined, but until 2011, no major academic registry existed to record treated cases and to track outcomes [5,6].

The International Registry for Hyperbaric Oxygen Treatment was formed to gather consistent outcome data from multiple centers [5]. The registry's goal is to improve the use of HBO_2 through evidence-based medicine. The registry records all hyperbaric medicine cases seen at participating centers and includes data on demographics, outcomes, complications, treatment duration, treatment pressure, and quality of life (QOL), among other markers. The registry started at the Dartmouth-Hitchcock Medical Center and Elliott Hospital in 2011 but expanded significantly in 2020 when the number and geographical distribution of participating centers grew. A total of 32 centers are entering data as of May 2024. The registry includes centers in the United States, the United Kingdom, and Australia (Table 1), and the data are used in publications about the use of HBO_2 [6-8].

An important outcome from the registry is identifying emerging medical indications for HBO_2 treatment. Particularly at academic centers, unique or challenging cases where hypoxia, inflammation, or both are considerations for referring patients for HBO_2 treatment. The types of cases referred and the outcomes from them can indicate which new indications may need further study in controlled trials. This information can also support the use of HBO_2 for individual conditions when other treatments are not effective. Since the registry's inception, 378 cases have been recorded where treatment was given for a condition falling outside of the current 15 UHMS-approved indications.

Objectives

The goal of this analysis is to: (1) quantify which non–UHMS-approved indications are being treated at registry centers and (2) provide outcomes for indications where sufficient cases exist. This analysis is important to: (1) identify indications deserving of further research, (2) inform both hyperbaric and other practitioners on new and emerging uses of HBO_2, and (3) identify potential applications of HBO_2 treatment across various medical and surgical specialties for challenging cases.

Methods

Overview

To guide the presentation of data in this report, the RECORD (Reporting of Studies Conducted Using Observational Routinely Collected Health Data) statement was used [9]. RECORD was created as an extension to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement to address reporting items specific to observational studies using routinely collected health data such as registries. The checklist is included as supplemental material.

Ethical Considerations

The structure of the web-based International Multicenter Registry for Hyperbaric Oxygen Therapy has been described previously [5]. Briefly, the registry is composed of hyperbaric centers that agree to follow the registry consortium agreement when becoming a member. Every site obtained institutional review board (IRB) approval and gathered informed consent in agreement with their IRB approval. Sites either obtain IRB approval from their own IRB or establish a reliance agreement with the IRB Dartmouth College (STUDY00024438). Informed consent differs across centers, with some centers having an approved waiver of consent and others requiring a separate consent from the hyperbaric treatment consent for all patients. Data are deidentified when they are sent to the data coordinating center. Participants do not receive compensation.

XSL•FO

RenderX

Registry Design and Data Collection

All centers use a free database application, REDCap (Research Electronic Data Capture; Vanderbilt University) for data entry. REDCap is a secure, web-based software platform designed to support data capture for research studies, providing: (1) an intuitive interface for validated data capture, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for data integration and interoperability with external sources. Registry data from each center are anonymized and collated every quarter at the coordinating center (Dartmouth) and are available to all users for research purposes [10,11].

Data are collected within a week of beginning and ending HBO_2 treatment. All patients have relevant demographic data recorded (age, biological sex, and race). Yes or no questions are asked about any history of prior HBO_2 treatment, prior seizures, or current pregnancy. Patients are asked about diabetes (whether controlled by diet, oral medications, or insulin) and about any current or prior smoking history or other nicotine use. At the end of treatment, the number of treatments given is recorded, along with any treatment complications that may have occurred.

Several patient-reported outcome questionnaires are used. All the questionnaires are maintained on the registry website. Any updates to documents are thus easily distributed to the centers that all have access. Patients are asked to complete the EuroQol EQ-5D-5L QOL questionnaire at the beginning and end of treatment [12]. This questionnaire asks about health in 5 dimensions: mobility, self-care, usual activities, pain or discomfort, and anxiety or depression. Each dimension has 5 levels, and the answers to the 5 questions are combined into 1 composite score or index. Scores range from –0.59 to 1, where 1 is the best possible reported health. Overall health is also rated on a 0 to 100 hash-marked, vertical visual analog scale (VAS). The EQ-5D-5L questionnaire is a copyrighted evidence-based assessment of health and has been registered for registry use. It has been incorporated into all entries collected since 2019 to evaluate overall health pre- and post-HBO_2 therapy. Patients treated before then do not have results for this questionnaire.

Depending on the indication, additional questionnaires (eg, urinary distress inventory for radiation cystitis, European Organisation for Research and Treatment of Cancer, Quality of Life Questionnaire, Head and Neck 35 QLQ-H&N35 for head and neck cancer) are administered in accordance with registry protocols. For patients with Crohn disease, the perianal Crohn symptom index is completed, which asks about the number of fistulas, fistula drainage, rectal drainage, bowel movement frequency, and the use of motility agents. The administration of this questionnaire began in 2019, and it is included in Multimedia Appendix 1. Patients with ulcerative colitis (UC) receive a questionnaire that asks about bowel movement frequency during the night and day, blood in the stool, urgency, and pain. The frequency, blood, urgency, and pain factors are combined into an overall score that ranges from 0 (no symptoms) to 17 (maximum symptoms) to characterize symptom severity. The administration of this questionnaire also started in 2019, and it is included in Multimedia Appendix 2. Because the Crohn and UC questionnaires were added later in the registry's development, patients treated before that time do not have results from these questionnaires.

Patients with head trauma and post–COVID-19 symptoms are presented with the Neurobehavioral Symptom Inventory (NSI) [13]. The NSI has 22 questions designed to cover symptoms related to concussion. Patients rate the severity of common symptoms such as headache, fatigue, and nausea on a scale ranging from 0 (none) to 4 (very severe), with the maximum total score of 88. Initially, this questionnaire was only administered to patients with carbon monoxide poisoning, but in 2022, this questionnaire was expanded to any brain-related condition, including those with post–COVID-19 condition (PCC; also known as postacute sequalae of COVID-19). For frostbite, the users are presented with a diagram of the hands and feet, and they select the affected areas (Figure 1).

As the data are coded by indication, records are classified into one or more of the 15 approved UHMS indications or categorized as "other." The design of this study was to focus on all those records where the indication was "other" and to combine data for those indications. Data entries fitting into the "other" category were isolated and subsequently further divided into subgroups for investigation in this study. Data were reviewed manually to determine if the record fit into one of the already recognized "other" indications or if it was an indication that did not exist within the registry. For example, Crohn disease is a selection on the "Other Indications" dropdown menu; however, this option was not always present in the registry. Previously, users would select "other" and then enter Crohn disease in a text box. So, these text entries were examined to ensure the cases were properly classified. Once the text had been identified, data were processed using MATLAB 2023a (The MathWorks Inc) using text-recognition algorithms to classify the reasons for treatment properly. These results were manually double-checked for accuracy using Microsoft Excel. The study size was determined by the number of entries for "other" indications in the registry from registry inception in 2011 through May 2024.

Figure 1. Data entry screen for frostbite injuries. The registry provides different approaches to data entry to make data entry easy and consistent.

frostbite_r_hand_pre   frostbite_r_hand_post
Missing Data Reasons

Either pre- or posttreatment data were missing for a variety of reasons. For some of the questionnaires, data collection did not start until the registry had been underway for several years. This is true for the EQ-5D-5L and the Crohn, UC, and NSI questionnaires. So, patients treated early in the registry did not have results for these questionnaires. In other cases, data were missing because the patient discontinued treatment, was discharged from the hospital, or transferred to another facility and was not available for the final questionnaire. Some patients were too ill to complete the questionnaires.

Statistical Analysis

For those indications with sufficient responses (n≥6) and complete pre- and posttreatment data for the variable in question, pre- and posttreatment values were compared statistically. Questionnaire responses or rating scales where the answers were categories were analyzed using the sign test (eg, EQ-5D-5L, NSI, and bowel questionnaire). Otherwise, data were compared using the Wilcoxon signed-rank test (eg, fistula number on the Crohn symptom index). Individuals who were missing a pre- or posttreatment value for a variable were not included in the primary analysis.

Treatment of Missing Data

The baseline characteristics of those with complete and incomplete data on Crohn-, UC-, and PCC-related questionnaires were calculated and presented in the results. We conducted sensitivity analyses to tease out the potential impacts of missing data as follows. Individuals who were missing EQ-5D questionnaire responses but had other data in the registry indicating they had a positive response to treatment were given pre- and posttreatment values based on the pre- and posttreatment mean values of those with complete data. For the remainder, we used best, worst, and average case scenarios. In the best case, we assumed all those with missing data improved to the same degree on average as those with complete data. For the worst case, we assumed all those with missing data worsened by the same average percentage that those with complete data improved. For the average case, we calculated the proportion of individuals with complete data that improved and applied that to the missing data. We took the view that sensitivity analyses were not appropriate when the number of cases with complete data was very small, and we used 10 as the limit, accepting that this is an arbitrary limit.

Results

Overview

As of May 2024, a total of 32 sites were actively entering data in the registry, and 24 (75%) of these centers contributed to the indications labeled "other" (Table 1). In total, 378 cases were marked as having diagnoses not currently UHMS approved and receiving at least 1 HBO$_2$ treatment. One center had an interest in PCC and contributed 141 (94.6%) out of 149 cases for that indication. Aside from PCC, UC was the most common condition (n=47, 12.4%), followed closely by Crohn disease (n=40, 10.6%). Combined, inflammatory bowel disease (IBD; n=87) accounted for 23% of hyperbaric cases treated as "other" (n=378). If combined with pouchitis (n=1) and pyoderma gangrenosum (n=7), which are both often associated with IBD, total IBD and related cases accounted for 25.1% (95/378) of cases treated. Of the remaining diagnoses treated, calciphylaxis (n=20, 5.3%), frostbite (n=18, 4.8%), and peripheral vascular disease ulcers (n=12, 3.2%) each had ≥10 cases. There were 23 diagnoses with only a single case (Table 2). The result of this was a series of case cohorts and individual case studies gathered into a single database.

Table 2. Summary of other indications (n=378)[a].

Indication	Values, n (%)
Post–COVID-19 condition	149 (39.4)
Ulcerative colitis	47 (12.4)
Crohn disease	40 (10.6)
Calciphylaxis	20 (5.3)
Frostbite	18 (4.8)
Peripheral vascular disease ulcer	12 (3.2)
Acute COVID-19	9 (2.4)
Pyoderma gangrenosum	7 (1.9)
Pterygium	7 (1.9)
Hypospadias	7 (1.9)
Osteonecrosis and avascular necrosis	6 (1.6)
Head trauma	5 (1.3)
Infected implanted hardware	5 (1.3)
Pneumatosis intestinalis	4 (1.1)
Facial filler	4 (1.1)
Ischemic bowel	3 (8)
Raynaud syndrome	2 (0.5)
Malignant otitis externa	2 (0.5)
Nonarteritic anterior ischemic optic neuropathy	2 (0.5)
Central retinal vein occlusion	2 (0.5)
Cyclophosphamide cystitis	2 (0.5)
Femoral head necrosis	2 (0.5)
Invasive fungal infection	1 (0.3)
Chronic anal fissure	1 (0.3)
Vasculitic ulcer	1 (0.3)
BK[b] virus cystitis	1 (0.3)
Levamisole vasculitis	1 (0.3)
Graft-vs-host disease	1 (0.3)
Decubitus ulcer	1 (0.3)
Greater trochanteric pain syndrome	1 (0.3)
Rectovaginal fistula	1 (0.3)
Argon poisoning	1 (0.3)
Pouchitis	1 (0.3)
Chemotherapy-related bladder ulcer	1 (0.3)
After surgery in irradiated tissue	1 (0.3)
Recurrent perianal abscess	1 (0.3)
Tinnitus	1 (0.3)
Clostridium enterocolitis	1 (0.3)
Ligament and cartilage injury	1 (0.3)
Branch retinal artery occlusion	1 (0.3)
Axonotmesis	1 (0.3)

Indication	Values, n (%)
Nonhealing bowel anastomosis	1 (0.3)
Multiple sclerosis	1 (0.3)
Inclusion body myositis	1 (0.3)
Epidermolysis bullosa	1 (0.3)

[a]Some of the indications were case series with several cases; others were case reports of individual cases.

[b]BK: human polyomavirus 1.

IBD and Related Conditions

Crohn Disease

The 40 patients with Crohn disease had a mean age of 37 (SD 13) years, with 14 (35%) men and 26 (65%) women. The racial breakdown was as follows: Asian (n=2, 5%); Black (n=2, 5%), White (n=28, 70%), more than 1 race (n=1, 2%), and missing (n=7, 18%). The median number of HBO_2 treatments completed was 30 (IQR 19.5-40.5). A total of 25 (62%) of the 40 patients with Crohn disease had complete pre- and posttreatment data for the EQ-5D-5L QOL measure; 7 (18%) patients were missing data because they had been entered into the registry before the adoption of the questionnaire; 3 (8%) did not complete the pretreatment questionnaire, and an additional 5 (12%) did not complete the posttreatment questionnaire. Of the 3 with no pretreatment questionnaire, 1 transferred to another HBO_2 center and 1 was reported to have improved. Of those 5 with pretreatment data but no posttreatment questionnaire data, 1 was improving, but insurance would not approve additional treatments, 1 had closed a fistula and stopped treatment, and 1 was discharged from the hospital and could not continue as an outpatient. One completed 6 treatments and was feeling too sick to continue. Of those who completed the EQ-5D (n=25), 20 (80%) reported improvement and 5 (20%) were unchanged ($P<.001$; Figure 2). Patients with perianal Crohn questionnaire results (n=18) reported a significant decrease in discharge from the fistulas after treatment ($P=.01$; Figure 3); 5 (28%) patients also reported a decrease in the number of fistulas.

Figure 2. Results from the EQ-5D visual analog scale for patients with Crohn disease. A total of 20 patients had complete pretreatment and posttreatment hyperbaric oxygen (HBO2) data. A sensitivity analysis using a best, worst, and average case for missing data shows that the results are significant in all those cases.
For the sensitivity analysis, the 7 individuals with missing EQ-5D questionnaires were slightly younger (32 vs 37 years) with a similar total number of treatments (n=40 vs n=37) and were considered to be missing at random. Of the remaining 8, a total of 3 (38%) were reported to have improved elsewhere in the registry and so were "given" values based on the pre- and posttreatment mean values of those with complete data, and 1 (12%) was reported to be too sick to continue, so was assumed to have worsened by the same average percentage that others had improved (28% in this case). For the remaining 4 (50%), the best, worst, and average case scenarios were used. The best case assumed that all the 4 individuals improved on the EQ-5D VAS by the average amount, and the worst case assumed that they worsened by the same average percentage that others had improved (28% in this case). For the average case, the same proportion of improvement for those with data (20/25, 80%) was applied to the 4 cases (ie, 3 improved and 1 worsened). These gave the best case (27/33, 82% improved; $P<.001$), worst case (23/33, 70% improved; $P=.001$), and average case (26/33, 79% improved; $P<.001$). If the 3 individuals with missing

EQ-5D data, but were noted to improve, were assumed to have worsened instead, this would still have been statistically significant (P=.04).

For the fistula discharge data (n=18), there were 18 (45%) individuals with complete data. For the sensitivity analysis, the 3 (7.5%) individuals who reported improvement elsewhere in the registry were treated the same as the others with missing data. The sensitivity analyses results are as follows: best (25/33, 76% improved; P<.001), worst (10/33, 30% improved; P=.33), and average (18/33, 55% improved; P=.08).

Figure 3. Reported fistula discharge pre- and post-HBO2 therapy in patients with Crohn disease who had complete pre- and post-HBO2 data. The sensitivity analyses results are follows: best case (25/33, 76% improved; P<.001), worst case 10/33, 30% improved; P=.33), and average case (18/33, 55% improved; P=.08).
HBO2 for UC

The 47 patients with UC had a mean age of 41 (SD 20.5) years, with 24 (51%) women and 23 (49%) men. The racial breakdown was as follows: Asian (n=1, 2%); Black (n=2, 4%); White (n=40, 85%); refused (n=1, 2%); and missing (n=3, 6%). The median number of treatments was 5 (IQR 2.6-7.4). A total of 19 (40%) patients had complete EQ-5D-5L questionnaire data; 6 (13%) were missing data because they were in the registry before the EQ-5D was adopted; 12 (26%) had no pretreatment questionnaire data; and an additional 10 (21%) had no posttreatment questionnaire data. Of those with no pretreatment questionnaire data (n=12), 1 had cognitive impairment, 1 was unable to complete the form, 2 declined, 1 decided to stop treatment, 1 stopped because of an unrelated medical problem, and 4 stopped because they had improved. For 2 the reason was not listed. Among those with no posttreatment questionnaire data (n=10) despite having a pretreatment result, 4 (40%) were discharged before completing the form; in 3 (30%) cases, the patient terminated treatment; and in an additional 3 (30%), treatment ended unexpectedly. The group without pretreatment questionnaire data tended to be older (mean 43 years, SD 23.2) and receive more treatments (median 8.5, IQR 5.3-11.8). The group missing posttreatment questionnaire data had a similar mean age (40 years, SD 17.7) and median number of treatments (4.5, IQR 2-7) to the group having the questionnaire data. Of the 19 patients with UC who completed the EQ-5D, 3 (16%) had slightly decreased QOL scores, while most (n=16, 84.2%) had improvement (P=.008; Figure 4). The patients with UC who had questionnaire results also reported lower (better) scores on the bowel questionnaire (Figure 5). For the sensitivity analyses, the 4 UC cases that reported improvement were assumed to have improved by the mean of those with data. For the remainder, data are as follows: best case (38/41, 93% improved; P<.001), worst case (19/41, 46% improved; P=.76), and average case (31/41, 76% improved; P=.002).

There were 7 individuals with pyoderma gangrenosum, 6 (86%) women and 1 (14%) man with a mean age of 46 (SD 20.6) years. The racial breakdown was as follows: Asian (n=1, 14.3%); Black (n=1, 14.3%); and White (n=5, 71.4%). The median number of treatments was 26 (IQR 17.4-34.6). The data for these cases are limited because standard wound measures for these cases were implemented late in the registry. Only 2 (29%) cases had EQ-5D measurements; 2 (29%) cases were entered in the registry before beginning EQ-5D assessments; 2 (29%) had no pretreatment value; and 1 (14%) had no posttreatment value. A total of 3 (60%) had subjective data on improvement, and those 3 were reported to improve. One (20%) patient stopped due to an unrelated medical problem, and another (n=1, 20%) decided to stop after 7 treatments. The registry also includes 1 patient with pouchitis who improved.

Figure 4. Results on the EQ-5D visual analog scale for patients with ulcerative colitis (UC) who had complete pre- and posthyperbaric oxygen (HBO2) data. The sensitivity analyses results are follows: best case (38/41, 93% improved; *P*<.001), worst case (19/41, 46% improved; *P*=.76), and average case (31/41, 76% improved; *P*=.002).
Figure 5. Results on the bowel questionnaire from the subset of patients with ulcerative colitis (UC) who had complete pre- and posthyperbaric oxygen (HBO2) data. The sensitivity analysis showed the best (38/41, 93%; *P*<.001) and worst (19/41, 46%; *P*=.14) cases, indicating that the results are sensitive to missing data.
Calciphylaxis

Calciphylaxis was the fourth most common "other" diagnosis (n=20; Table 3). The mean age was 61 (SD 15.9), with 12 (60%) women and 8 (40%) men. The racial breakdown was as follows: Black (n=2, 10%); White (n=15, 75%); refused (n=1, 5%); and missing (n=2, 100%). The median number of treatments was 27.5 (IQR 14.5-40.5). Only 3 (15%) patients had complete QOL data, while 5 (25%) individuals did not have EQ-5D data because they were treated before the EQ-5D was in the registry, 6 (30%) had no pretreatment questionnaire, and 6 (30%) had

no posttreatment questionnaire. Of the 20 patients, 4 (20%) discontinued treatment, as they were too sick to continue, and 2 of these patients died. While 2 (10%) patients healed their wounds, 5 (25%) showed notable improvement. For those who improved, the median number of treatment sessions was 39 (IQR 31.1-46.9). The median number of hyperbaric treatments in the remaining cases was 21 (IQR 7.9-34.1). Sensitivity analyses were not used because the most useful outcome for this condition is improvement versus no improvement because of the high mortality. Many of the patients missing data either died or were seriously ill.

Table 3. Outcomes for the patients with calciphylaxis.

Total HBO$_2$[a] treatments	Original size (cm), L×W×D	Decrease length (%)	Decrease width (%)	Decrease depth (%)	Pretreatment EQ-5D VAS[b]	Posttreatment EQ-5D VAS	Reason for missing EQ-5D	Notes on outcome
Improved

Frostbite

Frostbite was the fifth most common "other" diagnosis with 18 patients (Table 4). The mean age was 49 (SD 13.7) years, with 17 (94%) men and 1 (6%) woman. The racial breakdown was as follows: American Indian or Alaska Native (n=2, 11%); Black (n=1, 6%); White (n=12, 67%); other (n=2, 11%); and missing (n=1, 6%). The median number of treatments was 9 (IQR 7-11). Only 1 (6%) individual did not have EQ-5D data because the treatment occurred before the EQ-5D was in the registry, while 6 (33%) had no pretreatment questionnaire and 6 (33%) had no posttreatment questionnaire. For 2, the questionnaire was not done due to unspecified reasons; 3 either left treatment or refused treatment before completing the questionnaire; 1 had a language barrier; and 1 was not done due to inadequate staffing. For the 11 patients who had complete EQ-5D VAS data, there was a significant improvement (pretreatment score=48.2, posttreatment score=67.5; 9/11, 82% improved; P=.02). The sensitivity analyses results are as follows: the best case (16/18, 89% improved; P<.001), worst case (9/18, 50% improved; P=1.0), and average case (15/18, 83% improved; P=.002).

Peripheral Vascular Disease–Related Wounds

The sixth most commonly treated diagnosis was peripheral vascular disease–related wounds (Table 5). The mean age was 63 (SD 19.1) years, with 8 men and 4 women. The racial breakdown was as follows: 8 White, 2 Black, and 2 missing. The median number of treatments was 19.5 (IQR 8.3-30.8). Twelve cases were recorded, all involving arterial disease, but some also with concurrent venous disease. All wounds involved the lower extremities. Of those patients who had ≥20 HBO_2 sessions, 5 of 6 improved, with the remaining 1 lacking enough data to reach a conclusion. The remaining 6 cases had ≤15 sessions. Four of these were worse, with 2 not having sufficient data recorded. The main outcome recorded was improved versus not improved or insufficient data, and there were insufficient EQ-5D data to do a sensitivity analysis.

Table 5. Outcome for patients with peripheral vascular disease.

Total HBO_2[a] treatments	Decrease in length (%)	Decrease in width (%)	Decrease in depth (%)	EQ-5D VAS[b]	EQ-5D VAS	EQ-5D score	EQ-5D score	Reason for missing EQ-5D	Notes on outcome

Pterygium Surgery and Facial Filler Injections

One particularly interesting application of HBO_2 was for postoperative healing from pterygium surgery (Table 6). The mean age was 47 (SD 18.1) years, with 6 (86%) men and 1 (14%) woman, and all participants (7/7, 100%) classified as White. All cases came from a single center and were treated with 5 sessions each. One case had an unchanged QOL assessment before and after treatment but had no noted complications via notes after surgery, and 1 had worse QOL VAS scores after treatment (pretreatment score=85, posttreatment score=75), although the patient was noted to have uneventful recovery after surgery. The remaining patients (4/6, 67%) showed improvement in their QOL scores, with the overall median EQ-5D-5L VAS score increasing from 82.5 to 97.5, although this was not statistically significant (P=.38).

Table 6. Outcomes for patients with pterygium and facial filler injections.

Total HBO$_2$[a] treatments	Pretreatment EQ-5D VAS[b]	Posttreatment EQ-5D VAS	Pretreatment EQ-5D score	Posttreatment EQ-5D score	Reason for missing EQ-5D	Notes on outcome
Pterygium surgery						
5	85	75	1	0.83	—[c]	Uneventful
5	90	90	0.88	1	—	No postoperative problems
5	90	100	0.86	1	—	No postoperative problems
5	80	100	0.83	1	—	—

[a]HBO$_2$: hyperbaric oxygen.

[b]VAS: visual analog scale.

[c]Not available.

HBO$_2$ was also used for complications due to the use of facial fillers (Table 6). The mean age was 46 (SD 14.5) years. All participants (4/4, 100%) were women, with 2 (50%) classified as White and 2 (50%) as missing. Of the 4 cases in the registry, 2 (50%) occurred after the use of Radiesse, a calcium hydroxylapatite filler, while the other 2 (50%) were unspecified. Of the 4 cases recorded, all were treated in a multiplace chamber, and 3 (75%) showed improvement, with 2 (50%) stopping prescribed treatment sessions early due to recovery. Both that stopped early were on a twice twice-daily schedule, with 1 at 2.0 ATA and another at 2.4 ATA. One did not have a result listed other than stopping early secondary to a seizure as a complication, but this patient was taken to 2.8 ATA, which increases seizure risk. The final case was treated at 2.4 ATA daily, completing the prescribed 5 cases with improvement. All 4 cases were treated within 1 day of referral.

Non–Radiation-Related Osteonecrosis

Six cases of non–radiation-related osteonecrosis were treated (Table 7). The mean age was 58 (SD 17.1) years with 3 (50%) men and 3 (50%) women. The racial breakdown was as follows: White (n=4, 67%); more than 1 race (n=1, 17%); and missing (n=1, 17%). The median number of treatments was 30 (IQR 10-50). In general, these patients received long treatment courses. The improvements in QOL seen in most patients suggest that the treatment was generally successful.

Table 7. Outcomes for patients with non–radiation-related osteonecrosis[a].

Total HBO$_2$[b]	Anatomic location	Pretreatment EQ-5D VAS[c]	Posttreatment EQ-5D VAS	Pretreatment EQ-5D score	Posttreatment EQ-5D score	Reason for missing EQ-5D	Notes on outcome
20	Knee	__[d]	—	—	—	Not asked	—
60	Ankle	30	80	0.73	0.83	—	—
20	Lower leg	60	80	0.15	0.54	—	Uneventful course
60	Left knee	60	65	—	—	Only VAS	—
40	Jaw	35	50	0.23	0.57	—	Uneventful course
3	Sinuses or palate	50	—	0.76	—	Transferred before completion	Had lymphoma on bone biopsy, HBO$_2$ suspended

[a]Currently, no detailed outcome measures specific to osteonecrosis exist in the registry. The increase in the EQ-5D suggests improvement.

[b]HBO$_2$: hyperbaric oxygen.

[c]VAS: visual analog scale.

[d]Not available.

Infected Implanted Hardware

Infected hardware was treated in 5 patients. The mean age was 49 (SD 9.6) years with 1 (20%) man and 4 (80%) women; 3 (60%) were White, and 2 (40%) were missing a racial classification. A total of 2 (40%) cases had knee hardware infection, and 2 (40%) cases had spinal hardware infection. All were prescribed HBO$_2$ at 2.4 ATA for 10 to 40 treatments, but none completed >30% of their course for various reasons, including patient decision, transfer to a different facility, and significant visual disturbances. None of these patients had pre- and post-QOL measurements.

Hypospadias

HBO$_2$ was also used in the setting of hypospadias repair. Repairs of hypospadias can lead to failed grafts with scarring, fistulas, strictures, and potential deformities [14,15]. Some centers use HBO$_2$ before and after the repair to improve graft and surgical outcomes. A total of 7 cases were entered into the registry. The mean age was 3.7 (SD 2.6) years. The racial breakdown was as follows: Asian (n=2, 29%); Black (n=1, 14%); White (n=3, 43%); and missing (n=1, 14%). For 5 (71%), the graft was preserved and viable, while for 1 (14%), the graft was preserved and partially viable and 1 (14%) was missing outcome data.

HBO2 for PCC

A new application of HBO$_2$ was for PCC. All (n=141, 94.6%) but 8 (5.4%) of the 149 cases were reported by a single center, which has an interest in treating PCC with HBO$_2$ [16]. Complete pre- and post-HBO$_2$ NSI data were available on 127 (85.2%) patients (Figure 6). The NSI showed a significant improvement (pretreatment score=30.6, posttreatment score=14.4; P<.001). Complete EQ-5D data were available on 55 (36.9%) individuals. The EQ-5D VAS also improved significantly (pretreatment score=33.6, posttreatment score=64.1; P<.001). The group included 80 (53.7%) women and 69 (46.3%) men (total n=149); 5.4% (8/149) of patients were Asian, 0.7% (1/149) Black, 91.9% (136/149) White, 1.3% (2/149) more than 1 race and 1.3% (2/149) were missing data on race. The median number of HBO$_2$ treatments was 15 (11.5-18.5). The sensitivity analyses results are as follows: the best case (133/149, 89.3% improved; P<.001), worst case (111/149, 74.5% improved; P<.001), and average case (131/149, 87.9% improved; P<.001). For the EQ-5D, the cases are as follows: the best case (142/149, 95.3% improved; P<.001 toward improvement), worst case (49/149, 32.9% improved; P<.001 towards worsening), and average case (130/149, 87.2% improved; P<.001 toward improvement).

Figure 6. Results from the Neurobehavioral Symptom Inventory (NSI) for patients treated for post–COVID-19 condition. In the sensitivity analyses, the best (133/149, 89.3% improved; $P<.001$), worst (111/149, 74.5% improved; $P<.001$), and average (131/149, 87.9% improved; $P<.001$) cases all showed significant improvement.
Other Diagnoses

For the other diagnoses, 1 group of indications was related to the relief of hypoxia (eg, ischemic bowel, Raynaud syndrome, nonarteritic anterior ischemic optic neuropathy, central retinal vein occlusion, femoral head necrosis, branch retinal artery occlusion, vasculitic ulcer). The data on chronic anal fissures and Raynaud add to the existing case series for these conditions [17,18]. Several cases focused on the treatment of cystitis (eg, human polyomavirus 1 virus cystitis, cyclophosphamide cystitis) likely motivated by the use of HBO_2 for radiation cystitis treatment [7]. Not enough information exists to come to conclusions about the effectiveness of the treatment for these individual cases, but this likely will change as the registry matures.

Discussion

Principal Findings

The registry shows how HBO_2 is being used across a range of medical specialties for indications where hypoxia, inflammation, or both are significant factors. The emerging diagnosis treated most across the registry centers was IBD, primarily UC and Crohn disease. For Crohn disease, there were sufficient entries to show statistically significant patient-reported improvement that remained significant even with the worst-case scenario sensitivity analysis. Overall, the newly described PCC was the most commonly treated diagnosis in this cohort, although the results were predominantly from a single center. The patient-reported results showed improvement, which supports the need for further work in this area. The top 5 indications also included calciphylaxis and frostbite, which are both conditions where hypoxia is a significant consideration and where existing treatments are often inadequate.

The results also showed indications that were concentrated at particular centers, such as the use of HBO_2 after complications for facial filler injections or to improve outcomes with pterygium surgery. The number of patients for each of these indications is limited but indicates that they could be studied in more detail to determine whether this approach should be adopted more widely at other centers.

Comparison to Prior Work

IBD and Related Conditions

Several recent reviews have also concluded that HBO_2 could be useful for IBD [19-24]. The registry data on Crohn disease support other studies showing improvement with HBO_2 [19,25-29]. For fistulizing Crohn disease, a prospective trial has shown reduced disease activity, reduced drainage, and clinical remission when HBO_2 is used in refractory cases [26]. The improvement in the registry of Crohn cases is noteworthy because Crohn disease is not currently a UHMS-approved indication for HBO_2, and patients are almost always referred because standard treatments have not been successful. The patients reported significant improvement in QOL and reduced fistula and rectal discharge. Five patients had their fistulas closed. The QOL results were significant even with the worst-case approach to the sensitivity analysis. The fact that 5 patients were able to close fistulas is significant because these were likely refractory patients. Taken together, the results add to a growing set of case series and case studies that show improvement in difficult Crohn cases and support the need for large-scale trials.

For UC, HBO_2 therapy studies have shown clinical remission, avoidance of colectomy, or progression to second-line therapy in a randomized sham-controlled trial [30]. A follow-on phase 2B trial examined the dosing strategies and concluded that 5 sessions were superior to 3 for a UC flare [31]. Typically, HBO_2

is used adjunctively in UC with other treatments (steroids, biological agents, etc), although in 1 case study, HBO_2 was used successfully as monotherapy for UC in an individual who had contraindications to most standard treatments [32]. HBO_2 can be particularly useful in situations where the individual cannot receive standard treatment due to allergy, antibodies, shingles, or other reasons. The most common application of HBO_2 in IBD is patients admitted for an acute UC flare who are at risk for colectomy or who cannot receive steroids or biological agents or where there is a delay in being able to start those agents [30,31]. In addition, patients admitted for an acute UC flare who need a bridge between when IV steroids are begun and when biological agents (ie, infliximab) start to have an effect may benefit from HBO_2. These registry results support the idea that HBO_2 can be useful in UC but should be interpreted with caution. Many of the patients were hospitalized for treatment and were receiving intravenous steroids and other interventions. So, while the reports of improvement are encouraging, separating the effect of HBO_2 from the effects of standard treatment is not possible in this data set. In addition, the fact that 1 center (Dartmouth-Hitchcock) accounted for many of the treated cases (roughly 75%) and had been involved in an UC clinical trial may overrepresent the interest in UC cases across the registry centers. Also, the QOL and bowel questionnaire results were not significant in the worst-case scenario of the sensitivity analysis. Randomized controlled trials are needed to determine definitively if HBO_2 improves on standard care.

In addition to UC and Crohn disease, IBD-related conditions where hyperbaric treatment could be applied include pouchitis, nonhealing ileal pouch-anal anastomoses, and pyoderma gangrenosum [33-37]. Two published case series and a case report show relief of symptoms and decreased disease activity in pouchitis [33,34,38]. Case series and case studies also show reduced wound size in pyoderma gangrenosum [39]. The results from this study align with these conclusions, but the registry results are descriptive and do not include a control group for comparison (as is true for most case reports and case series).

The IBD results support the idea that HBO_2 could be considered in UC flares when standard therapy, such as steroids and biologics, is inadequate or not possible. Similarly, it could be useful in fistulizing perineal Crohn disease refractory to medical and surgical treatments. Pouchitis that has not responded to antibiotics and immunomodulators as standard therapy and pyoderma gangrenosum refractory to steroids and immunologics are also potential applications of HBO_2. IBD may be a disease process that should be evaluated as a UHMS-approved indication for HBO_2, as accumulating evidence shows promising results.

Calciphylaxis

Calciphylaxis was the fourth most treated diagnosis. Calcification of small blood vessels leads to hypoxic painful wounds, which led to the use of HBO_2 in these patients. No randomized control trials exist to guide the use of possible calciphylaxis interventions. Such trials would likely be very difficult to carry out because the disease is rare and disease severity varies widely. Also, calciphylaxis has a very high mortality. Most patients with calciphylaxis have end-stage renal disease (ESRD), and the 1-year mortality for those with ESRD and calciphylaxis is 45% to 80%; 1-year mortality is less but still significant for those without ESRD (25%-45%) [40]. On the basis of studies done to date, HBO_2 has been recommended by subject matter experts to facilitate healing of recalcitrant calciphylactic ulcers after accounting for cost, availability, and patient tolerance of treatment [41]. Physiologically, HBO_2 addresses the tissue hypoxia caused by the damage to small blood vessels, which is characteristic of calciphylaxis. HBO_2 greatly increases the amount of oxygen in circulation reaching hypoxic wounds, which promotes collagen formation and stimulates angiogenesis.

The results from this study support what has been seen in prior work. A retrospective study of HBO_2 therapy for calciphylaxis showed promising results; 34 patients received a full course of HBO_2, with 58% (n=20) of patients improving and 32% (n=11) completely healing their wounds [42]. In this prospective registry study, 45% (9/20) of patients improved. Similar to other studies, the registry results for calciphylaxis are mixed, which is not surprising considering the nature of this disease. Affected patients often have significant medical comorbidities, and the disease has a high morbidity and mortality rate secondary to sepsis. For example, in this cohort, 2 patients treated died of their disease, and 2 others were too sick to continue.

Nevertheless, there were several cases that improved significantly, and these successful cases had more sessions of therapy. Given the severe mortality and morbidity associated with the disease and the difficult course of standard care, HBO_2 is a treatment that has little risk with the potential for significant benefit. The results support previous positive case series and suggest that trials on HBO_2 and calciphylaxis are needed, and more research should be made to pursue calciphylaxis as a possible UHMS indication.

Frostbite

Frostbite causes hypoxia and necrosis in affected tissues, and HBO_2 has been considered as a potential therapy for many years. Kemper et al [43] summarized the literature on frostbite and HBO_2 in 2014. In 2021, Magnan et al [44] published a multicenter prospective single-arm study of individuals with stage 3 or 4 frostbite who received HBO_2 in addition to iloprost (n=28). The results were compared with a historical cohort that received iloprost alone (n=30). The results showed a significantly higher proportion of preserved frostbitten segments in the HBO_2+iloprost group. The registry results support the results from these previous studies. Most individuals with EQ-5D data reported an improved QOL. In the sensitivity analysis, this was significant in the best and average cases but not the worst case. Determining whether HBO_2 offers an additional benefit over standard treatment is not possible within the current registry design, but future expansion efforts could include trying to include registry centers without HBO_2 that treat similar cases.

Peripheral Vascular Disease–Related Wounds

Many of the emerging indications shared the underlying problem of tissue hypoxia. For the same reason that HBO_2 therapy would work in treating acute arterial insufficiency, it might assist in the healing of chronic peripheral arterial disease ulcers. A guideline from a wound care advisory panel for the treatment of arterial insufficiency ulcers recommends adjuvant HBO_2 for patients with nonreconstructable anatomy or whose ulcer is not healing despite revascularization. The guideline also recommends determining if the hypoxia is reversible by HBO_2 therapy [45].

The registry cases show that some people did respond. Successful cases had at least 30 treatment sessions, while those with <15 sessions generally did not improve. Detailed information regarding each case is not available within the registry, so it is not known whether those who improved did so because they received more treatments or if they received more treatments because they had fewer comorbidities or were showing early benefits. In addition, whether the patients were screened using in-chamber transcutaneous oxygen measurements to document a local tissue increase in oxygen levels with hyperbaric oxygenation is not recorded. Patient selection is probably critical for deriving the most benefit from HBO_2 in these patients because those with very severe hypoxia and vascular compromise may not respond. Further studies are needed to define how to select patients with peripheral vascular disease that might benefit from HBO_2. In addition, information on screening procedures used to select these patients for treatment should be added to the registry.

Other Applications

An interesting application of HBO_2 that was concentrated at 1 center, was the use of HBO_2 after pterygium surgery. The recurrence rate of simple surgical excision can be as high as 40% but can be lowered to 16% with a conjunctival autograft procedure, although the recurrence rates are increased if the pterygium is already recurrent when the procedure is used [46]. The use of postoperative HBO_2 treatment is based on a prospective trial published in 2011, which showed low recurrence rates when patients with pterygium underwent surgery with adjunctive HBO_2 afterward [47]. A short 5-session HBO_2 prescription was used. There were no complications noted with HBO_2 in these cases and, importantly, no reported recurrences of pterygium. This local protocol may be feasible to attempt at other centers, should collaboration with ophthalmology be obtained. At the very least, this is an interesting condition to further evaluate for using HBO_2 as a successful adjunct treatment to standard therapy. Another indication that is also focused on improving outcomes after surgery is the use of HBO_2 for individuals who have had hypospadias repairs. There were 7 individuals in the registry with this indication, and all reported preservation of the graft, although in 1, the graft was partially viable. These results are consistent with prior work [14]. In addition, this application could be considered as an extension of the approved UHMS indication of compromised flaps and grafts.

Facial filler complications present an emergency treatment opportunity well suited for HBO_2 and have been reported in several case reports [48-51]. This was identified in the registry cases as well. The experience of providers performing these outpatient facial filler procedures varies widely as does the ability and knowledge to address the complications. With rising interest in esthetic therapy, complications from these procedures are becoming more common. Facial fillers typically refer to hyaluronic acid fillers or particulate-based fillers, both of which are used for facial remodeling or tissue augmentation for cosmetic or reconstructive purposes. These injections can cause vascular obstruction and subsequent tissue ischemia; thus, the goal of treatment is to restore perfusion to the affected area. Although hyaluronic acid can be reversed with hyaluronidase, particulate injections such as calcium hydroxylapatite cannot easily be broken down, and HBO_2 may play an even greater role in these cases. Expert consensus protocols include HBO_2 in treatment algorithms for these complications [52]. Similar to acute arterial ischemic cases, success likely hinges on the hyperbaric medicine consult occurring close to the initial injury. Early intervention must be encouraged, as with other UHMS-approved indications where acute ischemia is prominent such as central retinal artery occlusion or compromised flaps, because earlier intervention leads to improved results. Half of the cases recorded were treated on the same day as the consult, although information on time elapsed since filler injection is not available. Ultimately, HBO_2 can support threatened tissue but cannot resuscitate dead tissue, and aggressive intervention and resuscitation should be advocated. Information about the use of HBO_2 for this indication needs to be available to other centers that administer facial filler injections.

When implanted hardware is infected, the medical standard of care typically calls for hardware removal. Removal from certain areas of the body (eg, brain and spine) can be difficult or involve complicated surgical intervention. In these instances, salvage of hardware has the lowest risk-to-benefit ratio or may be the only viable option [53]. Ridding foreign bodies of infection in vivo is notoriously difficult, which is why HBO_2 was likely attempted in these cases. None of the patients treated completed their course of treatment, which may suggest that these cases were refractory. The results suggest that the registry should be revised to collect more detailed information about these cases.

The newly recognized PCC was treated multiple times in the registry. The anti-inflammatory effects of HBO_2 are thought to be the mechanism of action underlying improvement. PCC is not yet completely understood but likely results from a dysregulated inflammatory process within the brain [54]. In general, patients reported improvement with treatment. This matches reports coming from case reports and series, as well as from a randomized control trial out of Israel [55]. The results need to be interpreted with caution, as placebo effects with HBO_2 are common. Nevertheless, the data support further sham-controlled trials and suggest that HBO_2 could be used to treat other postinfectious syndromes in the future.

Many of the other individual case reports within the registry are for indications where hypoxia is believed to be a significant

factor. For example, femoral head necrosis results from a compromised vascular supply, and healing of chronic anal fissures is believed to be hampered by local hypoxia [56]. Ophthalmological conditions such as branch retinal artery occlusion, retinal vein occlusion, and nonarteritic anterior ischemic neuropathy involve hypoxia and a compromised blood supply. Raynaud syndrome and vasculitic ulcers are also characterized by local hypoxia. Currently, not enough data exist within the registry to draw conclusions about outcomes for these various conditions, but over time, additional cases will accumulate.

The hyperbaric registry is still in its nascent stages. Greater adoption of the registry by the community will lead to more significant results. The cases highlighted in the report have identified additional data that should be recorded for some of these indications. For example, facial filler cases highlight the need for further information such as the time of injury to help determine the optimal timing for maximal HBO_2 efficacy. In addition, the facial filler cases should be documented in an identified category, as is done with indications such as UC or Crohn disease, rather than just marked as "other." More specific outcome measures are needed for non-radiation–related osteonecrosis cases. In addition, long-term follow-up will be essential for infected hardware cases because the outcome may not be known until well after the treatments have stopped.

Many of the involved centers are academic, nonprofit, and governmental entities with an interest in advancing evidence-based medicine and research. The contributions made by such centers are essential to evaluating the promise of HBO_2 in various conditions and may lead to the adoption of them as new UHMS indications. This review provides a snapshot to clinicians of the diagnoses that have been treated by HBO_2 that are not officially on the UHMS indications list. This can be useful in situations where patients are not improving with standard therapy, and other approaches are being sought that could address hypoxia and inflammation. It also focuses attention on specific diagnoses worthy of further study.

Limitations and Strengths of This Study

The registry has limitations. To keep the time required for data entry to a minimum, only a specific set of outcomes is collected. The registry does not include extensive data on medications, other comorbid conditions, or laboratory results. While this approach has been successful at making the registry practical for centers to adopt, it does affect the scope of conclusions that can be drawn.

The registry undergoes active review and expansion over time, so not all questionnaires currently in use existed in the registry when it started. Missing data, particularly for the EQ-5D in earlier cases, is understandable, as this questionnaire was added later in registry development. In addition, data collection can be missed if patients stop treatment early or unexpectedly or transfer to another center. Nevertheless, the missing data are a limitation of the registry. The registry does not include a control or standard treatment group for every condition, so it is not possible to compare outcomes with no treatment or placebo. Registry results can be compared with publicly reported treatment success rates of those using standard therapy.

For the analyses, the data were reviewed to fix indications that were misclassified (ie, UHMS-approved indications that were categorized as "other" or "other" indications that were inappropriately classified as UHMS-approved indications). There may be cases, however, that were missed. The data are dependent on data entry, and there may be variations in data entry quality between centers. Work is ongoing with data quality checks throughout the registry centers to ensure that these problems are limited in the future.

Nevertheless, the strength of the registry is that it allows outcomes from less common conditions to be combined across centers, which provides information that no individual center would be able to achieve independently. The accumulated results identify areas where more detailed trials would be useful. In addition, some centers are beginning long-term follow-up with treated patients to gather data on satisfaction with and longevity of the results. This will expand the capabilities of the registry although the responses will be affected by selection bias.

Conclusions

The registry is providing standardized outcome data on conditions that are not currently UHMS approved but are being treated with HBO_2 at participating centers. This is adding prospectively collected data to the mostly retrospective data that exist in the literature. Results show statistically significant improvements in patient-reported outcomes, such as QOL, for IBD, frostbite, and PCC. HBO_2 is also being used to improve surgical outcomes for pterygium and hypospadias procedures and to treat complications from facial filler injections. HBO_2 is also being tried for difficult cases involving hypoxia such as femoral head necrosis, Raynaud syndrome, and chronic anal fissures.

As time goes on and as more centers participate, significant trends can be identified, which may identify a valuable treatment option for medical conditions where hypoxia and inflammation are important contributing factors. Indications developed at a few centers initially can also be expanded to other centers based on the outcomes.

Abstract

Background: Advancements in technology have overcome geographical barriers, making telemedicine, which offers remote emergency services, healthcare, and medication guidance, increasingly popular. COVID-19 restrictions amplified its global importance by bridging distances.

Objective: This study aimed to analyze Chinese and global literature data, present new global telemedicine research trends, and clarify the development potential, collaborations, and deficiencies in China's telemedicine research.

Methods: We conducted bibliometrics and network analyses on relevant documents from the Web of Science database from 2001 to 2022. Data collection was completed on October 30, 2023. Considering COVID-19's impact, 2020 was used as a baseline, dividing the data into 2 periods: 2001-2019 and 2020-2022. The development potential was determined based on publication trends. An international coauthorship network analysis identified collaboration statuses and potential. Co-occurrence analysis was conducted for China and the world.

Results: We identified 25,333 telemedicine-related research papers published between 2001 and 2022, with a substantial increase during the COVID-19 period (2020-2022), particularly in China (1.93-fold increase), moving its global publication rank from tenth to sixth. The United States, the United Kingdom, and Australia contributed 62.96% of the literature, far ahead of China's 3.90%. Globally, telemedicine research increased significantly post-2020. Between 2001 and 2019, the United States and Australia were central in coauthor networks; post-2020, the United States remained the largest node. Network hubs included the United States, the United Kingdom, Australia, and Canada. Keyword co-occurrence analysis revealed 5 global clusters from 2001 to 2019 (system technology, health care applications, mobile health, mental health, and electronic health) and 2020 to 2022 (COVID-19, children's mental health, artificial intelligence, digital health, and rehabilitation of middle-aged and older adults). In China, the research trends aligned with global patterns, with rapid growth post-2020. From 2001 to 2019, China cooperated closely with Indonesia, India, Japan, Taiwan, and South Korea. From 2020 to 2022, cooperation expanded to Japan, Singapore, Malaysia, and South Korea, as well as Saudi Arabia, Egypt, South Africa, Ghana, Lebanon, and other African and Middle Eastern countries. Chinese keyword co-occurrence analysis showed focus areas in system technology, health care applications, mobile health, big data analysis, and electronic health (2001-2019) and COVID-19, artificial intelligence, digital health, and mental health (2020-2022). Although psychology research increased, studies on children's mental health and middle-aged and older adults' rehabilitation were limited.

Conclusions: We identified the latest trends in telemedicine research, demonstrating its significant potential in China and providing directions for future development and collaborations in telemedicine research.

Introduction

Development of personal computers, communication technology, and professional medical technology have led to improvements in medical-related technology. Telemedicine provides health care solutions in difficult-to-access areas. Health care organizations worldwide are becoming increasingly interested in implementing telemedicine technologies to improve care and services [1]. Telemedicine is the delivery of health care and the exchange of health care information across distances [2]. Telemedicine dates back to the mid-to-late 19th century [2]. Furthermore, one of the earliest reports was published in the early 20th century, with electrocardiogram data transmitted over telephone lines. Currently known telemedicine was formed in the 1920s to 1960s and was largely driven by military and space technology sectors [2,3]. Moreover, only a few individuals used off-the-shelf commercial equipment at the time [4]. Examples of early telemedicine technology include the use of televisions to facilitate consultations between specialists in institutions and general practitioners in state psychiatric hospitals [5]. Furthermore, it was also used to provide expert medical guidance to airport medical centers from major teaching hospitals [6]. Continued development of internet-based audio and video communication technologies, coupled with high demand for a convenient and efficient way to receive care, enabled the development of telemedicine applications [7]. With the rapid development of telemedicine equipment and information communication technology, telemedicine has developed rapidly and is used widely around the world as a new mode of medical service [8,9]. In particular, in China, telemedicine has been used as a crucial method by the government to address the inequality of medical resources between urban and rural areas [10]. The development of telemedicine in China began in the 1980s. In 1986, the Guangzhou Ocean Shipping Company conducted a cross-sea consultation for emergency patients on the oceangoing freighter through telegraph, which was the earliest telemedicine activity in China. In 1997, the Jinwei Medical Network in China was officially opened to provide remote, off-site, real-time, and dynamic live television consultations for patients with severe illness. Subsequently, the medical institutions at all levels in China began to explore and develop telemedicine. After years of effort, the development of telemedicine entered its golden age. In 2017, 22 provinces in China established telemedicine platforms covering 13,000 medical institutions, providing teleconsultation, telediagnosis, and remote medical education [10].

Travel was restricted owing to the COVID-19 pandemic starting in 2019 [11]. However, telemedicine is attracting attention worldwide as it can overcome the problems caused by distances.

Telemedicine was increasingly used during the COVID-19 pandemic as a tool to reduce the spread of potential diseases and fill gaps in health care services. Telemedicine emerged as a crucial tool during the COVID-19 pandemic, playing a significant role in health care delivery and management. The global health crisis prompted by the pandemic accelerated the adoption of telemedicine, highlighting its importance in ensuring the continuity of medical services and reducing the risk of infection transmission. Studies have shown that telemedicine was particularly valuable in providing care to patients while minimizing physical contact, especially in situations where in-person visits may have posed health risks due to the highly contagious nature of the virus [12]. Telemedicine could serve as a public health tool to reduce hospital burden, provide continuity of care, and support disease surveillance and management. Particularly, China took protective measures and relied on telemedicine as a response to the pandemic [13,14]. Zhang and Ma [15] quantified the differences between online and face-to-face delivery of health services during the COVID-19 pandemic through a discontinuous time series study in Beijing, China. Moreover, they compared the impact of COVID-19 on the primary outcomes of face-to-face (outpatient, emergency visits, and discharge) and online (online inquiry) health care services. The impact of COVID-19 on health care for different diseases was also analyzed. The average monthly outpatient and discharge volumes of 22 public hospitals in Beijing dropped by 36.33% (2020: 1,720,180 cases; 2019: 2,701,790 cases) and 35.75% (2020: 21,600 cases; 2019: 86,770 cases), respectively, compared with those in 2019. In addition, the average monthly online consultation volume increased by 90.06% (2020: 12,050 cases; 2019: 6340 cases) [15]. After the COVID-19 lockdown, patients with nonsevere disease opted for online consultations. Conversely, patients with severe disease chose hospital care.

Simultaneously, studies are increasingly focusing on the further development of telemedicine. Although telemedicine technology has developed rapidly around the world, research on China's specific development in this field, the challenges it faces, and the status and potential of international cooperation is still limited. Therefore, understanding the current trends and hot spots of publication in telemedicine is necessary. Understanding the pandemic's effect on telemedicine research through Chinese protective measures can play a significant role in promoting the development of telemedicine.

In light of this, understanding telemedicine research trends in China, where demand for telemedicine is high, and research relationships among China and other countries is of particular interest. This study aimed to analyze Chinese and global literature data, present new global trends in telemedicine research, and clarify the development potential of China's

telemedicine research, potential collaborations, and deficiencies in its own telemedicine research.

Bibliometric analysis is a research method that quantitatively analyzes data from scientific literature and publications. Results of a bibliometric analysis can guide future research by identifying the quality of research and major research areas [16,17]. It includes coauthorship analysis to identify the relationships between institutions and countries [16,17]. Co-occurrence analysis is another methodology used in bibliometric analysis. It investigates co-occurrence relationships between keywords in academic literature and reveals their relationships and structures [16,17]. Co-occurrence analysis allows the identification of research hot spots and the main research directions through keyword clustering. It also allows researchers to obtain information on topics of interest [17-19]. It helps researchers understand the trends in academic research and topics, areas of research focus, and evolution of research fields. Keywords are extracted through co-occurrence analysis [18].

Academically relevant literature on telemedicine bibliometric analyses to date includes the analysis by Armfield et al [20] of 17,932 articles published between 1970 and 2013 in the PubMed database. Furthermore, they divided the time period into 1970 to 1995 and 2009 to 2013. The study examined the themes during the early adoption of telemedicine and compared them with more recently published reports, which provided an understanding of the maturity, scope, and perceptions of telemedicine. Furthermore, they found that the focus of the field shifted from technical issues to clinical applications and assessment.

Sikandar et al [1] conducted a bibliometric analysis that extracted data from 2011 to 2020 from the Scopus database. This study analyzed 1401 articles to examine primary authors, journals, research institutions and countries, and articles with a high number of citations. However, this study lacked data from 2001 to 2011, which was not conducive to an overview of the development of telemedicine. They found that the United States, the Netherlands, and the United Kingdom had many publications in telemedicine. Furthermore, the 10 most studied keywords were identified: mobile health (mHealth), telemedicine, internet, eHealth literacy, technology, self-management, digital health, primary health care, mental health, and electronic health records. This study enabled researchers to understand that telemedicine was an emerging discipline as well as an understudied field. However, telemedicine experienced rapid development after 2020 due to the COVID-19 pandemic. Therefore, updating our understanding regarding telemedicine is essential.

Yanga et al [7] used the Web of Science database to obtain data on telemedicine over a 20-year period, from 1993 to 2012, which produced 7960 publications. Bibliometric analysis revealed that, although the total volume of telemedicine literature increased significantly over the past 20 years, publication activity in each country and region changed over time. The results revealed that the number of telemedicine publications per year increased from 10 in 1993 to 996 in 2012. There was annual growth from 1993 to 2000; however, the growth rate declined between 2000 and

2008. Despite this, growth in telemedicine publications continued to decrease and has remained steady since 2009 [7]. Although the United States leads the cumulative number of telemedicine publications, Norway ranked the highest when ranking countries by publications per capita. The study also found that the annual increase in the number of publications was inconsistent between 1993 and 2012. Moreover, neuroscience and nursing were 2 significant subresearch fields in telemedicine research.

Waqas et al [21] conducted a bibliometric analysis and extracted data through the Web of Science from 2010 to 2019, with a focus on English publications. They found that academic research in telemedicine increased significantly over the 10-year period. Furthermore, research on telemedicine was primarily conducted by institutions in high-income countries. In addition, telemedicine research shifted from radiology to specific disciplines, such as telemedicine, teledermatology, and telecare. Disciplines that promoted joint research included public environment and occupational health, psychiatry, pediatrics, health policy and services, nursing, rehabilitation, radiology, pharmacology, surgery, respiratory medicine, neuroscience, obstetrics, and geriatrics. However, after the COVID-19 pandemic, telemedicine research fostered telemedicine development, which implies the need for further analysis.

Lan et al [14] discussed the research direction of telemedicine during COVID-19, clarified the diseases for which telemedicine technology was used, and identified the medical services it provided. As of December 16, 2021, 5224 telemedicine research papers on COVID-19 were retrieved from the PubMed database. The United States had the most published articles on telemedicine. Simultaneously, most research was related to the provision of health care and mental health services. Although the study mainly explained the application of telemedicine during COVID-19, it did not consider the difference in the timeline before and after the COVID-19 pandemic. Hence, there is a need to further analyze the changes in telemedicine research motivated by COVID-19. Telemedicine's popularity and acceptance, as well as the awareness and recognition of it by patients and health care professionals, may have changed before and after the COVID-19 pandemic. Clarifying these changes is important when considering the future direction of telemedicine.

Waqas et al [21] also found that Web of Science indexed 6896 papers from 2010 to 2019, with an overall h-index of 87. Furthermore, each study was cited an average of 10.64 times. In total, 42,381 papers were cited 73,354 times. In addition, both the number of published papers and number of citations showed an increasing trend from 2010 to 2019. Regionally, publication output (in English) was highest in high-income countries: the United States, Australia, the United Kingdom, Canada, and Germany. However, 2 middle-income countries, India and China, also featured in the top 10 for publication output. These results demonstrated the rapid growth in telemedicine, even before the COVID-19 pandemic. We anticipated that the research landscape and implementation of telemedicine infrastructure would likely advance exponentially during and after the COVID-19 pandemic. This was echoed by a recent report from the American Medical Association, which predicted that "$250 billion in care could shift to telehealth in

the wake of COVID-19, boosting research and infrastructure" [22].

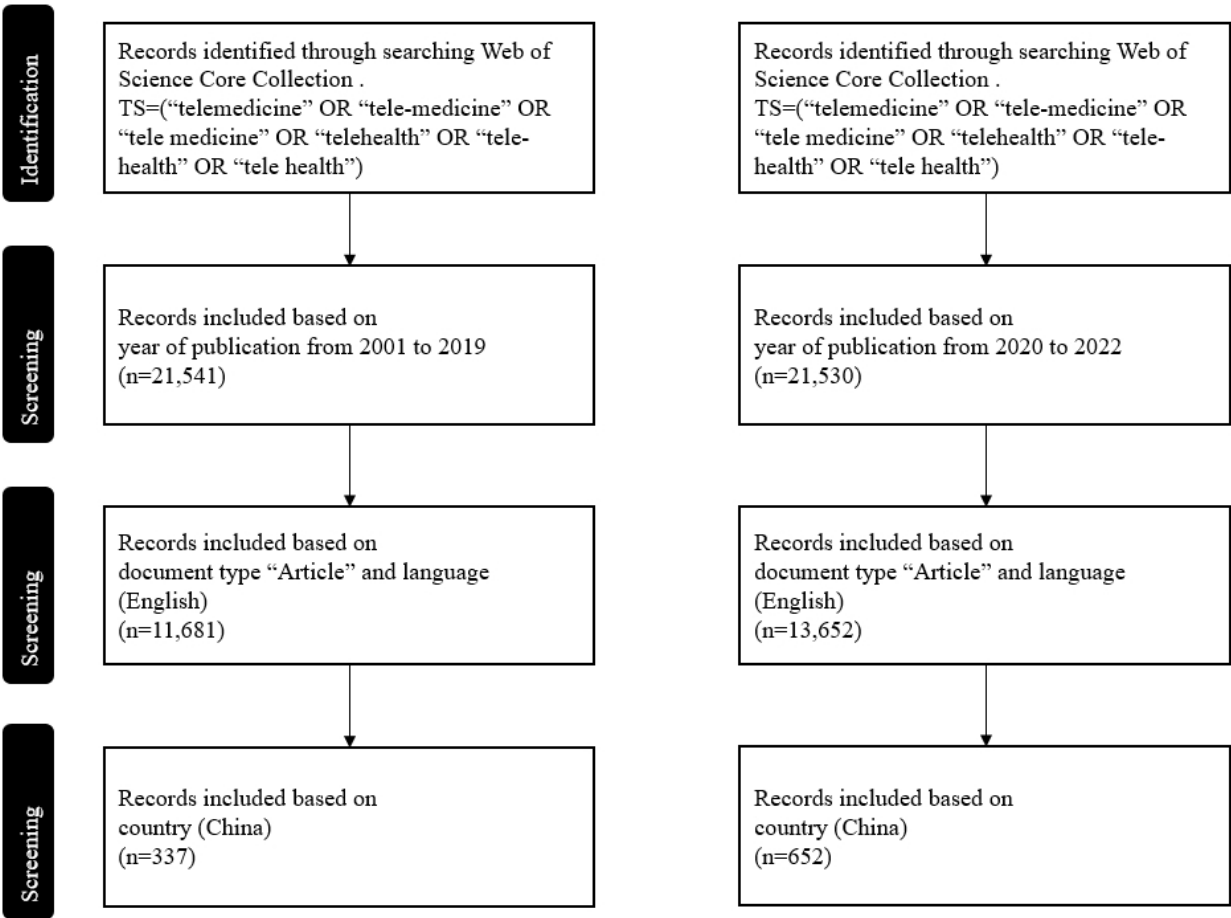
Through preliminary research in telemedicine, we found that the relevant literature increased or decreased every year [1,21]. However, the overall trend was rising. Simultaneously, the United States made the largest contribution to the literature [21]. Research hot spots ranged broadly, including early technology, teleconsultation, telepathology, teleradiology, teledermatology, chronic disease care, and home care.

This study aimed to analyze Chinese and global literature data, present new global trends in telemedicine research, and clarify the development potential of China's telemedicine research, potential collaborations, and deficiencies in its own telemedicine research. By identifying and understanding its own opportunities and shortcomings, China could further develop effective strategies to promote the innovation and development of telemedicine technologies and services. Identifying potential countries with which to collaborate will help China establish international collaboration in telemedicine, share knowledge and experience, and jointly respond to global health challenges, such as COVID-19.

Methods

Data Collection

We conducted a comprehensive literature search for telemedicine research articles published between 2001 and 2022 in the Web of Science database. A combination of the following keywords was used, with all relevant keywords in 1 search box: topic search = ("telemedicine" OR "tele-medicine" OR "tele medicine") or ("telehealth" OR "tele-health" OR "tele health"). This means that we searched for articles containing any "telemedicine"-related terms and any "telehealth"-related terms at once. In this way, we ensured that all results contained relevant keywords in the fields of telemedicine and telehealth. Our selection criteria were limited to articles published in English within a specified time frame. The search was divided into 2 periods: 2001-2019 and 2020-2022. As illustrated in Figure 1, the initial search yielded 11,681 and 13,652 articles in the first and second periods, respectively. Subsequently, we extracted data that pertained to publications from China, which resulted in 337 and 652 articles in the first and second periods, respectively. Data collection was completed on October 30, 2023.

Figure 1. Data collection strategy for the bibliometric analysis of telemedicine research. TS: topic search.


We selected the Web of Science database to extract data for our publication analysis. Since the use and definition of "telemedicine" were not uniformly standardized across the literature and had variations in spelling and terminology, it is critical to encompass such diversity. The term "telemedicine"

and its synonymous term "telehealth" were used interchangeably. A previous study highlighted the importance of including both "telemedicine" and "telehealth" in searches for comprehensive representation [7]. This database was chosen for 2 primary reasons. First, it provided extensive citation

coverage across more than 20,000 peer-reviewed journals in diverse fields, such as health, social sciences, and engineering. Second, it was the sole database that enabled citation management across 250 distinct subjects [21]. These features led numerous researchers to consider the Web of Science as an optimal resource for conducting bibliometric analyses [23-25].

Before conducting data analysis, it is crucial to ensure the data's accuracy and reliability. To this end, we performed data cleaning to check for and remove possible duplicate entries in the database, ensuring that each article appeared only once. Databases may list multiple institutions as affiliations for a single author due to the author's personal profile, which may not match the affiliation listed in the article. In such cases, we cleaned the entries to retain only the author's valid affiliation at the time of publication. If the affiliation field for the same author contained multiple institutions, we cleaned the data to reflect only the primary affiliation associated with the publication. This step is critical to preventing misrepresentation of institutional contributions and collaborations. Through these data cleaning steps, we ensured the data set's completeness and accuracy, avoiding bias in the research results due to duplicate or erroneous data, including titles, author names, journal names, and publication dates.

Use of Software

This study used Microsoft Excel (version 2019), VOSviewer (version 1.6.18), R studio (version 3.3.0), Bibliometrix package (version 4.1.3), Statnet package (version 2019.6), and CiteSpace (version 6.2.R4).

Data Analysis

We used Microsoft Excel (version 2019) to collect the statistics and organize the following literature data [26,27]: the annual number of publications in China and the world, the top 10 countries in the world in total number of publications from 2001 to 2022, the number of publications in these countries from 2001 to 2019 and 2020 to 2022, and magnification. We also used Microsoft Excel (version 2019) to calculate the ratio of the number of publications in each country to the total number of publications and determine the contribution of each country in this field. Magnification is the publication growth ratio in a period, that is, comparing the ratio of the number of publications in the 2 different time periods, 2001-2019 and 2020-2022. The calculation used the following formula: N_2/N_1, where N is the number of publications in each time period [28]. This comparison can be used to measure how quickly the telemedicine field or topic is growing or changing over time. This ratio helps understand whether the field of telemedicine

has experienced significant research growth during and after the COVID-19 pandemic.

Furthermore, we performed bibliometric analysis with VOSviewer (version 1.6.18). VOSviewer is a software tool designed to construct and visualize bibliometric networks [17]. Bibliometric analysis is the application of mathematics and statistics [16]. We used VOSviewer and generated bibliometric maps to visualize social networks based on geographical data, which thereby showed international collaborations within the telemedicine domain. Additional analyses were performed via R Studio (version 3.3.0) and incorporated the Bibliometrix and Statnet packages to delineate intercountry relationships in telemedicine research. These packages are tools for bibliometric analysis and scientific mapping, respectively. Bibliometrix is an R package specially designed for bibliometric analysis and provides functions for data import, cleaning, analysis, and bibliometric data visualization [29]. Conversely, Statnet is a software package used to describe and visualize networks of relationships between countries in bibliometric data, with a special focus on international research collaborations [30]. These tools are valuable for researchers who conducted bibliometric studies in various fields. They enable the analysis of publication trends, citation networks, coauthorship patterns, and international collaborations and provide insights into the structure and dynamics of scientific research. By leveraging these packages, researchers gain a comprehensive view of scholarly communications and identify key contributors, influential publications, and emerging trends. The use of Bibliometrix and Statnet in R Studio was consistent with the purpose of conducting bibliometric and network analyses to describe international collaborations in telemedicine. These tools facilitated the visualization and interpretation of social networks for academic collaboration, elucidated the relationships between countries, and disseminated research in telemedicine. We established thresholds, setting the minimum numbers of publications in a country and citations to 10 and 5 times, respectively, to ensure the relevance and importance of network analysis. This approach allowed us to identify China's role and evolution in international telemedicine collaboration [31,32].

Figure 2 presents a network diagram in which each point is shown as a node within the network structure. Connections between the points, indicative of relationships, are illustrated as edges. Degree centrality is a key measure within this context and was defined as the number of direct neighbors of a node. It was calculated by adding the total number of direct links that a node had with other nodes [33].

Figure 2. Description of a network diagram.
Betweenness centrality quantified a node's role as an intermediary within a network. It was measured by the frequency with which a node occurred on the shortest paths between pairs of nodes. In essence, a node with high betweenness centrality acted as a critical bridge within the network's shortest path structure. The calculation of betweenness centrality was derived from the aggregate shortest paths that passed through a given node:

where σst was the total number of shortest paths between nodes s and t and $\sigma st(\upsilon)$ was the number of paths passing through node υ [33,34].

Betweenness centrality is known as an "intermediary agency" role in the network. If one node was in the path to other unique nodes through communicating, connecting, transporting, or trading, then it could be important and is likely to have a high betweenness centrality [35].

We conducted co-occurrence analysis using author-provided keywords in VOSviewer to identify research hot spots in telemedicine. We chose binary counting when using VOSviewer for analysis. This means that each keyword is counted only once, no matter how many times it appears in the document. This is done to ensure that the weight of each keyword in the network graph is not affected by its frequency of occurrence in a single document but is based on its occurrence in multiple documents. The minimum number of co-occurrences was set to 50. This is to ensure that the keywords analyzed are sufficiently representative in international research. For China's data, since the amount of extracted data was lower, the minimum number of co-occurrences was set to 5. This ensures that important keywords are included even in smaller data sets. Due to the search strategy, the keywords telemedicine and telehealth (and keywords with similar meanings) appear more frequently and occupy a larger weight in the co-occurrence network graph.

Such keywords are considered to affect the distribution of the remaining keywords; therefore, when mapping the co-occurrence of keywords in China and the world, the keywords used in the search strategy that appeared in the results are deleted, and the results are concentrated on valuable research topic buzzwords [36]. Keywords were standardized, and synonyms and different spellings were merged. For example, we combined synonyms like "COVID19" and "covid-19" into 1 unified keyword.

To examine the changes in hot spots more comprehensively, we used CiteSpace (Basic version 6.2. R4) to visualize the changes over time for international telemedicine research trends [37]. We used CiteSpace (version 6.2. R4) to analyze keyword bursts. CiteSpace is popular scientometric software to analyze and visualize trends, patterns, and frontiers in scientific literature. It includes several key concepts, such as "keyword burst," and has 2 important concepts [38]. Keyword explosions refer to sharp increases in the frequency of the use of certain keywords within a specific period. An explosion could indicate that the represented concept, technology, or topic represented had received widespread attention or become a hot research topic during that period. CiteSpace's (version 6.2.R4) keyword burst analysis helps identify and track research trends and hot areas [38].

Results

Telemedicine Research Publications

The publication patterns in telemedicine revealed a global upward trajectory, which was particularly significant over the past 3 years. Although the growth from 2001 to 2019 was gradual, a marked acceleration in publication volume was observed after 2020. The number of telemedicine papers published by the top 10 countries from 2020 to 2022 surpassed those published in the preceding 19 years, as shown in Table 1. This was also notably true for China, where the publication counts from 2020 to 2022 were approximately 1.93 times the

aggregate for those in 2001 to 2019. Table 1 also shows the global ranking of Chinese telemedicine research publications. China's global ranking increased from tenth in 2001 to 2019 to sixth in 2020 to 2022. This surge highlighted the escalating significance of telemedicine, propelled by technological advancements in health care and intensified by the COVID-19 pandemic [20-22]. Figure 3 illustrates the burgeoning global interest in telemedicine research, a trend expected to persist. Figure 3 also charts the trajectory of telemedicine publications in China, which shows a steady increase from 2001 to 2019, followed by a sharp increase in the subsequent years. This pattern mirrored the global trend and highlighted China's intensified focus on telemedicine research in the face of recent health challenges.

Table 1. Top 10 countries by publication volume (total number of publications=25,333).

Rank	Country	Publications in the country, n (%)	Publications by time period		Magnification[a]
			2001-2019, n	2020-2022, n	
1	United States	12,112 (47.81)	5295	6817	1.29
2	Australia	2035 (8.03)	1002	1033	1.03
3	England	1804 (7.12)	873	931	1.07
4	Canada	1543 (6.09)	782	761	0.97
5	Italy	1201 (4.74)	485	716	1.48
6	Germany	1022 (4.03)	498	524	1.05
7	India	998 (3.93)	362	636	1.76
8	China	989 (3.9)	337	652	1.93
9	Spain	842 (3.32)	401	441	1.10
10	Netherlands	665 (2.62)	352	313	0.89

[a]Number of publications before and after 2020.

Figure 3. Number of international telemedicine publications.
International Coauthorship Network for the Telemedicine Research Field

Figures 4A and 4B depict the international coauthorship network in the telemedicine field. The size of each node corresponds to the number of publications in each country, and larger nodes indicate a higher volume. Proximity between 2 nodes suggest the degree of relatedness between the corresponding countries regarding research. An interconnecting line represents collaborative relationships, and thicker lines denote more frequent or substantial collaborative efforts. The different colors assigned by VOSviewer signifies different clusters within the network, where nodes of the same color typically share common properties or characteristics [39]. The network demonstrates the global scale of telemedicine research, showcasing various nations' contributions and cooperative efforts to improve health care through telemedicine technologies. As shown in Figure 4A, the United States and Australia emerged as central hubs for

coauthor networks between 2001 and 2019, which emphasizes their critical roles in telemedicine research collaboration. Although Brazil's node is relatively small, its proximity to the United States and the network's core suggests an important collaborative link. China maintained close cooperative relations with Indonesia, India, Japan, Taiwan, and South Korea. China's main cooperation collaboratives were neighboring Asian countries in the same geographical location. However, network density was more concentrated in Europe and North America, which could reflect more intensive collaboration in these regions.

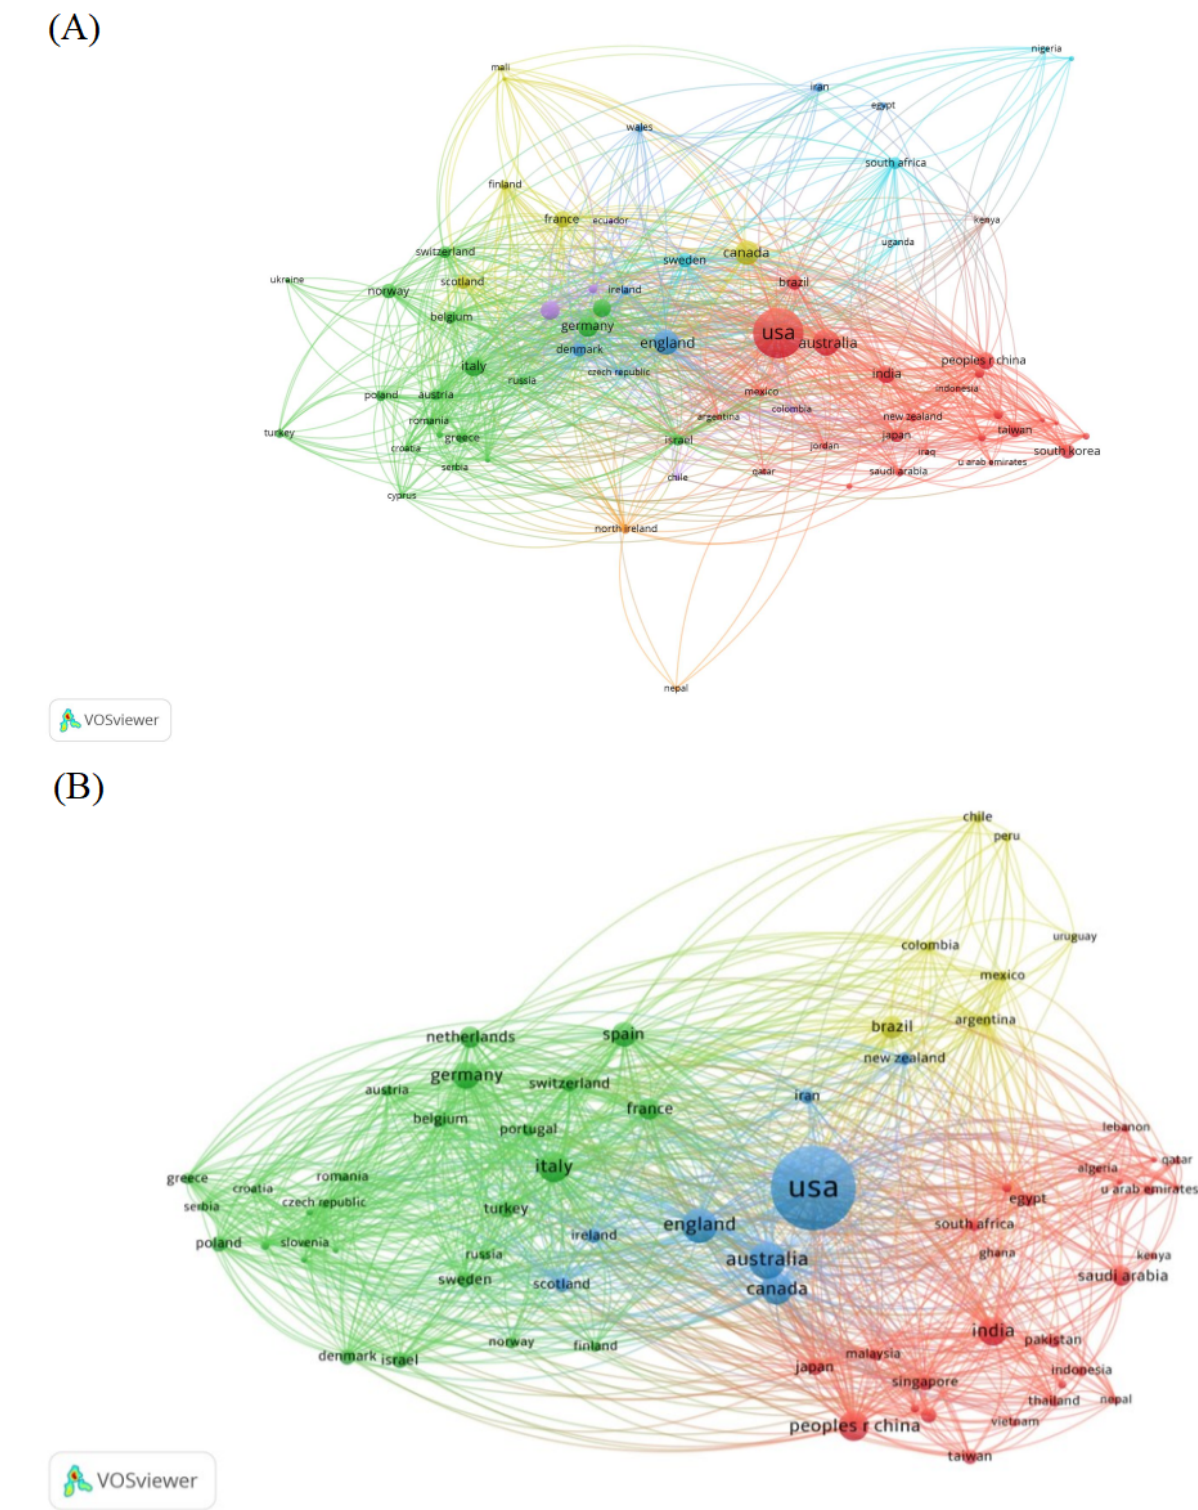
Figure 4. International co-authorship network in telemedicine: (A) 2001-2019 and (B) 2020-2022.


Figure 4B further illustrates the scale of international collaboration in telemedicine between 2020 and 2022. The United States remained the largest node, which represented the most extensive international collaboration. The countries in the center of the network included the United States, the United Kingdom, Australia, and Canada. Importantly, China maintained

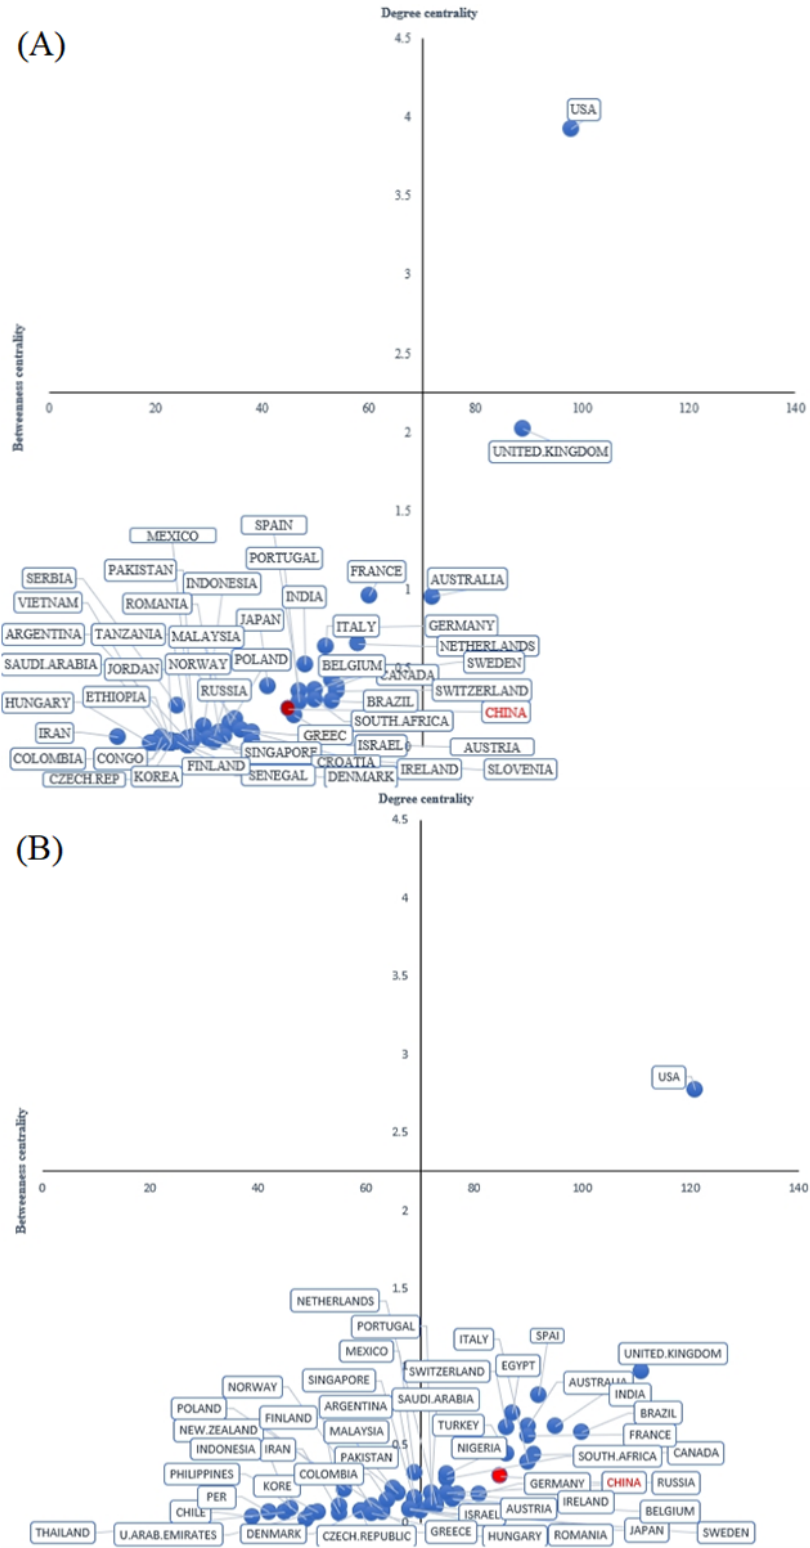
close cooperation with countries from Asia including Japan, Singapore, Malaysia, and South Korea. In addition, China, Saudi Arabia, Egypt, South Africa, Ghana, Lebanon, and other African and Middle Eastern countries unified from the different colored clusters in Figure 4A to a common red cluster in Figure 4B. Cooperation with countries in Africa and the Middle East was also strengthening. Simultaneously, European countries unified from the different colored clusters in Figure 4A to a common green cluster in Figure 4B. Italy is in the central area, and the size of the nodes is relatively large, which indicates more contributions to publications.

This study used RStudio (version 3.3.0) to generate the degree and betweenness centrality for 130 countries in the field of telemedicine. Matrices of the top 50 countries in degree and betweenness centrality from 2001 to 2019 (complete list shown in Multimedia Appendix 1) and 2020 to 2022 (complete list shown in Multimedia Appendix 2) are shown in Figures 5A and 5B, respectively. The central axis divides the matrix into 4 quadrants, with the degree centrality increasing along the X axis from left to right and the betweenness centrality increasing along the Y axis from bottom to top. The X axis quantifies the degree centrality, which reflects the number of connections a country has within the network. In contrast, the Y axis quantifies betweenness centrality, which indicates a country's role as an intermediary within the network.

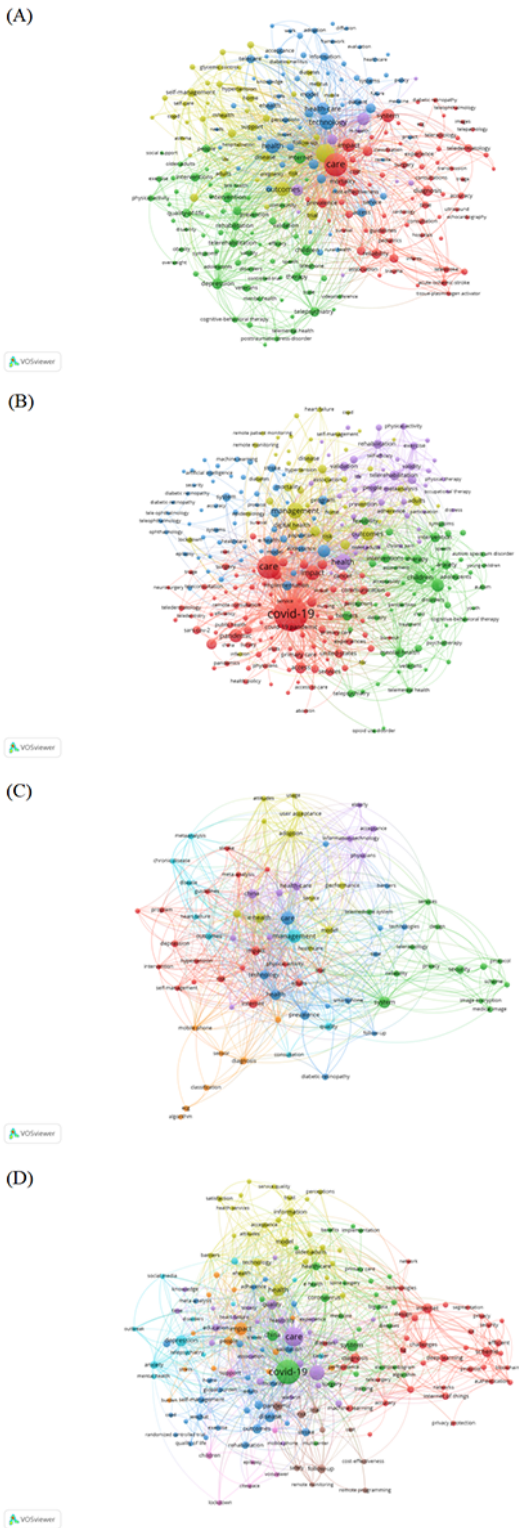
In Figure 5, the span of the X and Y axes ranged from 0 to 140 and 0 and 4.5, respectively. From 2001 to 2019, shown in Figure 5A, to 2020 to 2022, shown in Figure 5B, the countries as a whole moved to the right and downwards, indicating that countries within the international telemedicine research collaboration network exhibited a general increase in degree and decrease in betweenness centrality. This trend implies that, although the number of international collaborations increased, the role of these countries in the dissemination of research information diminished.

In Figure 5, the United States consistently occupied the quadrant characterized by high degree and betweenness centralities, which indicates its significant role as both a primary collaborator and vital conduit for information flow. In contrast, China was situated in a quadrant of low degree and betweenness centralities from 2001 to 2019. However, from 2020 to 2022, China shifted to the quadrant indicative of high degree centrality but low betweenness centrality, which aligns with the general trend in which international collaborations increased while the centrality in information dissemination decreased [40,41].

Figure 5. Matrix of degree and betweenness centrality in telemedicine: (A) 2001-2019 and (B) 2020-2022.


Co-Occurrence Analysis of Author Keywords for China and International Trends in the Telemedicine Research Field

Figure 6 presents the keyword co-occurrence network. Figures 6A and 6B represent international trends from 2001 to 2019 and 2020 to 2022, respectively. Figures 6C and 6D represent trends in China from 2001 to 2021 and 2020 to 2022, respectively.

Figure 6. Keyword co-occurrence network in telemedicine in (A) the world in 2001-2019, (B) the world in 2020-2022, (C) China in 2001-2019, and (D) China in 2020-2022.


In Figures 6A and 6C (2001-2019), the keyword analysis revealed that "care" and "health" were the predominant nodes, which signifies their foundational role in telemedicine research. The prominence of "technology" underscores its critical influence, while the association with terms, such as "mobile health" and "eHealth," reflects the importance of digital innovation in telemedicine service provision. The emergence of "user acceptance" and "self-management" as notable keywords denotes the sector's focus on consumer engagement and empowerment of patients in managing their health. The keyword "outcomes" highlights the significance of research results and evaluation of service efficacy in telemedicine. Moreover, the keyword "mobile" suggests an intensive research interest in the application of mobile technologies to telemedicine services. "Health information" and "data" highlight the importance of information management and data analysis, and

the emergence of "quality of care" underscores a commitment to service excellence.

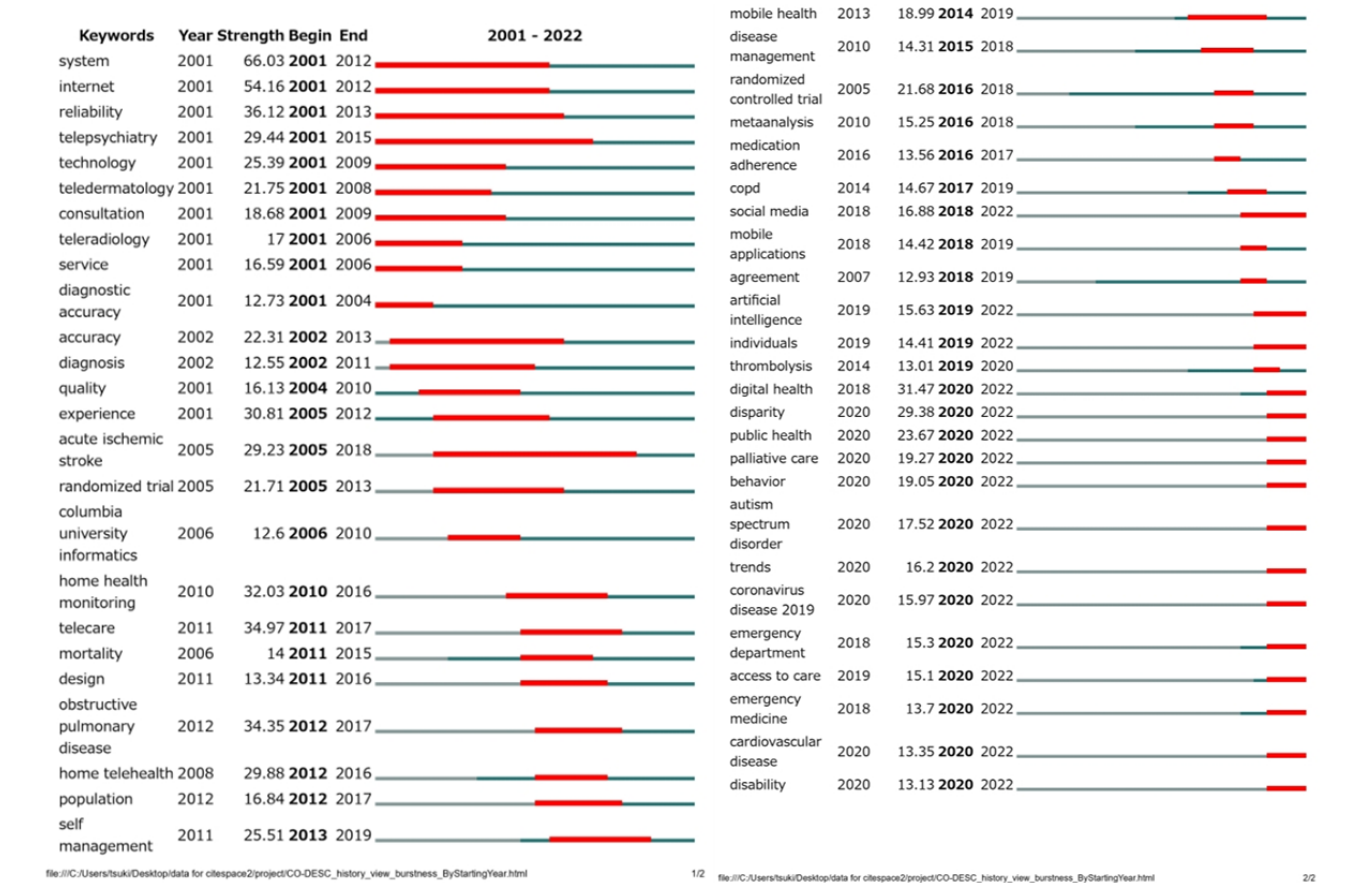
The focus on "security" and "privacy" in Chinese research indicates a growing awareness of the need for data protection measures in telemedicine services. Comparison of Figures 6A and 6C shows that, although international studies were inclined toward nursing and health, China had a unique focus on fundamental technology and systems management, with a special emphasis on health data collection and analysis. This difference could stem from specific telemedicine policies implemented in China [41]. However, compared with Figure 6A, which shows global keyword co-occurrence, Figure 6C shows that China's telemedicine research had fewer keywords in mental health.

As seen in Figures 6B and 6D, the keyword landscape from 2020 to 2022 was significantly reshaped by the emergence of the COVID-19 pandemic, with the importance of "COVID-19" and "pandemic." This was demonstrated in research discourse. These terms underscored the significant impact of health crises on telemedicine research and implementation. The increase in "mental health" keywords may have relationships with the widespread use of telemedicine in mental health services and psychotherapy. In addition, the mental health issues caused by the pandemic may have provided potential opportunities for telemedicine to implement psychological assistance. The prominent appearance of "data," "analytics," and "artificial intelligence" demonstrates an accelerated convergence of data analytics and artificial intelligence in telemedicine, which points to technological changes triggered by the pandemic. Additionally, consistent references to "telemedicine," "technology," and "digital" reaffirm the centrality of technological innovation in telemedicine services. The emergence of "children" as a keyword highlights the importance of telemedicine for pediatric care. "Patient engagement" and "self-management" suggest that patient autonomy was increasing, which could have been influenced by increased health awareness and limited access to physical care during the pandemic.

Consistent with the global pattern, the term "COVID-19" became the focus of telemedicine research in China during the pandemic. This reflects the significant impact of the pandemic on the health care system and the resulting shift in research focus toward telemedicine. The clustering of terms, such as "eHealth," "mHealth," and "digitalization," highlight the critical role that digital and mobile technologies played in health care delivery in China. The observed increases in the keywords "mental health" and "depression" may indicate an increasing focus in telemedicine research on mental health services and psychotherapy. In addition, the emergence of keywords such as "children" and "rehabilitation" in telemedicine research highlights the growing interest in specialist telemedicine applications. This may reflect an increased awareness of diverse health care needs, including those for the older adult population, pediatric care, and rehabilitation services. These needs may be impacted by the pandemic's broader impact on health care priorities and service delivery models.

Figure 7 shows the bursts of the top 50 global telemedicine keywords between 2001 and 2022. International trends in telemedicine have generally undergone 3 stages of transformation: early focus, mid-term evolution, near-term focus.

Keywords such as "system," "telepsychiatry," and "technology" experienced citation explosions between 2001 and 2012, which reflect the early days of telemedicine, system building, and technology applications in specific fields (eg, telemental health). From 2013 to 2017, there was a rapid increase in citations with keywords such as "telecare," "self-management," and "mobile health," which indicates that telemedicine was beginning to become more personalized as mobile technology became popular and self-management tools developed. This was an indication toward development in the direction of globalization and mobility. Beginning from 2018, there was an explosion of citations for keywords such as "social media," "disparity," and "emergency medicine," possibly due to the increased role of social media in health communication, which heightened concerns of inequalities in medical services and increased demand for remote emergency medical services. Beginning from 2020, pandemic-related keywords, such as "COVID-19," "coronavirus disease," and "emergency department," showed significant citation explosions, which highlights the profound impact of the new coronavirus pandemic on telemedicine research and practice. Telemedicine's focus underwent drastic changes from the initial technical foundation and system construction to the integration of mobile and self-management tools and application of social media during the pandemic.

Figure 7. Top 50 international trends with keywords from the co-occurrence network in telemedicine.


Discussion

Principal Findings

This study revealed significant insights into the evolution and status of telemedicine research globally, with a special focus on China. The primary findings indicate a substantial increase in telemedicine-related publications over the years, particularly noting a surge from 2020 to 2022, which aligns with the COVID-19 pandemic. This increase reflects the growing global and regional recognition of telemedicine as a critical component of health care systems, especially during times of crisis. We identified a total of 25,333 telemedicine-related research papers published between 2001 and 2022, with the United States, the United Kingdom, and Australia leading in publication numbers. However, China's contribution and global ranking in telemedicine research significantly improved after 2020, showcasing the country's rapidly growing interest and efforts in this field.

COVID-19 and Telemedicine Research

Overall, the development of communication and professional medical technologies made it easier for many people to access medical services [42]. Both international and Chinese trends steadily increased from 2001, according to literature on telemedicine. However, after 2010, the rapid development of smartphones and mobile technologies enabled the further development of telemedicine research [43]. The COVID-19 pandemic significantly influenced and increased the amount of telemedicine research and number of publications from 2020 to 2022. The COVID-19 pandemic resulted in a significant increase in telemedicine use across medical specialties and geographic locations [44]. Telehealth services expanded rapidly, with a significant shift toward virtual care. This shift was well received by patients and health care providers and had high patient satisfaction scores [45]. Additionally, the pandemic accelerated the adoption of telemedicine in clinical practice across various medical disciplines, such as dentistry, pediatric care, endocrinology, rheumatology, and sports medicine [46]. The widespread adoption of telemedicine facilitated continuity of care for patients and highlighted the potential for telemedicine to be integrated into health care services long after the pandemic [47]. In addition, telemedicine led to positive outcomes, such as reduced hospitalizations and emergency department visits, which demonstrated its effectiveness in remotely managing various medical conditions [48].

Potential Possibilities in Telemedicine Research

China's top researchers in telemedicine were actively engaged in research in various medical fields. Specifically, research conducted in western China demonstrated the feasibility, acceptability, and effectiveness of telemedicine during the COVID-19 pandemic. This highlighted the significant contribution of researchers in this region toward the advancement of telemedicine [49]. In addition, pilot studies focused on the evaluation of the utilization rate and cost-effectiveness of telemedicine programs in western China, which indicated that researchers were actively involved in the implementation and evaluation of telemedicine programs [50]. Simultaneously, research on the application of telemedicine in

Gansu Province, China, emphasized that developed cities, such as Beijing, Shanghai, and Guangzhou, had telemedicine consultation centers and successfully managed diseases, such as hypertension and diabetes [51]. Xu et al [52] examined regional heterogeneity in the application and effect of telemedicine in rural primary care centers in China and revealed the diverse implementation and impacts of telemedicine in different regions.

Overall, research by Chinese scholars in telemedicine spanned across many regions, which included western China, Gansu Province, and rural areas. This demonstrated comprehensive and extensive participation in advancing telemedicine practices and technologies.

From a Chinese perspective, Figure 3 shows a significant increase in the number of Chinese publications in telemedicine research over time, especially after 2020, which was consistent with global trends. This growth trend demonstrates China's increasing interest and investment in telemedicine research, which reflects active research activities and potential research momentum. Simultaneously, Table 1 shows China's global ranking in telemedicine research publications. China's global ranking is rising, which shows that its research is valued both domestically and internationally. Moreover, among the multiplier effects of publications in the top 10 countries in Table 1, China's multiplier effect was greater than that of the other countries, which further emphasizes its research potential.

International Coauthorship in Telemedicine

From 2001 to 2022, the United States was a central node in telemedicine research and had extensive cooperative relationships with other countries. During this period, China gradually developed from a lower degree centrality and lower betweenness centrality to a lower degree centrality and higher betweenness centrality. This indicates that its role as an information dissemination medium in the international collaboration network was small; however, the number of cooperating countries increased. International influence was improved to a certain extent. South American countries (mainly Brazil), western European countries (mainly Italy), and African countries (mainly Egypt and countries in west Africa) all grew in influence. China is currently conducting relatively close cooperative research with Asian and African countries, led by Egypt and countries in west Africa. However, joint research with South American countries (mainly Brazil) and western European countries (mainly Italy) remains relatively slow. These countries are potential research collaborators. Simultaneously, the United States, Australia, the United Kingdom, and Canada were the most influential countries and maintained close cooperation.

Research Hot Spots in Telemedicine

Between 2001 and 2019, "care" and "health" became the largest research nodes in telemedicine literature, which reflected that health care was the core of telemedicine research. Technology played a significant role in telemedicine, particularly in mHealth and eHealth applications. Telemedicine research in China focused on the management and application of technology. User acceptance, mobile technology, health information, and data analytics were key points in Chinese studies, which reflects China's special emphasis on telemedicine policy and data management. From 2020 to 2022, "COVID-19" and "pandemic" become prominent keywords in global telemedicine research, which indicates that the pandemic greatly affected telemedicine research and practice. This forced researchers to focus on various areas, such as pandemic management, public health, medical disparities, and digital health. Mental health, urgent care, and data analytics were also areas of focus, which indicates the impact of the pandemic on the demand for telehealth services and technology. Simultaneously, the emergence of keywords shown in Figure 7 reflects the forefront of the research field. The emergence of some keywords, such as "big data" and "artificial intelligence," indicates that telemedicine research was beginning to integrate advanced technologies, which could potentially completely change the field.

Simultaneously, the world is working on telemedicine for all ages. However, as far as Chinese keywords were concerned, relatively few studies focused on telerehabilitation for children and older adults. In addition, few studies examined telemental health for children. China should also consider strengthening telemedicine research across all age groups. The world's latest telemedicine research direction is toward the development of artificial intelligence, digital medicine, and individualization. China has also conducted extensive research in these fields. In the future, we will continue to deepen research on artificial intelligence and digital medicine in telemedicine.

Future Prospects for Research in Telemedicine

This study demonstrated China's significant development in the research field of telemedicine. However, betweenness centrality remained low, which indicates the need for Chinese researchers to seek opportunities that allow them to be the mediators while bonding in smaller subnetworks.

Through this analysis, we found that telemedicine research is likely to focus on improving service efficiency and quality with the advancement of technology, especially in artificial intelligence and mHealth. Future telemedicine research should explore the application and integration of these technologies in the medical field. Personalized medicine and increased patient engagement are expected to be crucial. As international collaboration increases, future telemedicine research should place greater emphasis on knowledge sharing and collaboration internationally. Special keywords, such as "lockdown" and "tracing," were revealed in the co-occurrence analysis for China, which suggests that telemedicine research also targeted specific regional, social, and cultural factors. This demonstrates that solutions must be identified for each culture, region, and country when it comes to mitigating social problems and health challenges through telemedicine development. Policy and regulation will remain an important topic in telemedicine research, particularly regarding data security and privacy protection.

Simultaneously, the impact of the COVID-19 pandemic on telemedicine will be reflected in future research, including the exploration of public health emergency management, vaccination, pandemic monitoring, and remote patient management. Future research is expected to explore how

telemedicine technology can help respond to global health crises. Different cultural and social contexts may bring different acceptance and needs for telemedicine. Considering how to provide medical services that are more adaptable to different cultural and social environments will be a direction for future research.

Limitations

This study has 4 limitations. First, we only collected bibliometric data from the Web of Science database and excluded other search engines, such as Scopus, PubMed, IEEE, and Google Scholar. Second, we extracted only articles published in English. Third, although we aimed to identify research trends in telemedicine in China, we obtained limited articles on telemedicine, as we only used those published in Web of Science. Fourth, some data in the literature data collected through Web of Science could be changed due to electronic publishing or document editing and publication time. Hence, this may impact the data analysis results.

Conclusions

This study provides the latest trends in telemedicine research, demonstrates that telemedicine research has considerable potential in China, and provides directions for future development. Simultaneously, China's future remote medical research collaboratives and research areas are also of reference value. Although this study shows significant growth in telemedicine research in China, it points out that China's status as a center for international collaboration is still low. In the future, telemedicine research is likely to focus on improving service efficiency and quality, particularly by leveraging technological advances in artificial intelligence and mHealth. In addition, personalized medicine and increased patient engagement will be important trends in the future.

Conflicts of Interest

KK has received research donations for Ritsumeikan University from Kumagaya Gumi, Sumitomo Life Insurance, Merge system, and Pasona. All other authors declare no conflicts of interest.

Abstract

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that requires frequent clinic and laboratory visits. However, patients with SLE, particularly those who are underresourced, have unacceptably high rates of no-shows.

Objective: This study aims to determine no-show rates associated with telemedicine visits during the COVID-19 pandemic in comparison to no-show rates associated with contemporaneous and historic in-person visits.

Methods: We performed a retrospective cohort study in a publicly funded county hospital system in Houston, Texas. We identified a cohort of established patients with SLE by the *International Classification of Diseases* codes that were independently confirmed as SLE by a review of medical records. We identified patients who were seen from March to December in 2018, 2019, and 2020 (to reflect the height of the COVID-19 pandemic and account for seasonal changes in disease activity). Our primary outcome was the percentage of no-shows for rheumatology clinic appointments. Our secondary outcome was laboratory use adherence, which was defined as lupus-specific blood and urine studies conducted within 30 days of the scheduled appointment. Covariates included age, sex, race, ethnicity, and SLE-related prescription drugs.

Results: We included 156 patients with SLE in our analysis. Most were female (n=141, 90.4%), were Hispanic (n=75, 49.3%), and had a median age of 43 (range 19-80) years. In 2020, the no-show rate for telemedicine was 5.5% (10/182) compared to a no-show rate of 16.2% (31/191) for in-person visits (P=.002). After multivariable adjustment for covariates, the odds of no-show were lower for telemedicine visits (odds ratio 0.39, 95% CI 0.20-0.77). There were no differences in adherence to laboratory testing.

Conclusions: Telemedicine visits had decreased odds of no-shows without difference in laboratory testing adherence after adjustment for covariates. More research is needed to determine the clinical impact of telemedicine on patients with SLE.

Introduction

The COVID-19 pandemic triggered widespread and emergent use of telemedicine as an option for patients to avoid exposure to the SARS-CoV-2 virus [1,2]. The use of telemedicine has been especially important in patients with chronic diseases, such as systemic lupus erythematosus (SLE), who are at a high risk of severe COVID-19 and may benefit from less public exposure [3,4]. Missed appointments in general are associated with an increased risk of mortality and adverse outcomes [5-7]. Telemedicine has the potential benefit of improving no-shows by making clinic visits more accessible. This may be particularly

important for patients of lower socioeconomic status (SES) who may have difficulties attending visits because of transportation, work, or financial factors. Yet, it has been suggested that telemedicine services are less likely to be used in populations with lower SES [8,9].

Despite the potential advantages of telemedicine, especially for patients of low SES, there are still important concerns, which should be considered when telemedicine is implemented for patients with SLE. First, patients with SLE are usually followed every 3 to 4 months and require serial evaluations including blood pressure monitoring, physical examination, and clinical laboratory tests—regardless of the presence or absence of symptoms or examination findings [10]. It is unclear how telemedicine may affect adherence to visits and adherence to laboratory testing since patients may be more likely to obtain blood work if they are already at the clinic.

We performed a retrospective cohort study among patients with SLE managed in a county hospital system in Houston, Texas. This population is highly diverse, with most patients being underinsured or uninsured and having low SES. We hypothesized that patients with SLE in this system will have lower no-show rates with telemedicine modalities, such as telephone and video visits, compared to in-person visits. Furthermore, we explored patient characteristics (such as medications and age) and their association with visit types. We also examined the impact of telemedicine on patients' adherence to laboratory testing.

Methods

Design and Patient Population

We performed a retrospective analysis of patients with SLE seen in the Harris Health System (HHS). The HHS is a fully integrated health care system that provides care to residents of Harris County, Texas, which has an estimated population of 4.7 million [11]. The patient population at the HHS includes 54% who are uninsured, 22% who have Medicaid, 12% who have Medicare, and 13% who have private insurance. Most uninsured patients qualify for HHS insurance ("the gold card") that provides partial or full reimbursement for care to patients with a household income that does not exceed 150% of the federal poverty level. Once a patient receives a gold card, the copay for any visits is dictated by income stratification and ranges.

Patient Selection

We identified a cohort of established patients with SLE using the *International Classification of Diseases, 10th Revision* diagnostic codes (M32.x, excluding M32.0). Patients with SLE were included if they were seen at the HHS rheumatology clinics by a rheumatologist at least once between March 2020 and September 2020 (at a time when telemedicine was implemented because of the pandemic). Data were initially collected through the information technology services provided by the HHS. Patients were seen at a large HHS rheumatology teaching clinic staffed by 7 rheumatologists. The diagnosis of SLE was independently confirmed by chart review by a rheumatologist (SB) if they met the American College of Rheumatology 2019 diagnostic criteria. Patients were offered telemedicine visits

either by telephone encounters or by video with a secured third-party platform (Doximity). Between March 2020 and September 2020, the HHS rheumatology clinic offered both in-person visits along with telemedicine encounters. The decision to have a telemedicine versus in-person encounter was driven by patient preference.

As controls, we identified cohorts of patients with SLE seen in the HHS rheumatology clinic from March to September of 2018 and 2019 (before the pandemic). We limited the control cohort to patients with SLE seen from March to September to account for potential seasonal changes in practice patterns and disease activity, which have been previously described [12]. We also identified a subgroup for analysis of patients who were seen at least once in both 2019 and 2020. This subgroup analysis of "no-shows" was performed to examine trends for the same patients who had attended at least 1 follow-up appointment each year.

Outcomes

Our primary outcome was the percentage of no-shows for rheumatology clinic follow-up appointments. No-shows were defined as visits for which patients did not show up or that were canceled by the patient within the same day. Clinic visits rescheduled by patients prior to 24 hours before the clinic appointment were not considered no-shows. Secondary outcomes included laboratory testing such as complete blood count, comprehensive metabolic panel, urinalysis, serum complement levels (C3 and C4), and serum titers of anti–double-stranded DNA (anti-dsDNA) antibodies within 30 days before or after each completed clinic visit. It is the standard in rheumatology clinics that all patients with SLE obtain laboratory testing and have a clinic appointment at least every 3 months, regardless of disease activity [10]. All laboratory studies for patients seen at HHS clinics are done within the HHS at 1 of 17 clinics or 2 large hospitals. Laboratory tests can be ordered as a preclinic laboratory test (performed within 14 days of a clinic appointment) or obtained on the day of their clinic visit. For telemedicine encounters, blood work can be obtained before the clinic or at patients' convenience for any day of their preference at the closest HHS clinical laboratory.

Covariates

Baseline demographics included age, sex, race, ethnicity, and use of SLE-related prescribed drugs at the initial visit in the period of interest. We included baseline demographics as a covariate due to multiple studies showing differences in digital literacy among patients of different ages, races, and ethnicities [13]. The insurance coverage for each specific visit appointment was not available, as insurance status can change over time; however, as previously mentioned, over 85% of patients that are seen in our clinics are uninsured or publicly insured.

We also included whether patients were prescribed SLE-specific drugs (hydroxychloroquine, mycophenolate, azathioprine, methotrexate, rituximab, belimumab, tacrolimus, prednisone, and cyclophosphamide) in 2018, 2019, or 2020. Our data included medications prescribed by providers at each visit but did not include whether patients had filled prescriptions (ie, could not measure adherence). Some patients may have a

6-month active prescription for a drug that may not necessarily be refilled at a 3-month follow-up visit. Due to this, we included SLE-specific drug prescriptions as a variable of whether the patient was ever (at any 1 time point) prescribed (or refilled) a medication throughout the year (2018, 2019, or 2020) as opposed to by visit. We also included codes for infusions of rituximab, belimumab, and cyclophosphamide. We assumed that drug therapies may be an important covariate as some drugs, for instance, mycophenolate mofetil, require more frequent laboratory monitoring than others, such as hydroxychloroquine. We did not use drug therapy as a surrogate for disease activity.

We also used our covariates to determine any associations with visit types in 2020 when telemedicine was more readily available. We divided patients into either all in-person visits, 2 or more telemedicine visits, or in-person visit with 1 telemedicine visit to determine if there were differences between the covariates.

Statistical Analysis

Patient and visit characteristics were summarized by means with SDs, median with ranges, or frequencies with percentages. Summary statistics were compared between groups using ANOVA, independent 1-tailed *t* tests, median regression, Wilcoxon rank sum, Fisher exact, or chi-square tests according to the type and distribution of each variable of interest. Pairwise tests with Holm *P* value adjustment were done when necessary. Since patients had multiple visits, some comparisons were performed using mixed effects linear regression or generalized estimating equations (GEEs) to account for the correlated data structure as appropriate. GEE models used an exchangeable correlation structure, when possible; otherwise, an independent correlation structure was used. A multiple GEE model was used to determine whether not showing up was associated with visit-type appointments. We included covariates that had statistical significance associated with a no-show or visit type (telemedicine vs in-person). For example, older age and certain medications (methotrexate and belimumab) were more associated with telemedicine visits and introduced into the GEE model. Among patients seen both in 2019 and 2020, GEE was used to determine factors associated with laboratory test adherence (defined as being performed within 1 month of the visit). For laboratory test visits, the first visit was used if a patient had multiple visits less than 6 weeks apart. The GEE models estimated odds ratios (ORs) with 95% CI. We performed the analysis of "no-shows" on our subgroup of patients that were seen in both 2019 and 2020 to account for the same patients that historically followed.

Ethical Considerations

This retrospective study was approved by the Baylor College of Medicine Institutional Review Board with waived informed consent under protocol number H-45296. As this was a retrospective review, a waiver of consent was granted. Our data were deidentified and all results were stored in secure and encrypted servers at the Baylor College of Medicine. The data collected were deidentified prior to analysis.

Results

Baseline Characteristics

Baseline characteristics of included patients are shown in Table 1.

There were 156 patients included in our analysis. Most patients were female (90.4%), were Hispanic (49.3%), had a median age of 43 (range 19-80) years, and had received hydroxychloroquine (n=144, 92%) or prednisone (n=120, 77%) throughout the follow-up period. Baseline characteristics broken down by visit type are shown in Table S1 in Multimedia Appendix 1. We included 771 in-person visits and 182 telemedicine (including telephone or video) visits in our analysis. We found that telemedicine visits were associated with older age (median 45.3, range 19.9-81.5 vs 41.2, range 19.2-82.1 years; *P*=.01) and were less likely to occur in patients who were prescribed mycophenolate (74/182, 40.7% vs 367/771, 47.6%; *P*=.03) or prednisone (142/182, 78% vs 644/771, 83.5%; *P*=.02) compared to in-person visits. Differences in all other characteristics were not statistically significant (all *P*>.05; Table S2 in Multimedia Appendix 1).

Table 1. Baseline characteristics of patients with SLE (N=156).

Baseline characteristics	Values
Sex, n (%)	
Female	141 (90.4)
Male	15 (9.6)
Race (n=150), n (%)	
Hispanic	74 (49.3)
Non-Hispanic Black	35 (23.3)
Non-Hispanic White	17 (11.3)
Other	24 (16)
Age (years), median (range)	43.2 (19.2-79.5)
Prescription drug use (ever prescribed as per medical record), n (%)	
Hydroxychloroquine	144 (92.3)
Mycophenolate	63 (40.4)
Azathioprine	41 (26.3)
Methotrexate	23 (14.7)
Rituximab	4 (2.6)
Belimumab	16 (10.3)
Tacrolimus	8 (5.1)
Prednisone	120 (77)
Cyclophosphamide	5 (3.2)

Patient Characteristics Associated With Visit Type

We determined differences in patient characteristics between those who had all in-person visits, 2 or more telemedicine visits, or an in-person visit and 1 telemedicine visit in 2020 (Table 2).

Patients who had 2 or more telemedicine appointments were less likely to be prescribed methotrexate (3/63, 4.8% vs 11/54, 20.4%; Holm adjusted P value=.03) or prednisone (27/63, 42.9% vs 37/54, 68.5%; Holm adjusted P value=.03) during the year compared to those with in-person appointments or only 1 telemedicine appointment. Whether the patient was prescribed mycophenolate was significantly different between visit types (P=.05), but when performing pairwise comparisons on each visit type category, none of them were significant (all P>.05). No patients had received cyclophosphamide in this study.

Table 2. Patient characteristics associated with visit types in 2020.

Patient characteristics	All in-person visits (n=21)	2 or more telemedicine visits[a] (n=63)	In-person visit + 1 telemedicine visit (n=54)	P value[b]	P value , significant pairwise comparison results[c]
Age (years; first 2020 visit), median (IQR)	36.7 (33.1-53)	45.1 (20.6-77.0)	45.2 (19.8-81.5)	.25	N/A[d]
Sex, n (%)					
Female	19 (90.5)	59 (93.7)	49 (90.7)	.76	N/A

[a]This includes patients who have only 1 visit in 2020, and that visit is a telemedicine visit.

[b]Calculated using median regression test, Fisher exact test, or chi-square test.

[c]Pairwise Fisher exact test with Holm P value adjustment.

[d]N/A: not applicable.

[e]All in-person visits: n=20; two or more telemedicine visits: n=61; and in-person visit + 1 telemedicine visit: n=51.

[f]NS: Not significant.

[g]Two or more telemedicine visits versus in-person visit + 1 telemedicine visit.

No-Shows for Clinic Visits

All clinic visits from March to September in 2018 and 2019 were in-person (275 in 2018 and 305 in 2019). From March 2020 to September 2020, of out a total of 373 visits, there were 191 (51.2%) in-person visits and 182 (48.8%) telemedicine visits (Table 3). There was no statistical difference in the no-show rates between in-person visits in 2018, 2019, and 2020 (31/275, 11.3% vs 38/305, 12.5% vs 31/191, 16.2%, respectively). In 2020, when telemedicine was implemented, the no-show rate for in-person visits was 16.2% (31/191) versus 5.5% (10/182) for telemedicine visits (P=.002). We used independent GEEs to determine any characteristics associated with no-shows (Table S3 in Multimedia Appendix 1). After adjusting for age and significant SLE prescription drugs

(methotrexate and belimumab) in a multiple GEE, there was a significantly decreased odds of no-shows for telemedicine versus in-person clinic appointments (adjusted OR 0.39, 95% CI 0.20-0.77; P=.007; Table S4 in Multimedia Appendix 1).

We also performed a subgroup analysis on patients who were seen at least once in 2019 and 2020. There were 300 visits in 2019 and 332 visits in 2020. The total no-show rates between 2019 and 2020 were similar (38/300, 11% vs 41/332, 10.5%; P=.85). Among these visits, we also found that telemedicine appointments had significantly lower odds of no-show compared to in-person appointments (adjusted OR 0.31, 95% CI 0.14-0.69) when adjusting for those SLE prescription drugs that were significantly different (only rituximab) according to the type of visit.

Table 3. Visit characteristics stratified by type of visit.

Visit characteristics	In-person visits (n=771)	Telephone visits (n=157)	Video visits (n=25)	Telephone or video visits (n=182)	Total, n (%)
Year, n (%)					
2018 (n=275)	275 (100)	0 (0)	0 (0)	0 (0)	275 (100)
2019 (n=305)	305 (100)	0 (0)	0 (0)	0 (0)	305 (100)
2020 (n=373)	191 (51.2)	157 (42.1)	25 (6.7)	182 (48.8)	373 (100)
No-shows, n/N (%)					
2018	31/275 (11.3)	N/A[a]	N/A	N/A	31/275 (11.3)
2019	38/305 (12.5)	N/A	N/A	N/A	38/305 (12.5)

[a]N/A: not applicable.

Laboratory Test Use

When comparing laboratory test use between 2019 and 2020, the only significant difference was in urinalysis which was more frequently performed for telemedicine visits than in-person visits (38/289, 13.1% vs 7/257, 2.7%; $P<.001$; Table 4). We also compared the use of laboratory tests between in-person and telemedicine visits in 2020 using GEE. No statistically significant differences were observed (all $P>.05$). We found that there were no differences in nonadherence to laboratory testing for all laboratory tests, although there was a trend toward significance for anti-dsDNA testing (4/136, 2.9% nonadherence for in-person visits vs 13/153, 8.5% nonadherence for telemedicine visits; $P=.06$; Table 4), but it was not statistically significant. We found that urine studies had the highest proportion of nonadherence (16/136, 11.8% for in-person visits vs 22/153, 14.4% for telemedicine visits; $P=.51$), although this could be explained by other factors not measured such as end-stage renal disease.

Table 4. Nonadherence to laboratory testing for completed visits in 2019 and 2020.

Laboratory studies not completed within 30 days of appointment	Total visits in 2019 (n=257), n (%)	Total visits in 2020 (n=289), n (%)	P value[a]	In-person visits in 2020 (n=136), n (%)	Telemedicine visits in 2020 (n=153), n (%)	P value[a]

Discussion

We evaluated adherence to telemedicine visits in the management of patients with SLE, at a publicly funded county hospital serving primarily underserved patients. We also determined whether there were differences in laboratory use between patients who received telemedicine versus in-person visits. Our results demonstrate that telemedicine encounters had significantly lower odds of no-shows compared to in-person encounters. We also found that no-show rates were similar for 2019 and 2020 despite the emergence of the COVID-19 pandemic, which could be due to the availability of telemedicine, as no-shows for telemedicine versus in-person in 2020 were significantly lower (10/182, 5.5% vs 31/191, 16.2%). Furthermore, to our knowledge, this is the first study that shows telemedicine visits do not affect laboratory use within 30 days of the clinic visits.

Studies have shown that telemedicine can play a role in the management of chronic diseases that require frequent clinic visits [14]. Other studies in SLE have shown that telemedicine was used as frequently as in-person visits during the initial COVID-19 pandemic, although this is the first study to demonstrate that this occurred in an underresourced patient population [15,16]. Of note, the widespread use of telemedicine is also seen in patients with severe chronic diseases such as SLE. A recently published randomized controlled trial in Hong

Kong found that the use of telemedicine in patients with lupus nephritis was associated with more hospitalizations [17]. Our study did not address disease activity or hospitalization, and further research is needed to assess how the widespread use of telemedicine may impact these factors.

Our study is consistent with studies in other populations that suggest that telemedicine may provide advantages for underserved populations by decreasing missed appointments. One systematic review of 28 studies reported on the use of telehealth for patients from racial and ethnic minority populations. Results showed that the implementation of telehealth improved access to care; however, there were still barriers related to the technology needed for telemedicine [13]. A separate study using administrative claims data also examined the use of telemedicine in general patient populations and found that telemedicine was associated with fewer missed appointments [18]. However, this study did not include patient populations such as SLE that require frequent clinic visits and laboratory studies (at least every 3 to 4 months). Although our study suggests that telemedicine may be a strategy to decrease the no-show rate in patients with low SES and SLE, more research is needed to determine how other characteristics (including primary language, digital literacy, and disease activity) influence telemedicine and potentially disease outcomes. Furthermore, telemedicine should now be studied as the COVID-19 pandemic has entered the endemic phase.

The strength of our study includes a large number of patients with SLE of low SES in 1 large hospital system where all clinic appointments and laboratory values are documented. There are several limitations in our study. First, we had a predominance of telephone encounters compared to video visits, albeit this has also been seen in other studies, especially among patients of Black and Hispanic ethnicity and of low SES, which were the majority [19]. The use of video visits may affect the no-show rate by presenting technological challenges. Second, our study did not adjust for disease severity according to validated indices as it was retrospective, and it only used prescription drug use as a surrogate for severity. Finally, we were unable to adequately control for insurance type at the time of the scheduled appointment as this information is not updated regularly; however, we do not expect this to change the results as over 85% of patients in the HHS are publicly insured or uninsured.

In conclusion, our study shows that the use of telemedicine during the initial phase of the COVID-19 pandemic was associated with a low rate of no-shows in a population of underserved patients with SLE without impacting laboratory use. To our knowledge, this is the first study to demonstrate that in patients with SLE telemedicine is not associated with decreased laboratory screening, which is a critical component to the care of patients with lupus. As such, we believe the results of this study warrant further investigation to determine the clinical impact of telemedicine on SLE in prospective studies, as the design of this study was not able to capture important clinical characteristics that may influence telemedicine and clinical outcomes, including digital literacy and disease activity.

Data Availability

The datasets generated during this study are not publicly available because the participants of this study did not give written consent for their data to be shared publicly but are available from the corresponding author on reasonable request.

Authors' Contributions

SB, MESA, and SKA conceptualized the study and study protocol. SB collected the data, and KAS did all the statistical analysis. Interpretation of data was done by all the authors. The manuscript was written by SB and reviewed by all authors. All authors reviewed the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: To generate behavioral insights for the development of effective vaccination interventions, we need approaches that combine rapid and inexpensive survey data collection with instruments based on easy-to-use behavior models. This study demonstrates how an inexpensive digital survey helped identify the drivers of COVID-19 vaccination in Nigeria.

Objective: This study aims to illustrate how behavioral insights can be generated through inexpensive digital surveys.

Methods: We designed and conducted a cross-sectional survey with multistage sampling. Data were collected from Nigerians (aged ≥18 years) from 120 strata based on age, sex, state, and urban or rural location. Respondents were recruited via advertisements on Meta platforms (Facebook and Instagram) using the Virtual Lab open-source tool. We used a Meta Messenger chatbot for data collection; participants were compensated with 400 naira (US $0.87 cents). Data collection took 2 weeks. In total, 957 respondents completed the survey, at an advertising cost of US $1.55 per respondent. An 18-item instrument measuring core motivators, ability barriers, sociodemographic characteristics, and respondents' vaccination status was pretested before data collection. We ran separate logistic regression models to examine the relationships between vaccine uptake and core motivators, ability barriers, and sociodemographic variables. A final model that predicted vaccine uptake included all 3 sets of variables.

Results: About 56% (n=540) of respondents reported that they had received at least 1 COVID-19 vaccination. Three core motivators were positively associated with vaccine uptake: the belief that the COVID-19 vaccine promised a better life (adjusted odds ratio [aOR] 3.51, 95% CI 2.23-5.52), the belief that the vaccine would allow respondents to do more things they enjoyed (aOR 1.97, 95% CI 1.33-2.93), and respondents' perception that their friends and family members accepted their decision to get vaccinated (aOR 1.62, 95% CI 1.06-2.48). Two ability barriers were negatively associated with vaccine uptake: cost- or income-related concerns lowered the odds of being vaccinated (aOR 0.35, 95% CI 0.24-0.50) and the lack of availability of vaccines at places respondents routinely visited also lowered their odds of being vaccinated (aOR 0.29, 95% CI 0.21-0.40). After adjusting for other variables, the perceived fear of getting COVID-19 and the hardship associated with the disease were no longer associated with vaccine uptake.

Conclusions: These findings suggest that hope is more important for Nigerians than fear when it comes to vaccine adoption, enjoying life is more important than worrying about getting the disease, and approval from friends and family is more powerful than their disapproval. These findings suggest that emphasizing the benefits of leading a fuller life after being vaccinated is more likely to succeed than increasing Nigerians' fear of COVID-19. This study identifies a very different set of factors associated with COVID-19 vaccine adoption than previous Nigerian studies.

Introduction

Background

Globally, the COVID-19 pandemic has highlighted the importance of behavioral insights for increasing the use of preventive behaviors such as wearing a mask, social distancing, and getting vaccinated. However, recent studies on COVID-19 vaccination emerging from Nigeria and other low- and middle-income countries (LMICs) have primarily focused on identifying gaps in knowledge, attitudes, and beliefs associated with vaccine hesitancy. A number of these studies recommend educating health care workers (HCWs) and members of the general population on vaccine safety and efficacy and assume that equipping people with factually correct information will allay their concerns, increase their perceived risk of acquiring COVID-19, and lead to higher rates of vaccine adoption [1,2].

Data from other Nigerian studies, however, raise questions regarding the strength of the relationship between risk perception and vaccine acceptance. A recent hospital-based study in southern Nigeria found that, while most HCWs perceived themselves at risk of COVID-19, only about half were willing to receive the COVID-19 vaccine [3]. Substantial gaps between risk perception and willingness to accept a COVID-19 vaccine have been observed in the general population in northern Nigeria as well [4]. A study that interviewed over 5000 respondents across all states in Nigeria found that COVID-19 was not perceived as a threat by most respondents [5].

What seems to be an important determinant of vaccine acceptability in Nigeria is trust in the vaccine manufacturing process, health system, government [6], and institutions involved in risk communication on behalf of the government [7]. Yet, despite multiple studies showing a weak relationship between risk perception and willingness to adopt a COVID-19 vaccine in Nigeria, researchers continue to recommend the provision of factually correct information to fill "information gaps" [4].

A recent systematic review of the COVID-19 literature in Nigeria shows that vaccination rates among those at high risk of COVID-19, such as HCWs, were lower than among those at low risk of COVID-19 [8]. Given the weak relationship between risk perception and vaccine uptake in Nigeria, it is not surprising that a recent evaluation found that risk communication efforts in Nigeria were inadequate in sustaining changes in behavior observed at the beginning of the pandemic [9]. Lawal [9] showed that during the first 30 days of the discovery of COVID-19 in Nigeria, and until the national lockdown, public interest in learning about the disease surged. Visits to public places such as grocery stores declined during this period as stringent government policies resulted in reduced mobility of the population. The study by Lawal [9] found that, as the Nigerian population started becoming aware of the disease, there was a slight decline in the number of COVID-19 cases. However, this decline occurred for a relatively short period of time. The number of new cases started increasing again as the initial effects of risk communication interventions dissipated. Lawal

[9] concluded that Nigerians listened to messages telling them to take preventive measures such as social distancing or masking for some time but eventually got tired of the messages and stopped responding to them. In part, this was because the recommended public health precautions did not fit well in the context in which they lived their lives [9].

A clear picture of the drivers of COVID-19 vaccine hesitancy does not emerge from the recent public health literature on Nigeria, in part because much of this work is not based on a behavioral framework. The importance of theory-based work to understand the drivers of vaccine acceptance and design appropriate interventions has been emphasized [10]. In the absence of a clearly articulated framework for understanding vaccine-related behavior, it is difficult to interpret the findings of individual studies and arrive at a clear picture of what drives vaccine uptake in Nigeria.

As a result, there is very limited guidance available to support Nigerian practitioners in designing interventions that might accelerate COVID-19 vaccine uptake. For example, although many recent studies emphasize the importance of implementing health promotion interventions or increasing HCWs' ability to communicate more effectively with members of the general public, most of these studies do not provide any guidance on what the content of this communication should be or what strategy should be used to persuade adults to get vaccinated. Thus, the available research is at a standstill in terms of providing insights that would help in designing more effective behavioral interventions to accelerate vaccine uptake in Nigeria.

An important reason that the literature does not provide a clear direction for the design of behavioral interventions is the lack of use of behavioral frameworks in explaining vaccine acceptance and uptake. Of the more than 20 peer-reviewed publications reviewed for this paper, we found only 1 that used a behavior model to interpret its findings [5]. This is not surprising as researchers have noted the limited use of behavioral frameworks in public health research and practice for over a decade [11-14].

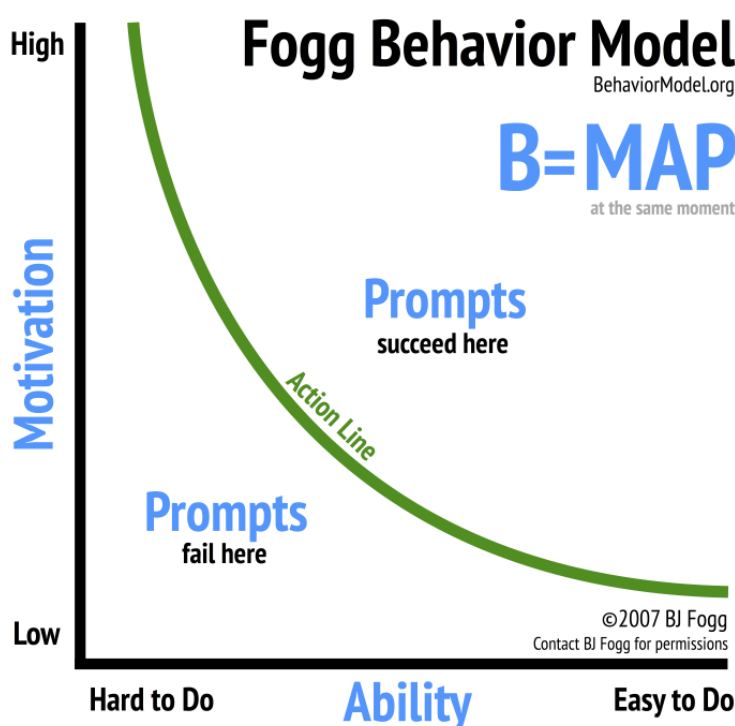
The need for a behavior model that can be used to explain the vaccine adoption process in simple terms that resonate with practitioners is urgent. While a broader discussion of what a practitioner-friendly behavior model should comprise of is merited, the characteristics of such a model have been proposed [15]. A minimum criterion should be that the use of the model leads to deliberate programmatic decisions, a greater emphasis on strengthening activities supported by behavioral research findings, and the elimination of activities that are not evidence based.

The practitioner-friendly model used in this study, the Fogg Behavior Model (FBM), was introduced in the public health literature in 2019 to explain the effects of a social marketing behavior change campaign on the adoption of condoms by married men in Pakistan [13]. More recently, it has been used to identify behavioral drivers associated with the (1) adoption

of COVID-19 vaccination by a low-income population in Cote d'Ivoire [16], (2) adoption of iron folate by pregnant women in India [15], (3) uptake of COVID-19 vaccination by HCWs in Nigeria [17,18], and (4) use of contraception by adolescent girls and young women in Nigeria [19]. A recent study also demonstrates the use of the FBM in making timely programmatic adjustments to a contraceptive social marketing intervention implemented in Nigeria [20]. To the best of our knowledge, this is the first time that the FBM is being applied to understand the dynamics of COVID-19 vaccine adoption in the general population of Nigeria.

FBM: Motivation and Ability as the Drivers of Behavior

The FBM is a model developed for use by practitioners to understand the drivers of human behavior and assist them in the design of behavior change interventions. Fogg states that behavior happens when motivation, ability, and a prompt happen at the same moment. As shown in Figure 1, the model can be visualized in 2 dimensions. Figure 1 shows motivation along the y-axis and ability along the x-axis. Motivation ranges from high to low for any behavior. Ability also ranges from high to low for any behavior. For simplicity, we describe a behavior as being easy to do or hard to do. For a prompt to work, a person needs to have sufficient motivation and ability. The motivation-ability threshold is reflected by an action line in the FBM. Behavior occurs when a person whose motivation and ability are above the action line is prompted. The prompt does not work if the person does not have sufficient motivation to undertake the behavior and finds the behavior hard to do, that is, they are below the action line [21].

Figure 1. Fogg Behavior Model (reproduced from Fogg [22], with permission from BJ Fogg).


Methods

Questionnaire Design: Core Motivators

Fogg defines motivation as having 3 components: anticipation, sensation, and belonging. Anticipation reflects the hopes and fears a person associates with a behavior. Sensation reflects the pleasure or pain a person associates with a behavior. Belonging is reflected by the acceptance or rejection of the behavior by people whose opinions a person considers important.

We conducted a review of the literature to identify relevant constructs and appropriate measures of motivation and ability. The survey questionnaire (Multimedia Appendix 1) was designed using instruments developed to test motivation and ability constructs in the FBM. These instruments had been previously tested in the general population in Cote d'Ivoire and with HCWs in Nigeria and had shown acceptable levels of reliability [16,18]. Respondents were allowed to answer how strongly they agreed or disagreed with 6-point Likert scale items measuring core motivators, such as hope, fear, pleasure, pain, acceptance, and rejection, associated with the adoption of the COVID-19 vaccine.

Ability Barriers

Fogg defines ability in terms of 5 barriers: time, money, the physical effort required to adopt a behavior, the mental effort required to adopt a behavior, and whether the behavior fits into the person's routine [21]. Fogg initially considered social

deviance (or social norms) as part of ability but did not include social norms as an ability barrier in later iterations of the model [22], possibly because of the complexity of the relationship between norms and behavior. To capture ability barriers, respondents could answer how strongly they agreed with items on a 5-point Likert scale. These items captured the 5 ability factors related to COVID-19 vaccine uptake: time, money, mental effort, physical effort, and routine. The instrument also contained questions on sociodemographic variables. In total, the instrument comprised 18 questionnaire items.

The instrument was pretested twice in Nigeria with samples of approximately 100 respondents. The first pretest showed that the relationship among variables measuring motivation, ability, and COVID-19 vaccine uptake was in the expected direction, with 1 exception. The variable measuring agreement or disagreement with the question "Many of my friends and family would think poorly of me if they knew I had taken the COVID-19 vaccine" did not demonstrate the expected relationship with vaccine uptake. This was replaced with the statement "Most people I know have obtained the COVID-19 vaccination." The second pretest showed that the latter response was associated with the outcome in the expected direction. All other items included in the instrument demonstrated the expected relationships with vaccine uptake in both pretests.

Survey Design and Sampling

We implemented a cross-sectional survey with multistage sampling. Nigeria is a large and diverse country with 36 states and the Federal Capital Territory of Abuja. These states and the Federal Capital Territory are grouped into 6 geopolitical zones: northwest, northeast, north central, southwest, southeast, and south-south. Although this survey was not designed to be a representative survey of Nigeria, we aimed to capture the diversity of the country's population by ensuring that respondents from 1 state within each geopolitical zone were sampled. Thus, the states were selected at the first stage. Sokoto state was selected from the northwest, Bauchi state from the northeast, Niger state from north central, Lagos state from the southwest, Anambra state from the southeast, and Rivers state from the south-south. The state selected within each zone reflects its socioeconomic, religious, and ethnic diversity. In addition, these 6 states had ongoing COVID-19 vaccination campaigns to help ensure that survey findings would be useful for COVID-19 program managers in Nigeria.

The sample was stratified by 6 states, 5 age groups, male and female sex, and urban or rural location. This resulted in 120 strata from which respondents were sampled. We ran a total of 120 different ad sets targeting respondents based on the characteristics mentioned above.

Respondents were recruited via advertisements on the Meta digital ad platforms (Facebook and Instagram) using the Virtual Lab open-source tool [23]. The Virtual Lab tool ran ads targeting respondents in all 120 strata. We used a Meta Messenger chatbot for the survey data collection, compensating respondents who completed the survey with 400 naira (US $0.87 cents) in mobile phone credit. Respondents who clicked on the ads were directed to the messenger bot. Of the 214,335 male and female respondents who reached through the ads, 3660 clicked on the

link, 1367 started the survey, and 1011 answered most survey questions.

Respondents could complete the survey in one go or start the survey, stop, and return to complete it later. In total, 957 respondents answered all questions in the survey at an advertising cost of US $1.55 per person. Data from these 957 respondents are used for the analysis.

The outcome of interest for this study was having received at least 1 COVID-19 vaccination. The Government of Nigeria's data on the number of vaccinations provided in 2022 suggested that 50% of Nigerians had received at least 1 COVID-19 vaccination. A sample size calculation was made using an outcome value of 50% and a design effect of 1.5. We estimated that a sample size of 900 would provide a margin of error of 4 percentage points on the outcome of interest.

Statistical Analysis: Relationships Among Core Motivators, Ability Barriers, and Vaccine Uptake

Univariate analysis was conducted to provide the frequency distributions of core motivators, ability barriers, and sociodemographic characteristics of the sample. Bivariate analysis was conducted to explore the relationships between core motivators, ability factors, sociodemographic characteristics, and having received at least 1 COVID-19 vaccination. Multivariate logistic regression analysis was conducted to identify which core motivators, ability factors, and sample characteristics had a significant relationship with vaccine uptake [24].

We also ran a final multivariate model to determine whether there was any change in the relationship between individual variables and vaccine uptake after taking the 3 sets of variables (core motivators, ability factors, and sociodemographic characteristics) into account. Adjusted odds ratios (aORs) from the analyses are shown in the tables. P values were considered statistically significant at $P<.05$.

Ethical Considerations

The ethical approval for the study was obtained from Nigeria's National Health Research Ethics Committee (NHREC/01/01/2007). Informed consent was obtained from all respondents to the quantitative survey. Respondents were assured that all written and recorded data would be kept confidential by using codes to identify participants instead of names or any other personal identifiers. Respondents were informed about their right to refuse to participate in the study or withdraw at any time during the interview.

Results

Core Motivators and COVID-19 Vaccine Uptake

Table 1 shows the frequency distributions of core elements of motivation identified by the FBM, cross-tabulations between core motivators and COVID-19 vaccine uptake and the aOR of COVID-19 vaccination. The first column of Table 1 shows that about three-fourths (n=726, 75.9%) of survey respondents agreed or strongly agreed with the statement that getting vaccinated against COVID-19 allows a person to live a better life, a measure of hope. Nearly half (n=444, 46.4%) of respondents

reported that getting vaccinated protected them and their families from hardship, a measure of fear. Nearly two-thirds (n=610, 63.7%) of respondents agreed or strongly agreed with the statement that getting vaccinated allows a person to do the things they enjoy, a measure of pleasure. About 81.5% (n=780) reported that vaccination reduces the likelihood of getting or spreading COVID-19, a measure of pain. About 79.1% (n=757)

of respondents reported that many of their family and friends approve of the COVID-19 vaccination, a variable measuring social acceptance. Consistent with the high social acceptance of the COVID-19 vaccination, rejection of the vaccine was much lower, that is, 37.1% (n=355) of respondents reported that most of their family and friends did not approve of the COVID-19 vaccination.

Table 1. Frequency distributions of core motivators, cross-tabulations, and the adjusted odds of COVID-19 vaccination in Nigeria.

Core motivators	Frequency distributions of core motivators (N=957, 100%), n (%)	Nigerian adults who obtained at least 1 vaccination (n=540, 56.4%), n (%)	P value	Adjusted odds of obtaining at least 1 COVID-19 vaccination, aOR (95% CI)[a]
Hope: Vaccination allows a person to live a better life			<.001	
Agree or strongly agree	726 (75.9)	483 (66.5)		3.40 (2.27-5.09)
Disagree or strongly disagree or do not know	231 (24.1)	57 (24.7)		1.00 (Reference)
Fear: Getting vaccinated protects people from hardship			<.001	
Agree or strongly agree	444 (46.4)	301 (67.8)		1.09 (0.78-1.51)
Disagree or strongly disagree or do not know	513 (53.6)	239 (46.6)		1.00 (Reference)
Pleasure: Getting vaccinated allows people to do more things they enjoy			<.001	
Agree or strongly agree	610 (63.7)	411 (67.4)		1.84 (1.30-2.62)
Disagree or strongly disagree or do not know	347 (36.3)	129 (37.2)		1.00 (Reference)
Pain: Getting vaccinated reduces the likelihood of getting or spreading COVID-19			<.001	
Agree or strongly agree	780 (81.5)	477 (61.2)		1.15 (0.76-1.73)
Disagree or strongly disagree or do not know	177 (18.5)	63 (35.6)		1.00 (Reference)
Acceptance: Many friends and family approve vaccination			<.001	
Agree or strongly agree	757 (79.1)	472 (62.4)		1.76 (1.21-2.58)
Disagree or strongly disagree or do not know	200 (20.9)	68 (34)		1.00 (Reference)
Rejection: Most family and friends do not approve of vaccination			.56	
Agree or strongly agree	355 (37.1)	344 (57.1)		1.06 (0.79-1.43)
Disagree or strongly disagree or do not know	602 (62.9)	196 (55.2)		1.00 (Reference)

[a]Pseudo R^2=11.85%

The second column of Table 1 shows cross-tabulations between the core motivators of vaccination and vaccine uptake. There were large differences in vaccine uptake by core motivators at the bivariate level. Respondents who associated a COVID-19 vaccination with the hope of a better life had a 42-percentage point higher rate of vaccination (n=483, 66.5% vs n=57, 24.7%; P<.001). Those who feared the hardship that COVID-19 infection would bring had a 21-percentage point higher vaccination rate than other respondents (n=301, 67.8% vs n=239, 46.6%; P<.001). The pleasure that respondents associated with being able to do what they enjoyed doing because of being vaccinated was reflected by a 30-percentage point higher rate of vaccination (n=411, 67.4% vs n=129, 37.2%; P<.001). Respondents' concern that not being vaccinated would result in getting or spreading COVID-19 was associated with a

25-percentage point higher rate of vaccination (n=477, 61.2% vs n=63, 35.6%; P<.001). Acceptance of the vaccine by friends and family was associated with a 28-percentage point higher vaccination rate (n=472, 62.4% vs n=68, 34%; P<.001). It is interesting that social rejection, or the lack of approval of the vaccination by family members, was not associated with vaccine uptake.

The third column of Table 1 shows the adjusted odds of COVID-19 vaccination. With all core motivators in the model, Nigerians who believed that COVID-19 vaccination was associated with a better life, had 3 times higher odds of getting vaccinated (aOR 3.40, 95% CI 2.27-5.09). Those who believed that getting vaccinated would allow them to do more things that they enjoyed were more likely to be vaccinated (aOR 1.84, 95% CI 1.30-2.62). Friends and family members' acceptance of their

decision to get vaccinated was associated with a higher vaccination rate (aOR 1.76, 95% CI 1.21-2.58).

Ability Barriers and COVID-19 Vaccine Uptake

Table 2 shows the frequency distributions of ability factors identified by the FBM, cross-tabulations between ability factors and COVID-19 vaccine uptake, and the adjusted odds of COVID-19 vaccination. The first column of Table 2 shows that about 54% (n=516) of respondents felt that their family or work responsibilities made it difficult for them to get vaccinated. This variable measures the constraint of time. Over a third (n=347,

36.3%) of respondents felt that the cost or loss of income associated with getting vaccinated was a barrier. Nearly 40% (n=382) of respondents felt that the physical effort required made it difficult to get vaccinated. Nearly half (n=437, 46%) of the respondents felt that the decision to get vaccinated was difficult. This variable measures the mental effort required to get vaccinated. About 42% (n=401) of respondents reported that not having the vaccine available in places they routinely visited was a barrier to getting vaccinated. The latter measures the routine associated with adopting a behavior.

Table 2. Frequency distributions of ability factors, cross-tabulations, and the adjusted odds of COVID-19 vaccination in Nigeria.

Ability	Frequency distributions of ability factors (N=957, 100%), n (%)	Nigerian adults who obtained at least one vaccination (n=540, 56.4%), n (%)	P value	Adjusted odds of obtaining at least one COVID-19 vaccination[a]
Time: Family or work responsibilities make it difficult to find time				
Agree or strongly agree	516 (53.9)	277 (53.7)	.06	0.94 (0.69-1.27)
Disagree or strongly disagree or do not know	441 (46.1)	263 (59.6)		1.00 (Reference)
Money: Costs or loss of income make it difficult				
Agree or strongly agree	347 (36.3)	158 (45.5)	<.001	0.45 (0.33-0.62)
Disagree or strongly disagree or do not know	610 (63.7)	382 (62.6)		1.00 (Reference)
Physical effort: Physical effort makes it difficult				
Agree or strongly agree	382 (39.9)	218 (57.1)	.74	1.46 (1.06-2.01)
Disagree or strongly disagree or do not know	575 (60.1)	322 (56.0)		1.00 (Reference)
Mental effort: Decision to get vaccine is difficult				
Agree or strongly agree	437 (45.7)	237 (54.2)	.21	0.94 (0.70-1.27)
Disagree or strongly disagree or do not know	520 (54.3)	303 (58.3)		1.00 (Reference)
Routine: Vaccine not available where I routinely visit				
Agree or strongly agree	401 (41.9)	141 (35.2)	<.001	0.21 (0.16-0.28)
Disagree or strongly disagree or do not know	556 (58.1)	399 (71.8)		1.00 (Reference)

[a]Pseudo R^2=12%.

The second column of Table 2 shows cross-tabulations between ability factors and vaccine uptake. Respondents who agreed or strongly agreed with the statement that costs or loss of income were a barrier reported a 17-percentage point lower vaccination rate compared to others (n=158, 45.5% vs n=382, 62.6%; P<.001). The lack of availability of the COVID-19 vaccine in places that they routinely visited was associated with a 37-percentage point lower rate of vaccination (n=141, 35.2% vs n=399, 71.8%; P<.001).

The third column of Table 2 shows the adjusted odds of a COVID-19 vaccination. With all ability factors in the model, Nigerians who believed that the cost or the loss of income made it difficult to obtain a COVID-19 vaccination were less likely to get vaccinated (aOR 0.45, 95% CI 0.33-0.62). The lack of availability of vaccines at places respondents routinely visited was associated with a lower likelihood of vaccination (aOR

0.21, 95% CI 0.16-0.28). Contrary to our expectations, respondents who felt that physical effort makes it difficult to get vaccinated were more likely to be vaccinated (aOR 1.46, 95% CI 1.06-2.01).

Sociodemographic Factors and COVID-19 Vaccine Uptake

Table 3 shows the frequency distributions of sociodemographic characteristics of respondents in the sample, cross-tabulations between these characteristics and vaccine uptake, and the adjusted odds of COVID-19 vaccination. The first column of Table 3 shows that, as expected from a digital survey, the sample had relatively young participants: 56% (n=531) of respondents were aged 18-29 years and 16% (n=151) were aged 40 years and older. Male participants represented a higher proportion of the sample (n=592, 61.9%). About 39% (n=371) of respondents had a primary or secondary school certificate, one quarter

(n=231, 24.1%) had an ordinary national diploma (OND) or a higher national diploma (HND), and one-third of respondents (n=317, 33.4%) had a bachelor's or higher degree. A majority of respondents were from urban areas: 57% (n=544) were from cities, 34% (n=323) from towns, and 9% (n=90) from rural areas.

Table 3. Frequency distributions of sociodemographic variables, cross-tabulations, and the adjusted odds of COVID-19 vaccination in Nigeria.

Demographic	Sample characteristics (N=957, 100%), n (%)	Nigerian adults who obtained at least 1 vaccination (n=540, 56.4%), n (%)	P value	Adjusted odds of obtaining at least 1 COVID-19 vaccination, aOR (95% CI)[a]
Age (years)			.71	
18-29	531 (55.5)	300 (56.5)		1.31 (0.89-1.93)
30-39	275 (28.7)	159 (57.8)		1.28 (0.85-1.93)
≥40	151 (15.8)	81 (53.8)		1.00 (Reference)
Sex			.06	
Male	592 (61.9)	348 (58.8)		1.00 (Reference)
Female	365 (38.1)	192 (52.6)		0.73 (0.56-0.95)
Education			<.001	
Primary or secondary school certificate	371 (38.8)	188 (50.7)		1.00 (Reference)
Ordinary national diploma (OND)	111 (11.6)	72 (64.9)		1.90 (1.22-2.98)
Higher national diploma (HND)	120 (12.5)	87 (72.5)		2.62 (1.64-4.19)
Bachelors or higher	317 (33.4)	169 (53.3)		1.12 (0.81-1.55)
Other	38 (4)	24 (63.2)		1.79 (0.89-3.60)
Location			.02	
City	544 (56.8)	320 (58.8)		1.00 (Reference)
Town	323 (33.8)	181 (56.0)		0.88 (0.68-1.17)
Rural	90 (9.4)	39 (43.3)		0.56 (0.35-0.89)

[a]Pseudo R^2=2.79%.

The second column of Table 3 shows cross-tabulations between sociodemographic characteristics and vaccine uptake. There was no statistically significant difference in the COVID-19 vaccination rate by age or sex. Education was associated with vaccine uptake: respondents with an OND (n=72, 64.9% vs n=188, 50.7%; *P*<.001) or an HND (n=87, 72.5% vs n=188 50.7%; *P*<.001) were more likely to be vaccinated than respondents with a primary or secondary school certificate. Urban residence was also associated with higher vaccine uptake: respondents from rural areas were significantly less likely to have obtained the COVID-19 vaccination (n=39, 43.3% vs n=320, 58.8%; *P*=.02).

The third column of Table 3 shows the adjusted odds of COVID-19 vaccination. With all sociodemographic characteristics in the model, female participants were less likely to get vaccinated (aOR 0.73, 95% CI 0.56-0.95). Having an OND (aOR 1.90, 95% CI 1.22-2.98) or a HND (aOR 2.62, 95% CI 1.64-4.19) increased a respondent's likelihood of being vaccinated. Nigerians living in rural areas were less likely to be vaccinated (aOR 0.56, 95% CI 0.35-0.89).

Full Model: Core Motivators, Ability Barriers, and Sociodemographic Characteristics

Table 4 shows the adjusted odds of COVID-19 vaccine uptake in Nigeria. The 3 core motivators identified earlier remained significant after adjusting for ability factors and sociodemographic characteristics. Nigerians who believed that the COVID-19 vaccination was associated with the promise of a better life were more likely to be vaccinated (aOR 3.51, 95% CI 2.23-5.52). Nigerians who felt that the vaccination would allow them to do more things they enjoyed were more likely to be vaccinated (aOR 1.97, 95% CI 1.33-2.93). Respondents' friends' and family members' acceptance of their decision to get vaccinated was associated with a higher likelihood of their being vaccinated (aOR 1.62, 95% CI 1.06-2.48).

Table 4. Adjusted odds (aOR) of COVID-19 vaccination in Nigeria.

	Adjusted odds of obtaining at least 1 COVID-19 vaccination, aOR (95% CI)[a]
Core motivators	
Getting vaccinated allows a person to live a better life (hope)	3.51 (2.23-5.52)
Getting vaccinated protects people from hardship (fear)	1.03 (0.71-1.49)
Allows people to do more things they enjoy (pleasure)	1.97 (1.33-2.93)
Reduces the likelihood of getting or spreading COVID-19 (pain)	1.17 (0.74-1.84)
Many friends and family approve vaccination (acceptance)	1.62 (1.06-2.48)
Most family and friends do not approve vaccination (rejection)	1.18 (0.83-1.67)
Ability factors	
Family or work responsibilities make it difficult (time)	0.85 (0.61-1.19)
Costs or loss of income make it difficult (money)	0.35 (0.24-0.50)
Physical effort makes it difficult (physical effort)	1.45 (1.02-2.07)
The decision to get the vaccine is difficult (mental effort)	1.08 (0.77-1.51)
Vaccine not available where I routinely visit (routine)	0.29 (0.21-0.40)

[a]Pseudo R^2=23.51%.

The relationships between ability factors and vaccine uptake remained important after adjusting for sociodemographic characteristics and core motivators. Nigerians with cost- or income-related concerns were less likely to obtain a COVID-19 vaccination (aOR 0.35, 95% CI 0.24-0.50). The lack of availability of vaccines at places they routinely visited made them less likely to get vaccinated (aOR 0.29, 95% CI 0.21-0.40).

After adjusting for motivation and ability, female participants were no longer less likely to obtain a COVID-19 vaccination. Respondents with an OND (aOR 2.27, 95% CI 1.34-3.84) or HND (aOR 3.57, 95% CI 2.04-6.24) were more likely to be vaccinated than those with primary or secondary school certificates. Rural residents were less likely to be vaccinated than residents living in cities (aOR 0.54, 95% CI 0.31-0.92).

Discussion

Principal Findings

The findings of this study show that 56.4% (n=540) of Nigerian adults who responded to the digital survey had obtained at least 1 COVID-19 vaccination by October 2022. Several core motivators were associated with vaccine uptake, after adjusting

XSL·FO
RenderX

for ability factors and sociodemographic variables. The beliefs that COVID-19 vaccination allows a person to live a better life and that it allows them to do more things that they enjoy increases the likelihood of being vaccinated. The belief that many friends and family members approve of COVID-19 vaccination is also associated with a greater likelihood of being vaccinated. Several ability barriers were also correlated with vaccine uptake, after adjusting for other variables. Respondents who felt that costs or loss of income associated with getting vaccinated made it difficult to get vaccinated were less likely to get vaccinated. The lack of availability of the COVID-19 vaccine at places respondents routinely visited was also negatively associated with vaccine uptake. The study also found a higher likelihood of Nigerians with OND or HND being vaccinated compared with those with primary or secondary school certificates and a lower likelihood of being vaccinated among rural respondents.

Strengths and Limitations

While this study provides useful insights for program design, its limitations should be acknowledged. The first limitation of this study is that no causal inferences can be made from it because of its cross-sectional design. This design limitation may explain an unexpected study finding: after adjusting for other variables, the physical effort required to get vaccinated was associated with a higher rate of vaccination. This finding may reflect reverse causality; those who are vaccinated may be more aware of the physical effort required to obtain a COVID-19 vaccination. Further investigation is needed to determine whether the positive relationship between the perceived physical effort required to get vaccinated and receiving a vaccination holds only for those who have been vaccinated or for the full sample.

The second limitation of this study is that variables that were not measured may be responsible for the observed relationships. For example, while the relationship between the belief that vaccination allows a person to enjoy life more and vaccine uptake is powerful, there is a possibility that unmeasured factors are driving this relationship. Thus, developing messages around how vaccination can help a person lead a fuller life and testing them through relatively inexpensive digital campaigns would be important prior to implementing an at-scale campaign that focuses on this message.

The third limitation of the study is that it is not representative of all Nigerians in the 6 states in which it was conducted. This is reflected in the higher educational status of the survey sample: about 33% (n=317) of respondents had a bachelor's or higher education. The participants were also relatively young; about 56% (n=531) of respondents were between 18 and 29 years. Moreover, male participants comprised a higher proportion of the sample than female participants. These findings are not uncommon for digital surveys conducted in LMICs.

A strength of this study is its cost efficiency and the timeliness with which the survey was conducted compared to face-to-face household surveys. A major barrier to the use of behavioral insights by practitioners in LMICs is the cost of data collection. Behavioral research is not well-funded in LMICs. Inexpensive digital surveys could substantially increase the ability of practitioners in LMICs to use behavioral insights to develop interventions that increase vaccine uptake.

Future Directions

We do not know the extent to which the findings from surveys conducted by recruiting respondents through web-based advertising are comparable to the findings from population-based household surveys. Although some studies show broadly similar patterns between digital and population-based surveys [25], more research is needed to identify what types of systematic differences may exist between these 2 survey modalities. It is important, for example, to learn whether inferences from digital surveys apply to the behavior of individuals who are not on digital platforms.

Given our inability to generalize these findings beyond Nigerians who are on Facebook and Instagram, how can the findings of this survey be used? First, the findings may be used to design interventions on digital platforms as well as to evaluate the effectiveness of those interventions. Digital behavior change interventions may be evaluated by experimental studies on digital platforms that compare vaccine uptake between intervention and control groups. A growing proportion of the Nigerian population is now on Facebook and Instagram: between 31 million and 36 million Nigerians 13 and older use Facebook and Instagram each month. High exposure to messages that associate the COVID-19 vaccination with a better, more fulfilling life is achievable through advertising on digital platforms and at a fraction of the cost of advertising on traditional mass media channels such as television.

Future interventions could build upon the findings of this study by conducting qualitative research to determine which motivation or ability factors are relevant in locations where interventions are planned. A survey conducted in the most densely populated, low-income commune in Yugpognon, Cote d'Ivoire, using the FBM found broadly comparable findings: motivation and ability were powerful drivers of vaccine adoption, although the specific elements of motivation and ability that were relevant in Yugpognon were, not surprisingly, different [16].

Our findings raise several questions that should be answered through additional research. Answers to these questions may help in the design of more effective COVID-19 service delivery interventions. It would be useful, for example, to learn whether some of the places routinely visited by Nigerians are amenable to serving as COVID-19 vaccine delivery sites. Are such potential vaccine delivery sites likely to vary by age, sex, by urban or rural residence and are they suitable for cost-efficient provision of COVID-19 vaccinations?

Our sample consisted primarily of Nigerians living in cities and towns, with a minority of respondents living in rural areas. A larger proportion of rural respondents may be obtained from digital surveys that oversample rural areas. This may be done by capping the number of respondents from urban areas and allowing more time for responses to come in from rural areas. This would, however, have implications for the cost of the rural component of the survey.

Comparison to Prior Work

Overall, the findings of our study provide a very different perspective on vaccine adoption in Nigeria than what is available in the peer-reviewed literature. Recent Nigerian studies on COVID-19 vaccine uptake have primarily focused on identifying gaps in knowledge, attitudes, and beliefs associated with vaccine hesitancy [1-3]. These studies place emphasis on the perceived risk of disease as a driver of vaccine uptake, despite mixed evidence on the role of risk perception on vaccine uptake in Nigeria [5,6,9]. Several of these recent studies propose that equipping people with factually correct information will allay their concerns, increase their perceived risk of acquiring COVID-19, and lead to higher rates of vaccine adoption. By contrast, a small but rapidly growing body of work is putting vaccine adoption in a behavioral context [13-19,26]. These studies take motivation and ability for behavior change into account in explaining the range of barriers that influence immunization decisions and suggest how programs should help individuals overcome them.

Conclusions

These findings help us consider a very different approach to intervention design—one that builds upon what people want for their future, what gives them pleasure, and how they are influenced by the approval of their friends and family members. Our findings suggest that hope is more important for Nigerians than fear when it comes to vaccine adoption, social approval is more powerful than social disapproval, and enjoying life is more important than worrying about getting the disease.

These findings suggest that an approach that is based on increasing the perception of hope and pleasure associated with vaccine adoption as well as increasing network members' social approval is likely to increase COVID-19 vaccine adoption in Nigeria. Our analysis also suggests that financial considerations play an important role in the uptake of COVID-19 vaccination in Nigeria. The costs associated with reaching a vaccination site or the loss of income associated with being away from work are important determinants of vaccine adoption. Nigerians with limited flexibility at work may find it challenging to visit a vaccination site during the hours that it is open. Consistent with this finding, making COVID-19 vaccines available at places that Nigerians visit routinely may have a large impact on vaccine uptake.

The use of a behavior model to understand drivers of COVID-19 vaccine uptake in Nigeria has helped provide a different perspective on vaccine-related decision-making in Nigeria than what is currently available in the published literature. The FBM, a model of human behavior rather than a model of health behavior per se, considers a broad range of factors influencing motivation, including an individual's hopes and fears, the sensation of pleasure or pain that they get from a particular behavior, and the social influences on them associated with their identity. The model also measures ability constraints including bandwidth-related constraints such as time or cognitive constraints, financial constraints, physical effort–related constraints, and habits or routine-related constraints. By comparison to behavior models that focus on perceived risk of and susceptibility to disease, the FBM situates behavior within the broader context of a person's life.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

IN developed and submitted the institutional review board protocol to Nigeria's National Health Research Ethics Committee. SA and DB conceptualized the study. SA conducted the statistical analysis and wrote the first draft of the report. IN provided important context on Nigeria that enabled the interpretation of the study findings. DB developed the survey instrument and interpreted the study findings. DB and SF were responsible for acquiring funding for the study. SF and NR designed the digital data collection instruments and implemented the data collection and quality control procedures. All authors read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The novel coronavirus SARS-CoV-2 caused the global COVID-19 pandemic. Emerging reports support lower mortality and reduced case numbers in highland areas; however, comparative studies on the cumulative impact of environmental factors and viral genetic diversity on COVID-19 infection rates have not been performed to date.

Objective: The aims of this study were to determine the difference in COVID-19 infection rates between high and low altitudes, and to explore whether the difference in the pandemic trend in the high-altitude region of China compared to that of the lowlands is influenced by environmental factors, population density, and biological mechanisms.

Methods: We examined the correlation between population density and COVID-19 cases through linear regression. A zero-shot model was applied to identify possible factors correlated to COVID-19 infection. We further analyzed the correlation of meteorological and air quality factors with infection cases using the Spearman correlation coefficient. Mixed-effects multiple linear regression was applied to evaluate the associations between selected factors and COVID-19 cases adjusting for covariates. Lastly, the relationship between environmental factors and mutation frequency was evaluated using the same correlation techniques mentioned above.

Results: Among the 24,826 confirmed COVID-19 cases reported from 40 cities in China from January 23, 2020, to July 7, 2022, 98.4% (n=24,430) were found in the lowlands. Population density was positively correlated with COVID-19 cases in all regions (ρ=0.641, *P*=.003). In high-altitude areas, the number of COVID-19 cases was negatively associated with temperature, sunlight hours, and UV index (*P*=.003, *P*=.001, and *P*=.009, respectively) and was positively associated with wind speed (ρ=0.388, *P*<.001), whereas no correlation was found between meteorological factors and COVID-19 cases in the lowlands. After controlling for covariates, the mixed-effects model also showed positive associations of fine particulate matter (PM2.5) and carbon monoxide (CO) with COVID-19 cases (*P*=.002 and *P*<.001, respectively). Sequence variant analysis showed lower genetic diversity among nucleotides for each SARS-CoV-2 genome (*P*<.001) and three open reading frames (*P*<.001) in high altitudes compared to 300 sequences analyzed from low altitudes. Moreover, the frequencies of 44 nonsynonymous mutations and 32 synonymous mutations were significantly different between the high- and low-altitude groups (*P*<.001, mutation frequency>0.1). Key nonsynonymous

mutations showed positive correlations with altitude, wind speed, and air pressure and showed negative correlations with temperature, UV index, and sunlight hours.

Conclusions: By comparison with the lowlands, the number of confirmed COVID-19 cases was substantially lower in high-altitude regions of China, and the population density, temperature, sunlight hours, UV index, wind speed, PM2.5, and CO influenced the cumulative pandemic trend in the highlands. The identified influence of environmental factors on SARS-CoV-2 sequence variants adds knowledge of the impact of altitude on COVID-19 infection, offering novel suggestions for preventive intervention.

KEYWORDS

COVID-19; environmental factors; altitude; population density; virus mutation

Introduction

Background

In recent years, the outbreak of COVID-19 has had substantial impacts on human health, social life, and economic trends worldwide. To comprehensively explore the impact of potential factors on the strength and speed of viral infection, we first used the zero-shot model to screen the literature related to broad respiratory infectious diseases, including COVID-19, to identify the major influencing factors through text mining [1]. A significant ranking list of environmental factors was obtained (Multimedia Appendix 1), in which temperature and atmospheric pressure were highly correlated with respiratory viruses. Earlier findings showed that the spread of COVID-19 was linked to various factors, including the environment, sequence variants of the virus, and government countermeasures to protect public health in the face of outbreaks [2,3].

Previous studies also investigated the correlation between COVID-19 and altitude. COVID-19 transmission in high-altitude regions appears to differ from the global pattern, with a lower number of cases reported at high altitudes [4-9]. Moreover, population density was identified as a basic factor that significantly catalyzed the spread of COVID-19 in numerous countries, including India, the United States, China, and Malaysia [10-13]. However, few studies have performed an in-depth analysis of the effects of population density, altitude, and environmental factors on the variation in the severity of the COVID-19 pandemic among regions at different altitudes.

Moreover, virus mutation is another important factor in escaping the immune protection derived from a previous infection or vaccination [14-16]. Several studies have shown that people living at high altitudes may be less susceptible to developing severe adverse effects from COVID-19, along with reduced case fatality rates [4,8]. Environmental factors have also been shown to actively influence virus mutation and to play regulatory roles in viral evolution [17-20]. Nevertheless, the underlying physiological mechanism linking virus mutation and altitude that could affect the rate of COVID-19 transmission remains unclear.

Purpose

To fill this research gap, we aimed to explore the potential factors contributing to the outcome of COVID-19 at high altitudes in China in comparison to the lowlands. Toward this end, we first assessed the contributions of altitude and population density on the total number of COVID-19 cases at different altitudes, and further explored the correlation between COVID-19 cases and environmental factors.

In addition, a more detailed correlation analysis among regions at different altitudes was performed at the city level using mixed-effects multiple linear regression models controlling for potential covariates, including meteorological and air quality factors. Furthermore, we studied the genome diversity, mutation frequency, and correlations with environmental factors in high- and low-altitude regions. Overall, we aim to provide a better understanding of the key factors that could influence the cumulative infection and transmission rate of COVID-19 in high-altitude regions of China, which can in turn help to inform establishing improved policies for preventive interventions.

Methods

Study Area

We focused on the high-altitude southwestern regions of China and several low-altitude regions from mainland China. A more detailed description of each province included in the study area along with city-level information is provided in Multimedia Appendix 2.

Collection of Confirmed COVID-19 Cases

Data on COVID-19, including total confirmed cases at the province level from January 23, 2020, to July 7, 2022, were collected from the Dingxiangyuan (DXY-DX Doctor) website [21]; historical cases at the city level over the same study period were collected using the R package "nCovid2019." The population density for each region was calculated by the following equation:

> Population density = population size/area of the land (km^2) **(1)**

The normalized daily number of confirmed COVID-19 cases was calculated using the following equation:

> Normalized COVID-19 cases = total number of confirmed cases/population density **(2)**

To reflect the COVID-19 infection situation in high-altitude regions of China during the study period, descriptive statistics were compiled for the daily average meteorological and air quality parameters, as shown in Multimedia Appendix 3.

XSL•FO

RenderX

Collection of Population, Meteorological, and Air Quality Factors

To analyze the correlation between altitude and COVID-19 cases in China, altitude information of highland regions (>1500 m) and lowland regions (<1500 m) was collected from the topographic map [22]. Meteorological factors were collected from the World Weather Online site [23]. Air quality variables were collected from the Statistical Yearbook for each municipality or province, along with associated data on population and land areas. Multimedia Appendix 4 provides a more detailed description of all these variables.

Collection of SARS-CoV-2 Genome Data

SARS-CoV-2 whole-genome sequencing data were collected from the GISAID (Global Initiative on Sharing All Influenza Data) website [24], including 300 sequences from high-altitude regions and 300 sequences randomly selected over the same time period from low-altitude regions. The accession numbers of the sequences included in this analysis are listed in Multimedia Appendix 5.

Statistical Analysis

The Kolmogorow-Smirnov test was performed for each variable (see Multimedia Appendix 6) with the null hypothesis of a normal distribution; since the *P* value of each variable was less than .05, the null hypothesis was rejected, indicating that the test distribution was not normally distributed. Therefore, we used the nonparametric Spearman correlation coefficient for the correlation analysis of environmental factors and mutation frequency with COVID-19 cases using SPSS software.

After taking into account the correlations for each of the independent variables, a mixed-effects multiple linear regression was used for an adjusted correlation analysis, with the model defined as follows:

$$Y = X\beta + Z\mu + \in \quad (3)$$

where $X\beta$ represents the fixed-effects set in this study, including the covariates meteorological and air quality, and $Z\mu$ represents an N×M design matrix containing each individual group (N) for each covariate (M) of the random effects. Four sets of mixed-effects models were analyzed using R software (version 4.2.1). Separate models were first run for each of the 12 random effects (environmental covariates), followed by two separate models that included all 6 meteorological indicators or air quality indicators as fixed effects simultaneously. The final model included all 12 indicators simultaneously.

Genome Analysis

The nucleotide sequences of the whole genome of SARS-CoV-2 were aligned to the reference sequence Wuhan-1 (NC_045512.2) using minimap2 2.17-r974. All mapped sequences were merged back with all others in a single alignment bam file. Variant calling was performed using bcftools mpileup v1.91. Gene sequences of SARS-CoV-2 were extracted and translated into amino acid sequences, which were aligned to the reference sequence by ClustalW. Variant calling was computed using an in-house–developed R script.

Sequence Diversity Calculation

Sequence diversity was calculated using the Shannon entropy (Sn) index in R software (version 4.2.1), which measures the diversity of nucleotides, amino acids, and their respective variant frequencies. The diversity of each nucleotide position (nucleotide 1 to 29,903) was calculated as the Sn according to the following formula [25]:

$$Sn = i\sum(pilnpi)/lnN \quad (4)$$

where pi represents the relative frequency of nucleotides or deletion at this position and N represents the total number of sequences. All high-altitude samples were compared with the low-altitude samples to identify differential sequence variations at both the nucleotide and amino acid levels.

Ethical Considerations

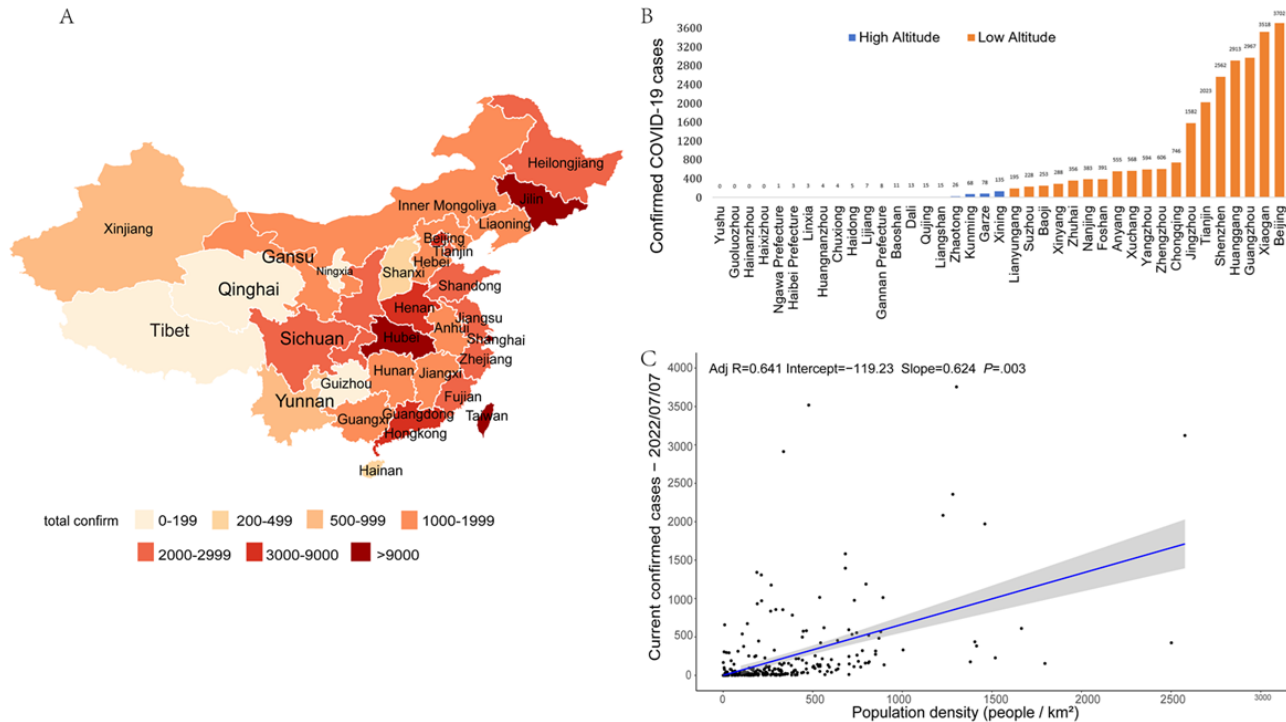
This study is based on an analysis of existing data and therefore received exemption from ethical approval (reference number 041797). Some data sets were slightly modified after the study received exemption from ethical approval; however, the updated data were collected from the same publicly available database. According to the University Research Ethics Policy, "the project does not involve human participants which will only use publicly available anonymized data; a project which will only use existing clinical or research data that has been robustly anonymized such that it no longer constitutes personal data" [26] (pp. 3.1.10, p. 20-21); therefore, ethical approval was not required for the above circumstance. In addition, Article 32 of the Ethical Review Measures for Human Life Science and Medical Research of the People's Republic of China declares that "research involving human life science and medicine under the circumstances of using anonymized information data, legally obtained publicly available data, or data generated through observation without interference with public behavior, which do not cause harm to the human body and do not involve sensitive personal information or commercial interests, can be exempt from ethical review to reduce unnecessary burdens on researchers and promote the development of human life science and medical research" [27] (chapter 3). Therefore, this study falls within the exempt category from the institutional review board. Further ethical approval by a review committee was not required since the data utilized in this study have been sourced from a publicly accessible database, ensuring full anonymization, and the research process involved no direct interaction with human subjects, solely relying on the analysis of pre-existing and publicly available data, as mentioned in the above legislation.

Results

Correlation Between Altitude and COVID-19 Cases

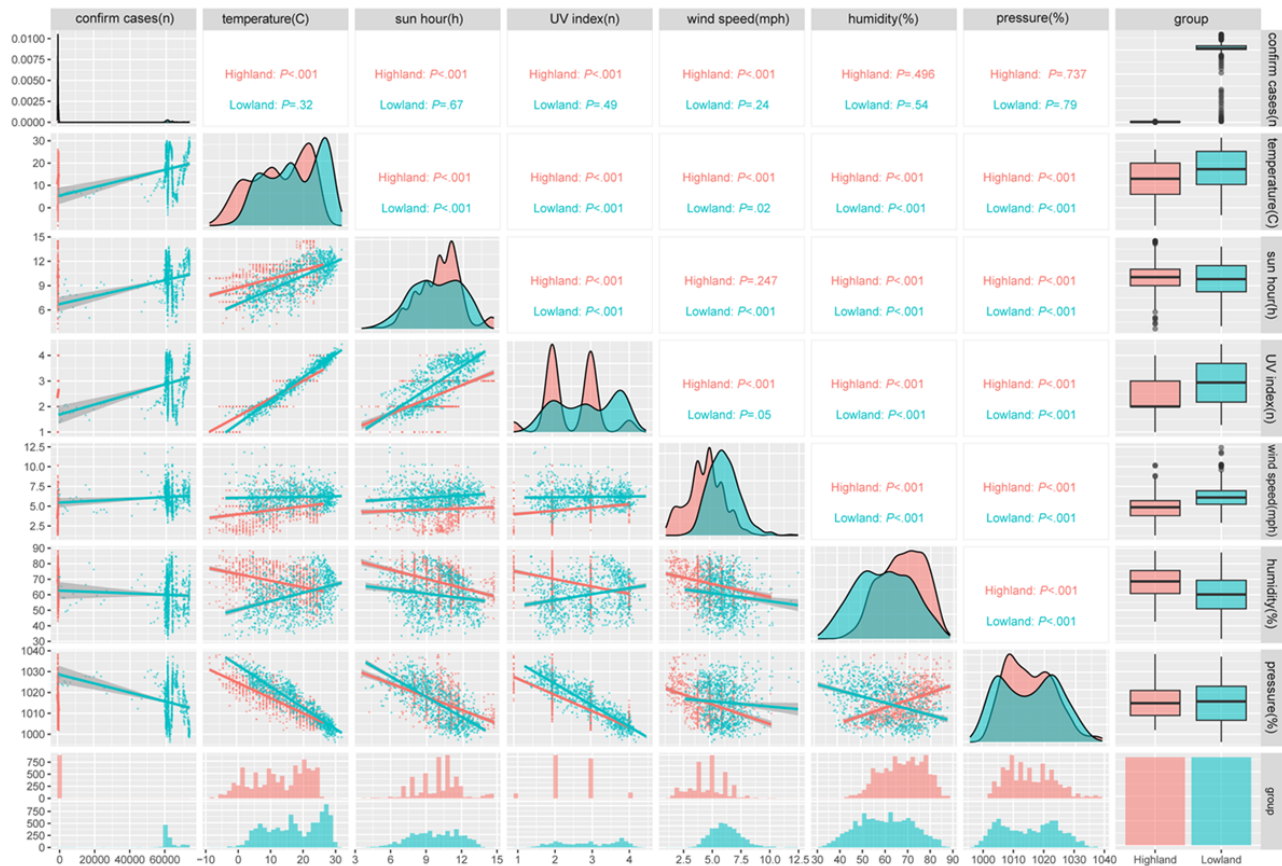
During the study period from January 23, 2020, to June 7, 2022, a total of 732 COVID-19 cases were officially reported in the high-altitude region of China, which excluded one imported case in Tibet. The total numbers of confirmed COVID-19 cases were lower in the high-altitude regions, including Tibet, Qinghai, and Gansu, than in the low-altitude regions (Figure 1A); despite variation among regions, 98.4% (24,430/24,826) of the total COVID-19 cases were found in the lowland regions (Figure

1B). Taking into account the hidden factors of the dimension of population size (Multimedia Appendix 2) in different areas, a significant positive correlation between confirmed COVID-19 cases and population density (Figure 1C) was found during the study period.

Figure 1. Pattern of confirmed COVID-19 cases at high altitudes within the study period. (A) Geographic patterns of confirmed COVID-19 cases in China as of July 7, 2022. (B) Comparison of confirmed COVID-19 cases reported in different cities at different altitudes. (C) Linear regression analysis between population density and confirmed COVID-19 cases in China.


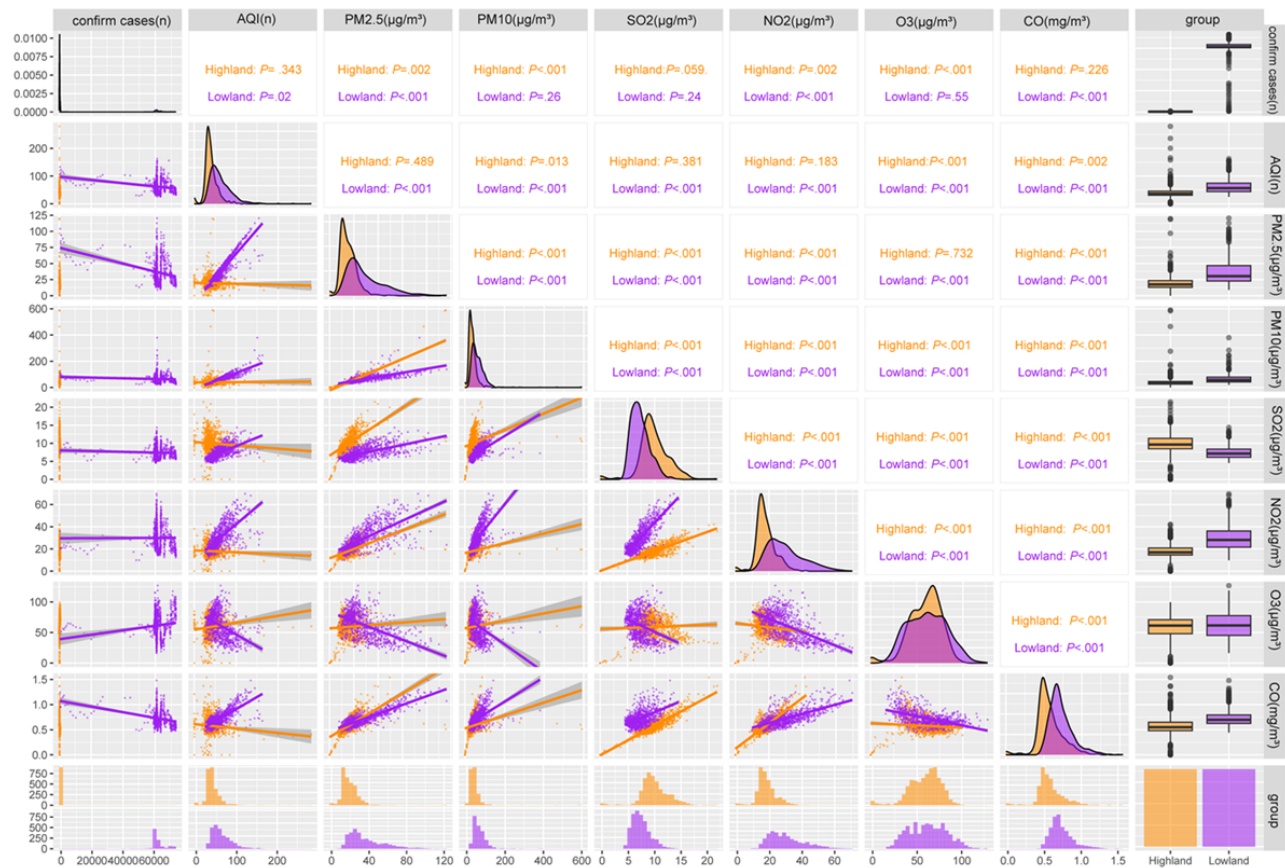
Correlation Between Meteorological Factors and Confirmed COVID-19 Cases in High- and Low-Altitude Regions

To gain a better understanding of the correlation of meteorological factors with the spread of COVID-19 in high-altitude regions when compared with that in the lowlands, we performed a comparative correlation analysis of each variable (Figure 2); the detailed numeric results are provided in Multimedia Appendix 7. In the highlands of China, average temperature (P=.003), sunlight hours (P<.001), and UV index (P=.009) were negatively correlated with the number of confirmed COVID-19 cases, whereas the wind speed (ρ=0.388, P<.001) was positively correlated with confirmed cases.

Figure 2. Spearman correlation analysis of confirmed COVID-19 cases and meteorological factors in high-altitude and low-altitude regions in China. The color represents each region group. Area charts represent frequencies and the scatterplots with lines represent the correlation. *P* values are based on 2-tailed tests; also see Multimedia Appendix 7.


Correlation Between Air Quality Factors and Confirmed COVID-19 Cases in High- and Low-Altitude Regions

As shown in Figure 3, we found significant correlations between air quality factors and COVID-19 cases at high and low altitudes. In the highlands, COVID-19 cases were positively correlated with fine particulate matter (PM2.5; *P*=.002), coarse particulate matter (PM10; *P*<.001), nitrogen dioxide (NO2; *P*=.02), and ozone (O3; *P*<.001). In the lowlands, a negative correlation was found between confirmed COVID-19 cases and air quality index (AQI; *P*=.01), whereas positive correlations were found for PM2.5 (*P*<.001), NO2 (*P*<.001), and carbon monoxide (CO; *P*<.001); in contrast to the pattern in the highlands, the average daily concentrations of PM10 and O3 were not significantly correlated with COVID-19 cases in lowland regions of China. The detailed results are shown in Multimedia Appendix 7.

Figure 3. Spearman correlation analysis of confirmed COVID-19 cases and air quality factors in high- and low-altitude regions in China. The color represents each region group. Area charts represent frequencies and the scatterplot with lines represent correlations. AQI: air quality index; CO: carbon monoxide; NO2: nitrogen dioxide; O3: ozone; PM2.5: fine particulate matter; PM10: coarse particulate matter; SO2: sulfur dioxide. *P* values are based on 2-tailed tests; also see Multimedia Appendix 7.


Correlations of Meteorological and Air Quality Factors With Normalized Confirmed COVID-19 Cases After Covariate Adjustment

The results of the mixed-effects multiple linear regression among the 12 provinces (Multimedia Appendix 2) at different altitudes are summarized in Table 1. In model 1, including each of the fixed-effect indicators in 12 separate models, a lower number of confirmed COVID-19 cases was significantly associated with average temperature, sunlight hours, UV index, air pressure, and air quality factors, including PM2.5, O3, and CO. However, in model 2, including all of the meteorological covariates considered simultaneously, only average temperature, UV index, and air pressure were significantly associated with the normalized confirmed COVID-19 cases. In model 3, including all of the air quality covariates considered simultaneously, only the average concentrations of O3 and CO were significantly correlated with confirmed COVID-19 cases. Finally, in model 4, including all 12 environmental indicators considered simultaneously, only average temperature, wind speed, and CO were significantly associated with confirmed COVID-19 cases.

Table 1. Mixed-effects multiple linear regression of the associations of normalized COVID-19 cases with meteorological and air quality factors including adjustment for covariates.

Diversity of SARS-CoV-2 Sequences in High- and Low-Altitude Groups

Comparable sequence diversity was found among the full-length SARS-CoV-2 genomes and 12 genes of SARS-CoV-2 in the high- and low-altitude groups (Figure 4). In the high-altitude group, the Sn values of nucleotides for each site were significantly lower than those in the low-altitude group (Figure 4A; *P*<.001). Likewise, the Sn values of amino acids for three open reading frames (ORFs; ORF1b, ORF7a, and ORF7b) in the high-altitude group were lower than those in the low-altitude group (Figure 4B; *P*<.001). Compared to those of the low-altitude group, the Sn values of the S and N genes were higher in the high-altitude group.

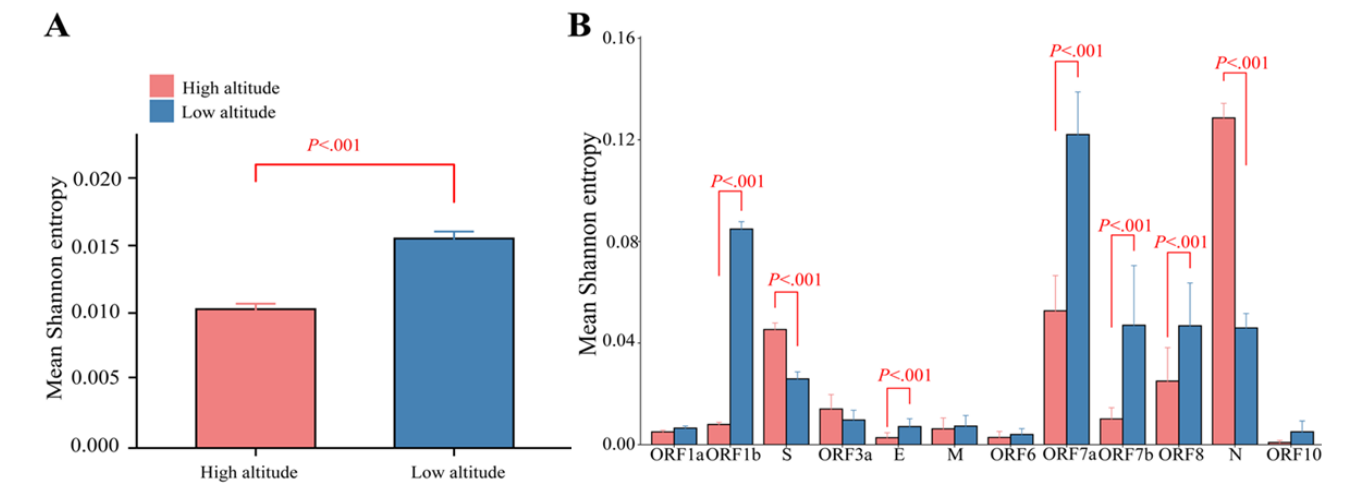
(A) Mean sequence diversity identified by Shannon entropy in nucleotides of the whole SARS-CoV-2 genome. (B) Mean sequence diversity identified by Shannon entropy in different amino acids. Error bars indicate SEM. *P* values are based on the Wilcoxon signed rank test.


Comparison of SARS-CoV-2 Gene Variant Frequencies in the High- and Low-Altitude Groups

To determine the gene variant frequency difference between the high- and low-altitude groups, the Wilcoxon signed rank test was used to evaluate the significance of variant frequency in each of the ORFs (Figure 5A). The amino acid mutation frequencies for the three ORFs (ORF1b, ORF7a, and ORF7b) were significantly lower in the high-altitude group than in the low-altitude group (*P*<.001) but were higher for the S and N genes (*P*<.001). Among these, 44 nonsynonymous mutations

and 32 synonymous mutations were found between the high- and low-altitude groups (Figure 5B; *P*<.001; mutation frequency>0.1). There was a greater proportion of nonsynonymous mutations in the low-altitude group than in the high-altitude group, whereas the opposite pattern was found for synonymous mutations. The –log10 *P* values for the differences in nonsynonymous and synonymous mutations for each ORF between the high- and low-altitude groups are shown in Figure 5C. Compared to the result in Figure 5A, the synonymous mutations of the S genes and N genes had relatively higher significance scores in the high-altitude group.

Figure 5. Distribution of mutations of SARS-CoV-2 in the high- and low-altitude groups. (A) Mean mutation frequency of open reading frames (ORFs) in the high- and low-altitude groups. (B) Comparison of frequencies of nonsynonymous and synonymous mutations between the high- and low-altitude groups. (C) Significance scores of nonsynonymous and synonymous mutations in each ORF. ***P*<.001.

Correlation Analysis Between Mutation Frequency and Environmental Factors

The impact of 7 environmental factors on the nonsynonymous mutation frequency was analyzed for all sequences (Figure 6 and Multimedia Appendix 8). Most of the nonsynonymous mutations had a positive correlation with altitude, wind speed, and atmospheric pressure, but had negative correlations with UV index, relative humidity, and sunlight hours. The highest correlation between mutation frequency and environmental factors was found for altitude with N_G29427A, ORF1b_C20320T, and ORF1a_C1191T (ρ=0.53, P<.001); followed by UV index with ORF8_C28093T and S_A23063T (ρ=–0.42, P<.001); and temperature with ORF8_C28093T, S_C23604A, S_A23063T, and ORF1a_G6671A. Some

significant nonsynonymous mutational events were also discovered in this study, including C22323T in the receptor-binding domain (RBD) of the S gene, which had a positive correlation with altitude (ρ=0.32, P<.001), indicating higher frequencies at high altitude. S gene mutations A23063T in the RBD region and C23604A in the fusion peptide (FP) region had higher frequencies at low altitude, and demonstrated a significant positive correlation with atmospheric pressure (ρ=0.34 and ρ=0.31, respectively; both P<.001) and a significant negative correlation with temperature and UV index (ρ=–0.42 and ρ=–0.41, respectively; both P<.001). Furthermore, co-occurring point mutations in the N gene, specifically G28881A, G28882A, and G28883C (R203K and G204R), had a higher mutation frequency at low altitude and were positively related to altitude (ρ=0.43, P<.001).

Discussion

Principal Findings

This study found that the lower number of confirmed COVID-19 cases in high-altitude regions of China may be related to population density and environmental factors. By further exploring SARS-CoV-2 sequences, we found different mutation frequencies in the high- and low-altitude regions, which were also correlated with environmental factors.

Population density is one of the most effective predictors related to the regional pandemic; a larger population greatly increases the infection and transmission rates of COVID-19 [28]. Therefore, our results suggest that when analyzing the correlation between COVID-19 cases in regions with different population dimensions and other possible factors, it is important to take into account the *normalized* number of COVID-19 cases to study the pandemic trend.

Meteorological factors may also influence COVID-19 transmission and cumulative infection in high-altitude regions. Previous studies indicated that higher temperature and UV radiation could contribute to a decrease in new cases of COVID-19 infection at high altitude [29-31]. This is supported

by our Spearman correlation analysis showing that the average daily temperature, sunlight hours, and UV index were negatively related to the normalized COVID-19 cases in high-altitude regions. A high-altitude environment is distinguished by lower temperatures compared with those of low-altitude regions, along with significant differences between daylight hours, air dryness, and levels of UV light radiation [32-34]. Importantly, our study further found that the wind speed in the high-altitude region of China was significantly associated with the reducing trend of COVID-19 cases, which is consistent with earlier studies conducted in Italy, New York, and Singapore [2,35]. Analyzing the correlation between covariates in regions at different altitudes with different population dimensions showed positive correlations of average temperature and wind speed with normalized confirmed COVID-19 cases, in line with previous research.

Air pollution is widely recognized as a major risk factor for respiratory infection in humans, which has also played a significant role in the spread of COVID-19. Previous research suggested that the concentrations of NO2, PM2.5, PM10, and O3 are positively correlated with the number of confirmed COVID-19 cases [33,34,36-38]. Our Spearman correlation results align with these previous findings. NO2 is often linked

with vehicle emissions and energy production [39], which is also an irritant of human respiratory diseases. Early research findings [40] support the results of this study, suggesting that travel restrictions should be among the specific actions implemented to reduce the spread of COVID-19. Previous studies indicated that PM2.5 and PM10 levels were positively correlated to the number of new daily confirmed COVID-19 cases in mainland China [41-43]. Consistently, our findings showed that lower average concentrations of PM2.5 and PM10 were related to a lower number of confirmed COVID-19 cases in the highlands.

It is clear that all of the above correlated factors may have influenced the cumulative infection trends of the pandemic in the highlands of China. The main sources of CO are motor vehicles and industrial source emissions; consequently, CO is closely related to population density and human activity. Therefore, taking into account the mixed correlations between all the covariates of focus in this study by including the related factors into a single mixed-effects model, among the air quality factors, only the average concentration of CO was positively associated with the normalized number of confirmed COVID-19 cases during the study period. This result also aligns with previous research conducted in China [43,44].

In terms of variations in the SARS-CoV-2 genome at high and low altitudes, the whole-genome sequences at high altitude showed lower diversity based on the mean Sn values of nucleotides and different amino acids compared to those in the low-altitude sites. Previous studies have suggested an impact of high altitude on the pathophysiology of COVID-19 [44,45], implying improved tolerance to SARS-CoV-2 infection for residents of high-altitude regions. Our study identified differences in the frequencies of SARS-CoV-2 sequence variants in various ORFs between high- and low-altitude regions, along with correlations between mutation frequency and environmental factors. Most of the nonsynonymous mutations identified have been reported previously and have important biological implications. We found that only the C22323T variant of the S gene had a positive correlation with altitude, with a greater frequency in the high-altitude group. Sivasubramanian et al [46] found that the S255F (C22323T) variant could reduce the affinity between the S protein and antibodies. We also identified the variant A23063T in the RBD region and the variant C23604A in the FP region of the S gene, with higher mutation frequencies detected at low altitude, showing a significantly positive correlation with atmospheric pressure and a strongly negative correlation with temperature and UV index. Previous studies found that the N501Y (A23063T) and Q493H variants enhanced the binding affinity to the human angiotensin converting-enzyme 2 receptor, thereby increasing infectivity [47], and that the Omicron peptide with variants N679K and P681H (C23604A) might increase viral infectivity and transmissibility [48]. These results suggest that atmospheric pressure, UV index, and temperature may affect the infectivity of COVID-19 driven by specific mutations of the S gene in low-altitude regions. In addition, three co-occurring variants (G28881A, G28882A, G28883C) in the N gene had higher mutation frequencies in the low-altitude group and were positively related to altitude; these mutations were previously reported to destabilize and decrease the overall structural flexibility of the SARS-CoV-2 genome [48].

Notably, the potential impact of the strategy implemented by the government in response to the pandemic in high-altitude regions on the observed differences should not be ignored. This study only included data collected from January 22, 2020, to March 19, 2021, during which time there was only one imported COVID-19 case in Tibet that was excluded from the analysis. However, after several consecutive months of no new cases, a newly confirmed case was reported in Tibet on August 7, 2022. Since then, eight new cases have been added with a total of 1437 confirmed cases reported to date [21]. Several reasons for this new outbreak are worth discussing. First, the virus underlying the epidemic in Tibet is Omicron BA.2.76, which has characteristics of strong, fast transmission ability and the potential to more readily escape from immune protection. Second, the first discovered infection on August 7 was a close contact of a family, with suspected transmission occurring at a family gathering, and August is the peak tourist season in Tibet. Thus, under the conditions of relatively relaxed travel restrictions, the close contact and population flow greatly increased the spread of the virus. Third, the lack of epidemic prevention and medical appliances in high-altitude regions limited access to health care systems, and the limited capacity for viral testing and contact tracing worsened the situation of the pandemic in Tibet. Therefore, effective and accurate government policies have played an important role in preventing Tibet from being affected by the epidemic, and the government policy in response to the pandemic must be considered; indeed, the response needs to be strengthened, although China indicated that they had ceased counting COVID-19 cases on December 23, 2022, and stated that the COVID-19 pandemic is effectively now over [49].

Limitations

Our study has some limitations. First, among the data available for confirmed COVID-19 cases, we only excluded the one known imported case in Tibet during the study period as of March 19, 2021, whereas the collected COVID-19 data from the other four areas may include both local and imported cases. This is mainly due to a lack of accurate publicly available COVID-19 data at the city level. Similarly, the incompleteness of some city-level information of genome sequences also led to difficulties in studying the differences in genetic variants among cities in the same province. Second, we aimed to evaluate whether virus mutations are associated with particular viral lineages. The sequences of SARS-CoV-2 in the high- and low-altitude groups represented 33 different virus lineages (Multimedia Appendix 9); B.1.617.2, AY.122, and B.1.36.16 were the major lineages, and the mutations of each lineage in which the mutation frequency was greater than 0.5 are listed in Multimedia Appendix 10. The number of different lineages between high- and low-altitude groups is also unbalanced. Third, we lacked the clinical information to study the potential relationships between mutations and clinical outcomes of infection at high and low altitudes. Therefore, future studies should focus on exploring the underlying mechanisms contributing to the links between patterns of SARS-CoV-2 mutation and case numbers at different altitudes.

Conclusions

Compared to that in the lowland area of China, the total number of confirmed COVID-19 cases in the highland was substantially lower. Population density and environmental factors, including average temperature, sunlight hours, UV index, wind speed, NO2, O3, PM2.5, and CO, were identified as indicators with a significant influence on the cumulative pandemic trend in the highlands. Among these factors, average temperature and CO were identified as the major meteorological and air quality factors associated with the spread of COVID-19 infection in China. Furthermore, we identified different mutations from SARS-CoV-2 isolates between high- and low-altitude regions, and there was a significant impact of environmental factors on virus mutation. Overall, this study adds important knowledge of the impact of altitude and related environmental factors on the cumulative infection rate of COVID-19, providing novel suggestions for preventive interventions.

Data Availability

The data sets generated and analyzed during the study are provided in the Multimedia Appendix files.

Authors' Contributions

YW and XZ supervised the study and reviewed the draft of the paper. ZD and YT performed the data collection, main statistical analysis, and manuscript writing. HH, MF, and MJCC participated in manuscript verification, revisions, and editing. All authors had full access to all the data in the study and accept the responsibility to submit it for publication.

Abstract

Background: Prior literature suggests a dose-response relationship between physical activity (PA) and depressive symptoms. The intensity and domain of PA are suggested to be critical to its protective effect against depression; however, existing literature has shown mixed results.

Objective: The purpose of this population-based study is to examine the associations between depressive symptoms and weekly duration of (1) total PA and (2) PA subset by intensity, domain, or both.

Methods: A cross-sectional analysis of National Health and Nutrition Examination Survey data from 2007 to 2018 was conducted using multivariable logistic and linear regression models and survey weights. Participants (N=29,730) were 20 years and older and completed the Physical Activity Questionnaire and Depression Screener. The primary outcome was the presence of depressive symptoms, and the secondary outcomes were cognitive-affective and somatic symptoms of depression.

Results: Participants (N=29,730) had a weighted mean age of 47.62 (SD 16.99) years, and 15,133 (51.34%) were female. On average, participants without depressive symptoms engaged in 10.87 hours of total PA per week, whereas participants with depressive symptoms engaged in 8.82 hours ($P<.001$). No significant associations were seen between the weekly duration of total PA and depressive symptom odds, somatic, or cognitive-affective symptoms (all $P>.05$). Participants with an increased weekly duration of recreational PA had decreases in depressive symptom odds (adjusted odds ratio [aOR] 0.965, 95% CI 0.944-0.986) and in somatic (adjusted coefficient [aβ]=–0.016, 95% CI –0.022 to –0.009) and cognitive-affective (aβ=–0.015, 95% CI –0.023 to –0.007) symptoms. When recreational PA was subset by intensity, participants with an increased weekly duration of vigorous-intensity recreational PA had decreases in depressive symptom odds (aOR 0.926, 95% CI 0.883-0.972) and in somatic (aβ=–0.021, 95% CI –0.032 to –0.010) and cognitive-affective (aβ=–0.022, 95% CI –0.035 to –0.009) symptoms. However, significant associations were not seen for the weekly duration of work-related, moderate- or vigorous-intensity PAs (all $P>.05$).

Conclusions: Findings suggest that recreational, not work-related PA is associated with reduced symptoms of depression. Future studies should explore the impact of the different types and contexts of PA on depressive symptomatology.

Introduction

Depression is the leading cause of disability, affecting 280 million individuals globally, with limited treatment accessibility due to stigmatization and financial barriers [1]. Physical activity (PA) can have a positive impact on mood and mental health [2] among individuals with a clinical diagnosis of depression, as well as nonclinical community subsamples [3], providing the potential for more accessible and cost-effective therapeutic modalities that improve well-being [4,5]. Further, PA can be protective against depression. A study on a community sample from Alameda County in the United States showed that individuals with low baseline levels of PA had a significantly higher risk of depression at follow-up compared to those with high baseline levels of PA [6].

PA intensity is determined by energy expenditure, which is expressed as multiples of the metabolic equivalent of task, and can be subdivided into 3 categories: light, moderate, or vigorous [7]. There is substantial variability in the literature regarding the optimal intensity for reducing depressive symptoms. Light-intensity PA has been reported to reduce depression as effectively as moderate-intensity PA among older adults [8]. Another study conducted with college students aged 15-24 years found an association between light-intensity PA and reduced depressive symptoms but not moderate- or vigorous-intensity PA [9]. A recent review suggested that moderate-intensity PA has a greater protective effect on depression than higher-intensity PA [10]. Despite these inconsistencies, the Centers for Disease Control and Prevention (CDC) recommends 150 minutes of moderate-intensity or 75 minutes of vigorous-intensity exercise per week or a combination of the 2 intensities to gain health benefits, including a reduced depression risk [7]. In line with these recommendations, a recent systematic review and meta-analysis found an inverse curvilinear association between PA and incident depression, wherein individuals with an activity volume of 150 or 75 minutes per week of moderate-intensity exercise reported a 25% and 18% lower risk of depression, respectively [11]. Similarly, one study using survey data of respondents to the Scottish Health Survey reported that 20 minutes per week of any type of PA (eg, low-intensity walking) is associated with a lower risk of psychological distress [12], while another study using data from the Swedish National March Cohort found that replacing 30 minutes of sedentary behavior per day with 30 minutes of light-intensity or moderate- to vigorous-intensity PA reduced the odds of depression by 13% and 19%, respectively [13]. This suggests that the benefits of PA may be noticeable well below the CDC's recommended levels.

PA can also be classified by domain, wherein it can be recreational (leisure) or work-related (nonleisure). PA domain has a significant impact on a person's psychosocial experience [14,15]. Recreational PA is considered more enjoyable, variable, and autonomous than work-related PA, which is often "obligatory, repetitive, or routine" [14]. Recreational PA also impacts one's perceived level of control and can act as a distraction from negative preoccupations [16]. As a result, studies have found leisure-time PA to be associated with a lower prevalence of depressive symptoms compared to nonleisure PA [14,17], suggesting that work-related PA may act as a source of stress [18]. Additionally, reducing sedentary work while controlling for leisure-time PA [19] and engaging in a greater frequency of domestic activities (eg, housework and gardening) have both been associated with lower odds of psychological distress [12]. There are also studies that have found no association between work-related PA and depression [15,20]. Given these conflicting results, it is essential to further explore the association between PA domain and depressive symptomatology.

Depression is a heterogeneous disorder characterized by several phenotypic manifestations. One modality of subtyping is based on cognitive-affective (eg, negative mood) and somatic symptom (eg, fatigue) domains [21,22]. By subdividing depression into the 2 symptom domains, we can better understand the mechanisms by which PA is associated with depression and can ultimately inform public health guidelines.

This study explored the relationship between PA intensity and domain and depressive symptoms using the National Health and Nutrition Examination Survey (NHANES). We investigated three primary aims: how are depressive symptoms related to the weekly duration of (1) total PA; (2) PA, subset by intensity; and (3) PA, subset by domain? We hypothesized that participants with a higher weekly duration of total PA, moderate- and vigorous-intensity PA, or recreational PA will experience a decrease in depressive symptom odds. Our secondary aim was to investigate the association between depressive symptoms and PA, subset by intensity and domain. We hypothesized that participants with a higher weekly duration of moderate- and vigorous-intensity recreational PA, but not moderate- and vigorous-intensity work-related PA, will experience lower depressive symptom odds. In an exploratory aim, we investigated the relationship between depressive symptom subgroups and the weekly duration of total PA and PA subset by intensity, domain, or both.

Methods

Study Population

The study data were obtained from the 2007-2018 NHANES, a cross-sectional survey administered by the National Center for Health Statistics (NCHS) and the CDC [23]. NHANES assesses the health and nutritional status of US civilians (excluding institutionalized individuals) via a home interview and a health examination. Sample selection included counties or groups of neighboring counties as primary sampling units, followed by selection of segments within primary sampling units, selection of households within segments, and finally selection of individuals within households [23]. This study population consisted of respondents 20 years and older who completed the Physical Activity Questionnaire (PAQ) and the Mental Health—Depression Screener, which uses a standardized depression scale (ie, the Patient Health Questionnaire-9 [PHQ-9]).

Ethical Considerations

The NHANES protocol was reviewed by the NCHS Research Ethics Review Board (protocols 2005-06, 2011-17, and 2018-01) with all participants providing informed consent prior to the interview and examination. The original consent provided by NHANES participants includes the use of their data for secondary analyses. As such, the secondary use of these data does not require additional consent from participants. The NHANES data are deidentified with the omission of all direct identifiers and characteristics that might lead to identification. This analysis did not receive approval from an institutional review board since the Data User Agreement provided by the NCHS specifies that the data in the data set can be used for statistical reporting and analysis [24].

Exposure

Exposure variables in this study included the weekly duration of total PA and weekly duration of PA subset by intensity (moderate and vigorous), domain (recreational and work-related), or both. Each PA variable was analyzed on a continuous scale of total hours per week. For details on the questionnaire items used for the exposure variables, see Table S1 in Multimedia Appendix 1.

Primary Outcome Measure

The primary outcome measure for this study was the sum of items 1 to 9 of the PHQ-9 from the Mental Health—Depression Screener. The PHQ-9 assessed the frequency of depressive symptoms over the past 2 weeks based on the *Diagnostic and Statistical Manual of Mental Disorders—Fourth Edition* major depressive disorder diagnostic criteria [25]. Responses were given on a 4-point Likert scale ranging from 0=not at all to 3=nearly every day. Participants were categorized as having depressive symptoms (score≥10) or not (score<10) [25]. This cutoff provides reliable sensitivity and specificity for the detection of major depressive disorder [25]. The PHQ-9 has also been shown to be a reliable measure of depression severity and has been validated [25]. As a sensitivity analysis, statistical analyses were conducted using continuous depressive symptom scores.

Secondary Outcomes

Secondary outcomes were cognitive-affective (sum of responses to PHQ-9 items 1, 2, 6, 7, 8, and 9) and somatic (sum of responses to PHQ-9 items 3, 4, and 5) symptoms of depression [21,26]. These symptom subgroups were analyzed on a continuous scale.

Covariates

To account for potential confounding bias in the relationship between PA and depressive symptoms, we adjusted for age [27], sex [28], race [29], education [30], marital status, socioeconomic status (ratio of family income-to-poverty threshold) [31], BMI [32], sleep time on weekdays or workdays [33], hours of sedentary activity [33], cigarette use [34], and general self-reported health condition. Age was continuous by 1-year increases. Sex was dichotomized. Race was categorized as Mexican American, non-Hispanic White, non-Hispanic Black, other Hispanic, and other race or multiracial. Education level was categorized as less than high school, high school or equivalent, some college or Associate of Arts degree, and college graduate or above. Marital status was categorized as married or living with partner, divorced or separated or widowed, and never married. The ratio of family income-to-poverty threshold was dichotomized: ≤1.3=low income and >1.3=mid-to-high income [35]. BMI was categorized as <18, 18 to <25, 25 to <30, and ≥30 kg/m^2 [36]. Sleep time and sedentary activity were continuous by hourly increases. General self-reported health condition was categorized as poor, fair, and good or above. Cigarette use was dichotomized; individuals who answered "Yes" to "Smoked at least 100 cigarettes in life" and answered "Every day" or "Some days" to "Do you now smoke cigarettes?" on the Smoking-Cigarette Use Questionnaire were considered cigarette users, and those who answered "No" or "Not at all" to the respective questions were considered nonusers.

Statistical Analysis

Statistical analyses were performed using R (version 4.2.1, R Foundation for Statistical Computing) and the package *survey* to account for the NHANES survey design. Mobile Examination Centre survey weights were used and divided by 6 to account for merging 6 survey cycles. Weighted means and SDs were estimated for continuous variables, and weighted proportions with unweighted frequencies were calculated for categorical variables. Continuous variables were compared using 2-tailed *t* tests, while categorical variables were compared using chi-square tests. The primary and secondary analyses for the outcome of depressive symptoms were performed using multivariable logistic regression models while adjusting for covariates. The exploratory analysis for the secondary outcomes, namely cognitive-affective and somatic symptoms scores, used multivariable linear regression models, also adjusting for covariates. The backward stepwise selection was used to develop the final multivariable models with null models including age, sex, race, and socioeconomic status. Statistical significance was established as *P*<.05, and *P* values were adjusted using the Holm method to account for multiple comparisons. Missing data were accounted for using an available case analysis. The sample size

depended on data availability and as such, no a priori power calculations were performed.

Results

Descriptive Statistics

The final study sample consisted of 29,730 participants (51.34%, n=15,133, were female) aged 20-80 (mean 47.62, SD 16.99)

years (refer to Figure 1 for a detailed breakdown of participant inclusion). Depressive symptom prevalence was 2739 (8.07%) participants. The descriptive statistics for each measure can be found in Table 1.

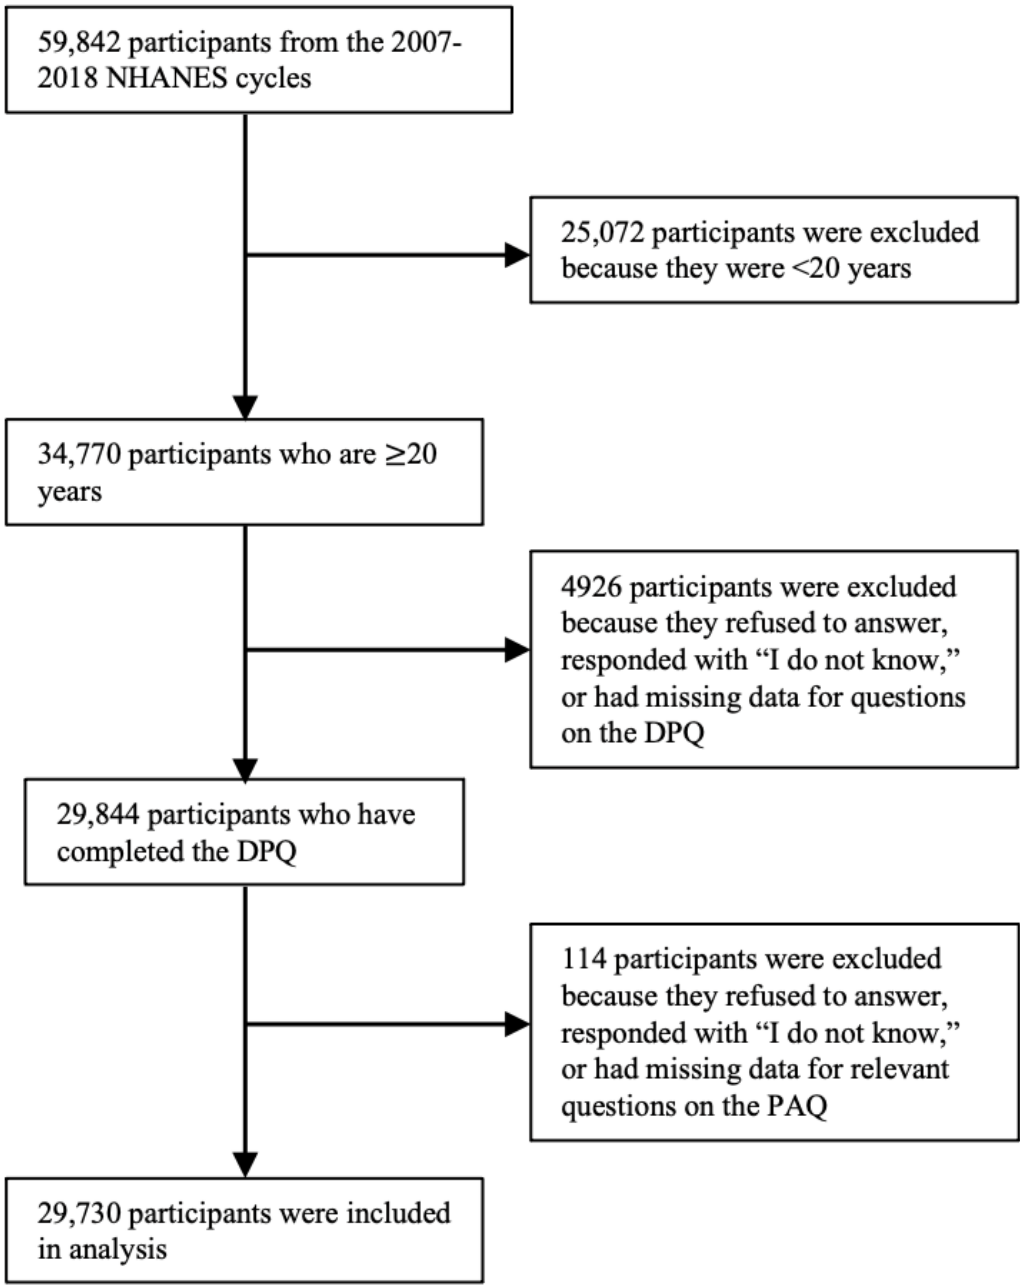
Figure 1. Flowchart of inclusion in the cross-sectional analyses; participants from a nationally representative sample of the United States obtained through the NHANES, 2007-2018. DPQ: Mental Health—Depression Screener; NHANES: National Health and Nutrition Examination Survey; PAQ: Physical Activity Questionnaire.


Table 1. Characteristics of included participants in the cross-sectional analyses from a nationally representative sample of the United States obtained through the National Health and Nutrition Examination Survey, 2007-2018[a].

Characteristics	No depressive symptoms (<10; n=26,991)	Depressive symptoms (≥10; n=2739)	*P* value

Weekly Duration of Total PA and Depressive Symptoms

After controlling for all covariates, for every 1-hour increase in the weekly duration of total PA, there was a nonsignificant decrease in the odds of depressive symptoms (Table 2) and a decrease in the somatic and cognitive-affective scores of depression (Table 3). The association with weekly duration of total PA remained nonsignificant in the sensitivity analysis (Table S2 in Multimedia Appendix 1).

Table 2. Weighted ORs[a] and aORs[b] for associations between PA[c] and depressive symptoms for the cross-sectional analyses of participants from a nationally representative sample of the United States obtained through the National Health and Nutrition Examination Survey, 2007-2018[d].

PA	Depressive symptoms (PHQ-9[e]≥10)

[a]PA: physical activity.

[b]$P \le .05$ indicates statistical significance, and *P* values are adjusted using the Holm method. Adjusted models adjusted for the following covariates: age, sex, race, education, marital status, socioeconomic status (ratio of family income-to-poverty threshold), BMI, sleep time on weekdays or workdays, hours of sedentary activity, cigarette use, and general self-reported health condition.

[c]aβ: adjusted coefficient.

Weekly Duration of PA, Subset by Intensity, and Depressive Symptoms

After adjusting for all covariates, for every 1-hour increase in the weekly duration of moderate- and vigorous-intensity PA, there was no significant association with the odds of depressive symptoms (all *P*>.05; Table 2) and the somatic and cognitive-affective scores of depression (all *P*>.05; Table 3). The association with weekly duration of moderate- and vigorous-intensity PA remained nonsignificant in the sensitivity analysis with the outcome of depressive symptoms (all *P*>.05; Table S2 in Multimedia Appendix 1).

Weekly Duration of PA, Subset by Domain, and Depressive Symptoms

After controlling for the covariates, for every 1-hour increase in the weekly duration of recreational PA, there was a significant decrease in the odds of depressive symptoms (aOR 0.965, 95% CI 0.944-0.986; *P*=.007; Table 2) and the somatic and cognitive-affective scores of depression (aOR –0.015, 95% CI –0.023 to –0.007; *P*=.003; Table 3). The association with the weekly duration of recreational PA remained statistically significant in the sensitivity analysis (*P*<.001; Table S2 in Multimedia Appendix 1).

Covariate-adjusted models showed that there was a nonsignificant relationship between increased weekly duration of work-related PA and decreased odds of depressive symptoms (*P*=.54; Table 2). Furthermore, for every 1-hour increase in the weekly duration of work-related PA, there was no significant association with cognitive-affective and somatic scores of depression (*P*=.36; Table 3). The association with weekly duration of work-related PA remained nonsignificant in the sensitivity analysis (*P*>.99; Table S2 in Multimedia Appendix 1).

Weekly Duration of PA, Subset by Domain and Intensity, and Depressive Symptoms

A 1-hour increase in the weekly duration of vigorous-intensity recreational PA (aOR 0.926, 95% CI 0.883-0.972; *P*=.009) was significantly associated with 7.4% lower odds of having depressive symptoms, but there was no significant association between depressive symptom odds and the weekly duration of moderate-intensity recreational PA (aOR 0.975, 95% CI 0.949-1.001; *P*=.19; Table 4). The association with the weekly duration of vigorous-intensity recreational PA (*P*=.001) and moderate-intensity recreational PA (*P*=.007) was statistically significant in the sensitivity analysis with the outcome of depressive symptoms (Table S3 in Multimedia Appendix 1). For every 1-hour increase in the weekly duration of vigorous-intensity recreational PA, the somatic (adjusted coefficient [aβ]=–0.021, 95% CI –0.032 to –0.010; *P*=.001) and cognitive-affective (aβ=–0.022, 95% CI –0.035 to –0.009; *P*=.005) scores of depression decreased significantly, but moderate-intensity recreational PA was only associated with significant decreases in somatic scores of depression (aβ=–0.016, 95% CI –0.025 to –0.007; *P*=.002). No significant associations were found for the weekly duration of vigorous-intensity work-related PA or moderate-intensity work-related PA and depressive symptoms (all *P*>.05; Table 5). The association with weekly duration of vigorous-intensity work-related PA or moderate-intensity work-related PA remained nonsignificant in the sensitivity analysis (all *P*>.05; Table S3 in Multimedia Appendix 1).

Discussion

Principal Findings

This study investigated the association of the weekly duration of PA (including subsets by intensity, domain, or both) with the overall presence of depressive symptoms and somatic and cognitive-affective depression symptomatology. The results of this study indicate that it is the PA domain, specifically recreational PA, that may be crucial to the relationship between PA and depressive symptoms. Depressive symptom odds decreased significantly with an increase in the weekly duration of recreational PA. When intensity was examined alone, neither vigorous- nor moderate-intensity PA was significantly associated with depressive symptoms. When domain and intensity were considered together, only an increase in vigorous-intensity recreational PA duration was significantly associated with a decrease in the odds of depressive symptoms. Notably, based on the demographic data collected in this study, participants with depressive symptoms were more likely to be female, have a higher BMI, have lower income, and participated in lower weekly durations of PA regardless of being subset by intensity

and domain. This coincides with prior studies that have shown gender [37], BMI [32], income status [38], and PA to be associated with the likelihood of depression. As a result, to address potential confounding bias, we incorporated these variables as covariates when examining the association between the weekly duration of PA and depressive symptoms.

Our findings coincide with results from previous studies that found a significant association between decreased recreational PA and greater depressive symptoms. In addition to the neurobiological changes, such as an increased release of endorphins and neurotransmitters like dopamine and norepinephrine [39-41], the protective effect of recreational PA involves social aspects and enjoyability of recreational activities [14]. Recreational activities can be social or self-focused, both providing time structure [42-44]. Social recreational PA offers an added benefit of pleasurable social interactions with others, which can provide a distraction from negative life events and increase perceptions of social support [43,44]. Alternatively, self-focused recreational PA can be conducted individually or within a group setting and buffers against negative events through personal transformation [43]. Thus, it may be expected that recreational PA has a more comprehensive effect on

XSL•FO

RenderX

depression with reduced cognitive-affective and somatic depressive symptoms. Our results demonstrated that recreational PA has similar associations with both symptom subgroups, suggesting that its impact is not limited to changes in one's psychosocial experience. The influence on somatic symptoms may be due to recreational PA frequently occurring outside, being more enjoyable, and producing euphoric feelings that are captured as somatic [45].

In examining the statistically significant associations between the different aspects of PA and depressive symptoms, it is important to note the statistical issue that the increased power in a large sample study leads to narrower CIs for the effect measures and smaller P values. However, by adjusting the statistical significance using the Holm method, the chances of false positives were minimized. Acknowledging that this can still cause one to claim impractical significance for very small effects, we prioritized clinical significance over statistical significance.

While work-related PA has been associated with higher levels of depression [17], our results did not reach statistical significance. This could be attributed to sample differences, as previous research examined adults aged 50 and older [17], whereas our sample size consisted of participants aged 20-80 years. Since most work-related PAs entail heavy lifting and strenuous overuse of the neck and back without adequate rest and recovery [46], it may act as a burden for all adults, including older adults, and contribute to higher depression levels. As this study included both younger and older individuals aged 20-80 years, the impact of work-related PA on depressive symptoms may be influenced by additional factors such as job satisfaction and job type [47,48]. Additionally, in this study, work-related PA encompassed paid and unpaid work, household chores, and yard work. Given that research has found a greater frequency of domestic activities, such as housework and gardening, to be associated with lower odds of psychological distress [12], our findings should be interpreted with caution, as the 2 types of work cannot be distinguished based on the NHANES questions. Furthermore, it is important to explore an individual's interest and competence in executing workplace PAs. Prior research suggests that within the work domain, PA may be associated with limited personal choice and is typically driven by the demands of work output and the flow of work, which can be strenuous [49]. Another study highlights the significance of occupation type, shedding light on how work-related PA can vary across different job categories [48]. For example, women in trade, labor, or transport-related jobs who engage in work-related walking experienced lower levels of psychological distress, but this association was not present when considering moderate or vigorous PAs [48]. This suggests that the nature of the job and the type of PA involved are linked to mental health outcomes. Further investigation into this will help parse out the mechanism by which work-related PA is associated with depressive symptoms.

Regular PA participation can provide a sense of mastery, improved body image, sense of achievement, and feelings of control that may distract one from negative thoughts [16]. However, this study found no significant association between the weekly duration of total PA and depressive symptom odds,

which challenges previous literature that found a greater frequency of PA has a protective effect on depressive symptoms [50,51]. This contradiction may be attributable to the absence of low-intensity PA duration in the total PA calculations due to its unavailability in the NHANES data. As low-intensity PAs involve reduced energy expenditure than moderate or vigorous-intensity PA [7], they may be easier to engage in more frequently and thus show important associations with depressive symptoms. In fact, previous studies have found that light and moderate intensities of PA were both associated with lower likelihoods of depression [8,52].

Contrary to previous research [53,54], we found that hourly increases in the weekly duration of moderate- and vigorous-intensity PA did not significantly decrease depressive symptom odds. Previous research shows intensity-dependent physiological responses caused by increased frequencies of higher-intensity PA, all of which correlate with reduced depressive symptoms [55]. These physiological responses include the adaptation of the hypothalamic-pituitary-adrenal axis activity leading to increased stress resiliency [56], increased neurogenesis from elevated brain-derived neurotrophic factor expression [57], and reduced inflammation creating an anti-inflammatory environment [40,55]. The discrepancy between our study and prior literature may be attributed to the fact that our PA variables are defined using weekly duration rather than frequency. Therefore, participants with the same weekly duration of moderate-intensity or vigorous-intensity PA may be engaging in a different PA frequency (eg, 50 minutes per day for 3 days vs 30 minutes per day for 5 days). Prior research has shown that <10 minutes of exercise contributes to minimal mood improvements, whereas a longer duration (>30 minutes) can contribute to fatigue and withdrawal-related responses [58].

Limitations

This study is not without limitations. The exposure and outcome variables were measured using self-report questionnaires, which are subject to participant biases, including recall, social desirability, and nonresponse bias. This study also used secondary data and was subject to limited predefined variables. As such, although data regarding PA domains were available, we did not have information on respondents' activities within recreational or work-related PA. Recreational PA encompasses sports, fitness, and brisk walking, whereas work-related PA encompasses paid, unpaid work, and domestic activities. Additionally, our analysis did not consider light-intensity PA since it was not available in the NHANES questionnaire. Finally, the cross-sectional design of the study limits the conclusions to correlational rather than causal. There is a bidirectional association between PA and depression, wherein it is possible that there is a reverse causal relationship called the inhibition hypothesis [59,60], which suggests that depression symptoms such as anhedonia, low mood, and lack of energy may inhibit individuals from engaging in PA due to a lack of interest or motivation [59].

Conclusions and Future Directions

This study demonstrates that PA domain, specifically recreational PA, might play an integral role in the protective

effect of PA on depressive symptoms. Future studies should further investigate the impact of different types of recreational PA (social and self-focused) and their impact on depressive symptoms. While we found that an increased weekly duration of work-related PA was not significantly associated with lower depressive symptoms, future studies should explore the different types of occupational and household-based PA to further elucidate which activities have a detrimental effect and which have a beneficial effect. Furthermore, occupational PA can be further subdivided into paid and unpaid work to examine their effects on depressive symptoms, as these are likely to be driven by different motivations.

Data Availability

The data sets analyzed during this study are available via the NHANES website [61].

Authors' Contributions

JKB and VB conceptualized the study. The investigation was led by JKB, who was also responsible for writing the original draft and visualization. Study conceptualization and manuscript writing were supervised by VB, VKT, and SD. MW and ZC were responsible for the methodology, data curation, and formal analysis. WL and HJ supervised formal analysis. All authors provided critical revision of the manuscript for important intellectual content and contributed to editing. All authors had full access to the data and read and approved the final manuscript.

Conflicts of Interest

JKB, SD, MW, VKT, SFD, VZC, ZC, HJ, and WL do not have any disclosures. VB is supported by an Academic Scholar Award from the University of Toronto Department of Psychiatry and has received research support from the Canadian Institutes of Health Research, Brain & Behaviour Foundation, Ontario Ministry of Health Innovation Funds, Royal College of Physicians and Surgeons of Canada, Department of National Defence (Government of Canada), New Frontiers in Research Fund, Associated Medical Services Inc Healthcare, American Foundation for Suicide Prevention, Roche Canada, Novartis, and Eisai.

Abstract

Background: There is evidence that anxiety and stress increased among college students during the COVID-19 pandemic. However, less is known about daily experiences of affect, worry, substance use behaviors, experiences of pleasure, concern over food security, experiences of bias or discrimination, feelings of belongingness, and other indicators of well-being and how they vary across days in this population.

Objective: This study surveyed a wide range of indicators of health and well-being in daily life over 21 days with a sample of college students in a large university system in the United States during the pandemic. The overall variance in each daily measure was partitioned to reflect the proportion due to (1) between-person differences versus (2) within-person, day-to-day variability. This is important because measures that vary primarily due to between-person differences may be more amenable to interventions that target particular students, whereas measures that vary more due to day-to-day variability may be more amenable to interventions that target day-level contextual factors.

Methods: A sample of 2068 young adult college students (aged 18-24, mean 19.8, SD 1.3 years; 66.6% women) completed a baseline survey; 97.3% (n=2012) then completed up to 21 consecutive daily surveys that assessed a comprehensive set of daily markers of health, behavior, and well-being. The daily diary study produced a total of 33,722 person-days.

Results: Among all person-days, a minority were substance use days (eg, 14.5% of days involved alcohol use, 5.6% vaping, and 5.5% cannabis). Experiences of pleasure were reported on most (73.5%) days. Between-person differences explained more than 50% of the variance in numerous indicators of health and well-being, including daily vaping, cannabis use, other illicit substance use, experiences of bias or discrimination, positive affect, negative affect, worry, food insecurity, and feelings of belonging at the university. In contrast, within-person differences explained more than 50% of the variance in daily alcohol use, cigarette use, stress, experiences of pleasure, where the student slept last night, and physical activity.

Conclusions: College student health and well-being are multifaceted, with some aspects likely driven by person-level characteristics and experiences and other aspects by more dynamic, contextual risk factors that occur in daily life. These findings implicate services and interventions that should target individual students versus those that should target days on which students are at high risk for poor experiences or behaviors.

Introduction

College students' well-being is multifaceted, including mental health, substance use behavior, stress, belonging, flourishing, and more. In terms of mental health, anxiety has been the most common problem reported by students [1]. Further, the prevalence of many substance use risk behaviors peaks during college ages, including 35% of young adults reporting past 30-day binge drinking (4+ and 5+ drinks in a row for females and males, respectively) [2]. This population also experiences high rates of acute consequences from alcohol use, including sexual assault and blacking out [3].

Much recent evidence shows that mental health problems among college students increased substantially during the COVID-19 pandemic [4,5]. However, while social isolation, anxiety, and depression increased during the pandemic, certain factors, such as a sense of belonging with their college, seem to be protective against the effects of the pandemic on key health outcomes, particularly among underrepresented racial or ethnic minority and first-generation students [6]. When considering college student health and well-being more broadly, a longitudinal study during the pandemic identified a large subgroup of students with either very low mental and behavioral health risk or elevated mental health symptoms but no other risks (eg, low rates of substance use, sexual activity, physical inactivity, and food insecurity) and a set of 4 smaller subgroups of students with particular configurations of problematic health and well-being, such as the intersection of elevated depression symptoms, recent cannabis use, and recent sexual activity [7].

A more intensive surveillance study of college students can shed important light on the dynamic nature of health and well-being by elucidating both individual characteristics and dynamic, contextual factors that may be linked to multiple facets of student physical and mental health and well-being. Toward this goal, the aim of the present study was to conduct a large daily diary study of college student experiences at the main campus of a large university in the Northeastern United States throughout the 2021 calendar year when the pandemic was still of great concern but students had fully returned to campus for primarily in-person learning. We sought to determine whether a broad range of daily indicators of health and well-being were attributable more to between-person differences or to day-to-day variability, which might indicate greater sensitivity to dynamic and contextualized experiences.

Methods

Recruitment and General Procedures

Data for this observational study were collected via web-based surveys from students at a large public university in spring 2021 and fall 2021 as part of the Student Engagement, Learning, and Flourishing study (ie, Project SELF). Over 35,000 undergraduate participants were invited to take part in the study. The inclusion criteria were that participants were full-time undergraduate students at this campus and aged 18-24 years.

Participants were sent the first recruitment email on a Tuesday, with a follow-up (if they had not yet completed the baseline survey) 1 week later. Undergraduate emails were separated into batches and uploaded into REDCap (Research Electronic Data Capture; REDCap Consortium). Participants received individualized survey links in recruitment emails and verified their school email accounts before proceeding. Once a participant with their unique student ID had completed the survey, they were no longer able to fill out another survey. Recruitment emails were staggered, with approximately 2700 students contacted per week, so that experiences throughout the spring and fall semesters would be captured. A total of 9 rounds of emails were sent in the spring 2021 semester, and 9 additional rounds were sent in the fall 2021 semester. Additionally, any spring 2021 nonresponders were given one additional opportunity to participate that fall. All questions were mandatory to answer before moving on to the next question, but every question had a "prefer not to answer" option. The survey was determined to be "complete" when the participant clicked the "submit" button at the end. In total, 2 automatic reminders were sent from REDCap if participants had provided consent and started the questionnaire but had not clicked the "submit" button. Once participants moved on to the next page of the survey, they were not able to go back and change an answer.

Surveys were comprised of multiple scales gathered from collaborating faculty across the university. After compilation and programming, the surveys were extensively tested for branching completeness and automation fluidity. Ongoing spot testing throughout the rollout process ensured that the recruitment and survey responses were imported correctly in REDCap.

Once participants completed the baseline survey, they entered their phone number to receive SMS text messages for the daily diary portion of the study. Daily diary prompts began on the day following baseline survey completion, sent as both an SMS text message and an email at 9 AM EST, with a reminder message 1 hour later to participants who had not yet completed that day's survey. To be considered valid, participants had to initiate the daily survey before midnight and complete the survey before 1:00 AM EST. The web-based consent and baseline survey were delivered securely via REDCap, which also coordinated all SMS text message and email survey invitations. For the daily diary portion of the study, REDCap invitations pushed out Qualtrics daily survey links.

A baseline survey was completed by 2068 young adult college students; 97.3% (n=2012) then participated in a 21-day diary study. All recruitment, consent, text messaging, reminders for the daily diary, and incentive payments were completed remotely.

Ethical Considerations

This research was reviewed and approved by the Pennsylvania State University's institutional review board (approval number: STUDY00015710). Prior to completing the baseline survey, participants completed the informed consent process digitally. This contained all the consent elements: purpose of study, typical length of time to complete surveys, data storage and security, potential risks to participants, and contact information for the principal investigator and institutional review board. Participants had an opportunity to download and print the

consent form. Data from the baseline and daily surveys were linked using numeric identifiers; personal identifying information was removed prior to data analysis.

Participants were compensated US $15 for completing the baseline survey and US $2 per daily diary survey, with 2 possible high-compliance bonuses of US $5, one if participants completed at least 6 daily surveys during the first week and one if participants completed at least 12 daily surveys during the second and third weeks combined. Participants could earn up to US $67 with high study compliance. Additionally, participants received 1 raffle ticket for each high-compliance bonus, for a 1 in 100 chance of winning a US $50 gift card for high compliance in the first week and a 1 in 100 chance of winning a US $100 gift card for high compliance in the second and third weeks. Of the 2012 students who participated in the daily diary study, 1599 (79.5%) completed at least 6 of the first 7 days, and 1284 (63.8%) completed at least 12 of the last 14 days.

Surveys

Baseline Survey

Participants who completed the 15-minute baseline survey were automatically enrolled in a 21-day diary study. The baseline survey assessed a variety of topics, including demographics, college standing, health, COVID-19 prevention behaviors and beliefs, housing and food insecurity, antiracism behavior, experiences of bias or discrimination, and substance use.

Demographic, Individual, and Family Characteristics

In the first part of the survey, general demographic questions were asked, including questions about participants' age, sex, gender, sexual or gender minority status, race or ethnicity, height, weight, current health conditions, and employment status during the academic year. Participants reported on their high school grade point average, recent and cumulative college grade point average, country of origin, political ideology, whether their permanent home was in or out of state, and their parents' highest degree (used to identify first-generation college students). Participants also reported on several different aspects of their relationship with their caregivers, including family cohesion and attachment, family conflict, identification with parents, and conflict behavior [8-11].

College-Specific Characteristics

Participants reported their class standing and were asked about their group affiliations in college (honors program, Greek system, other philanthropic organizations), previous participation in the university's early start program, and current learning modes. During the spring survey, participants could participate in remote classroom lectures. The majority of classes were reinstated in person for the duration of the fall survey; however, a remote option was often available as well. Participants were also asked about their use of on-campus health services and their feelings of belonging at the university.

Food and Housing Insecurity

Food insecurity was assessed by a validated 2-item screening instrument to assess participants' access to enough food every day. The screener asked about worries around food running out and not having enough money to buy more food [12]. Students'

housing security, homelessness, and living situation were assessed with modules from the Researching Basic Needs in Higher Education instruments [13].

General Experiences of Discrimination and Antiracist Behavior

Participants completed the 21-item Anti-racism Behavioral Inventory [14], which included items such as "When I hear people telling racist jokes and using negative racial stereotypes, I usually confront them." and "The police unfairly target Black men and Latinos." Participants also completed the 7-item Williams Everyday Discrimination Scale [15], which assessed perceptions such as people acting as if they think the individual is not smart or as if they are afraid of the individual.

Mental Health

Depression symptoms were assessed using the 10-item Center for Epidemiologic Studies Depression Scale (CESD-R-10) [16]. Anxiety symptoms were assessed using the 6-item General Anxiety subscale of the Center for Collegiate Mental Health Instrument (CCAPS-34) [17]. Social anxiety was assessed using the 6-item Social Interaction Anxiety Scale (SIAS-6) [18]. The adult attention-deficit/hyperactivity disorder (ADHD) Self-Report Scale (ASRS, version 1.1) [19] was used to assess adult symptoms of ADHD. Participants also completed the 16-item Social Responsiveness Scale (SRS-2-S) [20] and an 8-item instrument to assess their level of flourishing [21].

Behavior

Students' histories of alcohol, cannabis, nicotine (including vaping, cigarettes, and other tobacco products), and other illicit substance use behaviors were assessed, as was their perception of alcohol use on campus [22]. Recent sexual activity was assessed.

21-Day Daily Diary Survey

Each morning, beginning the day after completing the baseline survey, participants were sent a link to that day's 5-minute survey. Participants were required to click on the link to initiate the daily survey by midnight and had until 1:00 AM to complete the survey. Daily diary surveys asked in-depth questions about substances used the day before (alcohol, marijuana, smoking, and other illicit substances) and their consequences, health behaviors, sleep, pleasurable experiences, and feelings of belonging, engagement, and well-being, as well as COVID-19 prevention behaviors. If participants did not report any substance use the day before, they were asked an alternative set of questions about food and housing insecurity and physical activity instead of the in-depth questions about substance use and consequences.

Substance Use, Consequences, and Context of Use

Participants were asked if they used a substance (ie, alcohol, marijuana, cigarettes, prescription painkillers, heroin, psychedelics, sedatives, or stimulants). If they answered yes to any of the substances, they were asked follow-up questions regarding how much of each they took. If they answered yes to alcohol or marijuana, they were asked a follow-up question about impairment [23,24]. If a participant reported any substance use, they were asked about any positive (eg, feeling buzzed,

more energetic) or negative consequences (eg, blacking out or feeling nauseated) of using those substances [25]. For each substance participants reported using, they were asked where they used the substance (eg, home, a friend's house, and outdoors). They also reported if they used that substance around other people, and answered follow-up questions about who those people were.

Daily Experiences of Discrimination

Discrimination was asked with 1 question, adapted from the Williams Daily Discrimination Scale, assessing how strongly they experienced bias or discrimination yesterday on a scale from 0=not at all to 5=very strongly [15].

Mental Health

Daily stress was assessed on a 0-100 scale from 0=not at all to 100=very extremely, with follow-up questions asking if anything COVID-19–related increased that stress. Participants were then asked to rate how stressful school relationships with friends or roommates and family interactions were. Daily affect was assessed using a 10-item scale assessing different feelings and emotions. This experience sampling method affect scale, taken from Wichers et al [26], was modeled after the Positive and Negative Affect Schedule Instrument [27], specifically selecting high-loading items on the negative affect (ie, insecure, lonely, anxious, low, guilty, and suspicious) and positive affect (ie, cheerful, content, energetic, and enthusiastic) spectra. Participants also answered 2 questions assessing worry (ie, I worried what other people thought of me and I was worried that I would say or do the wrong things), drawn from the social anxiety scale from Kashdan and Steger [28].

Pleasure, Belonging, and Well-Being

Experiences of pleasure were measured with 3 questions asking participants if they had any pleasure in activities yesterday and, if so, what type of activities they were and with what intensity they experienced pleasure [29]. Belonging questions asked the extent to which the participant felt like they belonged in the university environment [30]. Participants were asked 5 questions from the flourishing scale about whether they led a purposeful or meaningful life and were satisfied with their life, bored, or engaged [21].

Eating and Food Insecurity

Participants reported where they ate yesterday. To assess food insecurity, they were asked whether they were worried about paying for food tomorrow and what their food situation was the day before (food insecurity screening instrument) [12]. To help balance the questionnaire length across all days, participants were asked these questions only on days when they reported no substance use.

Sleep and Physical Activity

Each day, participants reported the time they went to bed, the time they woke up, and where they slept the night before (eg, college housing, apartment, and family home). Physical activity was assessed by 3 questions asking about vigorous and moderate-intensity exercise and sitting and reclining time. Participants were asked these questions only on days when they reported no substance use.

Data Analysis

Scale Construction for Baseline Constructs

For the *depression scale* (based on the CESD-10), 10 items with choices ranging from 0=rarely to 3=most of the time were summed to create a depression score, which ranged from 0 to 30. For the *anxiety scale* (based on CCAPS-34), 6 items with choices ranging from 0=not at all like me to 4=extremely like me were averaged to create an anxiety score, which ranged from 0 to 4. For the *social anxiety scale* (based on SIAS-6B), 6 items with choices ranging from 0 (not at all) to 4 (extremely) were summed to create a social anxiety score, which ranged from 0 to 24. The *ADHD symptoms scale* (based on ASRS_part A) was based on 6 items with response options from 0 (never) to 4 (very often); these items were converted to binary variables, wherein 3 of the items were scored as 1 if their value was greater than 1 (0 otherwise) and the remaining 3 items were scored as 1 if their value was greater than 2 (0 otherwise) [19,31]. The sum of these binary indicators created the ADHD symptoms scale, with a possible range of 0-6. For the *social responsiveness score* (based on the SRS-2-S), 16 items with response options from 0 (not true) to 3 (almost always true) were summed to create an SRS-2-S score, which ranged from 0 to 48. The original SRS-2 has 65 items, and scores could range from 0 to 195. The SRS-2-S scores were converted to an estimated SRS-2 score based on the recommended conversion table [32]. This estimated score could range from 5.7 (corresponding to SRS-2-S values of 0) to 181.5 (corresponding to SRS-2-S values of 48). For the *flourishing scale* at baseline, 8 items with response options ranging from 1=strongly disagree to 7=strongly agree were summed. The 8 items on this scale had high reliability (Cronbach α=0.98). To calculate the *closeness with caregivers scale*, 4 items with response options ranging from 0 (almost never) to 100 (almost always) were averaged. The items asked about whether caregivers respected participants' feelings and encouraged them to talk about difficulties and whether they feel close to caregivers and tell caregivers about problems. This scale had high reliability (Cronbach α=0.87).

Scale Construction for Daily Constructs

For each observed day, the following scale scores were created. In total, 3 items tailored to assess aspects of flourishing in daily life were averaged to create a *daily flourishing scale*: All things considered, I am satisfied with my life yesterday; I was engaged and interested in my activities yesterday; and I led a purposeful and meaningful life yesterday. Each item had response options of 1=strongly disagree to 7=strongly agree. A *daily positive affect score* and a *daily negative affect score* were calculated using items from a 10-item scale where choices ranged from 1=never to 7=always [26]. In total, 4 of the items were averaged to create a positive affect score, and the remaining 6 items were averaged to create a negative affect score. A *daily worry score* was calculated by averaging 2 items that asked participants the extent to which they worried about what others thought of them and the extent to which they worried they would say or do the wrong things. Response options ranged from 1=not at all or slightly to 5=extremely. This scale had high reliability (Cronbach α=0.88).

Statistical Modeling

Descriptive statistics were calculated for a variety of constructs at baseline and in the daily study. Then, variance in daily response variables due to between- versus within-person sources was partitioned using multilevel models, with a separate intercept-only linear mixed model specified for each variable. In the case of a discrete outcome, this estimated percentage is an approximation; this is a reasonable approximation when the underlying probability of the response is not close to 0 or 1 [33].

All descriptive statistics and multilevel models were conducted using R (version 4.1.2; The R Foundation).

Results

A summary of descriptive statistics from the baseline assessment appears in Table 1, and Table 2 presents descriptive statistics from the daily surveys, along with the proportion of variance that can be attributed to between-person versus person-level sources of variability.

Table 1. Descriptive statistics from the baseline survey.

Baseline measure	Study sample (N=2068)	Population of UP[a] students (N=39,392)
Identify as female gender, n (%)	1378 (66.6)	18,639 (47.3)
Race or ethnicity, n (%)		
Hispanic ethnicity	162 (7.8)	3029 (7.7)
Non-Hispanic Black	56 (2.7)	1713 (4.3)
Non-Hispanic White	1433 (69.3)	25,674 (65.2)
Non-Hispanic Asian	307 (14.8)	2651 (6.7)
Other and multiple race categories	110 (5.3)	6325 (16.1)
Class standing, n (%)		
Lower undergraduates (first or second year)	1039 (50.2)	18,192 (46.2)
Upper undergraduates (third year or later)	1025 (49.6)	21,200 (53.8)
Foreign-born student, n (%)	284 (13.7)	3988 (10.1)[b]
First-generation student, n (%)	348 (16.8)	6621 (16.8)
In-state student status, n (%)	1330 (64.3)	23,289 (59.1)
Age (years), mean (SD)	19.8 (1.3)	—[b]
Employment status, n (%)		
Full-time	20 (1.0)	—
Part-time	771 (37.3)	—
Not employed	1234 (59.7)	—
Sexual or gender minority, n (%)	361 (17.5)	—
Engaged with Greek system, n (%)	286 (13.8)	—
Food insecure (past month), n (%)	395 (19.1)	—
Housing insecure (past month), n (%)	170 (8.2)	—
Past-month alcohol use, n (%)	1316 (63.6)	—
Past-month heavy episodic drinking, n (%)	419 (20.3)	—
Past-month vaping, n (%)	372 (18.0)	—
Past-month cigarette use, n (%)	127 (6.1)	—
Past-month cannabis use, n (%)	378 (18.3)	—
High school GPA[c], median (IQR)	3.9 (0.4)	—
Cumulative college GPA, mean (SD)	3.5 (0.4)	—
Antiracism behavior: scale of 21-105, mean (SD)	67.7 (15.6)	—
General experiences of discrimination: scale of 1=almost daily to 6=never, mean (SD)	4.85 (0.9)	—
Depression: scale of 0-30, mean (SD)	11.0 (6.4)	—
General anxiety: scale of 0-4, mean (SD)	1.40 (1.0)	—
Social anxiety: scale of 0-24, mean (SD)	8.5 (6.0)	—
ADHD[d] symptoms: scale of 0-6, mean (SD)	2.5 (1.8)	—
Social responsiveness: scale of 5.7-181.5, mean (SD)	49.4 (25.6)	—
Flourishing: scale of 8-56, mean (SD)	45.3 (7.4)	—
Closeness with caregivers: scale of 0-100, mean (SD)	74.0 (20.7)	—

[b]Not applicable.

[c]GPA: grade point average.

[d]ADHD: attention-deficit/hyperactivity disorder.

Table 2. Descriptive statistics from daily diary study (based on 33,722 total person-days from n=2012 participants).

Daily measure	Values	Proportion of variance, %	
		Between-person	Within-person
Alcohol use day	4902 (14.5)[a]	19.4%	80.6%
Heavy episodic drinking day	2453 (7.3)[a]	15.5%	84.5%
Vaping day	1888 (5.6)[a]	69.8%	30.2%
Cigarette use day	254 (0.8)[a]	40%	60%
Cannabis use day	1846 (5.5)[a]	56%	44%
Other illicit substance use day	879 (2.6)[a]	70.1%	29.9%
Experienced interest or pleasure in activity	24,771 (73.5)[a]	40.7%	59.3%
Stress: how stressful was yesterday on scale of 0=not at all to 100=extremely	36.3 (27.2)[b]	37.4%	62.6%
How strongly experienced bias or discrimination: 0=not at all to 5=very strongly	1.17 (0.5)[b]	52.3%	47.7%
Positive affect: 1=never to 7=always	3.68 (1.5)[b]	57.5%	42.5%
Negative affect: 1=never to 7=always	2.28 (1.1)[b]	63.6%	36.4%
Worried: 1=not at all or slightly to 5=extremely	2.16 (1.1)[b]	67.7%	32.3%
Feelings of belonging at the university: 1=strongly disagree to 7=strongly agree	5.1 (1.6)[b]	70.7%	29.3%
Flourishing: 1=strongly disagree to 7=strongly agree	4.63 (1.5)[b]	60.2%	29.8%
Poor food situation in past 24 hours[c]	6103 (23.5)[b]	55.9%	44.1%
Worried about how to pay for food tomorrow[c]	855 (3.3)[b]	52%	48%
Slept in own dorm or room or apartment or family home last night[c]	24,554 (94.4)[b]	29.8%	70.2%
Engaged in moderate or vigorous physical activity[c]	22,095 (84.9)[b]	44.8%	55.2%

[a]Values are n (%). Estimated percentages of variance are based on intraclass correlation coefficients in multilevel models; these numbers are approximations in the case of binary response variables.

[b]Values are mean (SD).

[c]Questions only asked on non–substance use days; thus, percentages are based on 26,020 days.

Participant Characteristics at Baseline

A total of 2068 students completed the baseline survey, including 1378 (66.6%) female students. The participants' ages ranged from 18 to 24 (mean 19.8, SD 1.3) years at baseline. The sample included 1039 lower-level undergraduates (50.2% in the first or second year) and 1025 upper-level undergraduates (49.6% in the third year or later).

Sample Versus Population Characteristics

Table 1 shows descriptive statistics for the data about the population of 39,392 undergraduate students. Data are from the Penn State data digest [34], compiled for the fall 2021 semester. The racial-ethnic composition of the sample (7.8% Hispanic or Latinx, 2.7% non-Hispanic Black, 69.3% non-Hispanic White, 14.8% non-Hispanic Asian, and 5.3% other or mixed races) was similar to that of the population of students at this campus (7.7% Hispanic or Latinx, 4.3% non-Hispanic Black, 65.2% non-Hispanic White, 6.7% non-Hispanic Asian, and 16.1% other or mixed races). The sample had a larger proportion of

female students than the broader university population (47.3% in population), and slightly higher percentages of lower-level students (50.2% vs 46.2% in the population), foreign-born students (13.7% vs 10.1%), and in-state students (64.3% vs 59.1%). The proportion of first-generation students was 16.8% in both the sample and the population.

Additional Sample Characteristics

Of participants who completed the baseline survey, 38.3% (n=791) were employed, 17.5% (n=361) identified as a sexual or gender minority, 13.8% (n=286) were affiliated with the Greek system, 19.1% (n=395) reported food insecurity, and 8.2% (n=170) reported housing insecurity. The prevalence of past-month substance use behaviors was 63.6% (n=1316) for any alcohol use, 20.3% (n=419) for heavy episodic drinking (ie, binge drinking), 18% (n=372) for vaping, 6.1% (n=127) for cigarette use, and 18.3% (n=378) for cannabis use. The median high school grade point average was 3.9 with an IQR of 0.4, and their mean cumulative grade point average in college was 3.5 (SD 0.4). Mean scale scores for antiracism behavior,

discrimination, depression, general anxiety, social anxiety, ADHD symptoms, social responsiveness, flourishing, and closeness with caregivers are provided in Table 1.

Student Health and Well-Being in Daily Life

On 21 consecutive days, participants were prompted to complete a survey that assessed a comprehensive set of daily markers of health, health behaviors, and well-being. Students completed the daily survey in an average of 16.8 (SD 5.7) days.

Substance Use, Stress, Discrimination, Affect, and Flourishing

Of the 33,722 person-days, a minority were substance use days; 4902 days (14.5%) involved alcohol use, 2453 days with heavy episodic drinking (7.3%), 1888 days with vaping (5.6%), 254 days with cigarettes (0.8%), 1846 days with cannabis (5.5%), and 879 days with other illicit substance use (2.6%). Experiences of pleasure were reported on 24,771 of 33,722 days (73.5%). Mean scale scores for daily stress, experiences of bias or discrimination, positive affect, negative affect, worry, feelings of belonging, and flourishing are provided in Table 2.

Additional Indicators of Well-Being

Based on data from the 26,020 person-days with no reported substance use, a poor food situation was reported on 6103 days (23.5%); worry about how to pay for food tomorrow was reported on 855 (3.3%) days; students slept in their own dormitory, room, apartment, or family home on 24,554 (94.4%) days; and students engaged in moderate or vigorous physical activity on 22,095 (84.9%) days.

Between- Versus Within-Person Variability

Partitioning variance into between- versus within-person sources of variance for daily indicators of health and well-being provides insight into which constructs tend to be more person-specific and potentially explainable by person-level characteristics, as opposed to those that are more day-specific and potentially explainable by the contextual characteristics of a particular day. Between-person differences explained the majority of variance in daily vaping (69.8% attributable to between-person differences), cannabis use (56%), other illicit substance use (70.1%), experiences of bias or discrimination (52.3%), positive affect (57.5%), negative affect (63.6%), worry (67.7%), feelings of belonging at the university (70.7%), flourishing (60.2%), poor food situation (55.9%), and worry about how to pay for food (52%).

In contrast, within-person differences (ie, day-to-day fluctuations within individuals) explained the majority of the variance in daily alcohol use (80.6% attributable to within-person differences), heavy episodic drinking (84.5%), cigarette use (60%), experiences of pleasure (59.3%), stress (62.6%), where a student slept last night (70.2%), and physical activity (55.2%), indicating that day-level contextual factors may be more relevant for these daily experiences and behaviors.

Discussion

Principal Results

This study examined a wide range of health and well-being indicators among college students in daily life during the COVID-19 pandemic. Consistent with prior research on substance use in daily life, the proportion of variance attributed to within-person fluctuations was particularly high for daily alcohol use, heavy episodic drinking, and cigarette use, suggesting that these behaviors are highly sensitive to contextual characteristics [35-38]. In contrast, daily vaping behavior and other illicit substance use behavior tended to be most stable as person-level characteristics; this is consistent with recent research that has shown level of dependence to be positively associated with stability of behavior across days [39]. Variance in other aspects of daily mental health (belonging, flourishing, positive affect, negative affect, and worry) was also primarily attributable to between-person (ie, trait-like) differences. This finding is consistent with a coordinated analysis of 6 intensive longitudinal studies of positive and negative affect; variance decomposition of daily data reliably showed affect to be more strongly characterized by between-person differences [40].

These findings suggest where student programming and intervention efforts may be most effectively appropriated in this population. For example, available mental health services and interventions directed to certain individuals who would benefit most may be the best strategy for resource allocation on college campuses, whereas the provision of just-in-time mental health interventions on days of particularly high negative affect or worry or low positive affect may be less effective. In contrast, interventions designed to reduce problematic alcohol use and cigarette use may be best targeted toward risky contexts that students move in and out of throughout their days.

This type of intensive surveillance provides data that characterize not just population-average levels on aspects of health and well-being and their correlates, but also sheds light on day-to-day variability in student health and well-being and dynamic contexts that may place students at heightened risk for poor outcomes on a given day. By partitioning the variance of daily indicators of health and well-being, this study design provides the opportunity to determine which indicators of health and well-being are more trait-like and which are more state-like.

Limitations and Future Work

One limitation of this study was the low rate of participation. This may produce nonresponse bias, which has been documented among college students, with survey respondents more likely to be female, socially engaged, and financially secure, with differences in personality compared to nonresponders (eg, [41]). Another limitation of this study was that rolling recruitment spanned from February through November 2020 (with no recruitment during the summer term); thus, students participated in the study at qualitatively distinct times during the COVID-19 pandemic. Most notably, vaccinations became widely available in mid-2020, which could have impacted student mental health and social behaviors. Thus, it may be important to determine whether these findings replicate in future analyses using daily diary data collected after the pandemic.

Conclusions

Certain daily experiences and behaviors related to college students' health and well-being, such as vaping, negative affect, and feelings of belonging at one's university, distinguish at-risk individuals from other students. In contrast, other experiences and behaviors, such as alcohol use and cigarette use, stress, and physical activity, may be driven more by contextual risk factors operating on certain days. These findings suggest that some aspects of health and well-being may be most amenable to services that target students more generally, while others may be more amenable to interventions that target particularly risky students, days, or contexts.

Daily diary studies can inform practical policy recommendations to higher-education institutions, enabling them to make data-informed decisions on university closures and the development of programs to support student health and well-being. This approach is essentially a community-based surveillance system that can provide insight into student characteristics and contextual factors that place individuals at risk for negative outcomes.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

STL conceptualized the study, secured funding for the study, supervised the project, and produced the original draft and edited further versions of this manuscript. CW administered all aspects of data collection, compiled sources for all instruments used in the study, and reviewed and edited the manuscript. SB served as the data manager, conducted all analyses, and reviewed and edited the manuscript.

Abstract

Background: Clinical routine data derived from university hospitals hold immense value for health-related research on large cohorts. However, using secondary data for hypothesis testing necessitates adherence to scientific, legal (such as the General Data Protection Regulation, federal and state protection legislations), technical, and administrative requirements. This process is intricate, time-consuming, and susceptible to errors.

Objective: This study aims to develop a platform that enables clinicians to use current real-world data for testing research and evaluate advantages and limitations at a large university medical center (542,944 patients in 2022).

Methods: We identified requirements from clinical practitioners, conceptualized and implemented a platform based on the existing components, and assessed its applicability in clinical reality quantitatively and qualitatively.

Results: The proposed platform was established at the University Medical Center Hamburg-Eppendorf and made 639 forms encompassing 10,629 data elements accessible to all resident scientists and clinicians. Every day, the number of patients rises, and parts of their electronic health records are made accessible through the platform. Qualitatively, we were able to conduct a retrospective analysis of Parkinson disease over 777 patients, where we provide additional evidence for a significantly higher proportion of action tremors in patients with rest tremors (340/777, 43.8%) compared with those without rest tremors (255/777, 32.8%), as determined by a chi-square test ($P<.001$). Quantitatively, our findings demonstrate increased user engagement within the last 90 days, underscoring clinicians' increasing adoption of the platform in their regular research activities. Notably, the platform facilitated the retrieval of clinical data from 600,000 patients, emphasizing its substantial added value.

Conclusions: This study demonstrates the feasibility of simplifying the use of clinical data to enhance exploration and sustainability in scientific research. The proposed platform emerges as a potential technological and legal framework for other medical centers, providing them with the means to unlock untapped potential within their routine data.

Introduction

In recent years, there has been a growing interest in using clinical routine data, especially electronic medical records, for research [1]. Known as secondary data use, this practice is significantly influenced by legislative actions such as the Health Information Technology for Economic and Clinical Health Act in the United States of America and publicly founded initiatives

like the Medical Informatics Initiative (MII) in Germany [2,3]. University hospitals now serve as central hubs in bridging the gap between research and patient care. Achieving connectivity between previously isolated data silos necessitates adherence to detailed standards, such as the custom FHIR (Fast Healthcare Interoperability Resources) profile "Kerndatensatz" in Germany and effective communication among diverse stakeholders within national health systems [4]. Despite the inherent complexity, these concerted efforts are expected to establish a new foundation for evidence-based science.

Despite the advantages of adopting a state-wide approach to secondary data use, we contend that certain research could be more effectively conducted at the local level within individual hospitals. Specifically, we have identified 2 critical use cases where hypothesis testing on unmapped raw data is essential for advancing evidence-based medicine:

First, to verify hypotheses derived from clinical practice on a larger database, clinicians should be able to validate their experiences easily through data-driven investigations. These studies may involve data elements not comprehensively covered by standardized data sets. In addition, expecting clinicians to create intricate mappings between used data elements and state-wide standards may prove ineffective.

Second, the replication of existing publications to assess their generalizability must always consider the local context. Conducting public health research, for example on large cohorts of patients with Parkinson disease (PD), might miss important external factors [5,6]. Accordingly, testing external validity on a schema applied in practice rather than one developed for collaboration appears more appropriate.

Beyond the clinical perspective, local solutions may better accommodate regional or local legal requirements, as many collaborative standardizations tend to converge on the "smallest common divisor" between partners. Consequently, the implementation of complementary systems for secondary data analysis at both the local and global levels is deemed appropriate.

Developments in recent years have led to the emergence of research platforms that enable the analysis of clinical data in compliance with data protection guidelines. Notable examples include EPOCH and ePRISM (IP-ITT Corporation) [7], KETOS (Friedrich-Alexander University Erlangen-Nürnberg) [8], and Medical-Blocks (University of Bern) [9]. These platforms provide environments that allow clinical scientists to train and deploy statistical models. However, their primary focus is on translating these models back into clinical practice rather than testing hypotheses through the secondary use of data. In addition, works such as EHR4CR (Electronic Health Records for Clinical Research) [10] have implemented infrastructures that enable the use of clinical data across multiple European sites in a secure and privacy-preserving manner without focusing on the subsequent analysis. Given our knowledge, a platform for hypothesis testing on routine data has not been implemented and evaluated in clinical reality.

This paper addresses this gap in research by introducing and evaluating a novel platform explicitly designed for hypothesis testing on clinical routine data. Starting by collecting the requirements of clinicians, we strive to design and implement a modular and, consequently, reusable platform. Similar to other states, the federal law of Hamburg permits pseudonymized retrospective data analysis without patient consent given specific guarantees regarding data protection. The platform ensures those guarantees in accordance with all European and German laws and is directly integrated into the technical infrastructure of the University Medical Center Hamburg-Eppendorf (UKE). The evaluation process encompasses quantitative assessment, exemplified by the replication of a public health finding in the context of PD, and qualitative evaluation through the examination of clinicians' use in real-world clinical scenarios. This dual-pronged evaluation strategy aims to judge both the quantitative efficacy and practical use of the proposed platform in clinical reality.

Methods

Technical Considerations

For developing the platform, we examined the challenges of using routine hospital data for hypothesis testing through extensive communication with the different business divisions of the UKE, like the infrastructure department, division for information technology, research data facility, data protection officers, and internal boards. Informed by the project meetings and discussions with clinicians as later users, we identified and prioritized 4 critical process components necessitating optimization.

Defining Appropriate Hypotheses

Precise hypothesis formulation relies on a thorough understanding of metadata within the clinical information system. For researchers, the accessibility of relevant data fields may not be immediately evident. Challenges arise from both nontechnical limitations and the opacity of data type and structure. Filtering cohorts based on specific criteria may yield statistically inappropriate sizes, and requested data may be inadequately recorded [11]. The feasibility of research ideas is thus not guaranteed, necessitating extensive consultation with data integration experts for hypothesis refinement.

Obtaining Data From the Infrastructure

Efficient storage and retrieval of routine hospital data are crucial for medical treatment and research. Hospitals use diverse IT architectures, often a mix of specialized systems with proprietary data structures and nonstandardized file formats. Access and control vary widely, from centralized systems to more federated approaches led by individual clinics. Clinicians aiming to test hypotheses face challenges in accessing required documentation, understanding these structures, and communicating with the responsible data manager.

Analysis of the Hypotheses

To facilitate hypothesis tests, clinicians expressed a need for a comprehensive and heterogeneous array of tools, encompassing table-based software and standard scripting languages like Python (Python Software Foundation) or R (R Foundation for Statistical Computing). Established research data management

platforms, such as Kaggle (Google) [12], Paperspace Gradient (DigitalOcean) [13], Colab (Google) [14], or CodaLab (Microsoft Research) [15], provide ideal support for efficient data analysis: An integrated and simplified development environment, a separate space for data analysis with access to high-performance computing, and the ability to communicate and collaborate with other users of the research community. Rather than developing a novel solution, leveraging a platform that accommodates diverse analysis methods appears to be a pragmatic approach.

Reuse of Established Components

Based upon the preliminary work of the MII and the existing research landscape, the following tools were explored as relevant in the context of our work.

Data Integration

Data integration centers (DICs) enable the cross-site and cross-institutional use of digital health data from patient care and biomedical research in Germany [2,3,16]. All DICs are located at university medical sites and have access to routinely collected patient data. To this end, they build up interoperable databases with quality-assured and internationally harmonized data (based on HL7 [Health Level Seven International] FHIR) and metadata. These are made available in anonymized form through trustees. DICs make an important contribution to the development of a research-orientated infrastructure for the German health care system. The first use cases using the functionalities are already in operation [17]. These functionalities are reusable and valuable for our work. For further details, we refer to the literature regarding the MII [2,3].

Data Usage Considerations

European, national, and local laws govern the use of sensitive routine data. Those projects necessitate ethical approval and explicit consent, a crucial yet burdensome process for both researchers and ethics committee members. As the legislators have already identified the need for simplification, we were able to use §12 of the "Hamburgisches Landeskrankenhausgesetz" [18]. This statute permits pseudonymized retrospective data analysis without patient consent, allowing us to forego consent-based data usage. With approval from the ethics committee for hypothesis testing, the board and the individual researcher might focus more on the research question rather than time-consuming bureaucratic processes. Without this general approval for hypothesis testing, researchers would normally not be able to query the data without extensive knowledge regarding the infrastructure and the law. Furthermore, the UKE has established an independent trust center, which is largely autonomous in legal terms. This center uses suitable pseudonymization techniques to safeguard patient data identity.

Metadata Processing

The processing of metadata is crucial in the context of data harmonization with multiple data sources, as intended in this project. Metadata repositories (MDRs) enable the structuring of data for the technical extract, transform, and load (ETL) process. They are also applications that make the syntax and semantics of the data understandable for the end user. Both attributes are relevant in our context. Numerous systems have already been tested and evaluated in use [15-17]. In this case, we prefer an MDR that is a further development of the already used Samply.MDR [19], an ISO/IEC 11179-based metadata repository built on a graph-based backend, making the MDR applicable to many hierarchical data structures.

Quantitative and Qualitative Analysis

In the evaluation of the proposed tool, a dual assessment was conducted, encompassing a qualitative analysis of its suitability for replicating a public health-focused study and a quantitative examination of clinicians' usage behavior within the hospital.

Qualitative Analysis: Hypothesis Testing

The capabilities of the proposed platform for testing scientific hypotheses appear to be valuable for replicating studies in other cohorts. Comparable to existing publications [8], we applied the platform to underscore its efficacy in promoting sound scientific practices and for examining the generalizability of findings regarding the circumstances present at a specific hospital.

Due to its notable clinical implications [20,21], we chose PD as a neurodegenerative disorder of interest for which routine data may provide helpful insights. The International Parkinson and Movement Disorder Society (MDS) developed a scoring system to measure the severity of PD motor symptoms. This movement test is called the Unified Parkinson's Disease Rating Scale (UPDRS) and is widely used in clinical routine [22]. While postural, kinetic, and isometric tremor are subcategories of action tremor, the isometric tremor is difficult to measure in routine clinical settings and is not routinely assessed [23,24]. Nonetheless, the exact relationship between these distinct types of tremors remains incompletely understood.

Motivated by the findings of Gupta et al [25], our objective is to validate their proposed correlation between rest tremor and action tremor in patients with PD [26]. Consequently, we aim to replicate their observation of a significantly higher prevalence of action tremor in individuals also experiencing resting tremor.

By leveraging the proposed platform, we gained access to routine data, expanding beyond the use of public data sets used in the original study: The Parkinson Progression Marker Initiative (PPMI) [27], the Fox Investigation for New Discovery of Biomarkers (BioFIND) [28], and the Parkinson's Disease Biomarkers Program (PDBP) [29] data sets are 3 distinct clinical oriented, observational studies collecting relevant disease-specific data from patients with PD. The PPMI study focuses on early-stage patients with PD who have recently been diagnosed and are not yet receiving dopaminergic treatment. In contrast, the BioFIND and PDBP studies encompass patients at varying stages of PD, ranging from moderate to advanced and early to advanced, respectively. Consequently, the PPMI data set exclusively includes patients in the medication-off state, while the latter 2 data sets include patients in both the medication-off and medication-on states.

As the first step of the analysis, we identified those forms within the clinical information system used to store classifications according to the MDS-UPRDS. The platform facilitated the

selection of a well-defined cohort, ensuring precise inclusion criteria for the data query. Accordingly, we included all patients with the designated *ICD-10-GM* (*International Statistical Classification of Diseases and Related Health Problems, Tenth Revision, German Modification*) code for Parkinson disease (G20). Furthermore, we limited our cohort to admissions that occurred between February 24, 2018, and February 24, 2023. Although age limitations can be applied, we did not impose any restrictions for the presented cohort. Leveraging the aforementioned criteria, we executed the query and retrieved all corresponding records stored in the system.

Quantitative Analysis

For the quantitative analysis, we focus on performance indicators critical for assessing the relevance of our platform in clinical reality. The practical use of the platform is measured with the cumulative probability distribution and the absolute number of requests after the initialization of the platform. The waiting times are critical for user experience, which is expected of the researcher's experience when they receive the requested data.

Ethical Considerations

Based on the proposed pipeline for pseudonymization and data security, the ethics committee of the Hamburg chamber of physicians agreed on approval for all hypothesis tests conducted through the platform (2022-100891-BO-ff).

Results

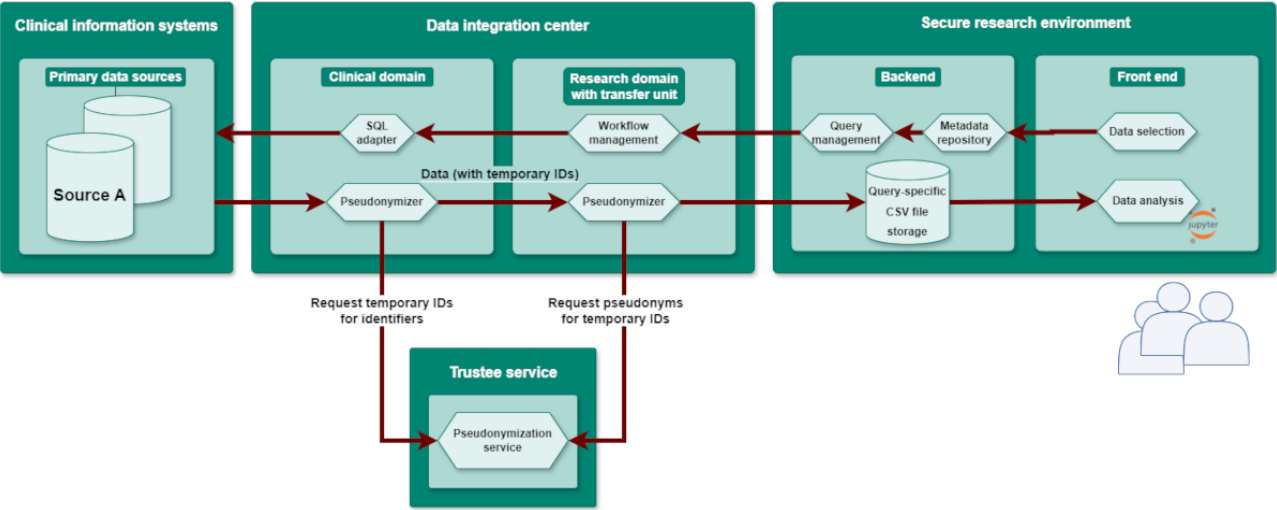
Technical Realization Within Clinical Reality

The central implementation detail of the platform is the usage of the established systems through strategic interfacing within the DIC. Notably, it circumvents the integration phase by directly querying the databases of clinical systems. The platform's backend is incorporated into the DIC's clinical and research domains, using the central trustee service for pseudonymization and the transfer unit for managing workflows and facilitating data delivery to researchers. The underlying architecture is constructed using standardized web technologies, specifically HTTPS and REST (Representational State Transfer).

These procedural steps are fully automated, furnishing transparent feedback on the ongoing progress (Figure 1).

The data architecture is organized into 3 primary sections: clinical information systems, data integration center, and secure research environment. A researcher initiates hypothesis testing using the web application in the front end of the secure research environment. Data selection for this process is facilitated through a catalog of data elements supplied by the metadata repository. The data integration center, which is divided into 2 domains, the clinical domain, and the research domain, is responsible for converting the researcher's query into potentially multiple SQL (Structured Query Language) commands to retrieve data from the clinical information system's database. The output is exported as a CSV (comma-separated values) file and subjected to the pseudonymization triangle, where identifiers like medical record numbers and visit numbers are replaced with temporary IDs by the clinical domain before transmitting the data set to the research domain. The trustee service ensures that data from various sources are assigned consistent pseudonyms, maintaining the integrity of the hypothesis testing context. Subsequently, the pseudonymized data is stored in the query-specific CSV file storage within the backend of the secure research environment. Researchers have access to these data sets for further analysis and can use analytical tools such as Jupyter notebooks, which are available on the front end.

Text data or images that contain sensitive information are not exported. Subsequently, the research domain decodes temporary IDs into definitive pseudonyms and stores the data set for subsequent researcher access. Both the clinical and research domains obtain temporary IDs and pseudonyms from the trustee service, configured to issue unique ones for each identifier type (eg, medical record number or visit number). The linkage between original IDs and pseudonyms remains confidential to both domains; solely, the trustee service retains this information throughout the project's duration. After this process, the resulting file is automatically downloaded into a separate network designed for research and stored on a file system accessible only to the requesting clinician.

Figure 1. Components and data processing architecture of the platform. CSV: comma-separated value; SQL: Structured Query Language.


Using a widely recognized solution for both clinicians and data scientists, we incorporated JupyterLab, a prominent open-source web-based development environment, as the principal front end for ensuing data analyses. As a result, the proposed platform empowers users to leverage a diverse array of tools and libraries on the 639 forms encompassing 10,629 data elements that we have made accessible from clinical routine.

Qualitative Results: Example of a Hypothesis Testing

For the qualitative assessment, all patients with the designated *ICD-10-GM* code G20 and admissions that occurred between February 24, 2018, and February 24, 2023, were included. The majority of patients underwent multiple assessments during their hospital visit. We only considered the first assessment to ensure independent samples and discarded subsequent assessments. This was necessary since we were mainly interested in the patient cohort with any of the 3 basic tremor types rather than the overall occurrence of all tremors assessed at any given time point. The decision to choose the first assessment was made since not every subject was assessed more than once, but always at the beginning of their hospitalization, thereby ensuring uniformity in tremor severity assessments shortly after admission. Afterward, we derived the subtypes described in the original work by considering the MDS-UPDRS items 3.17, 3.15, and 3.16 as surrogates for rest tremor, postural tremor of the hands, and kinetic tremor of the hands, respectively. As a result, we were able to include 777 patients in our qualitative assessment.

Table 1 presents the prevalence of the primary tremor types and the association between rest tremor and action tremor. The table includes 4 distinct data sets, with the first 3 data sets obtained from Gupta et al [25] and the fourth data set corresponding to our analysis conducted using the proposed tool (UKE). The provided values for rest tremor, postural tremor, and kinetic tremor represent the count of patients with PD exhibiting each respective tremor type while at rest, while holding their hands stretched out, or during a finger-to-nose maneuver, respectively. The severity rating for each tremor type is equal to or above 1, as outlined in the MDS-UPDRS guideline. The aggregated values presented in the table were derived following the published protocol.

Table 1. Comparison of the tremor subtypes and their occurrences within the cohorts reported by Gupta et al [25]. In addition, the last column shows the obtained results from routine data based on the proposed platform.

	PPMI[a] (N=423), n (%)	BioFIND[b] (N=118), n (%)	PDBP[c] (N=874), n (%)	UKE[d] (N=777), n (%)
Rest tremor	290 (68.6)	75 (63.6)	459 (52)	340 (43.8)
Pure rest tremor	87 (20.6)	15 (12.7)	104 (11.8)	57 (7.3)
Action tremor	156 (36.9)	46 (39)	316 (35.8)	255 (32.8)
Pure action tremor	40 (9.5)	10 (8.5)	87 (9.9)	76 (9.8)
Postural tremor	223 (52.7)	69 (58.5)	412 (46.7)	416 (53.5)

[c]PDBP: Parkinson's Disease Biomarkers Program.

[d]UKE: University Medical Center Hamburg-Eppendorf.

Our results represent a cohort of patients with PD irrespective of any dopaminergic treatment since many patients lack information regarding medication status due to the subsequent addition of this data field into the clinical information system. Through our data analysis, we observed a prevalence of 43.8% (340/777) for rest tremors and 7.3% (57/777) for pure rest tremors within the cohort. In contrast, the prevalence of total action tremor was 32.8% (255/777), with a corresponding occurrence of 9.8% (76/777) for pure action tremor. The incidences of postural tremor and pure postural tremor were found to be 53.5% (416/777) and 9.3% (72/777), respectively. We identified a prevalence of 38.7% (301/777) for kinetic tremor and 4.0% (31/777) for pure kinetic tremor. Finally, we calculated the occurrence of patients exhibiting all 3 tremor types simultaneously, the absence of any tremor, and the presence of at least 1 tremor type, resulting in proportions of 23.0% (179/777), 33.2% (258/777), and 66.8% (519/777), respectively. These relative figures closely resemble the reported values from the original authors. Importantly, we also observed a significantly higher proportion of action tremors in patients with rest tremors (43.8%) compared with those without rest tremors (32.8%), as determined by a chi-square test ($P<.001$).

Our analysis of routine data has yielded additional evidence that aligns with the published findings, suggesting that action tremor may be part of a broader tremor syndrome observed in PD. This discovery emphasizes the need for a more dynamic approach to tremor classification, considering the progressive

worsening of rest tremor severity over time [30] and its potential association with the occurrence of action tremor. Specifically, our data set corroborates the previous findings by Gupta et al [25], which propose a relationship between rest tremor and the emergence of action tremor. The data we have obtained further suggests that action tremor may represent a manifestation of the underlying basal ganglia disease, highlighting the potential requirement for additional neuroimaging studies to elucidate this connection.

Quantitative Results

In the realm of quantitative results, we focus on performance indicators critical for assessing the relevance of our platform within the clinical reality. To that end, we compiled a comprehensive list of successful queries executed using our proposed tool before October 30, 2023. Subsequently, we exclude queries carried out by members of the development teams, as they were primarily intended for debugging purposes.

Figure 2 illustrates the cumulative probability distribution of all incorporated queries across the temporal dimension. A conspicuous observation is the initial absence of queries in the early phase, signifying a notable delay in the adoption of the tool by clinical researchers, spanning nearly 6 months. The

discernible rightward shift indicates an increasing interest among researchers following an initial habituation period. Nevertheless, the following data points reveal a marked acceleration in query use, with over 50% of the total queries executed within the most recent 3-month period.

Our platform offers the unique advantage of accessing multiple systems integral to clinical care. However, it's important to note that these platforms are not optimized for the specific nature of the queries in question. Substantial delays in data retrieval could significantly impede the quality of research conducted using our tool. Consequently, we analyzed to evaluate the waiting times experienced by clinical researchers before they received the requested data.

Figure 3 displays the distribution of the time it took for the queried data to become available to the researcher. The plot reveals a notable range of waiting times. While more than 50% of all requests were processed within a time frame of 50 hours, the longest queries extended to nearly a week. The pronounced initial ascent up to the median highlights the prompt reception of a substantial proportion of data despite the existence of instances where requests experience prolonged processing durations.

Figure 2. Cumulative probability distribution of researcher-initiated queries over time, starting from the public announcement of the platform, as extracted from the platform logs.
Figure 3. The percentiles illustrate all queries conducted by researchers until the availability of data for analysis extracted from the platform logs.
Discussion

Principal Findings

The development of a novel data platform at the University Medical Center Hamburg-Eppendorf for hypothesis testing on current clinical routine data according to all European and German data protection laws is accepted and used by clinicians. Accordingly, designing, implementing, and establishing a streamlined process for conducting hypothesis testing in public health by using secondary data appears possible. The initial version presented in this study involves the development of an analytical platform with a data protection-compliant infrastructure and a comprehensive ethical mandate, which will be extended with respect to semantic and syntactic interoperability found in the literature. This innovation has culminated in the establishment of a tool in clinical reality, which occupies a unique niche within the national health care landscape.

Given the illustrative use case, our findings indicate that routine data can facilitate the creation of data sets on scales comparable to prospective studies within significantly shorter time frames than those. This observation carries profound implications for diverse hospital roles: Patients gain transparency and trust in research processes, as the platform serves as a reliable authority for consent, enhancing confidence in the hospital's practices. Clinicians find empirical support for hypothesis testing, aiding in evidence-based decision-making and simplifying time-consuming replication studies. The Data Protection Officer benefits from automated queries, reducing project-related risk management burdens and minimizing infringement risks through a secure, tested architecture. Research data infrastructure experts receive structured support for handling researchers' queries. Finally, the hospital itself benefits from the efficient use of routine clinical data, offering potential cost savings, increased efficiency, and enhanced competitiveness.

Beyond the scope of our study, there is a discernible increase in interest in the tool within clinical reality. Over the last 90 days, the number of successful queries has doubled, and in total, clinical data from 600,000 patients or 1.6 million cases were retrieved from the platform. Although the absolute figures remain constrained, there is evident adoption by clinical researchers, indicating active use of the new tool for their hypothesis tests.

Limitations

Our investigation underscores that the long execution times of queries on general-purpose databases in clinical systems, which are not inherently designed for the queries executed by the research platform, can limit the interactivity of researchers with the clinical data. Similar systems in other hospitals may likely face comparable issues. The complexity of supporting various query formulations through SQL query adapters further complicates optimization, often resulting in less efficient query statements compared with those that are meticulously crafted by hand. To enhance our platform and achieve shorter execution times, further development is essential. By now, we established a time limitation for queries, terminating excessively large ones. In the future, we plan to use strategies such as horizontally scaling the data sources, using alternative data stores or data caches, or using FHIR search or the Clinical Query Language as the query mechanism instead of traditional SQL [31].

Furthermore, our observations indicate a lack of universal intuitiveness among clinical users in our hospital regarding the Jupyter Notebooks used for analysis. Despite the formulation of data queries, the execution of analyses experienced a notable decline. The participation of clinicians in platform design underscores a potential gap in data literacy among individual

XSL•FO
RenderX

physicians. To mitigate this, we advocate for an additional reduction in the entry barrier through the introduction of user-friendly, broadly applicable dashboards and visualizations tailored to each data query.

An additional aspect that holds potential for enhancing usability in the future is the ability to share access to analysis spaces. This feature would enable users with limited statistical expertise to invite statistical or biomedical experts into their analysis space, gradually receiving support throughout the analysis process. By allowing collaborative access, inexperienced users can benefit from the guidance and assistance of domain experts, facilitating their learning and development in statistical analysis. Accordingly, this feature is currently under development.

Conclusions

With the presented research platform, we were able to establish a valuable tool for hypothesis testing and secondary use of clinical data. By automating the retrieval process of pseudonymized clinical data and providing a clear legal framework, the platform contributes to the facilitation of the research process. The practical usability of the platform was demonstrated through the replication of a scientific study using the example of PD, confirming the validity of the concept. In further development stages and through the integration of additional clinical data sources, we aim to continuously increase the quantity of data and the usability of the platform. In the long term, through further modularization and standardization, the platform should be made usable for additional national and European sites, significantly facilitating the secondary use of clinical data.

Data Availability

The anonymized data sets regarding the usage behavior analyzed during this study are available in the ZFDM repository [32]. The clinical data sets are not publicly available due to the missing legal foundation for the export of routine data but are available from the corresponding author on reasonable request and given permission from the required access committees.

Authors' Contributions

CG and KG wrote the manuscript. CG and AJW conducted the analysis. MA, MW, and JG led the technical development. FÜ, MW, and JG edited the manuscript. CG is the corresponding author of this paper.

Abstract

Background: The Delta variant (B.1.617.2) was considered the most dangerous SARS-CoV-2 strain; however, in-depth studies on its impact based on demographic and clinical characteristics of COVID-19 are scarce.

Objective: We aimed to investigate the shift in demographic and clinical characteristics of the COVID-19 pandemic with the emergence of the SARS-CoV-2 Delta variant compared with the wild-type (WT) strain (B.1).

Methods: A cross-sectional study of COVID-19 cases in the Indian population caused by the WT strain (B.1) and Delta variant of SARS-CoV-2 was performed. The viral genomic sequence metadata containing demographic, vaccination, and patient status details (N=9500, N_{Delta}=6238, N_{WT}=3262) were statistically analyzed.

Results: With the Delta variant, in comparison with the WT strain, a higher proportion of young individuals (<20 years) were infected (0-9 years: Delta: 281/6238, 4.5% vs B.1: 75/3262, 2.3%; 10-19 years: Delta: 562/6238, 9% vs B.1: 229/3262, 7%; P<.001). The proportion of women contracting infection increased (Delta: 2557/6238, 41% vs B.1: 1174/3262, 36%; P<.001). However, it decreased for men (Delta: 3681/6238, 59% vs B.1: 2088/3262, 64%; P<.001). An increased proportion of the young population developed symptomatic illness and were hospitalized (Delta: 27/262, 10.3% vs B.1: 5/130, 3.8%; P=.02). Moreover, an increased proportion of the women (albeit not men) from the young (Delta: 37/262, 14.1% vs B.1: 4/130, 3.1%; P<.001) and

adult (Delta: 197/262, 75.2% vs B.1: 72/130, 55.4%; *P*<.001) groups developed symptomatic illness and were hospitalized. The mean age of men and women who contracted infection (Delta: men=37.9, SD 17.2 years; women=36.6, SD 17.6 years; *P*<.001; B.1: men=39.6, SD 16.9 years; women=40.1, SD 17.4 years; *P*<.001) as well as developing symptoms or being hospitalized (Delta: men=39.6, SD 17.4 years; women=35.6, SD 16.9 years, *P*<.001; B.1: men=47, SD 18 years; women=49.5, SD 20.9 years, *P*<.001) were considerably lower with the Delta variant than the B.1 strain. The total mortality was about 1.8 times higher with the Delta variant than with the WT strain. With the Delta variant, compared with B.1, mortality decreased for men (Delta: 58/85, 68% vs B.1: 15/20, 75%; *P*<.001); in contrast, it increased for women (Delta: 27/85, 32% vs B.1: 5/20, 25%; *P*<.001). The odds of death increased with age, irrespective of sex (odds ratio 3.034, 95% CI 1.7-5.2, *P*<.001). Frequent postvaccination infections (24/6238) occurred with the Delta variant following complete doses.

Conclusions: The increased involvement of young people and women, the lower mean age for illness, higher mortality, and frequent postvaccination infections were significant epidemiological concerns with the Delta variant.

Introduction

The Delta variant (B.1.617.2) of SARS-CoV-2 caused COVID-19 waves and spikes in 2021 in multiple countries [1]. Structural and functional analyses of the lineage characterizing mutations in the spike glycoprotein have predicted potential alterations in virus-host interactions and masking of the antibody binding sites, leading to increased transmissibility, lethality, and immune escape capabilities for this variant [2-4], which were further validated in recent animal models [5,6] and human studies [7-10]. Available studies precisely indicate that the Delta variant is at least 50% to 60% more transmissible than the Alpha variant (B.1.1.7) [11] and is capable of immune escape against natural infections with previous SARS-CoV-2 strains, COVID-19 vaccines, and therapeutically used monoclonal antibodies [5-11].

The emerging SARS-CoV-2 variants reportedly vary in demographic characteristics, such as age- and sex-based vulnerability for contracting infection, developing severe illness, and mortality risk from wild-type (WT) strains (Wuhan strain and B.1) [4,12-15]. Against the established pattern of higher susceptibility for older adults and men, which is explained by documented immunological reasons [16-20], the emerging variants involve increasing proportions of the young and female sex [4,12-15]. However, studies that have examined the shift in demographic and clinical characteristics for the Delta variant are currently limited. A devastating second COVID-19 wave occurred in India in 2021, driven by the Delta variant [11,21]. An analysis of the official epidemiological data released by the government of India suggested [21] that a rise in new cases was recorded by February 2021; however, the rate of increase of new cases was slow until the beginning of March and was not reflective of an imminent second wave. A distinct new wave was not in view before the end of March when a sudden spurt was recorded in new cases. The rise in new cases then continued throughout April and peaked by the end of the first week of May 2021, when all global records were surpassed, reporting more than 0.4 million new cases daily. As early as April 2021, nearly 7 million new COVID-19 cases were recorded from the 19 million cases recorded in India during the pandemic. In addition, more than 48,000 deaths occurred in April, of 0.2 million deaths due to COVID-19 reported at that point in India [22]. A sudden rise in cases nationwide [21] shocked the health response system. The first COVID-19 wave, as in other parts of the world, was driven by WT strains in India [21]. The first variant with significantly increased transmissibility and lethality was the Alpha variant, which turned out to be a dominant strain by 2020 [21]. The Alpha variant caused a frequent increase in daily cases across the Indian states. In between, multiple other variants were also reported; however, none of those variants were able to contribute to a significant COVID-19 wave until the arrival of the Delta variant [21]. The first case of the Delta variant was reported in India by December 2020 [21]; however, an exclusive rise in Delta cases was only evident by the end of March 2021 [21]. The Delta variant–driven second wave continued for months, only seeing a decline in July 2021 [21].

As per the official estimates in September 2022, more than 3.4 million cases and 0.52 million deaths were recorded in India, and more than 89 million COVID-19 tests (632,930 per million population) and 200 million vaccinations (at least a single dose) were recorded in India [23]. Notably, the second wave contributed significantly to the total cases and deaths [21].

Plausibly higher transmissibility and virulence of the Delta variant and a lack of substantial vaccination at the time of the second wave could have been the likely reasons for the massive surge in new cases [4,11,21].

This study analyzed the shift in demographic and clinical characteristics of the COVID-19 pandemic in the Indian population with the emergence of the SARS-CoV-2 Delta variant compared with the WT strain (B.1).

Methods

Data Collection and Processing

A cross-sectional study was conducted to study the critical differences in demographic and clinical characteristics of the SARS-CoV-2 B.1.617.2 (Delta) variant infections compared with those caused by the WT B.1 strain (Wuhan strain with the D614G mutation) in the Indian population. Genomic sequencing

XSL•FO

RenderX

of the virus strain isolated from patient samples is a standard method for confirmatory diagnosis of COVID-19 and identification of the causative SARS-CoV-2 variant. We analyzed the patient metadata information attached to the genomic sequence reports for the SARS-CoV-2 Delta and WT (B.1) strains detected in the patient samples from the Indian population. The SARS-CoV-2 genomic sequence reports from India (patient sample collection date no later than July 31, 2021) were accessed from the EpiCoV database of the Global Initiative on Sharing All Influenza Data (GISAID) [24] using the automatic search function for information by geographical location, SARS-CoV-2 lineage, and collection dates. A similar search strategy was used to retrieve comparative metadata for the COVID-19 cases with the WT B.1 strain reported on GISAID since the first COVID-19 wave. The metadata files of the Delta variant (test group) and WT (control group) strain sequences were downloaded from the individual GISAID accession numbers, checked and confirmed for accuracy of the lineage information, and screened for demographic details (age and sex) and vaccination status (for 2 complete doses). Further, the clinical outcomes (information about the illness severity and mortality during the disease course) of the WT and Delta variant strains cases were assessed using a repeat search entering "patient status" as additional input. The collected data were filtered by discarding the sequence reports containing no or incomplete information and duplications (repeat sequencing from the same individuals). To prevent selection bias in the data collection, no specific filters for age, sex, date of collection, and geographical location were used during the search. A team of 3 investigators rechecked and verified the sampling and data entry errors of the complete data set by matching the original details in the metadata files.

The sample size for the study was guided by serosurvey reports from the Indian population during successive waves of the pandemic [25,26]. Of note, nationwide seroprevalences of 24.1% and 67.6% were reported in the studies conducted at the end of the first and second waves, respectively [25,26]. Considering a minimum of 24.1% seroprevalence in the current population of India (approximately 1.35 billion) at 5% relative precision (1.25% absolute precision) and 95% CI, a minimum sample size of 4866 was determined for the study.

Data Analysis and Presentation

Quantitative Variables

The final data were entered in Excel sheets, and the distribution was analyzed by age and sex. The age distribution of the Delta variant infections was presented at 10-year intervals. Additionally, for the analysis of clinical outcomes, all cases were divided into 3 broad age groups as follows: "young" (0-19 years), "adult" (20-59 years), and "older adult" (≥60 years).

Clinical Outcomes

Clinical outcomes of the positive cases were categorized as "asymptomatic/mildly symptomatic" (including cases in home isolation and/or quarantine with no overt symptoms or mild symptoms), "symptomatic/hospitalized" (including cases with overt symptoms, currently hospitalized, or released or recovered

after hospitalization), and "demised." These were also the significant outcomes assessed in this study.

Data Distribution and Analysis, Statistical Assessment, and Graphical Presentation

Individual outcomes were analyzed by age and sex distribution. To determine mortality, the statuses of all the categories other than "demised" were considered "living." Categorical data are presented as frequency or proportion. Continuous data are presented as mean (or median) and SD. The relative contribution of the geographical locations within India (states and union territories) in the total available genomic data from India in the study period was noted; however, no further distinction of specific geographical locations was made while analyzing the final data.

Statistical tests were performed to evaluate intergroup differences in clinical outcomes with the help of Microsoft Excel 2019 and the XLSTAT package. The normality of the data was examined using the Kolmogorov-Smirnov test. For normally distributed data, 2-sample Student t tests and ANOVAs were used. The Games-Howell post hoc test was applied for intergroup comparisons. The Kruskal Wallis H test was used to analyze skewed data. The chi-square test was used for categorical variables. Multinomial logistic regression analysis was used to estimate the relative measures of effect, considering "demised" and "symptomatic/hospitalized" as the clinical outcomes in reference to the Delta variant versus the WT (B.1) strain. No specific theoretical nor statistical criteria were adopted for "age"; however, "B.1" for the virus strain and "men" for sex were set as the baseline or reference in the regression model.

Results were considered statistically significant at a P value ≤.05. Graphs were plotted to visualize the data trends.

Ethical Considerations

Approval from the institute ethics committee was precluded, as the study used open-access data from the EpiCoVTM database from the GISAID [24]. GISAID permits open access to data to all individuals who agree to identify themselves and follow the GISAID sharing mechanism governed by its Database Access Agreement [27].

Results

Incidence

We assessed the genomic sequence reports for 8269 and 3767 cases with the Delta variant and WT B.1 strains, respectively, that were uploaded on GISAID from the first case to July 31, 2021. The SARS-CoV-2 genomic sequences were noted from nearly all the Indian states and union territories (Figure S1 in Multimedia Appendix 1). After filtering the data, 6238 Delta variant and 3262 WT B.1 strain cases were available for demographic analysis.

Among the screened cases, there were 24 Delta infections following 2 complete vaccine doses; however, no postvaccination infections were noted with B.1. In the database, 659 and 320 sequence reports with information on "patient status" were present for Delta and B.1 strains, respectively, and after filtering the data, 647 and 276 cases, respectively, were

available for analysis regarding illness severity and mortality in terms of age and sex.

Demographic Distribution

Frequent incidences of Delta variant as well as B.1 strain infections (N=6238) were noted across the age groups, including in the young group (0-19 years; Figure 1). The prevalence of infections was higher with the Delta variant than with the B.1 strain in the young group (0-19 years), with the highest difference in prevalence in those aged 0 years to 9 years followed by those aged 10 years to 19 years (*P*<.001). Conversely, the differences in prevalences were relatively low

in those aged 20 years to 60 years, with a few exceptions (*P*<.001; Figure 1). Although a greater proportion of men were infected with both variants (both sexes: N_{Delta}=6238; N_{WT} =3262) than women (Delta: 3681/6238, 59% vs 2557/6238, 41%; WT: 2088/3262, 64% vs 1174/3262, 36%), the proportion of women contracting infection was higher with Delta than with B.1 (Delta: 2557/6238, 41% vs B.1: 1174/3262, 36%; *P*<.001). The mean ages when infected with the Delta variant were 37.9 (SD 17.2) years for men and 36.6 (SD 17.6) years for women and when infected with the B.1 strain were 39.6 (SD 16.9) years for men and 40.1 (SD 17.4) years for women (*P*<.001).

Figure 1. Demographic distribution of SARS-CoV-2 B.1.617.2 (Delta) variant versus the wild type (WT) strain (B.1) infections in Indian population.
Patient Status

The cases were noted for all categories for the Delta variant as well as B.1 (asymptomatic/mildly symptomatic: N_{Delta}=72, N_{WT}=24; symptomatic/hospitalized: N_{Delta}=262, N_{WT}=130; living but symptom status not known: N_{Delta}=228, N_{WT}=102; demised: N_{Delta} =85, N_{WT}=20). The demographic (age groups and sex) distributions by patient status are shown in Figure S2 in Multimedia Appendix 1.

Symptomatic Illness and Hospitalization

The cases who developed symptoms and required hospitalization were reported in each age group, including the young group (0-19 years) for both strains (Figure 2A). However, the young group (0-19 years; Delta: 27/262, 10.3% vs B.1: 5/130, 3.8%; *P*=.02) contributed to the increased proportion of the total

number of symptomatic or hospitalized cases with the Delta variant. Further, higher proportions of young (Delta: 37/262, 14.1% vs B.1: 4/130, 3.1%) and adult (Delta: 197/262, 75.2% vs B.1: 72/130, 55.4%) women, but not men, developed symptoms and required hospitalization with the Delta variant than with B.1 (*P*<.001; Figure 2B). The mean ages at developing symptoms or hospitalization for men and women were 39.6 (SD 17.4) years and 35.6 (SD 16.9) years, respectively, with the Delta variant and 47 (SD 18) years and 49.5 (SD 20.9) years, respectively, with the B.1 strain (*P*<.001). However, in the multinomial logistic regression model, the risk of symptomatic illness or hospitalization was marginally higher for those of a lower age, with borderline statistical significance (odds ratio [OR] −1.1992, 95% CI 0.95-0.99; *P*=.046) for both strains. The viral lineage (OR 0.695, 95% CI 0.415-1.166; *P*=.17) and sex (OR 1.052, 95% CI 0.659-1.679; *P*=.83) had no significant effect on the estimates (Table 1).

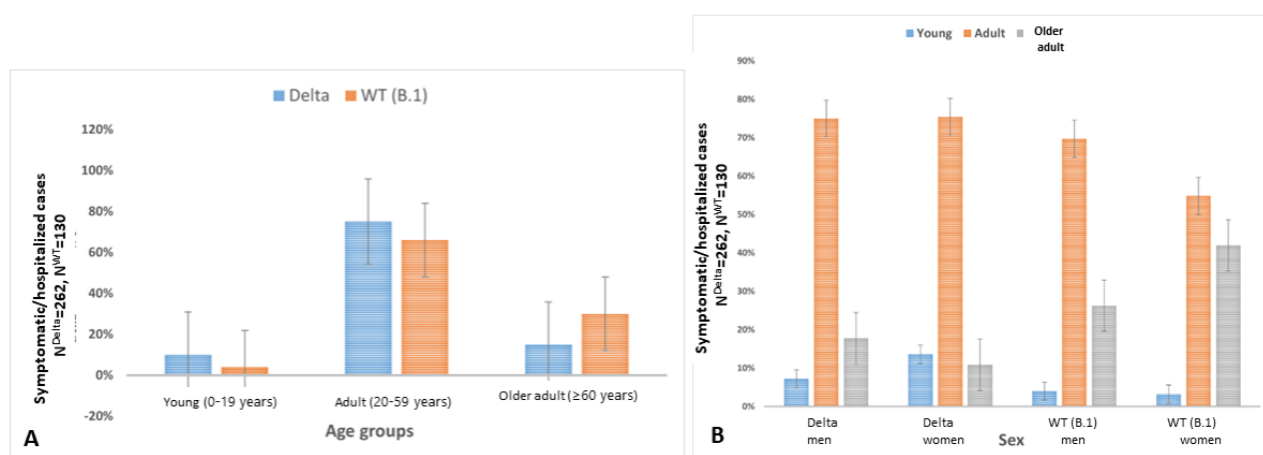
Figure 2. Distribution of symptomatic or hospitalized cases with SARS-CoV-2 B.1.617.2 (Delta) variant or wild-type (WT) strain (B.1) infections by (A) age (*P*=.02; statistical significance set at *P*<.05) and (B) sex (*P*<.001; statistical significance set at *P*<.001).


Table 1. The viral and host factors influencing the clinical outcomes of death and symptomatic illness or hospitalization.

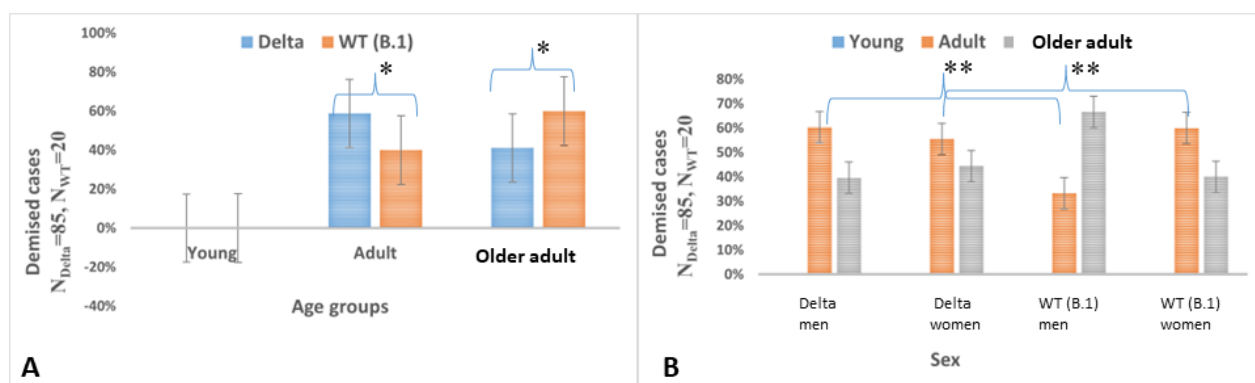
Clinical outcome and predictors	*z* distribution	*P* value	Odds ratio (95% CI)
Death			
SARS-CoV-2 lineage: B.1[a]-Delta	3.93	<.001	3.034 (1.744-5.277)
Age	–9.10	<.001	0.934 (0.920-0.947)
Sex: men[a]-women	–1.11	.27	0.765 (0.477-1.227)
Symptomatic illness or hospitalized			
SARS-CoV-2 lineage: B.1[a]-Delta	–1.378	.17	0.695 (0.415-1.166)
Age	–1.992	.046	0.977 (0.956-0.999)
Sex: men[a]-women	0.213	.83	1.052 (0.659-1.679)

[a]Reference predictors: SARS-CoV-2 lineage, age, and sex.

Total Mortality and Odds of Death

Of the total cases, approximately 13.1% (85/647) and 7.2% (20/276) died due to COVID-19 caused by the Delta and B.1 strains, respectively. However, no deaths were reported for the Delta variant nor B.1 strain in those aged <20 years (Figure 3A). Further, the adult group contributed to a higher mortality with Delta variant infections than with B.1 strain infections (50/85, 59% vs 8/20, 40%; *P*=.01). When the adult and older adult age groups were analyzed together, there was greater mortality for men than women with the Delta variant (men: 58/85, 68% vs women: 27/85, 32%) and B.1 strain (men: 15/20, 75% vs women: 5/20, 25%; *P*<.001; Figure 3B). Notably,

mortality with the Delta variant was lower for men (Delta: 58/85, 68% vs B.1: 15/20, 75%) but higher for women (Delta: 27/85, 32% vs B.1: 5/20, 25%) than with the B.1 strain (*P*<.001). The mean ages at illness-related mortality for men and women were 56.6 (SD 13.5) years and 58.8 (SD 11.4) years, respectively, with the Delta variant and 60.7 (SD 15.5) years and 50.2 (SD 15.7) years, respectively, with the B.1 strain (*P*<.001). The odds of death were higher with Delta variant infections irrespective of sex (OR 3.034, 95% CI 1.7-5.2; *P*<.001). Age but not sex influenced the effect estimates. Lower age was marginally protective (OR 0.934, 95% CI 0.92-0.95; *P*<.001) with both strains (Table 1).

Figure 3. Distribution of demised cases with SARS-CoV-2 B.1.617.2 (Delta) variant versus wild type (WT) strain (B.1) infections by (A) age and (B) sex. *Statistical significance set at $P<.05$; **statistical significance set at $P<.001$.


Postvaccination Infections

Of all the screened cases with the Delta variant or B.1 strain, Delta infections following 2 complete doses of vaccines did occur (24/6238: men=12, women=12); however, no postvaccination infections were noted with B.1 (0/3262). Postvaccination infections with the Delta variant were reported across the age groups (except for those aged 0-9 years or 10-19 years, which is explained by the fact that COVID-19 vaccines were not administered to individuals younger than 18 years in India until the period of this study) and for both sexes (Figure 4). The mean ages at postvaccination infection were 44.48 (SD 16.17) years for all cases, 40.4 (SD 11.9) years for men, and 47.8 (SD 20.4) years for women. No significant differences were noted in the frequency of postvaccination infections in terms of age groups and sex. Of all postvaccination infections, 88% (21/24) were with Covishield [28], and the rest (3/24, 12%) were with Covaxin [29].

Figure 4. Demographic distribution of postvaccination (2 complete doses) SARS-CoV-2 B.1.617.2 (Delta) variant infections.
Discussion

Principal Findings

Our analyses revealed essential observations indicating a shift in clinical and epidemiological characteristics of the COVID-19 pandemic from the WT strain B.1 to the Delta variant. With the Delta variant, more young individuals (<20 years) and adult women contracted the infection. In addition, an increased proportion of the young (<20 years) and adult population developed symptoms and required hospitalization. The mean age at COVID-19 infection and developing symptomatic illness or hospitalization was considerably lower. A disproportionate number of cases who developed symptomatic illness or were hospitalized was noted by sex: An increased proportion of young and adult women was affected. The mortality rate was about

1.8 times higher. Sex-specific contributions to the mortality data were lower for men but higher for women. However, the odds of death increased with age, irrespective of sex. Further, we noted multiple COVID-19 infections with the Delta variant following 2 complete vaccine doses.

Studies analyzing the demographic characteristics of the Delta variant in the Indian population are currently scarce. Recently, Kumar et al [30] presented their observations on the Indian population using data from the national clinical registry for COVID-19. The authors studied the clinical profiles of hospitalized patients during the second COVID-19 wave, mainly driven by the Delta variant [11,21]. Authors have also studied hospitalized cases in the first COVID-19 wave, primarily caused by WT strains [11,21]. However, the diagnosis of COVID-19 in cases included in this study was based on polymerase chain reaction test results, and no viral genomic sequencing was performed to ensure that the analyzed cases only represented those caused by the Delta variant or WT strains in the respective waves. The authors noted a decrease in the mean age of the total population who contracted infection and a reduction in the proportion of cases who were men during the second wave. The authors noted that mortality among hospitalized patients was 13.26% in the second wave, which was 3.1% higher than in the first wave. The increase in mortality was seen in all age groups in their study except for those aged <20 years, for whom mortality decreased [30]. We observed a similar trend in the susceptibility for contracting infection and risk of mortality in terms of age and sex, except we noted greater total mortality with the Delta variant (13.1%) than with the WT strain (7.2%). However, no deaths with either strain were noted in those aged <20 years in this study.

India is one of the world's most populated countries, with a very high proportion of young people (approximately 45% are <20 years old) [31]. Our analyses show that, in comparison with B.1, Delta variant infections have occurred at considerably higher proportions in those <20 years old, particularly for those aged 0 years to 9 years (Delta: 4.5% vs B.1: 2.3%). The proportion of symptomatic cases and those requiring hospital admission was also higher in the young group (Delta: 10% vs B.1: 4%; Figure 2A). These findings indicate an age shift for the Delta variant, as COVID-19 infections with the WT strains were not common in young people and development of severe symptoms and the need for hospitalization were primarily limited to adults, more specifically older adults [17,18].

We observed that a higher proportion of women than men contracted the infection and developed symptoms or were hospitalized; in addition, mortality was lower in men but higher in women with the Delta variant than with the B.1 strain. Biologically, the severity of illness and mortality risks are considered lower for women than men for infectious diseases that affect mammals, including humans [32]. A higher vulnerability for contracting infection and symptomatic disease for women and narrowing the sex gap in mortality risk with the Delta variant present a paramount epidemiological concern.

Increased involvement of the younger age groups, primarily those aged 0 years to 19 years and of the female sex, in Delta variant infections compared with WT strains was indicated by

studies and surveillance reports in the United Kingdom following a surge in Delta variant infections [8,33]. Despite the established immunological advantage for younger individuals [19,20,34] and women [16], as were reflected in infections with WT strains [16,18], increased risks of contracting infection and greater illness severity in these demographic groups indicate enhanced virulence and lethality with the Delta variant.

Last, the multiple Delta variant infections following 2 complete doses of COVID-19 vaccines in our study are supported by previous reports of vaccine breakthrough infections with this variant, including those from the Indian population [9,35].

The findings of this study and others describing demographic and clinical involvement in Delta variant infections confirm a shift from the established pattern for WT strains. Multiple factors could contribute to this epidemiological shift, most importantly, the variant's intrinsic properties, such as increased transmissibility, virulence, and immune escape capabilities, as have been indicated by recent studies [7-9,11,30,36]. A sudden spurt in the number of cases during the second wave and consequent burden on the emergency health response system could have contributed to the increased mortality noted with the Delta variant. In contrast, the prioritized vaccination of those aged >45 years might have protected the vaccinated older adult population and contributed to lowering the mean age for COVID-19 involvement. On the other hand, in the initial period of the first COVID-19 wave, there was a shortage of diagnostic and COVID-19 care facilities and skilled health personnel in the country as well as limited knowledge about the prevention and therapeutic management of the pandemic. When combined, these limitations might have had an impact on the quality of the available epidemiological and clinical data related to WT strains.

Limitations of the Study

Our study has multiple limitations that must be considered when interpreting the findings. First, our data for reporting postvaccination infections and patient status are limited; hence, related observations may require further validation from studies with a larger sample size. Second, the vaccination status data were unavailable in most of the accessed genomic sequence reports; hence, our data for postvaccination infections do not reflect the incidences of such cases in the total population. Our study does not rule out that actual incidences of postvaccination infections (after 2 complete doses) with the Delta variant could be higher. In addition, the noted 0 postvaccination infections with B.1 in our study could be an underestimation, as COVID-19 vaccines were yet to be made available to the masses in India during the first wave when the WT strains caused most of the infections.

Moreover, owing to the limited availability of vaccination status details for the screened cases in the studied database, we cannot comment conclusively on the efficacy of the vaccines noted in this study. Third, we have not considered the influence of confounding factors, such as comorbidities, vaccination status, and previous COVID-19 infection, on the clinical outcomes of the studied cases, which may have influenced the quality of the results. Last, although we applied no age, sex, nor region-specific filters when acquiring the data, a complete absence of selection bias cannot be assured when uploading the

primary data on GISAID. However, any inherent bias in the primary data will likely be nondifferential and may not significantly impact the comparative analysis between the viral strains.

greater mortality, and frequent postvaccination infections with the Delta variant than with the WT (B.1) strain. Collectively, the findings of this study elaborate on the changing demographic characteristics of the COVID-19 pandemic with the emergence of the Delta variant. These findings are essential because we have only considered in the analyses those COVID-19 cases for whom Delta variant infections were confirmed by genomic sequencing, ensuring the accuracy of the presented data.

Conclusions

In conclusion, our study reveals greater proportions of infected young individuals and women, a lower mean age for illness,

Acknowledgments

This study used SARS-CoV-2 genomic sequence data from the EpiCoV database of the Global Initiative on Sharing All Influenza Data (GISAID) [24].

Data Availability

The primary data for this study are publicly available on the SARS-CoV-2 genomic sequence-GISAID database [24]. The tabulated data can be obtained from the corresponding author upon reasonable request.

Authors' Contributions

AK designed the study and wrote the first draft of the manuscript. KR, RKN, RKJ, AS, GK, and PD performed the data collection and analysis. AA performed the statistical analyses. AA, RKN, CS, CK, MK, RM, GK, HK, KS, SNP, RP, KK, and SK reviewed and edited the manuscript. All authors consented to the submission of the final draft.

Abstract

Background: There has been a global decrease in seasonal influenza activity since the onset of the COVID-19 pandemic.

Objective: We aimed to describe influenza activity during the 2021/2022 season and compare it to the trends from 2012 to 2023. We also explored the influence of social and public health prevention measures during the COVID-19 pandemic on influenza activity.

Methods: We obtained influenza data from January 1, 2012, to February 5, 2023, from publicly available platforms for China, the United States, and Australia. Mitigation measures were evaluated per the stringency index, a composite index with 9 measures. A general additive model was used to assess the stringency index and the influenza positivity rate correlation, and the deviance explained was calculated.

Results: We used over 200,000 influenza surveillance data. Influenza activity remained low in the United States and Australia during the 2021/2022 season. However, it increased in the United States with a positive rate of 26.2% in the 49th week of 2022. During the 2021/2022 season, influenza activity significantly increased compared with the previous year in southern and northern China, with peak positivity rates of 28.1% and 35.1% in the second week of 2022, respectively. After the COVID-19 pandemic, the dominant influenza virus genotype in China was type B/Victoria, during the 2021/2022 season, and accounted for >98% (24,541/24,908 in the South and 20,543/20,634 in the North) of all cases. Influenza virus type B/Yamagata was not detected in all these areas after the COVID-19 pandemic. Several measures individually significantly influence local influenza activity, except for influenza type B in Australia. When combined with all the measures, the deviance explained values for influenza A and B were 87.4% (*P*<.05 for measures of close public transport and restrictions on international travel) and 77.6% in southern China and 83.4% (*P*<.05 for measures of school closing and close public transport) and 81.4% in northern China, respectively. In the United States, the association was relatively stronger, with deviance-explained values of 98.6% for influenza A and 99.1% (*P*<.05 for measures of restrictions on international travel and public information campaign) for influenza B. There were no discernible effects on influenza B activity in Australia between 2020 and 2022 due to the incredibly low positive rate of influenza B. Additionally, the deviance explained values were 95.8% (*P*<.05 for measures of restrictions on gathering size and restrictions on international travel) for influenza A and 72.7% for influenza B.

Conclusions: Influenza activity has increased gradually since 2021. Mitigation measures for COVID-19 showed correlations with influenza activity, mainly driven by the early stage of the pandemic. During late 2021 and 2022, the influence of mitigation management for COVID-19 seemingly decreased gradually, as the activity of influenza increased compared to the 2020/2021 season.

Introduction

Seasonal influenza is an epidemic disease caused by the influenza virus with a high burden and severity. The World Health Organization (WHO) and the Centers for Disease Control and Prevention of most countries jointly coordinate influenza surveillance and report weekly data on human seasonal influenza viruses, including the activities of A (H1N1), A (H3N2), B/Victoria, and B/Yamagata. Data obtained through virology surveillance in temperate locations have demonstrated a consistent seasonal pattern with this seasonality being weaker in subtropical and tropical locations [1].

The WHO declared the COVID-19 pandemic on March 11, 2020. Accordingly, governments worldwide launched different levels of mitigation strategies. Subsequently, several northern-hemisphere countries showed a notable decrease in the acute respiratory tract infection or influenza-like illness (ILI) consultation rates at the end of the 2019/2020 season and during the 2020/2021 season compared with the rates in previous years [2-4]. In 2020, there were decreased influenza burdens and activity in southern-hemisphere countries, which varied among the countries [5]. In China, compared to the average levels during 2012-2019, the positive rate of influenza virus decreased during 2020 with changes of –87.6% [6]. Similar variations have been observed for other respiratory viruses in China and the United States [6,7].

Decreased influenza transmission dynamics during the 2019/2020 season mainly resulted from the public health and social measures implemented to mitigate the COVID-19 pandemic [8,9]. The reducing outpatient ILI consultations in cities of China were also caused by the mitigation measures [10]. Influenza activity and seasonal patterns were influenced by COVID-19, and the activity of these 2 diseases suppressed and competed with each other, showing a seesaw effect [11]. The study also found that population susceptibility increased in both China and the United States, which might lead to large, high-intensity influenza outbreaks in the 2022/2023 season [12]. Furthermore, the lack of exposure to influenza together with unpredictable antigenic changes may have reduced population immunity, which could lead to a more severe influenza season after the COVID-19 mitigation measures are lifted [13].

Prior to the COVID-19 pandemic, influenza virus subtypes and lineages were cocirculated and the predominant subtypes varied each year, while after the pandemic the B/Victoria lineage dominated in 2020/2021 in Chongqing, China [14]. Large changes occurred in influenza subtype distribution during the pandemic, including the sharp decrease in the global prevalence of B/Yamagata viruses and a temporal increased prevalence of B/Victoria virus in the Western Pacific Region [15]. The unexpected activities of these viruses were potential risks. Therefore, there is a need to elucidate variations in the epidemiology and transmission characteristics of the influenza virus since the COVID-19 pandemic [16]. Meanwhile, it is necessary to monitor and update knowledge on the circulation types and subtypes to prepare for future outbreaks [17]. Moreover, given the uncertainty regarding incoming influenza strains and the influence of COVID-19 prevention measures, it is important to perform surveillance of influenza activity and reevaluate the influence of COVID-19 measures on it. Using influenza surveillance data collected from the WHO, we aimed to describe the epidemiologic characteristics of influenza from 2012 to 2023 as well as to explore the correlation between influenza activity and public health and social measures.

Methods

Data Collection

We obtained influenza data from January 1, 2012, to February 5, 2023 (data download on February 17, 2023) for the countries and areas of the United States, and Australia from the publicly available platform WHO FluNet, which is remotely provided by the National Influenza Centers of the Global Influenza Surveillance and Response System (GISRS). We also obtained data for the southern and northern areas of China from the Chinese National Influenza Center database. We analyzed data differently by region in China because influenza epidemiologic features differ between the South and North [8]. Meanwhile, the 2 regions have different climatic characteristics. We chose these areas because they are members of WHO Collaborating Centers, meanwhile, the United States and Australia are also members of the WHO Essential Regulatory Laboratories within GISRS, and we believed that there would be accurate data reported to the GISRS from these areas. Meanwhile, China, the United States, and Australia were selected as countries representing each of the 3 WHO transmission zones, where each zone covers a geographical group of countries with different influenza transmission patterns [18]. China and the United States both include tropical, subtropical, and temperate zones, and they are part of the Eastern Asia influenza transmission zone, and the North America influenza transmission zone, respectively. Australia is mainly temperate and located in the Oceania, Melanesia, and Polynesia influenza transmission zones. The influenza activity from 2012 to 2023 is detailed in Figure 1, Table 1, and Multimedia Appendix 1. Then the influenza-positive rates among surveillance samples are further illustrated in Figure 2, and the proportion of influenza subtypes is detailed in Figure 3.

Figure 1. Seasonal influenza activity from 2012 to early 2023 with virus types or subtypes across different areas. Surveillance data are obtained from WHO FluNet and the Chinese National Influenza Center database.

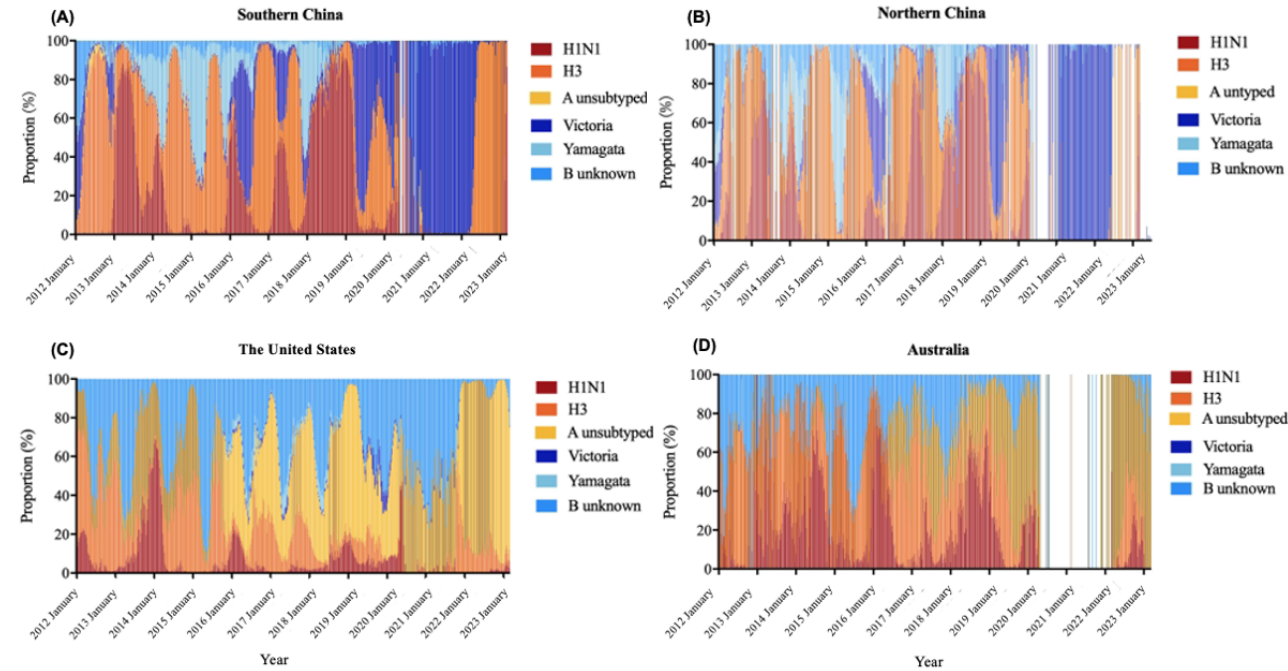
Figure 2. Influenza activity after the COVID-19 pandemic in China, the United States, and Australia. Surveillance data are obtained from WHO FluNet and the Chinese National Influenza Center database. The dark red and red dot lines indicate positivity rates of 10% and 5%, respectively.
Figure 3. Influenza virus subtypes distribution from 2012 to early 2023 among different areas. (A) Southern China. (B) Northern China. (C) The United States. (D) Australia. Red indicates the presence of the H1N1 influenza virus. Orange indicates the H3 influenza virus. Yellow indicates the unsubtyped influenza A. Dark blue indicates the influenza virus of the Victoria lineage. Light blue indicates the influenza virus of the Yamagata lineage. Blue indicates an unknown influenza virus of type B. The white areas indicate no reported cases of influenza from Australia to the FluNet during the period from 2020 week 17 to 2022 week 6, and no reported cases to the Chinese National Influenza Center database from 2020 week 16 to 2020 week 53 in China.


The stringency index (SI) is a composite index for measuring the strictness of "lockdown style" policies that primarily restrict people's behaviors, and it is rescaled to a value from 0 to 100 (100=strictest). It was proposed by the Balavatnik School of Government, University of Oxford [19]. The SI is calculated using 9 metrics as follows: C1, school closing; C2, workplace closing; C3, cancel public events; C4, restrictions on gathering size; C5, close public transport; C6, "shelter-in-place" and home confinement orders; C7, restrictions on internal movements;

C8, restrictions on international travel; and H1, public information campaign. Each index for all the 9 strategies was calculated and acquired from the publicly available platform proposed by the Balavatnik School of Government, University of Oxford [20]. This data was downloaded on September 27, 2023, and updated until December 31, 2022. Further analysis of the correlation between influenza activity and SI was detailed in Tables 2 and 3, Figure 4, and Multimedia Appendix 1.

Table 2. Influence of individual management measure on influenza virus A and B activity in China, the United States, and Australia during 2020-2022[a].

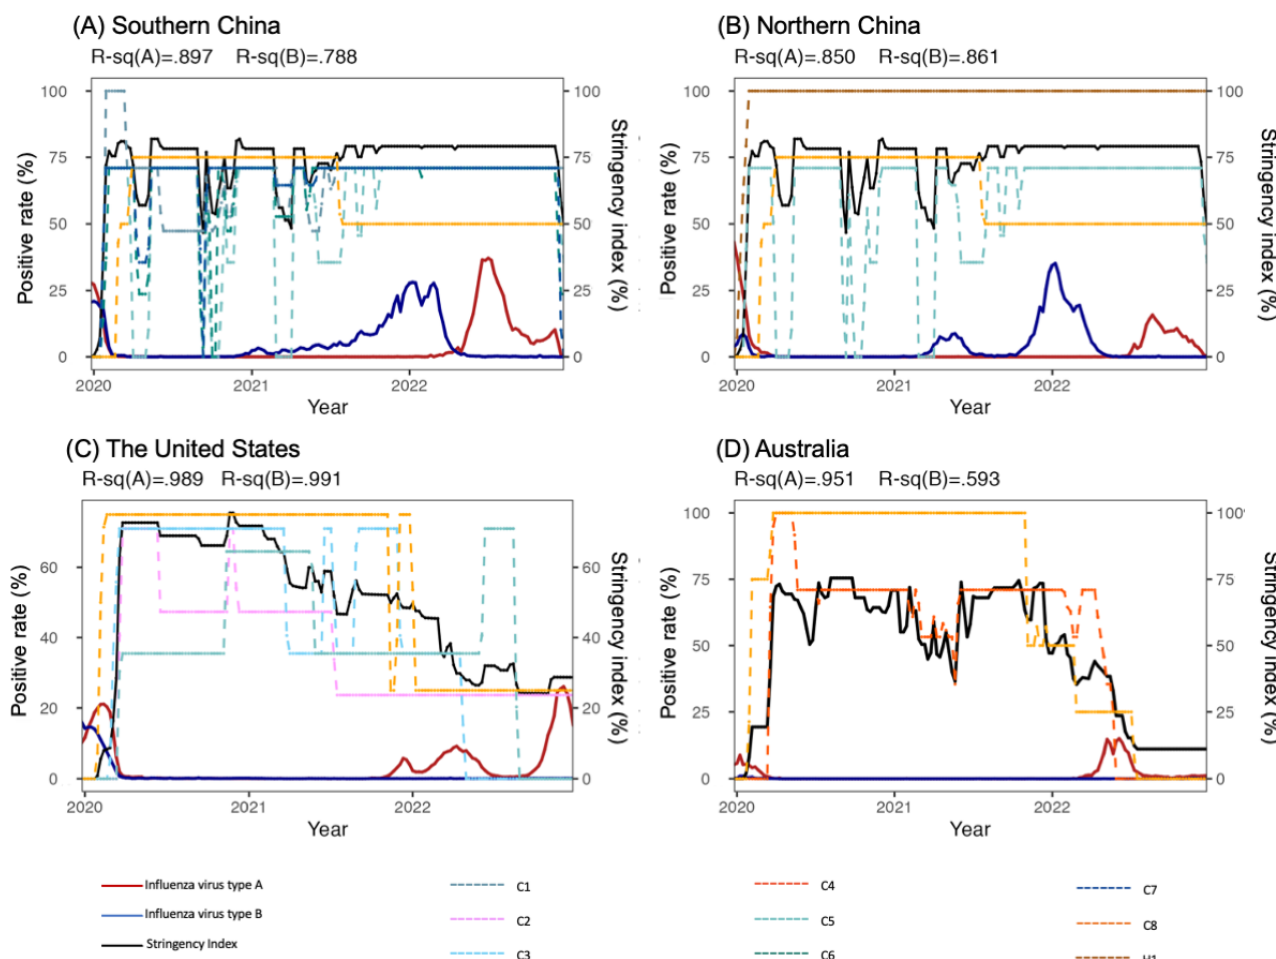
Figure 4. Correlation between the stringency index and the influenza positivity rate in different countries or areas since the COVID-19 pandemic. (A) Southern China. (B) Northern China. (C) The United States. (D) Australia. The dark line represents the stringency index. The red line represents the positivity rate of influenza type A, and the blue line represents the positivity rate of influenza type B. R-sq(A) represents the determination coefficient between influenza type A and the stringency index. In contrast, R-sq(B) represents the determination coefficient between influenza type B and the stringency index. Dashed lines indicate different management measures, including C1, C2, C3, C4, C5, C6, C7, C8, and H1. The measures that significantly affected influenza activity are displayed in the figure. C1: school closing; C2: workplace closing; C3: canceling public events; C4: restrictions on gathering size; C5: closing public transport; C6: stay-at-home requirements; C7: restrictions on internal movement; C8: restrictions on international travel; H1: public information campaign.


Related Definitions

All of these 3 areas test for influenza virus through ILI cases, and different countries followed their own definition for the diagnosis of ILI. An ILI case in China is defined as a fever (temperature ≥38 ℃) with a cough or sore throat [21]. ILI in the United States is defined as a fever (temperature of 100 °F [37.8 °C] or greater) and a cough or a sore throat [22]. The Communicable Diseases Network Australia guidelines define ILI as a triad of fever ≥38 °C, respiratory symptoms, and systemic symptoms [23]. The WHO case definition for ILI is an acute respiratory tract infection with temperature ≥38 ℃ and cough, with onset within the last 10 days [23].

The number of specimens that tested positive for influenza virus (with confirmation of the type and subtype) is presented as a percentage of the total number of tested specimens. An influenza positivity rate of ≥10% and <10% for ≥2 consecutive weeks indicates the start and end of seasonal influenza activity, respectively. Weeks were defined using the International Organization for Standardization 8601 standard weeks. Each

season was analyzed from week 40 of the previous year to week 39 of the next year in China and the United States, and for Australia, it was from the 45th week of the previous year to the 44th week of the next year.

Statistical Analysis

Heat maps were applied to depict the influenza virus subtypes epidemiologic characteristics from 2012 to early 2023 (Figure 1). The influenza virus subtypes proportion was illustrated from 2012 to early 2023, and graphs were generated by Prime 8 (version 8.3.1; GraphPad Software, LLC; Figure 3). In the current analysis, we used the SI as an index for the evaluation of public health and social measures (Tables 2 and 3, Figure 4, and Multimedia Appendix 1). The value of the index is the average of 9 subindices about the individual policy indicators, each taking a value from 0 to 100. The Balavatnik School of Government provided daily SI, and the daily SI data were converted to weekly averages to be consistent with the ILI data, detailed in Multimedia Appendix 1. The general additive model was used to assess the correlation between the SIs (defined as an independent variable, X_i) and the influenza-positive rate

(defined as the dependent variable, Y_t). The deviance explained was calculated to estimate the contribution value of the independent variable to the dependent variable, and the determination coefficient (R^2) was calculated to assess the goodness of fit of the models (Multimedia Appendix 1).

Statistical analyses were conducted using R (version 4.2.3; The R Foundation). Statistical significance was set at $P<.05$.

Ethical Considerations

This study was conducted with data from publicly available platforms, where the data were published. The research involves the use of collections of information or data from which all personal identifiers have been removed before being received by the researchers. Additionally, according to the ethical requirement from China (article 32), the United States (page 4), and Australia (section 5, article 5.1.17), the research using these data may be eligible for a grant of exemption from ethics review [24-26].

Results

Characteristics Regarding Seasonal Influenza Activity From 2012 to Early 2023

We used over 200,000 influenza surveillance data in the current analysis. In mainland China, the United States, and Australia, the influenza activity showed obvious seasonal peaks previous to the COVID-19 pandemic. Figure 1 shows the distribution of all influenza genotypes from 2012 to 2023 (Figure 1). The influenza epidemiologic features in these 4 regions differed before and during the pandemic, and the new epidemiologic features are also different in each area. Since the COVID-19 pandemic, there has been a gradual decrease in the influenza positivity rate, which was <10% in China and Australia by the time WHO declared COVID-19 a pandemic (Figure 2). The influenza positivity rate remained <5% during the 2020/2021 season in all 4 regions. Influenza activity remained low in the United States, and Australia during the 2021/2022 season, with peak positivity rates of 9.2% (mainly influenza A), 7682 of 83,426 surveillance samples, in week 15, 2022, and 15.1% (mainly influenza A), 1460 of 9662 surveillance samples, in week 24, 2022, respectively. During the 2021/2022 season, influenza activity significantly increased compared with the previous year in southern and northern China, with peak positivity rates of 28.1% (mainly influenza B), 1471 of 5244 surveillance samples, and 35.1% (mainly influenza B), 1738 of 4946 surveillance samples, in the second week of 2022, respectively, and with 2 seasonal influenza activity peaks during winter and summer in northern instead of southern China (Figure 2 and Table 1).

For China, the influenza season durations were significantly shorter during the 2019/2020, and 2020/2021 seasons, however, the durations tended to be similar to the prepandemic during the 2021/2022 season (22 weeks in the south and 17 weeks in the north). The influenza season durations were significantly shorter during the 2020/2021 (0 weeks) and 2021/2022 seasons (0 weeks) in the United States, and during the 2019/2020 (0 weeks), 2020/2021 (0 weeks), and 2021/2022 seasons (7 weeks) in Australia (Table 1). For China and Australia, compared to the 2020/2021 season, the influenza season duration was much longer, and the activity peaks were higher during the 2021/2022 season (Table 1). For the United States, influenza activity increased with a positivity rate of over 10% at the end of 2022 (Figure 2).

Variations in the Features of the Influenza Virus Since the COVID-19 Pandemic

Figure 3 details the influenza virus types and subtypes. During the last 8 prepandemic years, type A was the dominant influenza virus genotype for most of the time in all 3 areas. The dominant influenza virus genotype after the COVID-19 pandemic gradually became type B (mainly Victoria) in China during the winter of 2021/2022 (proportion >98%, 24,541/24,908 in the South and 20,543/20,634 in the North). Then in April 2022, type B/Victoria was decreased. However, type A (H3) became the dominant subtype (proportion >99%) in southern China (18,667/18,822) first and in northern China (3268/3278) later. Contrastingly, the dominant influenza virus genotype during the 2021/2022 season was type A in the United States and Australia (proportion >90%, 153,735/155,565 and 8752/8769, respectively) for the 2 countries. In all these 4 areas, influenza virus type B/Yamagata has not been detected since the COVID-19 pandemic.

Correlation of Public Health and Social Measures for COVID-19 With Seasonal Influenza Activity

Seasonal influenza activity was impacted by the COVID-19 pandemic. We analyzed the correlation between the SI and the influenza positivity rate (Tables 2 and 3, and Figure 4). All 9 management measures were individually evaluated and detailed in Table 2. Most of these measures significantly affected the positive rate of influenza types A and B. However, for influenza B in Australia, measures C1 (school closing), C5 (closing public transport), and C6 (shelter-in-place and home confinement orders) affected the positive rate without significant differences (Table 2).

We further analyzed the combined effect of all measures on influenza-positive rates (Table 3 and Figure 4). When combined, measures C1 (school closing), C5 (closing public transport), C6 (shelter-in-place and home confinement orders), C7 (restrictions on internal movements), and C8 (restrictions on international travel) significantly affected influenza A or B activity ($P<.05$) in southern China. In northern China, C1 and C5 significantly affected influenza (both A and B) activity ($P<.05$), and C8 significantly affected influenza B activity ($P<.05$). The deviance explained value for influenza A was 87.4% and for influenza B was 77.6% in southern China, while for influenza A and B in northern China, it was 83.4% and 81.4%, respectively. In the United States, C2 (workplace closing), C3 (cancel public events), C5, and H1 (public information campaign) significantly affected the influenza A positive rate, and C8 and H1 affected the positive rate of influenza B. The correlation between the SI and influenza activity was relatively stronger, with deviance-explained values of 98.6% for influenza A and 99.1% for influenza B in the United States (Table 3). In Australia, C5 and C8 affected influenza A activity significantly ($P<.05$). As the positive rate of influenza B was extremely low from 2020 to 2022, no

significant effects were found on the influenza B activity. The correlation between the SI and the influenza positivity rate in Australia was 95.8% for influenza type A and 72.7% for influenza type B. However, despite the high level of the SI in China, influenza activity increased in 2021 compared to 2020.

Discussion

Principal Results

We analyzed influenza surveillance data from China, the United States, and Australia to describe influenza activity within 10 years before and after the COVID-19 pandemic. The implementation of public health and social measures in China and the United States contributed to decreased influenza activity during the 2019/2021 season [7,8]. However, we observed a gradual increase in influenza activity starting from the beginning of 2021 reaching 28.1% (1471/5244) in southern China and 35.1% (1738/4946) in northern China by the second week of 2022. Contrastingly, influenza activity in the United States, and Australia during the 2021/2022 season remained low, even though it was slightly higher than during the 2020/2021 season (Figure 2 and Table 1). However, by the end of 2022 and early 2023, influenza activity increased in the United States, with a positivity rate of 26.2% in the 49th week of 2022. Notably, the dominant influenza virus genotype since the COVID-19 pandemic in China, especially during the 2021/2022 season, was type B/Victoria, which then transformed to type A (H3) in April 2022. The dominant virus was type A in the United States and Australia during 2022 and early 2023. Postpandemic variations in influenza activity were correlated with the public health and social measures for COVID-19. However, it is important to consider that there may be other factors affecting influenza activity and emerging as new epidemiological features.

In Canada, surveillance data obtained during the 2021/2022 season revealed persistent sporadic influenza activity, with the predominant virus subtype being A (H3N2) [27]. Similarly, type A (H3) was predominant in the United States, with laboratory-confirmed influenza showing a low positivity rate during the 2021/2022 season. However, the positivity rate increased at the end of 2022 and then decreased at the beginning of 2023. In Australia, type A (H3) was dominant in May and June 2022, and then the influenza positivity decreased and maintained a low level until 2023. China showed unique changes in the dominant influenza virus type, which was type B/Victoria during the 2021/2022 season. Another study found that before the COVID-19 outbreak, influenza A viruses dominated in China, whereas influenza B/Victoria viruses dominated during the 2020/2021 season [15]. Our results underscored that type B/Victoria dominated in China until April 2022, with a positivity rate of over 25% in both southern and northern regions during the 2021/2022 winter. During the influenza season, type B usually results in mild symptoms and less frequent epidemics and has never caused pandemics in humans [28]. The epidemiological characteristics of influenza during the 2021/2022 season in China, specifically before January 2022, included single-type spreading and a relatively higher activity peak compared to the previous year. These characteristics could be attributed to restricted inbound travels and within-country

transmission, which was also the dominant transmission mechanism for COVID-19 in China [29]. As results displayed in our study, in China during 2020-2021, the SI remained at a high level. However, the restrictions on population internal movements were fluctuant, and sometimes even measures such as "restrictions on internal movements" or "close public transport" were canceled (Figure S1 in Multimedia Appendix 1). This led to the emergence of influenza cases in 2021, albeit at a low level. Compared to domestic movement mitigation, the mitigation of international travel had a larger effect [30]. The measure of restrictions on international travel significantly affected the activities of influenza in China, and the positive rate of influenza (B/Victoria) increased by over 10% after the relaxation of international travel in 2021 (Figure 4 and Table 3). Influenza type A (H3N2) first emerged in southwestern China in early 2022, extensively spreading in southern China, and finally reaching northern China in July 2022. It may have entered China from Southeast Asia.

Currently, promoting vaccination coverage remains the primary strategy for controlling influenza [31]. The COVID-19 pandemic increased the likelihood of receiving an influenza vaccine in the United States [32], England [13], and Australia [33]. However, in China, the influenza vaccination rate remains low; moreover, parental acceptance of childhood vaccination is still low (29% in northwestern China) [34]. This could explain the relatively higher influenza activity in China compared with the United States, and Australia.

The low influenza activity during the 2020/2021 season is mainly attributable to public health and social measures [8]. A modeling study predicted that influenza activity would return to prepandemic levels during the 2021/2022 season after easing the current mitigation measures for COVID-19 [35]. Even though significant correlations between the SI and influenza positivity rates were found in Australia and the United States, these correlations were mainly driven by the early phase of the pandemic and fluctuations in mitigation measures during 2022. Although we observed a relatively higher influenza activity peak during the 2021/2022 season in China, the local mitigation measures were still strictly implemented, as indicated by the SI. The potential explanation might be that the SI was a composite index, and the high number of SIs for China might be driven by international travel controls instead of restrictions on internal movements (Figure S1 in Multimedia Appendix 1). However, there are differences in the effectiveness of various mitigation measures in reducing virus transmission. For example, a previous study showed that mask-wearing was more effective than mitigating travel or movement, while interventions targeting international travel were more effective than those targeting domestic travel [30]. Implementing optimized strategies with composite measures would help in quickly responding to unpredictable respiratory infectious diseases. Furthermore, it is necessary to evaluate the effectiveness of different measures, which can help establish optimized strategies in the future.

There are immunopathological similarities between the influenza virus and SARS-CoV-2 [36]. Additionally, influenza vaccination is associated with reduced susceptibility to or severity of COVID-19 [37]. Therefore, the observed correlations in this

study might not be limited to the influence of public health and social measures. Multi-pathogen mutual interference might also play an important role in current influenza activities. During the current unstable phase, it is important to monitor influenza and other respiratory pathogens' activities simultaneously. Rapid integration of multi-pathogen testing and surveillance would help prevent emerging pathogens from evolving into another pandemic [38]. Currently, it is crucial and timely to track the activity of influenza and re-evaluate the effect of COVID-19 mitigation measures, because as the pandemic progresses and after, more factors will emerge that affect influenza activity. Meanwhile, it is also essential to strictly surveil the seasonal influenza activity and the variation of pathogens because the COVID-19 pandemic influenced the features of seasonal activities.

Limitations

This study has several limitations. First, the evaluation of the effect of other measures, such as mask-wearing, was not supported by the currently available data, despite their reported significant impact on influenza activities. Second, we did not consider climate and environmental factors. In the early stage of the COVID-19 pandemic, public health and social measures had the strongest influence on influenza activity [6]. However, temperature, wind speed, and a particulate matter level of 2.5 also influence the transmission of some respiratory infectious diseases [39].

Conclusions

This study provides an updated report on influenza activity in 4 areas from 2012 to early 2023, as well as the impact of public health and social measures for COVID-19 on influenza activity. Our findings indicate an increase in influenza activity in these 3 countries. While there were correlations between mitigation measures for COVID-19 and influenza activity, the main driving force was the early stage of the pandemic. The role of mitigation management in influencing influenza activity varied across different stages of the pandemic and among different countries. It is crucial to maintain vigilance to prevent influenza and other respiratory pathogens from causing epidemics. Further studies are warranted to investigate the reasons behind the variations in dominant virus subtypes across regions and to assess the influence of individual mitigation measures, climate factors, and the activity of other pathogens on influenza.

Data Availability

Data on influenza activity are available on the WHO FluNet and data on the SI are available on the website of the Balavatnik School of Government, the University of Oxford. Processed datasets used in this analysis are available from the corresponding author upon reasonable request.

Abstract

Background: There is a lack of investigation into the dynamics of blood lipids before, during, and after diurnal fasting, especially in inactive men.

Objective: This study determined dynamic changes in blood lipids in inactive men before, during, and after they underwent diurnal fasting.

Methods: A total of 44 young men aged a mean 27.6 (SD 5.8) years were recruited to evaluate their habitual physical activity and diet using a questionnaire developed for this study. Body composition was evaluated using a bioelectrical impedance analysis machine (Tanita BC-980). An 8-ml blood sample was collected to evaluate blood lipids and glucose. All measurements were taken 2-3 days before Ramadan, during Ramadan (at week 2 and week 3), and 1 month after Ramadan. A 1-way repeated measures ANOVA was used to compare the measured variables before, during, and after the month of Ramadan. When a significant difference was found, post hoc testing was used. Differences were considered significant at $P<.05$.

Results: There was a significant reduction in low-density lipoprotein during Ramadan compared to before and after Ramadan (83.49 mg/dl at week 3 vs 93.11 mg/dl before Ramadan [$P=.02$] and 101.59 mg/dl after Ramadan [$P=.007$]). There were significant elevations in fasting blood glucose (74.60 mmol/L before Ramadan vs 81.52 mmol/L at week 3 [$P=.03$] and 86.51 mmol/L after Ramadan [$P=.01$]) and blood pressure (109 mm Hg before Ramadan vs 114 mm Hg after Ramadan; $P=.02$) reported during and even after the month of Ramadan, although both fasting blood glucose and blood pressure were within normal levels.

Conclusions: Ramadan fasting could be an independent factor in reducing low-density lipoprotein. Further investigations are encouraged to clarify the impact of diurnal fasting on blood lipids in people with special conditions.

Introduction

Ramadan is a lunar month that varies between 29 and 30 days. The world's Muslim population is about 1.5 billion [1] and is expected to increase to 2.2 billion by 2030 [2]. Ramadan fasting is a form of religious diurnal fasting in which adult Muslims abstain from having food and drink (unless necessary) during the daylight hours, from dawn to sunset. The average diurnal fasting time during Ramadan month is 15 (SD 3) hours per day, depending on the season and the country's geographical location.

During the month of Ramadan, Muslims usually change their daily lifestyle [3,4]. Muslim adults usually become less active during Ramadan, especially in the daytime compared to the nighttime [5-7]. These changes, in addition to diurnal fasting, may negatively affect health-related blood biomarkers. Previous evidence concluded that metabolic disease biomarkers, including blood lipids, were elevated in women and urban residents [6]. Genetic factors are key in metabolic disease biomarkers, including high blood cholesterol, in different ethnic groups [8]. For example, some studies reported heritability of up to 70% for genes involving high-density lipoprotein (HDL) [9]. Diurnal fasting has been found to improve blood lipids [4,5,10,11].

The negative role of physical inactivity on blood lipids is evident. Physical inactivity has been found to play a key role in developing cardiovascular and metabolic disease risk factors such as obesity [12-15]. In a recent study conducted with young Saudi medical students, one of the most common risk factors of cardiovascular and metabolic disease was physical inactivity (57.9%) [16]. Insufficient physical activity is responsible for around 10% of all deaths globally, and sedentary behavior (SB) costs global health care organizations billions of dollars each year. Furthermore, the accumulation of low-density lipoprotein (LDL) cholesterol in artery walls causes narrowing of the arteries, which may lead to the development of cardiovascular disease (CVD) [17].

The number of studies investigating the association between Ramadan fasting and health promotion dramatically increased from 2010 to 2021, with 1276 studies being published [18]. Although there is robust available evidence exploring the impact of Ramadan fasting on health-related biomarkers, reports on the effect of diurnal fasting on blood lipids in inactive adults are scattered [5,11,18-20]. The impact of fasting during Ramadan on body composition and physiological parameters has been widely investigated [21-24]. During the month of Ramadan, people may achieve a significant reduction in body fat mass and blood lipids such as LDL. Some studies did not report significant improvement in triglyceride (TG) levels and fasting blood glucose (FBG) [23]. On the other hand, some blood and metabolic changes that occur during Ramadan fasting are temporary [21,25,26]. It seems that the positive change in LDL levels as a result of diurnal Ramadan fasting is one of these temporary changes [25]. The major changes in blood parameters observed in previous studies could have been due to the lifestyle of participants [22,24].

Despite the results of previous studies, there are few recent studies that investigated the impact of fasting in the month of Ramadan (this fasting lasts about 15 hours during the daytime) during the summer season, where temperatures reach a mean 45 ℃ (SD 3 ℃) during the daytime and about 35 ℃ (SD 5 ℃) during the night. Thus, the main aim of this study was to investigate the dynamics of blood lipids before, during, and after diurnal fasting in inactive men in hot environments.

Methods

Participants

This quasi-experimental pre-post design study was conducted at 4 different time points (before Ramadan, at week 2 and week 3 during Ramadan, and after Ramadan). A total of 44 inactive male students (mean age 27.6, SD 5.8 years) were recruited to participate in this study. Inclusion criteria were being male, an adult (aged 18-39 years), and inactive, that is, performing less than the recommended level of physical activity (PA) for adults (150 min of moderate PA per week, 75 min of vigorous PA per week, or an equivalent amount of moderate-to-vigorous PA per week). Smokers or individuals taking medicines that may have affected the results were excluded from participating in this study. The sample size was calculated based on the change in LDL concentration reported in a previous study [27] with the 95% CI and 80% power for the test. The estimated sample size was 38 participants. The number of recruited participants was increased by about 10% to prevent the results being affected by withdrawals or incomplete data; thus, 44 apparently healthy inactive male students were recruited to participate in this study.

Ethical Considerations

A consent form was read and signed by each participant before taking part in this study. Ethical approval was obtained from the Deanship of Graduate Studies and Scientific Research at King Saud University (CSSPA-22-07-35). The participants did not receive any compensation. All data were saved anonymously in a safe and confidential format by the principal investigator.

Procedures

Each participant was instructed by the principle investigator to visit the laboratory on the same day of the week on all 4 occasions. The measured variables were obtained at each visit. The first visit was 2 to 3 days before the month of Ramadan, and the second and third visits were in the second week and third week of Ramadan. The fourth visit took place 6 weeks after the month of Ramadan. The procedures of this study were performed consistently as described in the following sections.

Physical Characteristics

Body mass (BM), height, and waist circumference (WC) were measured. BMI was calculated by dividing body weight in kilograms by height in meters squared (kg/m^2). Fat-free mass (FFM), body fat (BF) percentage, and total body water (TBW) percentage were evaluated using bioelectrical impedance analysis (BC-418; Tanita) [28].

PA and Diet Assessment

PA and diet behavior were evaluated using a valid and reliable self-reported questionnaire for the assessment of PA and diet behavior in youth aged 15 to 25 years [29]. Each participant was instructed on how to fill out the PA and diet questionnaire. The questionnaire provided continuous variables (time in minutes). The average time to complete the questionnaire was 10 minutes. The diet behavior section assessed the type and frequency of the consumed food.

Physiological and Lipid Profile

Resting heart rate (HR) and blood pressure (BP) were recorded following 10 minutes of being seated on a chair. All participants were instructed to fast at least 10 hours before attending the laboratory for blood collection. A venous blood sample of 8 ml was drawn by a phlebotomist to evaluate blood lipids, including TG, total cholesterol (TC), HDL, and LDL. Blood samples were analyzed in a specialized medical laboratory at the university.

Statistical Analysis

Data from this study were analyzed using SPSS (version 24.0; IBM Corp). Results were illustrated as means with SDs. A 1-way repeated measures ANOVA was used to compare the measured variables before, during, and after the month of Ramadan. The Tukey post hoc test was used when a significant difference was found. The χ^2 test was used to determine the statistical significance of associations between food consumed per week for participants across all trials. Results were considered statistically significant at $P<.05$.

Results

The main aim of this study was to investigate the dynamics of blood lipids before, during, and after diurnal fasting in inactive men. Table 1 shows the physical characteristics of the participants before, during, and after Ramadan. This study did not observe significant changes in any of the body composition variables, including BM, BMI, WC, BF mass, BF percentage, FFM, FFM percentage, and TBW between all measured occasions.

Table 1. Measurements of body composition at the 4 time points (N=44).

Body composition measurements	Before Ramadan, mean (SD)	Ramadan week 2, mean (SD)	Ramadan week 3, mean (SD)	After Ramadan, mean (SD)	F test (df)	P value
Body mass (kg)	70.0 (12.6)	69.6 (12.4)	69.6 (12.8)	69.9 (12.9)	0.03 (43)	.99
BMI (kg/m^2)	24.5 (4.0)	24.3 (4.0)	24.3 (3.8)	24.3 (4.0)	0.04 (43)	.99
Waist circumference (cm)	82.9 (10.9)	82.3 (10.6)	81.8 (10.5)	81.8 (11.0)	0. 10 (43)	.96
Body fat mass (kg)	14.7 (6.6)	14.0 (6.9)	13.9 (6.8)	14.5 (6.9)	0.13 (43)	.94
Body fat percentage (%)	20.2 (6.2)	19.5 (6.7)	19.4 (6.6)	19.7 (6.5)	0.22 (43)	.88
Fat-free mass (kg)	55.3 (8.6)	55.6 (6.9)	55.5 (7.5)	55.8 (7.3)	0.04 (43)	.99
Fat-free mass percentage (%)	79.8 (6.2)	80.5 (9.0)	80.6 (6.7)	80.3 (6.5)	0.13 (43)	.94
Total body water (liters)	40.1 (6.0)	41.6 (6.8)	40.5 (5.8)	40.6 (5.4)	0.49 (43)	.69
Total body water percentage (%)	56.9 (7.2)	59.0 (5.0)	59.3 (5.3)	58.9 (5.0)	1.56 (43)	.20

Physical Activity

Based on the PA guidelines (moderate-to-vigorous PA ≥150 min/week for ≥5 days/week or ≥70 min/week for ≥3 days/week) [30], participants were physically inactive. Moreover, there was no significant change in PA level across the 4 time points (99.8, SD 210.9; 125.7, SD 260.4; 111.0, SD 275.4; and 56.7, SD 151.0 minutes before Ramadan, in the second and third weeks of Ramadan, and after Ramadan, respectively; Table 2). The average sedentary time of the participants was less than 6 hours (ranging from 5.2, SD 1.9 to 5.8, SD 2.2 h/day) across all 4 time points.

Table 2. Physical activity levels across all 4 time points (before Ramadan, in the second and third weeks of Ramadan, and after Ramadan; N=44).

Physical activity and sleeping time	Before Ramadan, mean (SD)	Ramadan week 2, mean (SD)	Ramadan week 3, mean (SD)	After Ramadan, mean (SD)	F test (df)	P value
Moderate activity (min/wk)	50.9 (121.7)	64.4 (137.6)	50.2 (154.51)	34.6 (89.5)	0.40 (43)	.75
Vigorous activity (min/wk)	48.9 (108.4)	61.3 (143.9)	60.8 (162.4)	22.2 (76.0)	0.92 (43)	.43
Moderate + vigorous (min/wk)	99.8 (210.9)	125.7 (260.4)	111.0 (275.4)	56.7 (151.0)	0.74 (43)	.53
Sedentary behavior (h/day)	5.8 (2.2)	5.2 (1. 9)	5.7 (3.0)	5.5 (2.6)	0.56 (43)	.64
Sleeping duration (h/day)	6.9 (1.0)	6.6 (1.1)	6.7 (1.0)	6.3 (1.1)	2.58 (43)	.06

Diet Behavior

Diet behavior was reported by evaluating types and frequencies of consumed food. Diet behavior is one of the essential factors that could have impacted this study's outcomes. Thus, participants' diet behavior was evaluated across all 4 time points.

Table 3 demonstrates the consumed food per week at all 4 time points. The frequency of the consumed food was classified into 3 categories: no more than twice per week, 3 to 5 times per week, and ≥6 times per week. There were no significant changes in the frequency of consumed food per week across the 4 time points.

Table 3. Percentage of consumed food per week for participants across all 4 time points (before Ramadan, in the second and third weeks of Ramadan, and after Ramadan; N=44).

Food types	Frequency of consumed food per week (participants), n (%)			Chi-square (df)	P value
	<2 times/w	<3-5 times/w	>6 times/w		
Vegetables	12 (28)	17 (40)	14 (32)	3.97 (43)	.68
Fruit	9 (21)	21 (48)	14 (32)	9.11 (43)	.17
Milk and dairy products	13 (30)	18 (40)	13 (30)	5.62 (43)	.47
Soda and soft drinks	19 (44)	15 (34)	10 (22)	11.37 (43)	.08
Energy drinks	39 (89)	4 (10)	2 (1)	3.90 (43)	.27
Fast food	19 (43)	18 (43)	6 (14)	6.20 (43)	.40
Chips and french fries	20 (46)	17 (40)	6 (14)	3.70 (43)	.72
Biscuits and cake	24 (55)	11 (26)	9 (20)	11.97 (43)	.22
Chocolate and sweets	16 (36)	13 (31)	14 (33)	9.30 (43)	.16

Physiological and Blood Parameters

Physiological and blood parameters, including resting HR, BP, and blood lipids, were analyzed. The results of this study showed a significant effect of diurnal fasting on both FBG and LDL (Figure 1). Furthermore, a significant elevation was recorded in systolic blood pressure (SBP) 1 month after Ramadan compared to before Ramadan (109 mm Hg before Ramadan vs 114 mm Hg after Ramadan). Similarly, FBG was slightly elevated during week 3 of Ramadan and after Ramadan compared to before Ramadan (74.60 mmol/L before Ramadan, 81.52 mmol/L at week 3, and 86.51 mmol/L after Ramadan). However, the results showed an obvious reduction in LDL during week 3 of Ramadan compared to before and after Ramadan month (83.49 mg/dl at week 3 vs 93.11 mg/dl before Ramadan [P=.02] and 101.59 mg/dl after Ramadan [P=.007]).

Figure 1. The effect of Ramadan fasting on resting heart rate (HR), systolic blood pressure, diastolic blood pressure, glucose, total cholesterol, triglyceride, high density lipoprotein (HDL) and low-density lipoprotein (LDL), (n=44).
Discussion

Principal Findings

The impact of diurnal fasting during the month of Ramadan on blood lipids in inactive men was limited but positive and very obvious for LDL. Although there were no significant changes in PA or SB across all trials (P=.53 for moderate-to-vigorous PA; P=.64 for SB), some blood lipids, such as LDL, may be affected positively during fasting in the month of Ramadan. The novelty of this study was controlling for the main related factors that may affect blood lipid variables. In contrast, this study did not find significant changes in the participants' diet behavior across the investigated time points (all P>.05). In general, the findings of this study may help inactive individuals control blood lipids, especially LDL, while fasting diurnally.

Body Composition

All body composition variables investigated in this study did not change significantly across any of the 4 time points. The novelty of this study was examining the impact of Ramadan fasting in a hot and dry environment (≥45 ℃) on blood lipids. In this study, body mass, BMI, and WC decreased gradually, especially during the third week of Ramadan, compared to before Ramadan. However, the recorded reduction was not significant (P=.88 for BF percentage, P=.94 for FFM percentage, P=.20 for BW percentage, P=.99 for both BM and BMI, and P=.96 for WC). While some previous studies have reported significant decreases in body composition parameters at the end of Ramadan compared to measurements taken before Ramadan [21], numerous previous studies have concurred with the findings of this study [7,25,26,31-33]. In fact, the results of this study are reasonable, as most of the participants were within normal weight. However, some studies have reported a reduction in BW due to a decrease in skeletal muscle mass and FFM [34]. Furthermore, the significant reduction in body composition in the previous literature may be linked to the obesity status of the participants [35]. The majority of the participants in this study were within normal body composition measurements. Therefore, the impact of Ramadan fasting may not influence body composition in individuals with normal body composition [36]. Focusing on apparently healthy men could be one of the limitations of this study. Further studies in different ages and genders are encouraged to understand the impact of diurnal fasting on body composition parameters.

Physiological and Blood Parameters

The results for both SBP and FBG were elevated significantly during the month of Ramadan (P=.02 and P=.01, respectively), especially during the end of Ramadan (week 3) compared to levels before Ramadan. These findings concur with previous studies [22,37]. However, the elevated values of SBP and FBG were within the healthy range (SBP: 109 mm Hg before Ramadan vs 114 mm Hg after Ramadan; FBG: 74.60 mmol/L before Ramadan vs 81.52 mmol/L at week 3 and 86.51 mmol/L after Ramadan). One novel aspect of this study was the impact of diurnal fasting on LDL, as there were no significant changes in the main factors that may impact LDL concentration, such as body composition, PA, and diet behavior. Thus, diurnal fasting itself could be an independent factor that positively improved LDL. Our findings concur with the results of a previous study that investigated the impact of Ramadan fasting on college students [23,36,38]. However, it seems that the observed positive, significant change in LDL concentration as a result of diurnal fasting during the month of Ramadan was temporary [25,38]. The novelty of this study is its examination of the impact of diurnal fasting on blood lipids in inactive men with a stable lifestyle. Blood biomarkers, including blood lipid concentration, may be positively improved by diurnal fasting. However, this study discovered that the changes in blood lipid variables were limited in healthy but inactive young men. The major changes in blood parameters observed in previous studies may refer to the nature of participants' lifestyles [22,24,39]. Further investigations are encouraged to clarify the impact of diurnal fasting on blood lipids in people with special conditions, such as older age and obesity.

This study has some limitations. First, it was conducted with apparently healthy young adult men. Second, physical activity was not assessed by an objective measurement such as an accelerometer. Third, some other confounders were not evaluated, such as the total energy expenditure and basal metabolic rate of the participants. Moreover, the sample size of the study may not have been enough to detect differences between the time points.

Conclusion

Diurnal intermittent fasting seems to be an independent factor that could improve blood lipids, including LDL, even in healthy but inactive adults. Moreover, diurnal fasting has been found to decrease LDL even in inactive adults with normal LDL levels. However, the results of this study concur with previous studies in terms of the temporary effect of diurnal fasting during the month of Ramadan on blood lipids. More research is encouraged to examine the impact of Ramadan fasting in people with special health conditions, such as obesity or older age.

Abstract

Background: The integration of artificial intelligence (AI) into health care has the potential to transform the industry, but it also raises ethical, regulatory, and safety concerns. This review paper provides an in-depth examination of the benefits and risks associated with AI in health care, with a focus on issues like biases, transparency, data privacy, and safety.

Objective: This study aims to evaluate the advantages and drawbacks of incorporating AI in health care. This assessment centers on the potential biases in AI algorithms, transparency challenges, data privacy issues, and safety risks in health care settings.

Methods: Studies included in this review were selected based on their relevance to AI applications in health care, focusing on ethical, regulatory, and safety considerations. Inclusion criteria encompassed peer-reviewed articles, reviews, and relevant research papers published in English. Exclusion criteria included non–peer-reviewed articles, editorials, and studies not directly related to AI in health care. A comprehensive literature search was conducted across 8 databases: OVID MEDLINE, OVID Embase, OVID PsycINFO, EBSCO CINAHL Plus with Full Text, ProQuest Sociological Abstracts, ProQuest Philosopher's Index, ProQuest Advanced Technologies & Aerospace, and Wiley Cochrane Library. The search was last updated on June 23, 2023. Results were synthesized using qualitative methods to identify key themes and findings related to the benefits and risks of AI in health care.

Results: The literature search yielded 8796 articles. After removing duplicates and applying the inclusion and exclusion criteria, 44 studies were included in the qualitative synthesis. This review highlights the significant promise that AI holds in health care, such as enhancing health care delivery by providing more accurate diagnoses, personalized treatment plans, and efficient resource allocation. However, persistent concerns remain, including biases ingrained in AI algorithms, a lack of transparency in decision-making, potential compromises of patient data privacy, and safety risks associated with AI implementation in clinical settings.

Conclusions: In conclusion, while AI presents the opportunity for a health care revolution, it is imperative to address the ethical, regulatory, and safety challenges linked to its integration. Proactive measures are required to ensure that AI technologies are developed and deployed responsibly, striking a balance between innovation and the safeguarding of patient well-being.

Introduction

Artificial intelligence (AI) has rapidly proliferated across various sectors in recent years, with the health care industry emerging as a primary arena for its transformative potential. This technological advancement holds promise for revolutionizing patient care and administrative operations by leveraging vast longitudinal patient data [1]. AI encompasses a spectrum of technologies, including machine learning (ML), natural language processing (NLP), rule-based expert systems (RBES), physical robots, and robotic process automation, each offering unique capabilities from predictive modeling and disease detection to enhancing surgical precision and automating administrative

tasks [2-7]. The integration of AI into health care promises heightened diagnostic accuracy, informed decision-making, and optimized treatment planning, thereby potentially reducing medical errors and improving patient outcomes [1].

However, alongside these promising developments, AI adoption in health care is accompanied by significant ethical and regulatory challenges that require careful consideration [8]. Concerns range from safeguarding patient data privacy to addressing algorithmic biases that may perpetuate disparities in health care outcomes [9,10]. The regulatory landscape is evolving to keep pace with technological advancements, aiming to establish robust governance frameworks that ensure the responsible use of AI in health care settings. Furthermore, the advent of pretrained large language models, exemplified by models like BERT (Bidirectional Encoder Representations from Transformers), GPT (Generative Pre-trained Transformer), and their variants, has further expanded the capabilities of AI in health care [11-14]. These models leverage vast amounts of text data to learn rich representations of language, enabling tasks ranging from clinical documentation improvement to automated summarization of medical literature [15,16].

Against this backdrop, this study presents a narrative review aimed at comprehensively exploring the multifaceted role of AI in health care. By synthesizing existing literature, this research aims to provide insights into the diverse applications of AI, its associated benefits, and the ethical and regulatory considerations that underpin its integration into clinical practice [9,10,17]. This review aims to facilitate informed decision-making among health care professionals, policy makers, and researchers, fostering a balanced approach that maximizes the benefits of AI while mitigating potential risks within the health care landscape.

This review seeks to contribute to ongoing discussions on AI ethics, governance, and effective deployment strategies, thereby guiding the responsible and impactful adoption of AI technologies in health care. By examining current trends, challenges, and future directions, this review aims to lay the groundwork for advancing AI's role in enhancing health care delivery, improving patient outcomes, and supporting health care systems globally.

Methods

Overview

This narrative review aims to assess the benefits and risks associated with the integration of AI into health care, with a primary focus on potential biases, transparency issues, data privacy concerns, and safety risks. A literature review was conducted to explore the current landscape of AI applications in health care and to identify relevant ethical, regulatory, and safety considerations.

Eligibility Criteria

Specific inclusion and exclusion criteria were established to guide the selection of studies for this narrative review. Studies were included if they were relevant to the 3 core concepts of AI, ethics, and health and were written in the English language. Articles were excluded if they did not explicitly address each

of the core concepts of AI, ethics, and health or if they were not written in English. In addition, studies focusing solely on ethics and big data without explicit mention of AI methods or applications were excluded. Non–peer-reviewed academic literature, such as letters and non–peer-reviewed conference proceedings, as well as books and book chapters, were also excluded as they were deemed irrelevant to this review. No restrictions were applied regarding the publication date or study design to ensure a broad overview of the topic.

Information Sources

The literature search used 8 electronic databases: OVID MEDLINE (1946-present), OVID Embase (1947-present), OVID PsycINFO (1806-present), EBSCO CINAHL Plus with Full Text (1937-present), ProQuest Sociological Abstracts (1952-present), ProQuest Philosopher's Index (1940-present), ProQuest Advanced Technologies & Aerospace (1962-present), and Wiley Cochrane Library. Search strategies were tailored to each database (Multimedia Appendix 1), using controlled vocabulary, Medical Subject Headings (MeSH) terms, EMTREE terms, American Psychological Association's Thesaurus of Psychological Index Terms, CINAHL headings, Sociological Thesaurus, Philosopher's Index subject headings, and Advanced Technologies & Aerospace subject headings. The searches were limited to English language–only articles, and filters excluding animal studies were applied to specific databases. In addition, a filter for health or medicine-related studies was applied to the Advanced Technologies & Aerospace database.

The final searches of the peer-reviewed literature were completed on June 23, 2023. Gray literature was not searched in this narrative review.

Selection and Sources of Evidence

All identified records from the academic literature searches were imported into the reference management software EndNote (Clarivate). After removing duplicate records, screening was conducted in 2 steps: initial title and abstract screening followed by full-text review. Full-text reviews were conducted to ensure that the selected studies provided substantial insights for the narrative synthesis.

Data Charting Process

Data charting forms were developed and refined based on the narrative review research question. The forms included fields for recording data such as the objective of each paper, institutional affiliations of authors, publication year, country of the first and corresponding authors, conflict of interest disclosures, health context of interest, AI applications or technologies discussed, ethical concepts, issues or implications raised, reference to global health, and recommendations for future research, policy, or practice. Data were recorded directly into the data charting form with corresponding page numbers to ensure accuracy.

Synthesis of Results

Data analysis included thematic components. Thematic analysis was conducted inductively, generating open descriptive codes from a sample of records. Codes were applied to relevant data points across all records, with new codes added as needed. These

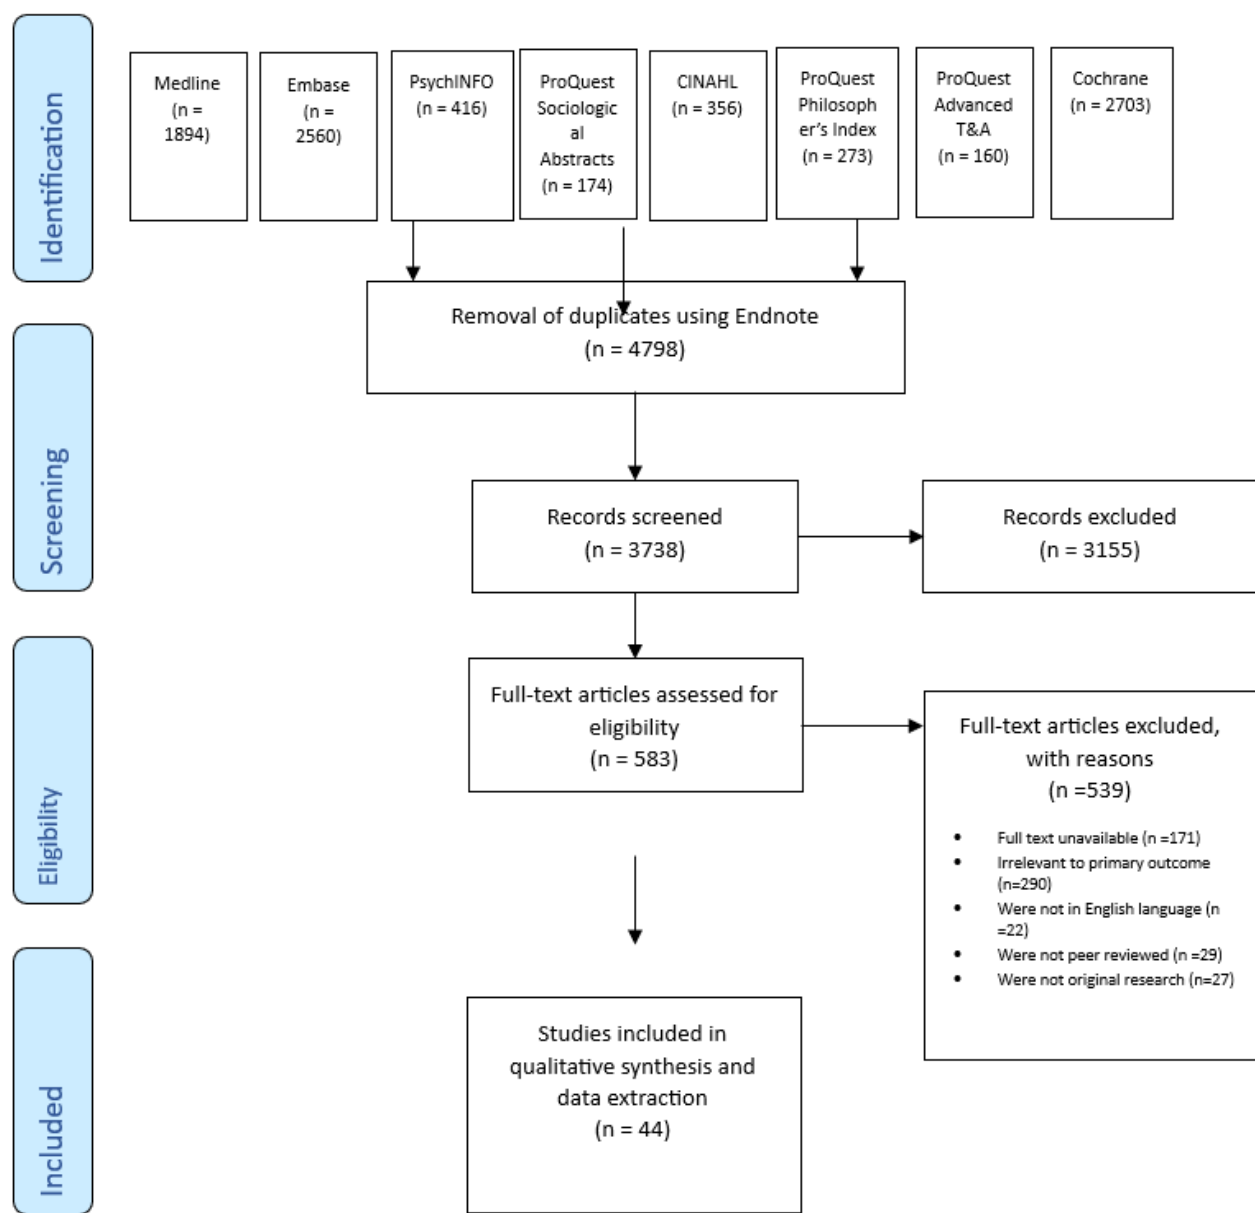
codes were then organized into themes, allowing for the identification of commonalities and gaps in the literature. Results are presented in a narrative format.

Results

Overview

Within the realm of integrating AI into health care, this narrative review has revealed a broad range of insights that span a spectrum of possibilities and challenges. This section categorizes the findings into 2 overarching categories: "Benefits" and "Risks." Each category encapsulates a tapestry of themes that emerged from an exploration of academic literature. As these themes are explored, the multifaceted landscape of AI's influence on health care is illuminated. The "Benefits" section unveils the potential for AI to revolutionize health care delivery, ushering in more accurate diagnoses, personalized treatment regimens, and streamlined resource allocation. Conversely, the "Risks" section delves into the intricate ethical, privacy, and safety concerns that accompany the integration of AI into clinical settings. Through a comprehensive examination of these themes, this review provides a nuanced perspective on the implications and imperatives in harnessing AI's potential for the betterment of health care.

The systematic literature review process, as illustrated in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 1), outlines a thorough and rigorous methodology. Initial searches across multiple databases—MEDLINE, Embase, PsycINFO, ProQuest Sociological Abstracts, CINAHL, ProQuest Philosopher's Index, ProQuest Advanced Technologies & Aerospace, and Cochrane Library—yielded a total of 8796 articles. After removing 4798 duplicates using Endnote, 3738 unique records were screened for relevance. Of these, 3155 articles were excluded based on title and abstract review for not meeting the inclusion criteria. The remaining 583 articles underwent full-text assessment for eligibility. Further evaluation led to the exclusion of 539 articles due to various reasons, such as unavailability of full text (n=171), irrelevance to the primary outcome (n=290), non-English language (n=22), not being peer-reviewed (n=29), and not being original research (n=27). Ultimately, 44 studies were included in the qualitative synthesis and data extraction. This meticulous selection process ensured that the final set of studies provided a robust and representative foundation for examining the integration of AI in health care.

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) study selection flow diagram outlining the literature review process when searching for articles on various databases.


Benefits of AI in Health Care

Textbox 1 below describes the main benefits of implementing AI in health care. The benefits are explained in detail below.

Textbox 1. Benefits of artificial intelligence (AI) in health care.

Medical benefits

- Helps in prediction of various risks and diseases

- Helps in prevention and control of various diseases

- Leads to better data-driven decisions within the health care system

- Assists in improving surgery

- Supports mental health

Economic and social benefits

- Reduction in posttreatment expenditures

- Cost saving through early diagnosis

- Cost saving with enhanced clinical trials

- Patient empowerment

- Relieving medical practitioners' workload

Medical Benefits

AI adoption in health care offers various medical, economic, and social benefits. This section discusses some of the key medical benefits of AI.

Prediction of Risks and Diseases

AI leverages big data to predict diseases and assess risk exposure among patients. For example, Google collaborates with health delivery networks to develop prediction models that alert clinicians of high-risk illnesses like sepsis and heart failure [18]. ML models can also be used to forecast populations at risk of specific diseases or accidents [19,20]. In addition, AI algorithms, such as deep learning, aid in disease classification and enable more personalized care [21].

Prevention and Control of Diseases

AI can play a significant role in the prevention and control of diseases. For instance, AI can enhance sexually transmitted infection (STI) prevention and control by improving surveillance and intervention. By analyzing publicly available social media data, AI can predict county-level syphilis prevalence, enabling faster and more efficient monitoring [22]. AI can also analyze trends in web data to reduce the stigma associated with STI prevention and care and identify and flag STI-related misinformation [22].

Data-Driven Decision Making

AI enables better data-driven decisions within the health care system. In a digitalized health care environment, the quality of decision-making relies on the availability and accuracy of underlying data [23]. AI can assist in decision-making by offering real-time recommendations based on clinical guidelines or advancements, reducing the likelihood of medical mistakes [24]. For example, IBM Watson Health uses ML to provide clinical decision support and achieved a high level of agreement with physician recommendations [25].

Improvement in Surgery

AI has made significant advancements in surgical procedures. Robotic surgery, such as in gynecologic, prostate, and oral and maxillofacial surgery, enhances surgical precision and predictability [7,26]. Telesurgical techniques driven by AI enable remote surgery and provide better supervision of surgeons [27]. AI-powered surgical mentorship allows skilled surgeons to offer real-time advice and guidance to other surgeons during procedures, improving surgical outcomes [28].

Mental Health Support.

AI use in mental health treatments is growing as patients prefer simple and quick feedback [29]. According to Lovejoy et al [30], psychiatric professionals have historically relied on therapeutic discourse and patient narrative to assess mental health since language is the primary means to communicate our emotional and mental well-being. Recent advancements in AI have opened up new perspectives on the subject by enabling technology to infer emotional meaning from more data sources [30]. According to Habermann [31], with a unique combination of NLP and sentiment analysis, data scientists have developed algorithms to comprehend human emotion from the text. Le Glaz et al [32] mentions that in recent years, NLP models have been used to track mental self-disclosure on Twitter, forecast suicide risk online, and identify suicidal thoughts in clinical notes. These models are used in medicine to give complete details about a patient's emotional and psychological health [31].

Economic and Social Benefits

In addition to the medical health benefits, using AI in health care has other economic and social advantages, as discussed below.

Reduction in Posttreatment Expenditures.

AI-powered systems can analyze posttreatment result patterns and identify the most effective remedies based on patient profiles. This personalized approach to care can significantly reduce the expenses associated with posttreatment complications, which are a major cost driver in health care

systems worldwide [33]. By providing immediate diagnosis and appropriate interventions, AI can help minimize the financial burden of posttreatment complications and lead to substantial cost savings.

Cost Saving Through Early Diagnosis.

AI has demonstrated superior accuracy and speed in analyzing medical images, such as mammograms, leading to the early detection of diseases like breast cancer. By enabling prompt diagnosis and action before issues escalate, AI can help reduce health care costs associated with late-stage diagnoses [28]. In addition, AI's ability to process and interpret various medical tests, such as computed tomography scans, with high accuracy reduces the likelihood of physician errors, contributing to cost savings.

Cost Saving with Enhanced Clinical Trials.

AI-powered programs can simulate and evaluate numerous potential treatments to predict their effectiveness against various diseases, optimizing the drug development process in clinical trials [34]. By leveraging biomarker monitoring frameworks and analyzing large volumes of patient data, AI accelerates the evaluation of potential treatments, leading to significant cost savings in the development of life-saving medications.

Patient Empowerment.

AI has the potential to empower individuals in managing their health. Wearable devices, such as smartwatches, can collect standard health data, which AI algorithms can analyze to provide personalized health recommendations and warnings for potential diseases [35]. Smartphone apps that use ML algorithms can help patients with chronic diseases better manage their conditions, leading to healthier populations and reduced health care expenses [36].

Relieving Medical Practitioners' Workload.

AI technologies can alleviate the burden on health care workers by assisting with administrative tasks, data analysis, and image interpretation. AI can automate clerical responsibilities, analyze patient data more efficiently, and aid in diagnosing various medical conditions [37,38]. By reducing manual labor and prioritizing critical cases, AI helps save time and resources for medical practitioners, ultimately leading to increased productivity and improved patient care.

Risks of AI in Health Care

The risks of AI in health care are listed in Textbox 2.

Textbox 2. Risks of artificial intelligence (AI) in health care.

Risks of AI in health care

- AI diagnosis is not always superior to human diagnosis
- AI programs may be difficult to understand and overly ambitious
- Implementation issues
- Transparency issues and risks with data sharing
- Biases
- Mistakes in disease diagnosis or AI cannot be held accountable
- Data availability and accessibility
- Regulatory concerns
- Social challenges

AI Diagnosis Is Not Always Superior to Human Diagnosis.

While AI has the potential to improve accurate diagnosis, it is not always superior to human diagnosis. Early AI systems, such as the MYCIN program developed in the 1970s, showed promise in diagnosing and treating diseases but did not outperform human diagnosticians [39]. These RBES needed better integration with clinical workflows and medical record systems to be practical and effective. In addition, AI models can suffer from overfitting, generating irrelevant correlations between patient characteristics and outcomes, which can lead to incorrect predictions when applied to new cases [40].

Challenges in Understanding and Ambition of AI Programs

Physicians may find it challenging to understand AI programs, particularly in complex domains like cancer diagnosis and treatment. IBM's Watson program, which combines ML and NLP, garnered attention for its focus on precision medicine. However, integrating Watson into care processes and systems and programming it to handle certain types of cancer has proven difficult [41]. The ambition of AI programs, such as tackling complex cancer therapy, may exceed their current capabilities.

Implementation Issues

Implementing AI in health care faces several challenges. RBES embedded in electronic health care systems are commonly used but may lack the accuracy of algorithmic systems based on ML. These RBES struggle to keep up with evolving medical knowledge and handle large amounts of data [42]. The lack of empirical evidence confirming the efficacy of AI-based treatments in prospective clinical trials hinders successful implementation [43]. Much of the AI research in health care is preclinical and lacks real-world validation [44]. Integration into physician workflow is crucial for successful implementation, but there are limited examples of AI integration into clinical

treatment, and training physicians to use AI effectively can be a time-consuming process [45].

Transparency Issues and Risks With Data Sharing

The use of intelligent machines in health care decision-making raises concerns about accountability, transparency, permission, and privacy [2]. Understanding and interpreting AI systems, such as deep learning algorithms used in image analysis, can be challenging [2]. Physicians who lack comprehension of the inner workings of AI models may struggle to communicate the medical treatment process to patients [46]. Increased reliance on AI may lead to automated decision-making, limiting the contact and communication between health care workers and patients [46].

The rapid emergence of new technologies in health care has sparked skepticism due to the risks associated with data sharing [17]. There is a need for public norms that ensure data governance and openness, as well as improve patient understanding of how and why data are used [17]. Concerns about privacy violations arise from the collection of large data sets and the potential for AI to anticipate personal information [47]. Patients may perceive this as a violation of their privacy, especially if the findings are made public to third parties [48].

Respecting patient confidentiality and acquiring informed consent for data use are ethically required [49]. AI systems should be protected from privacy breaches to prevent psychological and reputational harm to patients [49]. Recent incidents, such as the misuse of Facebook personal data by Cambridge Analytica and the sharing of patient data without explicit consent by the Royal Free London NHS Foundation Trust, have raised concerns about privacy violations [49,50].

Biases

ML systems in health care can be prone to algorithmic bias, leading to predictions based on noncausal factors like gender or ethnicity [51]. Prejudice and inequality are among the risks associated with health care AI [28]. Biases present in the data used to train AI systems can result in inaccurate outcomes, especially if certain races or genders are underrepresented [28]. Unrepresentative data can further perpetuate health inequities and lead to risk underestimation or overestimation in specific patient populations [52].

Mistakes in Disease Diagnosis and Lack of Accountability

AI systems can make mistakes in patient diagnosis and treatment, creating potential harm [28]. Holding AI systems accountable can be challenging, as liability concerns arise regarding errors and the allocation of responsibility [53]. The lack of explanation from deep learning algorithms can hinder both legal accountability and scientific understanding, potentially eroding patients' trust in the system [54].

Determining accountability for AI failures is an ongoing challenge, as holding the physician accountable may seem unjust, while holding the developer accountable may be too removed from the clinical setting [24]. The question of who should be held accountable when AI systems fail remains to be answered [24].

Data Availability and Accessibility

Large amounts of data from various sources are required to train AI algorithms in health care [55]. However, accessing health data can be challenging due to fragmentation across different platforms and systems [55]. Data availability in health care is limited, and there is often a reluctance to share data between hospitals [56]. The continuous availability of data for ongoing improvement of ML-based systems can be difficult due to organizational resistance [57]. Technological advancements and improved algorithms can help address the problem of limited data sets [57].

Regulatory Concerns

The autolearn feature of AI software poses regulatory challenges as algorithms evolve continuously with use [58]. This creates the need for additional policies and procedures to ensure patient safety [58]. Many countries have yet to formalize regulatory guidelines for assessing AI algorithmic safety, which can hinder AI adoption and lead to risky practices [59]. The lack of industry rules on the ethical usage of AI in health care further complicates the accountability issue [60]. Efforts by the Food and Drug Administration and National Health Service to establish guidelines and standards are ongoing but pose barriers to regulatory approval [60,61].

Social Challenges

Misconceptions about AI replacing health care jobs lead to skepticism and aversion to AI-based interventions [43]. However, the arrival of AI does not necessarily mean job obsolescence but rather job reengineering [62]. Overcoming skepticism and fostering trust in AI requires a better understanding of its capabilities and meaningful public discourse [62]. Improving public and health care professionals' understanding of AI is essential to managing expectations and addressing concerns.

Discussion

Principal Findings

This narrative review delves into the dynamic landscape of AI integration in health care, aiming to uncover a spectrum of perspectives, concerns, and opportunities. This exploration encompasses a diverse range of health care settings from different countries and regions, unveiling a rich tapestry of AI adoption. Overall, AI offers tremendous potential and will continue to play a crucial role in future health care decisions. If AI is successfully used, it can reduce pressure on health care workers while improving work quality by lowering mistakes and improving precision. It has the potential to give people more control over their health decisions and can lower avoidable hospitalizations. It can broaden the scope of medical knowledge and build on the present clinical guidelines. Given its advantages and capability to drive the development of precision medicine, it is universally acknowledged to be a much-needed enhancement in medicine. AI is anticipated to eventually master most of the essential domains within health care.

However, there are some difficulties associated with incorporating AI in health care. Acquiring enough data to train

precise algorithms is a continual effort that necessitates a shift in attitude towards data sharing that promotes technical advancement. Specific guidelines on how to securely adopt and evaluate AI technology and research on AI's potential and limitations are required. Robust research is also required to empirically demonstrate the benefits of AI use in the actual world. While the perfect conditions for successful AI adoption may not yet exist, there is still room for AI advancement in health care.

Given that AI has tremendous potential and is the future, there are a few crucial points to consider when using AI in health care. First, given the need for more general agreement in AI governance, it may be impossible to develop AI-based systems whose algorithms can be generalized across all health care domains. As a result, it may be wise to concentrate on systems that can be implemented and used effectively in the health care institutions for which they were designed. Fundamentally, patient care must take priority over the excitement of cutting-edge technology. The AI system's safety and competence must be weighed for use only when appropriate and valuable to patients.

Second, AI in health care must still be complemented with human input. Although AI has advantages in speed and accuracy, physicians are still needed for more cognitively complex or psychological elements and activities. Similarly, although the detection and monitoring of vital disease symptoms are now automated, the objective behind AI is not to eliminate physician input but to focus their expertise on areas where they are more necessary and on what computers cannot and may never imitate. Therefore, focusing on developing complementarity between the use of AI and physicians by training is essential.

In addition, while it is critical to lower expectations, it is also critical not to be excessively gloomy about the role of AI in health care. While physicians may need to comprehend the processes of AI algorithms, most physicians understand magnetic resonance imaging or computed tomography to some level. Despite a lack of individual physician comprehension of their specific process, these studies are extensively used. The lack of transparency in ML algorithms may thus be tolerable if the algorithm's efficacy can be demonstrated. Again, this can be achieved with training and familiarizing the physician with the AI system.

Rather than putting AI to a standard of either perfect or nil results, one should compare the outcomes of using AI to those of the natural world, where physicians can and will make mistakes. Importantly, AI is dynamic in nature and can improve using more extensive data sets. As a result, it is entirely possible that the combined usage of physician and AI input would be more successful over time. However, it is critical not to overstate the status of AI. Its implementation in health care will be a careful, deliberate, and progressive process, including strict control and monitoring of its use and efficacy. AI can help patients and increase the quality of care when combined with input and oversight from health care professionals. AI systems will not wholly replace human clinicians but will supplement their efforts to care for patients. Human therapists may

eventually shift towards jobs and job designs that require distinctly human skills, such as enthusiasm and knowledge to use AI in health care.

As global communities live longer lives and the prevalence of chronic disease rises, the rising cost of health care will remain a hot topic among health care stakeholders. It is time to seek the assistance of machines as they can potentially reduce economic costs. Furthermore, coordination between government and private sector industry partners is vital to realize this potential and take advantage of AI's full potential in health care delivery.

With all this, the key challenge for AI in many sectors of health care is ensuring its adoption in daily clinical practice rather than whether the technologies will be equipped to be effective. AI systems must be approved by regulators, linked with electronic health record systems, standardized to the point that similar products perform similarly, taught to medical practitioners, paid for by public or private payer organizations, and modified in the field over time for widespread adoption to occur shortly. Since AI has a significant and lasting impact on lives and is the future of health care, it is essential to address the associated concerns. Given its importance, AI needs proper policy guidelines and regulations regarding its usage in health care to reap its maximum benefits.

Comparison With Previous Literature

In comparing the findings of this review with existing literature, several key similarities and differences emerge. This review aligns with Gazquez-Garcia et al [63] and Mooghali et al [64] in highlighting the crucial role of health care professional training for effective AI integration. Both emphasize the need for proficiency in AI fundamentals, data analytics, and ethical considerations, reinforcing the notion that successful AI adoption requires a well-prepared workforce. The review also echoes Sapci and Sapci's [65] advocacy for incorporating AI education into medical curricula to address future challenges.

However, this review diverges in its emphasis on practical AI implementation challenges. While Moghadasi et al [66] and Muley et al [67] discuss the risks associated with AI, including the need for enhanced transparency and stakeholder collaboration, this review adds a nuanced perspective on balancing AI's potential benefits with its ethical risks. For instance, this review highlights the importance of human oversight and the complementarity of AI with clinician expertise, which aligns with Morley et al [68] and Zhang and Zhang [69] but also offers additional insights into practical implementation issues not fully covered in the previous reviews.

In terms of public perception, this review supports Kerstan [70] and Castagno and Khalifa [71] by acknowledging that trust in AI is influenced by knowledge and transparency. However, it further explores the dynamic interaction between AI's promise and the necessity for rigorous validation and ethical governance, as discussed by Macrae [72] and Tulk Jesso et al [73]. This review underscores that while AI has the potential to revolutionize health care, its integration must be handled with careful consideration of both practical and ethical dimensions

to achieve meaningful improvements in patient care and outcomes.

Strengths and Limitations

First, the generalizability of the findings may be affected by the inherent variations in study methodologies, AI implementations, and health care settings across different regions. This heterogeneity introduces variability that could influence the applicability of the conclusions. To mitigate this limitation, rigorous search strategies were used across multiple databases to include a diverse range of studies. Future reviews could benefit from incorporating more standardized studies to enhance generalizability. Second, the reliance on published literature from electronic databases introduces potential publication bias. Studies with positive outcomes related to AI integration in health care may be more likely to be published, which could skew perceptions of AI effectiveness and adoption rates. Efforts were made to address this bias by including a broad range of databases and emphasizing recent literature. Future research should aim to include unpublished studies or grey literature to provide a more balanced view. Third, the rapid evolution of AI technologies means that newer developments and implementations may not have been fully captured in this review. The review focused on the most current literature available at the time of the search to address this issue. Regular updates will be necessary to incorporate the latest advancements and ensure the review remains relevant. In addition, the absence of details around stakeholder engagement could have enriched the study by providing additional depth and perspective. Engaging stakeholders in such a dynamic field would offer diverse viewpoints and further validate the conclusions. Future research should consider incorporating stakeholder engagement to enhance the robustness and applicability of the findings.

Despite these limitations, this review offers several notable strengths. It provides a comprehensive overview of AI integration in health care, leveraging rigorous search strategies across multiple databases to ensure a diverse and current collection of literature. This approach contributes to a nuanced understanding of AI's potential and limitations. Furthermore, the emphasis on recent developments helps ensure that the review reflects the most current trends and advancements in AI technologies.

Future Directions

Moving forward, further research in the field of AI integration in health care should address several key areas to advance understanding and application. First, studies should prioritize incorporating stakeholder engagement, including health care providers, patients, policymakers, and technology developers, to provide diverse perspectives on AI adoption and implementation strategies, enhancing relevance and acceptance in clinical practice. Second, longitudinal studies are crucial to assess the long-term impacts of AI technologies in health care settings, providing insights into sustainability, scalability, and real-world effectiveness over time. Third, comprehensive research focusing on the ethical implications of AI, including data privacy, algorithm bias, patient consent, and regulatory frameworks, is needed to build trust and ensure responsible deployment. In addition, comparative effectiveness research comparing AI-assisted interventions with standard care protocols can provide evidence of AI's impact on clinical outcomes, patient safety, and health care efficiency. Interdisciplinary collaboration between computer scientists, health care professionals, social scientists, and ethicists is essential to foster innovative approaches aligned with health care needs. Education and training programs for health care professionals on AI technologies will ensure proficiency in interpreting AI-generated insights and integrating them into patient care effectively. Finally, research should explore how AI can reduce health care disparities and improve access to quality care, particularly in underserved communities and low-resource settings. Addressing these priorities will realize AI's potential in transforming health care delivery and improving patient outcomes globally.

Conclusions

In summary, AI presents a transformative force in health care, with the potential to enhance patient care, reduce errors, and broaden medical knowledge. However, its successful integration requires adaptability; complementarity with human expertise; transparency; and a deliberate, incremental approach. AI's impact on health care is evolutionary, not revolutionary, and collaboration between stakeholders, standardization, education, and robust policies are essential to harness its full potential while upholding patient-centric care and innovation.

Data Availability

All data generated or analyzed during this study are included in this published paper and its supplementary information files.

Authors' Contributions

As the sole author of this manuscript, MC was responsible for all aspects of the study, including conceptualization, literature review, writing, and editing.

Conflicts of Interest

None declared.

Abstract

Background: Traditionally, patients who are critically ill with infection and fever have been treated with antipyretics or even physically cooled. Presumed benefits of the reduction of body temperature are mostly based on decreased metabolic demands. However, it has been shown that decreasing body temperature in patients who are critically ill is not associated with improvement in treatment outcomes. Additionally, there is some data to support the use of temperature modulation (therapeutic hyperthermia) as an adjuvant treatment strategy in patients with infection.

Objective: This study aims to determine the effect of body temperature on the course of intensive care unit (ICU) treatment of patients who are mechanically ventilated with pneumonia, sepsis, and positive tracheal aspirates on admission.

Methods: We performed a single-center retrospective study. Core body temperature was measured in all patients. We analyzed associations between average temperatures in the first 48 hours after admission to ICU and ICU treatment parameters. Additionally, patients were divided into three groups: patients with negative tracheal aspirates 1 week after ICU admission (P-N group), patients with a different pathogen in tracheal aspirates 1 week after ICU admission (P-HAP group), and patients with a persisting pathogen in tracheal aspirates 1 week after ICU admission (P-P group). Differences in body temperature and interventions aimed at temperature modulation were determined.

Results: We observed a significantly higher average temperature in the first 48 hours after admission to ICU in patients who survived to hospital discharge compared to nonsurvivors (mean 37.2 °C, SD 1 °C vs mean 36.9 °C, SD 1.6 °C; P=.04). We observed no associations between average temperatures in the first 48 hours after ICU admission and days of mechanical ventilation in the first 7 days of treatment (ρ=–0.090; P=.30), the average maximum daily requirement for noradrenaline in the first 7 days of treatment (ρ=–0.029; P=.80), average maximum FiO_2 in the first 7 days of ICU treatment (ρ=0.040; P=.70), and requirement for renal replacement therapy in the first 7 days of ICU treatment (mean 37.3 °C, SD 1.4 °C vs mean 37.0 °C, SD 1.3 °C; P=.23). In an additional analysis, we observed a significantly greater use of paracetamol in the P-N group (mean 1.0, SD 1.1 g vs mean 0.4, SD 0.7 g vs mean 0.4, SD 0.8 g; P=.009), a trend toward greater use of active cooling in the first 24 hours after ICU admission in the P-N group (n=11, 44% vs n=14, 33.3% vs n=16, 32%; P=.57), and no other significant differences in parameters of ICU treatment between patient groups.

Conclusions: We observed better survival in patients who developed higher body temperatures in the first 48 hours after admission to the ICU; however, we observed no changes in other treatment parameters. Similarly, we observed greater use of

XSL•FO

paracetamol in patients with negative tracheal aspirates 1 week after ICU admission. Our results support the strategy of temperature tolerance in patients who are intubated with pneumonia and sepsis.

Introduction

Increased body temperature has been recognized as a sign of illness for more than 2000 years and antipyretics have been used for at least 100 years with the aim of lowering body temperature in patients who are febrile [1]. However, a body of evidence exists ranging from studies in the preantibiotic era to a recently published pilot trial, where increased body temperature is investigated as a treatment option in patients with infection [2-4]. A fever-range increase of body temperature is a highly preserved response that is probably beneficial in patients who develop fever as a part of a normal immune response to infection [5]. Recently, we have observed that patients with lower body temperatures are at a higher risk of acquiring the presence of multidrug-resistant pathogens [6]. The aim of this study was to investigate the association between body temperature and the course of intensive care unit (ICU) treatment in patients with pneumonia and sepsis and to evaluate the effect of temperature on the persistence of positive control tracheal aspirates.

Methods

Study Design and Settings

We performed retrospective observational data collection from January 1, 2018, to December 31, 2021. The study was performed in a medical ICU in a tertiary center and supported by an institutional research grant (grant IRP-2022/01-01).

Ethical Considerations

The study was approved by University Medical Centre Maribor Ethical Committee, and informed consent was waived because of the observational and retrospective nature of the study (No. UKC-MB-KME-35/22). Patients' data have been anonymized and deidentified. No compensation was provided to the participants.

Study Population

We included adult (aged >18 years) patients with pneumonia, septic shock, positive tracheal aspirates within 24 hours after admission ("admission" tracheal aspirates), and tracheal aspirates withdrawn 8-14 days after admission to ICU ("week 2" tracheal aspirates). We excluded patients who were treated with targeted temperature management for accidental hypo- or hyperthermia, patients after cardiac arrest, and patients who are neurocritical (eg, patients with meningitis, encephalitis, ischemic or hemorrhagic stroke, or subarachnoid hemorrhage). Temperature management in our patient cohort was as per the treating physician.

Measurements

We collected basic demographic data and data related to ICU treatment, namely outcome of ICU treatment, ICU length of stay, core body temperature during ICU stay, use of renal replacement therapy, use of acetaminophen, maximum concentration of noradrenaline, maximum fraction of inspired oxygen, maximum level of positive end-expiratory pressure and maximum minute ventilation, and microbiological results of tracheal aspirates. Source data was paper based for temperature and therapeutic charts and electronic for other data. Core body temperature was used for study data. As per department policy, temperature was measured via thermal probe urinary catheters (Rüsch Sensor Urinary Catheters, Teleflex Medical, Athlone, Ireland), and temperature measurements were continuously displayed on ICU monitors (Philips IntelliVue MX800 Patient Monitoring System, Koninklijke Philips N.V., Amsterdam, Netherlands). If insertion of a urinary catheter is not possible, then an esophageal temperature probe is inserted, but temperature measurement in all of the included patients was performed via a urinary catheter. Temperature results from 2-hourly notations were used for statistical analysis. We compared the association between body temperature and course of treatment parameters between three groups of patients: patients with sterile week 2 tracheal aspirates (P-N group), patients with a different pathogen in week 2 tracheal aspirates (P-HAP group), and patients with a persistent pathogen presence in week 2 tracheal aspirates (P-P group).

Data Analysis

Statistical analyses were carried out using R (version 4.1.1; R Foundation for Statistical Computing). Nominal variables are presented with frequencies (percentages) and numerical variables with means (SDs) or medians (IQRs) when the normality assumption is violated. For the comparison of nominal dichotomous variables, the Fisher exact test was used. Continuous variables were first assessed for normality using the D'Agostino omnibus test. A comparison of continuous variables across groups was carried out using the Kruskal-Wallis test. Dunn post hoc test with Bonferroni correction was used to adjust for multiple comparisons. The association between average temperature in the first 48 hours and the duration of mechanical ventilation, the average maximum daily requirement for noradrenaline and the average maximum FiO_2 in the first 7 days was evaluated using Spearman correlation. Generalized linear models were used to additionally estimate the ICU and hospital survival in association with the abovementioned risk factors. A statistically significant observation was considered at $P<.05$.

Results

Baseline Characteristics

In all, 117 patients were included in the study analysis; 84 (71.8%) were male, and the mean age was 63.7 (SD 13.5) years. All patients were invasively mechanically ventilated in the ICU on day 1. Mean APACHE II and SOFA scores on admission were 21.7 (SD 6.6) and 10.1 (SD 2.6), respectively. A total of 77 (65.8%) were discharged alive from the ICU, and 46 (39.3%)

patients were discharged alive from the hospital. P-N, P-HAP, and P-P groups consisted of 25, 42, and 50 patients, respectively. We observed no significant differences between the P-N, P-HAP, and P-P groups in all treatment parameters apart from the use of paracetamol on day 1, which was significantly greater in the P-N group (mean 1.0, SD 1.1 g vs mean 0.4, SD 0.7 g vs mean 0.4, SD 0.8 g; *P*=.009). General demographic data and parameters describing the course of the treatment in the ICU are described in Table 1. The study patient population and inclusion flowchart are presented in Figure 1.

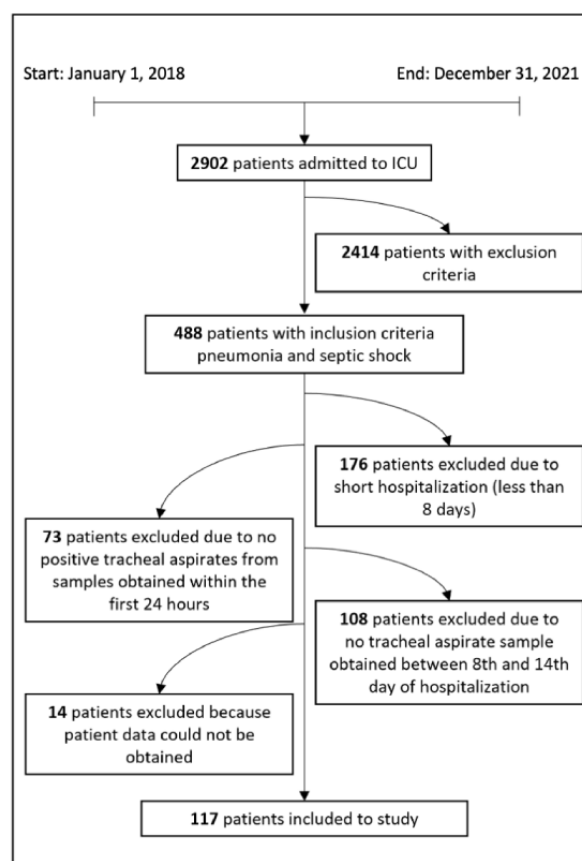
Figure 1. Study patient population and inclusion flowchart. ICU: intensive care unit.


Main Results

Body temperature changes in the first 28 days of treatment are presented in Figure 2. We observed a significantly higher average temperature in the first 48 hours after admission to ICU in patients who survived to hospital discharge compared to nonsurvivors (mean 37.2 °C, SD 1 °C vs mean 36.9 °C, SD 1.6 °C; *P*=.04) and nonsignificant differences in average temperatures in the first 48 hours after admission to ICU between survivors and nonsurvivors to ICU discharge (mean

37.0 °C, SD 1.3 °C vs mean 37.0 °C, SD 1.2 °C; *P*=.60). We observed no associations between average temperatures in the first 48 hours after ICU admission and days of mechanical ventilation in the first 7 days of treatment (ρ=–0.090; *P*=.30), the average maximum daily requirement for noradrenaline in the first 7 days of treatment (ρ=–0.029; *P*=.80), average maximum FiO_2 in the first 7 days of ICU treatment (ρ=0.040; *P*=.70), and requirement for renal replacement therapy in the first 7 days of ICU treatment (mean 37.3 °C, SD 1.4 °C vs mean 37.0 °C, SD 1.3 °C; *P*=.23).

Figure 2. Average body temperature by groups in the first 28 days of treatment in the intensive care unit. P-HAP: patients with a different pathogen in week 2 tracheal aspirates; P-N: patients with sterile week 2 tracheal aspirates; P-P: patients with a persistent pathogen presence in week 2 tracheal aspirates.
P-N, P-HAP, and P-P groups consisted of 25, 42, and 50 patients each, respectively. No significant differences in average body temperature in the first 48 hours were observed between the P-P, P-HAP, and P-N groups. Temperature variations increased after day 16 (Figure 2), however, and approximately two-thirds of patients were discharged from the ICU or died before day 16. Both hospital and ICU survival were higher in the P-N group compared to the P-HAP and P-P groups; however, the differences were not statistically significant (Figure 3). We observed statistically significant greater use of paracetamol in the first 24 hours after ICU admission in the P-N group compared to the P-HAP and P-P groups (mean 1.0, SD 1.1 g vs mean 0.4, SD 0.7 g vs mean 0.4, SD 0.8 g; P=.009). Active cooling was used more frequently on day 1 in the P-N group, but no significant differences were observed (Figure 4).

Figure 3. Intensive care unit (ICU) and hospital survival by groups. P-HAP: patients with a different pathogen in week 2 tracheal aspirates; P-N: patients with sterile week 2 tracheal aspirates; P-P: patients with a persistent pathogen presence in week 2 tracheal aspirates.
Figure 4. Active cooling on day one of hospitalization in the intensive care unit divided by groups. P-HAP: patients with a different pathogen in week 2 tracheal aspirates; P-N: patients with sterile week 2 tracheal aspirates; P-P: patients with a persistent pathogen presence in week 2 tracheal aspirates.
Microbiological Data

In all, 148 different causal pathogens were isolated. In admission tracheal aspirates, the majority (n=124, 66%) of pathogens were gram-negative bacteria, followed by gram-positive bacteria (n=56, 29.8%) and fungal pathogens (4.3%). In week 2 tracheal aspirates, the majority (n=128, 86.5%) of pathogens were gram-negative bacteria, followed by gram-positive bacteria (n=14, 9.5%) and fungal pathogens (n=6, 4.1%). We observed no differences between the P-N, P-HAP, and P-P groups in causative pathogens in admission tracheal aspirates (Table 2). There were no differences between the P-N, P-HAP, and P-P groups in the rate of change of antimicrobial therapy within the first week after ICU admission, and we observed no changes in the duration of initial (combined empiric and antibiogram-guided antimicrobial therapy) and cumulative ICU-stay antibiotic therapy (mean 7.6, SD 2.7 days vs mean 8.4, SD 3.1 days vs mean 8.2, SD 2.9 days; P=.55; mean 15.2, SD 5.6 days vs mean 14.8, SD 6.8 days vs mean 15.9, SD 6.2 days; P=.70; respectively).

Table 2. Isolated pathogens from the first and second samples divided by groups.

Discussion

Principal Findings

We observed higher initial body temperatures in patients who survived to hospital discharge and a trend toward higher initial temperatures in patients who survived to ICU discharge. We did not observe any differences in body temperature between the P-N, P-HAP, and P-P groups of patients, but we did observe a significantly greater use of paracetamol in the P-N group of patients and a trend toward greater use of active cooling in the P-N group of patients. Additionally, we observed a trend toward better survival to ICU and hospital discharge in the P-N group of patients.

Traditionally, antipyretic therapy (mostly paracetamol), and in some cases active cooling, have been used to lower body temperature in patients who are febrile with infection. The presumed patient benefit comes from decreased metabolic demands associated with lower body temperature [7,8].

The survival of our patients is comparable to studies performed by Gursel and Demirtas [9], Depuydt et al [10], and Qiao et al [11] who reported survival to ICU discharge of patients who were critically ill with pneumonia in the range between 46% and 75%, compared to 65.8% survival to ICU discharge in our patients. They included patients with similar severity of illness, with SOFA scores in the range between 4 and 6 points and APACHE II scores around 20 points, compared to the SOFA score 10.1 (SD 2.6) and APACHE II score 21.7 (SD 6.6) in our study.

Our findings are in line with a number of other studies where better survival was observed in patients with infection and physiological-grade fever (ie, body temperature between around 37 °C and 39 °C). Both Kushimoto et al [12] in a prospective observational study and Shimazui et al [13] in a retrospective observational study observed higher mortality in patients with sepsis and lower body temperature on admission. Lee et al [14] also observed lower mortality in patients with physiological-grade fever in their prospective study. Rumbus et al [15] performed a meta-analysis of 42 studies reporting body temperature and mortality in patients with sepsis. They discovered a correlation between higher body temperature and lower mortality; higher body temperature predicted better survival, and hypothermia predicted lower survival. Similar to our findings the number of patients with body temperature over 39.5 °C was very low. Thomas-Rüddel et al [16] performed a secondary analysis of a large data set of patients with sepsis and discovered that initial body temperatures were distributed in two peaks: a smaller peak at around 35.5 °C and a larger peak approximately twice as large at around 38 °C. Again, the highest survival rate was observed in patients with hyperthermia and the lowest in patients with hypothermia. They also observed that ambient temperatures were significantly associated with body temperatures; lower ambient temperatures were associated with hypothermia, and higher outside temperatures were associated with hyperthermia. The potential benefits of active warming of patients with infection were further highlighted by Drewry et al [4], who performed a pilot randomized controlled study evaluating the use of therapeutic hyperthermia in patients with sepsis and observed a significantly better survival in the hyperthermia group; however, there were no differences in the primary results.

We can speculate that higher doses of paracetamol and greater use of active cooling probably decreased body temperatures in the P-N group of patients; however, this was not associated with any improvement during ICU treatment. We observed no differences in the use of noradrenalin, parameters of mechanical ventilation, requirement for renal replacement therapy, or organ dysfunction scores, and we observed a trend toward greater ICU and hospital survival in the P-N group. Our results suggest that there is probably no clinical benefit associated with the treatment of physiological-grade fever. Similarly, Zhang et al [17] and Ye et al [18] performed retrospective studies on patients with fever and sepsis, and they observed no beneficial effects of antipyretic therapy and possible harm associated with the use of external cooling. In a prospective randomized controlled trial, Young et al [19] observed approximately 0.5 °C lower body temperature in patients who received paracetamol (4 g daily) compared to patients who received a placebo. They also observed that patients who received more paracetamol experienced a longer ICU stay if they were nonsurvivors, and shorter ICU stay if they were survivors, which was explained by the probable effect of lower body temperature on clinicians' perception of the patients' prognosis. Lower body temperature in the paracetamol group was not associated with any improvement in the ICU course of treatment parameters [19,20].

To our knowledge, there is no other data to compare our results regarding the clearance or persistence of pathogens in tracheal aspirates. In 42.7% (n=50) of our patients (ie, the P-P group of patients), the same pathogen persisted in tracheal aspirates 1 week after initial samples were obtained. There were no differences in causative pathogens between the P-N, P-HAP, and P-P groups of patients, and we observed no significant changes in baseline data between the groups, including the rate of change of empiric antibiotic therapy. There was a trend toward higher temperature in the first 48 hours in the P-N group, compared to the P-HAP and P-P groups, possibly indicating that tolerance of hyperthermia could be beneficial for patients who are intubated with pneumonia and sepsis. There were no significant differences in the course of ICU treatment parameters despite greater use of paracetamol and active cooling, indicating that pharmacological or active cooling has no benefit in patients where fever is part of an appropriate response to infection.

There are a number of limitations to our study. We performed a single-center retrospective observational study with all inherent biases associated with this study design. Of the initial 488 patients with pneumonia, 249 were not included because there were no tracheal aspirates 1 week after ICU admission (because of extubation, death, or no clinical need for obtaining samples if the patients were still intubated). Additionally, target temperatures were defined by the treating physicians. However, there are no guidelines regarding target temperatures for this patient population, and we observed no differences in baseline data between the different groups.

RenderX

Conclusions

To conclude, we observed better survival in patients who developed higher body temperatures in the first 48 hours after admission to the ICU; however, we observed no changes in other treatment parameters. Additionally, we observed greater use of interventions aimed at cooling the patients (use of paracetamol and a trend toward greater use of active cooling) in patients with negative tracheal aspirates 1 week after ICU admission. Additionally, in this group of patients, we observed a trend toward better survival. Our results speak against the use of interventions aimed at the reduction of body temperature and support the strategy of temperature tolerance in patients who are mechanically ventilated with pneumonia and sepsis.

Authors' Contributions

AM, JF, and ŽK conceptualized the study. AM and PPB developed the methodology. PPB used the software. AM and PPB performed the validation. PPB performed the formal analysis. DG, AG, and NG conducted the investigation and acquired the resources. AM curated the data curation. DG, AG, and NG prepared the original draft. AM, PPB, JF, ŽK, DG, AG, and NG reviewed and edited the paper. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: COPD (chronic obstructive pulmonary disease) and bronchiectasis are common, and exacerbations contribute to their morbidity and mortality. Predictive factors for the frequency of future exacerbations include previous exacerbation frequency and airway colonization. Earlier treatment of exacerbations is likely to reduce severity.

Objective: This study tested the hypothesis that, in a population with bronchiectasis, COPD, or both who have frequent exacerbations and airway colonization, changes in symptom scores or physiological variables within 10 days prior to an exacerbation would allow the prediction of the event.

Methods: We performed a 6-month, longitudinal, observational, cohort study among 30 participants with bronchiectasis, COPD, or both; at least 2 exacerbations per year; and colonization with *Pseudomonas aeruginosa* or *Haemophilus influenzae*. Daily symptom and physiological data were collected, comprising pulse rate, blood pressure, oxygen saturation, peak flow rate, step count, weight, and temperature. Exacerbations (defined as the onset of new antibiotic use for respiratory symptoms) were collected, and predictive values for abnormal values in the 10 days prior to an exacerbation were calculated.

Results: A total of 30 participants were recruited, collecting a total of 39,534 physiological and 25,334 symptom data points across 5358 participant-days; these included 78 exacerbations across 27 participants, with the remaining 3 participants not having exacerbations within the 6-month observation period. Peak flow rate, oxygen saturation, and weight were significantly different at the point of exacerbation (all *P*<.001), but no significant trends around exacerbation were noted and no clinically beneficial predictive value was found in the overall or individually adjusted model. Symptom scores tended to worsen for 10 days on either side of an exacerbation but were of insufficient magnitude for prediction, with area under the receiver operating characteristic curve values of ranging from 0.4 to 0.6.

Conclusions: Within this small cohort with bronchiectasis, COPD, or both and airway colonization, physiological and symptom variables did not show sufficient predictive value for exacerbations to be of clinical utility. The self-management education provided as standard of care may be superior to either of these approaches, but benefit in another or larger cohort cannot be excluded.

International Registered Report Identifier (IRRID): RR2-10.2196/resprot.6636

Introduction

COPD (chronic obstructive pulmonary disease) and bronchiectasis are common causes of morbidity and mortality across the world [1,2]. Much of this morbidity and mortality is associated with exacerbations—acute deteriorations of the disease [3,4]. Exacerbations often require additional treatment, up to and including hospitalization, and are a risk factor for progressive disease [5,6]. Certain factors are known to be associated with increased risk of future exacerbations, including recurrent previous exacerbation [7,8] and airway colonization with organisms such as *Pseudomonas aeruginosa* [9,10].

It is thought that earlier treatment of exacerbations is associated with improved outcomes, including time to recovery and reduced risk of a severe exacerbation [11], but overtreatment risks side effects from the treating medications (eg, corticosteroids or antibiotics). Accurate prediction of exacerbations is therefore required. Predictive factors may be physiological (eg, heart rate or oxygen saturations) or symptomatic (eg, degree of breathlessness or fatigue). The monitoring of physiological variables has shown value in predicting mortality in hospital and prehospital care (eg, National Early Warning Score [12,13]), including mortality in patients with COPD [14]. However, the same has not been consistently demonstrated for other metrics, such as exacerbations of disease, and previous studies focusing on lung function monitoring have not demonstrated predictive benefit [15,16]. Multiple predictors of exacerbation risk exist [17-20], such as the COPD Assessment Test score for COPD and the FACED score for bronchiectasis, but these do not help predict individual exacerbations. In order to predict exacerbations in either physiological or symptom modalities, monitoring must be remote and performed in the home environment.

We conducted a longitudinal, observational, cohort study examining the capability of physiological and symptom variables to predict exacerbations of airway disease in participants with chronic bronchitis with frequent exacerbation and airway colonization with *P aeruginosa* or *Haemophilus influenzae.* We hypothesized that changes in symptom scores or physiological variables within 10 days prior to an exacerbation would allow the prediction of the event.

Methods

Study Design and Setting

We conducted a 6-month, blinded, longitudinal, observational, cohort study, recruiting 30 adult participants from secondary care with a diagnosis of COPD, bronchiectasis, or both. Participants were recruited from a secondary care clinic during 2014, and the study ran from September 2014 for 6 months.

Participants

Participants were required to have had a least 2 exacerbations in the last 12 months, at least 1 of which was within the last 6 months. Participants were required to be colonized by *P aeruginosa* or *H influenzae*, demonstrated by at least 2 cultures at exacerbation in the last 12 months without culture of the other organism. Participants were required to be able to give informed consent, comply with study procedures, and produce at least 5 mL of sputum most days. A full study protocol has been previously published [21], and the participant flow diagram is shown in the Figure S1 in Multimedia Appendix 1.

Variables

At enrollment, participants provided clinical history, underwent spirometry testing, and completed symptom questionnaires including the St. George's Respiratory Questionnaire (SGRQ). A home visit was conducted when participants were provided with home physiological monitoring equipment [21], specifically a digital peak flow meter, pulse oximeter, physical activity (step) tracker, infrared thermometer, automatic sphygmomanometer, and weighing scales (see Table S1 in Multimedia Appendix 1 for the models of the equipment); they were linked by Bluetooth to an iPad, which was also used collected symptom scores on a 10-point visual analog scale for appetite, breathing, cough, energy, and wellness. These data were transmitted daily to a secure cloud-based database, and the study team were blinded to the data until all participants had completed the study, except for a single unblinded technical observer who ensured that data were being received from each participant. Participants were asked to record whether they had started a course of antibiotics at home (defined as a moderate exacerbation as per guidelines) or whether they were in hospital (defined as a severe exacerbation) [22].

Outcomes

The outcome under investigation was the accuracy of abnormal values of the physiological and symptom variables listed above to predict a moderate exacerbation of airway disease, as defined by patient-reported initiation of antibiotics for a worsening in respiratory symptomatology. Independent variables were therefore symptom scores (appetite, breathing, cough, energy, and wellness) and physiological values (heart rate, blood pressure, peripheral oxygen saturation, temperature, weight, and daily step count).

Study Size

To establish an association between predictive markers and the occurrence of exacerbations, the study was designed around the identification of a presymptomatic period. Based on clinical expertise and literature review, we determined that a 10-day window before the onset of an exacerbation is a critical timeframe in which deviations in predictive markers can be most reliably attributed to a forthcoming exacerbation. This period selection aligns with the natural history of exacerbations

as detailed in prior studies. Given the adoption of a 10-day cycle as a unit of observation, we anticipated a minimum of 12 such units per participant across an expected follow-up duration of 4 months. This frequency follows from the inclusion criterion requiring participants to have had at least 2 exacerbations in the previous year, paralleling the exacerbation frequency described by Seemungal et al [23].

For the study to hold clinical relevance, we aimed to achieve a positive predictive value (PPV) of 60% and a negative predictive value (NPV) of 90%. This was based on the study team's experience rather than published data. On the assumption that each participant would experience at least 1 exacerbation during the study period and using a significance threshold of 5% with 90% statistical power to discern the prescribed PPV and NPV, the initial calculation suggested the need for 120 time units of observation.

However, to address the statistical challenge posed by the nonindependence of repeated measurements from individual participants—each contributing multiple observation periods—an intraclass correlation coefficient of 0.18 was used to adjust for within-participant correlation. The resulting design effect, reflecting this lack of independence, was calculated to be approximately 3. This design effect was used to multiply the basic sample size estimate, leading to a final requirement of 360 observational time periods. Consequently, a total cohort of 30 participants would satisfy this criterion, meeting the robust statistical power necessary for the intended analyses.

Statistical Methods

Data analysis was conducted using SPSS (version 28; IBM Corp), alongside visualization in Tableau Desktop (Tableau Software) and data management in Excel 365 (Microsoft). Descriptive statistics were used to characterize the study data, using mean and SD for normally distributed variables and median and IQR for nonnormally distributed variables. The determination of normality was guided by kurtosis and skewness indices, with thresholds set at absolute values less than 1 for normal distribution.

Comparative analyses between groups were executed using the Student *t* test (2-tailed) for normally distributed data and the Mann-Whitney *U* test for data that deviated from normal distribution. The onset of an exacerbation was defined as the day on which a participant initiated an antibiotic treatment course; any subsequent antibiotic courses beginning within 10 days of the initial course's end were considered part of the ongoing exacerbation and not as discrete events.

The monitoring tool, a modified National Early Warning Score, was calculated with the exclusion of respiratory rate, as it could not be accurately measured remotely with the equipment provided to participants. Data were assessed longitudinally to establish individualized normal ranges for each participant by calculating variable SDs from the participant's average, while omitting any data from a 20-day span encompassing each exacerbation (10 days before and 10 days after).

An abnormal value occurring within the 10-day presymptomatic window preceding an exacerbation was classified as a true positive. Conversely, abnormal values within 10 days following

an exacerbation were designated as "late" positives. Abnormal values outside of these windows were flagged as false positives. For the negative results, days featuring no abnormal values were declared true negatives unless they fell within a 10-day period preceding an exacerbation; in such cases, they were categorized as false negatives. We defined "episode sensitivity" for each variable as the detection of at least 1 abnormal result outside of the participant's normal range within the pre-exacerbation period.

Ethical Considerations

Ethical approval was given by the NHS South Central Research Ethics Committee (14/SC/0298), and all participants gave written, informed consent. Participants were allowed to keep study equipment at the completion of the study but there was no financial compensation. Data were anonymized for analysis to safeguard participant information. Anonymized data can be made available for suitable studies on written request.

Results

Overview

A total of 30 participants were recruited, with study population baseline data shown in Table 1. A CONSORT (Consolidated Standards of Reporting Trials) diagram of study recruitment is shown in Figure S1 in Multimedia Appendix 1. A total of 39,534 physiological and 25,334 symptom data points were collected across 5358 participant-days. A total of 78 exacerbations were reported during the 6-month study period by 27 (90%) of 30 participants, with the median exacerbation count being 3 (IQR 1-3.75), and the remaining 3 (10%) participants not having exacerbations during the study period. During the study, 4 participants recorded a total of 6 hospital admissions for respiratory symptoms, giving an overall annualized rate of 0.2 per year compared to 0.6 per year (17 emergency hospital attendances from 7 participants) in the year prior to admission. Participant-level physiological and symptom data showed high interindividual differences around the point of exacerbation, as shown in Figures S2 and S3 in Multimedia Appendix 1.

Physiological data (Table 2) were compared using individualized *z* scores to adjust for interparticipant differences in exacerbation frequency. Values from exacerbation and 10 days on either side were compared with nonexacerbation days outside of this window. Peak flow rates and oxygen saturations were significantly lower during the exacerbation window, whereas weight and modified National Early Warning Score were significantly higher (all *P*<.001). Mean values of temperature, pulse rate, peak expiratory flow rate, and systolic blood pressure around exacerbation are shown in Figure 1.

Average appetite, breathing, cough, energy, and wellness symptom scores in the first week of data collection were correlated with overall SGRQ, giving correlation coefficients of –0.694, –0.761, –0.718, –0.798, and –0.805, respectively (all *P*<.001), showing good correlation between patient-reported symptom scores and a validated quality-of-life questionnaire. Symptom scores were also compared using individualized *z* scores to adjust for interparticipant differences in exacerbation frequency. Values from exacerbation and 10 days on either side

were compared with nonexacerbation days outside of this window. All symptom scores including the total symptom score were significantly lower at and around exacerbation compared to outside this range, as shown in Table 3 (*P*<.001 for each).

The trend of symptom scores around the point of exacerbation are shown in Figure 2, showing a gradual worsening in mean symptom score each day leading to the point of exacerbation, with gradual recovery following this. However, the magnitude of the decline is small, with each score decreasing by a mean of less than 1 point and by a similar magnitude.

The trends of total symptom scores through the study were examined. While the average total symptom score showed a slight improvement over time, this was not true for those with sputum *P aeruginosa*, who started with poorer symptom scores and showed a trend toward worsening over time, as shown in Figure 3.

Table 1. Study population baseline data. All participants with chronic obstructive lung disease (COPD) had a GOLD (Global Initiative for COPD) grade of D.

Variable	Value (N=30)
Participants, n (%)	30 (100)

Figure 3. Change in mean total symptom score by sputum culture, demonstrating worsening symptoms over time in the Pseudomonas aeruginosa group (lower line, n=20) and improving symptoms in the Haemophilus influenzae group (upper line, n=10). VAS: visual analog scale.
Predictive Values

Individual control limits of variable widths were calculated as above. Table 4 shows predictive values at 2 SDs, which gave a balance between PPV and sensitivity. A range of control interval widths were calculated, and PPV for physiological variables were highest at 27.9% (at 3.3 SDs), while PPV for symptom variables peaked at 62.4% (at 4 SDs), which predicted 17.6% and 26.1% of episodes, respectively (Figures S4 and S5 in Multimedia Appendix 1). Individual-level data demonstrating the range of predictive values at control widths of 2 SDs for each participant are shown in Table S2 in Multimedia Appendix 1. Comparison between results for participants with COPD and bronchiectasis is shown in Table S3 in Multimedia Appendix 1, showing slightly higher PPV and episode sensitivity for participants with COPD but still less than 50%.

Physiological and symptom variables were analyzed using receiver operating characteristic analysis (Figure S6 in Multimedia Appendix 1), and no area under the curve (AUC) values were outside the range of 0.4-0.6, indicating no significant predictive value. This was repeated with z scores (Figures S7 and S8 in Multimedia Appendix 1) to normalize for individual variation, and all AUC values were within the 0.45-0.55 range, again showing no significant predictive value (Figure S9 in Multimedia Appendix 1). Receiver operating characteristic analysis was also conducted for COPD and bronchiectasis alone and for *P aeruginosa* and *H influenzae* colonization alone; in each analysis, no curve exceeded an AUC of 0.4-0.6, with the exception of peak flow in participants with *H influenzae,* which had an AUC of 0.374.

Table 4. Predictive values of abnormal results for physiological and symptom results with individualized control limits of 2 SDs.

Physiological and symptom variables	PPV[a] (%)	NPV[b] (%)	Sensitivity (%)	Specificity (%)	Accuracy (%)	Episode sensitivity (%)
Weight	27.23	82.76	7.26	95.82	80.14	24.36
Steps	13.51	82.51	3.46	95.36	79.45	19.23

Discussion

Our study has revealed the limited predictive value of physiological markers and symptom scores in this population with airway disease and chronic colonization. The variability of physiological data and the subtlety of symptom changes challenge the reliance on these measures alone for predicting imminent exacerbations. Symptom scores on a population level indicated some deterioration around the time of exacerbation but were insufficient as stand-alone individual level predictors. Our approach to personalize reference ranges, accounting for intraparticipant variability, has been proven valuable but still fell short in enhancing predictive accuracy.

Despite these limitations, the role of these indicators cannot be entirely discounted. Physiological variables and symptom scores remain crucial components of a comprehensive disease monitoring plan for many respiratory diseases. The differentiation between physiological changes and symptom deterioration is important; while physiological parameters may not predict exacerbations with high accuracy, they provide valuable information on a patient's baseline health status, which can be crucial when responding to symptoms that suggest an exacerbation and therefore guide clinical decision-making, particularly when considered alongside an individual's typical symptomatology and exacerbation patterns. This approach was used in the PROMETE study for example, which showed that monitoring physiological values with respiratory physician reviews reduced hospital and emergency department attendances over 7 months, with more exacerbations being managed at home [24].

Moreover, the aggregated symptom score highlighted in our study, while not overtly predictive, could have potential applications when considering temporal trends over more extended periods, as some data suggest that telemonitoring is more beneficial over a longer term than in our study [25]. While acute predictive value is limited, monitoring this score could be useful for assessing overall disease management and quality of life across broader timeframes, which may be of interest in longitudinal studies. Systematic reviews of previous studies of the effectiveness of remote monitoring of airway disease have focused on COPD and have shown mixed results [26,27]. Of particular interest, physiological deterioration over time was noted in our study in those colonized by *P aeruginosa*, and this is consistent with previously reported data, suggesting a particularly high-risk group of patients [28].

Our study also reflects the multifaceted nature of exacerbations in chronic airway diseases, which likely result from a combination of factors, ranging from environmental triggers to individual patient behaviors. Furthermore, the findings underscore the essential role of education and self-management. The decrease in admission rates during the study, compared to the year prior, may indicate that equipping patients with self-management plans may help avert the most severe manifestations of exacerbations, thereby reducing hospital visits.

While our study has provided valuable insights into the management of chronic airway disease, the inherent limitations must be acknowledged. The relatively small cohort size and the specific inclusion of patients with known chronic airway colonization restrict the generalizability of the findings. The observational period did not extend across a full year, resulting in a potential underrepresentation of seasonal variations, although it crucially encompassed the winter months when exacerbations are generally more prevalent and severe. The exclusion of respiratory rate—a potentially significant physiological marker—from our data collection may have

omitted a critical variable with predictive capability. Additionally, while the symptom scores used in the study were less complex and showed good correlation with established measures such as the SGRQ, there remains the possibility that more nuanced symptom evaluation tools could yield stronger predictive correlations. Another notable aspect of the study was participant access to their own longitudinal data, which introduces the potential for reporting bias. However, the anticipated direction of such bias would more commonly lead to an overestimation of symptoms, resulting in false-positive identifications of exacerbations—a phenomenon not observed in our data. This suggests that while participant awareness of their data could be a confounding factor, its impact on the study's outcomes may be minimal. Despite these limitations, the study's strengths also warrant mention. By methodically tracking daily symptomatic and physiological changes within a clearly defined patient group, the study provides nuanced insight into the patterns preceding exacerbations. Moreover, the inclusion of the winter months offers pertinent data from a period of high clinical relevance due to the increased exacerbation risk.

Further studies examining respiratory rate, other symptom assessment, or continuous monitoring may be of benefit, but a strongly predictive single factor seems unlikely and alternative approaches to monitoring airway disease such as combining multiple sources of predictive data in the home setting are more likely to be useful.

Abstract

Background: Postoperative fever frequently indicates surgical complications and is commonly used to evaluate the efficacy of interventions against surgical stress. However, the presence of circadian rhythms in body temperature may compromise the accurate detection of fever.

Objective: This study aimed to investigate the detection rate of fever under intermittent measurement.

Methods: We retrospectively reviewed the clinical records of patients who underwent nonemergency gastrointestinal surgery between November 2020 and April 2021. Patients' temperature data were continuously collected every 4 seconds using a wireless axillary thermometer, and fever was defined as a temperature exceeding 38 °C within a day. To simulate intermittent measurement in clinical practice, the body temperature at each hour was selected from the continuously collected temperature dataset. Considering that temperatures are measured multiple times per day, all possible measurement plans using intermittent measurement were composed by combining 1-24 time points from the 24-hour daily cycle. Fever was clinically diagnosed based on the temperature readings at the selected time points per day. The fever detection rates for each plan, with varying measurement times, were listed and ranked.

Results: Based on the temperature data continuously collected by the thermometer, fever occurred in 60 (40.8%) of the 147 included patients within 3 days after surgery. Of the measurement plans that included 1-24 measurements daily, the fever detection rates ranged from 3.3% (2/60) to 85% (51/60). The highest detection rates and corresponding timings for measurement plans with 1, 2, 3, and 4 measurements daily were 38.3% (23/60; at 8 PM), 56.7% (34/60; at 3 AM and 7 or 8 PM), 65% (39/60; at 3 AM, 8 PM, and 10 or 11 PM), and 70% (42/60; at 12 AM, 3 AM, 8 PM, and 11 PM), respectively; and the lowest detection rates were 3.3% (2/60), 6.7% (4/60), 6.7% (4/60), and 8.3% (5/60), respectively. Although fever within 3 days after surgery was not correlated with an increased incidence of postoperative complications (5/60, 8.3% vs 6/87, 6.9%; *P*=.76), it was correlated with a longer hospital stay (median 7, IQR 6-9 days vs median 6, IQR 5-7 days; *P*<.001).

Conclusions: The fever detection rate of the intermittent approach is determined by the timing and frequency of measurement. Measuring at randomly selected time points can miss many fever events after gastrointestinal surgery. However, we can improve the fever detection rate by optimizing the timing and frequency of measurement.

Introduction

Fever commonly ensues following a diverse array of surgical interventions, including gastrointestinal procedures. Postoperative fever frequently stems from surgical stress and complicating factors [1,2]. In the context of gastrointestinal surgery, fever not only reflects elevated levels of surgical stress but may also signal the potential for complications, such as thrombosis, gastrointestinal leaks, intra-abdominal infections, and pulmonary infections [3-7]. In addition, fever manifestations are integral to the evaluation of targets and outcome measures for various Enhanced Recovery After Surgery (ERAS) interventions [8-14]. Therefore, precise fever detection is imperative for ensuring clinical safety and for the accurate appraisal of treatment efficacy. Time and accurate detection of fever promotes the early identification of patients at heightened risk for complications and supports the precise assessment of the efficacy of perioperative stress mitigation strategies.

To detect postoperative fever, patient temperatures are routinely measured at intervals of several hours against a predetermined threshold. A majority of health care facilities use a body temperature over 38 °C as the criterion for fever diagnosis [15]. This threshold is also commonly used in many clinical studies [5,16,17]. Nevertheless, there is often a failure to account for the timing of temperature measurements, which is pivotal since body temperature naturally oscillates, reaching a nadir at 6 AM and peaking between 4 PM and 6 PM [18]. As such, disparate measurement timings can result in substantial variance in the detected rates of fever within study cohorts. The question arises as to the optimal timing for temperature checks to identify fever. To date, neither a consensus nor guidelines exist to address this issue. Furthermore, the timing of temperature measurement is rarely specified in the literature on postoperative fever, with common practices including twice daily [17], during morning rounds [16], every 8 hours [19,20], or not report at all in certain studies [5,9,17,21-25]. This inconsistency in monitoring may overlook many febrile episodes, impeding the ability to evaluate the relationship between fever and surgical outcomes, as well as the effectiveness of perioperative antistress interventions.

Enhancing the frequency of temperature measurements could potentially improve fever detection rates; however, the practicality of such a method is low, incurring a substantial increase in medical workload for relatively little gain. Research has explored the use of wireless sensors for continuous real-time monitoring of patients' body temperatures. These sensors, transmitting temperature data to a central processor at frequent intervals, offer a more precise reflection of temperature fluctuations [26,27], which can facilitate prompt identification of postoperative complications [28]. Nonetheless, the functionality of these sensors is heavily dependent on reliable local network infrastructure and related devices. In settings bereft of sensor technology, alternative strategies must be considered. Harding et al [29] noted that fever patterns correspond to the diurnal variation in body temperature, peaking and troughing at consistent times, with nighttime fever incidence in the emergency department exceeding morning rates by a factor of 2.5. Such findings imply that adjusting measurement timings could improve fever detection rates. However, the optimal intervals and frequency of temperature assessments for maximal fever detection efficacy are yet to be determined. This study gathered data on the hour from a continuous temperature dataset and systematically constructed various hypothetical measurement schedules, subsequently evaluating the fever detection rate of each regimen to ascertain the most effective timing for temperature checks.

Methods

Study Design and Participants

This was a retrospective cross-sectional study. Between November 29, 2020, and April 1, 2021, consecutive patients who were aged 18 years or older and underwent nonemergency gastrointestinal surgery were included. Patients who took immunosuppressive drugs within 4 weeks before surgery, who had used antibiotics or antipyretic analgesics in the week before admission, and who were pregnant were excluded. To avoid the interference of nonsurgical fever, we also excluded patients who presented with fever before surgery. Patients whose temperature data were missing for any reason were also excluded. Demographic characteristics, surgical types, length of hospital stay, and in-hospital complications were collected.

Ethical Considerations

This study was approved by the Ethics Committee of the First Affiliated Hospital of Air Force Medical University (approved KY20222271-C-1). The patients' data have been anonymized. As a retrospective study, there was no compensation, and the requirement for informed consent was waived.

Body Temperature Measurement

Body temperature was continuously measured every 4 seconds by a wireless axillary thermometer (iThermonitor; Raiing Medical Company). The measurement accuracy of the sensor is 0.01 °C, and the readings are consistent with those of mercury thermometers [30]. On admission, a hypoallergenic adhesive patch (Raiing Medical Company) was used to securely position the iThermonitor in the shaved axilla of the patient. The temperature data were transmitted to a repeater through low-energy Bluetooth and then transferred to a central workstation, where the data were saved on an electronic monitoring panel. A detailed description of the technical parameters of the iThermonitor can be found in Multimedia Appendix 1. The temperature data on the day of surgery were dismissed, and the temperature data of the next 3 days were retrieved and named the first-, second-, and third-day temperatures.

End Points

Taking into consideration previous research reports and consensus outcomes, fever was defined as a body temperature that exceeded 38 °C [5,15-17]. Based on the definition of fever

and the data conscientiously collected by the sensors, the fever incidence on each day of the first 3 days and the total fever incidence of the first 3 days were investigated.

Patients were divided into a fever group and a nonfever group, and the clinical outcomes were compared between the 2 groups. The correlation between fever on the first day and fever in the next 2 days was investigated.

Intermittent Measurement Simulation

In the simulated clinical temperature measurement analysis, we included all patients who were determined to have a fever based on sensor temperature data. In clinical practice, for ease of implementation and documentation, temperature measurements are typically taken on the hour. Therefore, the temperature data for every hour were selected from the consecutively collected dataset.

A brute force strategy was used to list the fever detection rate of every possible measurement plan with varied measurement time points per day. The simulated intermittent measurement plans, where every possible temperature measurement plan in clinical practice, including 1 to 24 time points, were composed of n time points from the 24 hours, such as C (24, 1), C (24, 2), C (24, 3), C (24, 4), C (24, 6), C (24, 8), C (24, 12), and C (24, 24). If the temperature data at any time points included in the temperature measurement plan exceed 38 °C, it was considered that the clinical temperature measurement plan has detected a fever.

For example, C (24, 2) means diagnosing fever based on temperatures at any 2 time points in 24 hours, such as 12 AM and 1 AM, 12 AM and 2 AM, or 12 AM and 3 AM. The total number of combinations of C (24, 2) was 276. Fever was clinically diagnosed based on the temperature at the selected time points, and the fever detection rates of every plan with varied measurement times were listed and ranked.

Statistical Analysis

Temperature data processing, including the combination of the measurement timings, calculation of fever incidence, and calculation of fever detection rate, was managed by Python (version 3.7.3; Python Software Foundation), pandas (version 1.1.3; Pandas Development Team), and NumPy (version 1.21.6; NumPy Community). The statistical analysis was conducted by SPSS 22.0 (IBM Corp). Categorical data are reported as numbers with proportions, and quantitative data are reported as the mean with SD or, where appropriate, as the median with an IQR. Categorical data were compared using the chi-square test or Fisher exact test, where appropriate. For continuous data, the Student t test (2-tailed) or Mann-Whitney U test was used. A 2-sided P value of <.05 was considered statistically significant. Because of the exploratory nature of this survey, the sample size calculation was not performed.

Results

Patient Characteristics and Clinical Outcomes

A total of 147 patients who underwent gastrointestinal surgery were included. All the patients had complete temperature data within 3 days after surgery, and no missing values needed to be processed. Temperature data that were continuously collected by the sensor were used. Fever was detected in a total of 40.8% (60/147) patients within 3 days after surgery. Table 1 shows the demographic characteristics, surgical types, length of hospital stay after surgery, and in-hospital complications. The median age of the patients was 60 (IQR 53-67) years, and 62.6% (92/147) of the patients were male. The median length of hospital stay was 6 (IQR 5-8) days. Compared with the patients without fever within 3 days after surgery, patients with fever experienced a longer length of hospital stay (median 7, IQR 6-9 days vs median 6, IQR 5-7 days; P<.001). No significant difference in the postoperative complication rate was found between patients with and without fever within the 3 days (5/60, 8.3% vs 6/87, 6.9%; P=.76).

Fluctuation of Body Temperature and Fever Detection Rate

The fluctuations in body temperature on the first, second, and third days after surgery are shown in Figure 1A-C. The mean body temperature ranged from 36.88 °C to 37.24 °C, and the mean body temperatures in the first 3 days after surgery were 37.02 °C, 37.08 °C, and 37.06 °C, respectively.

The average body temperature in 1 day is shown in Figure 1D, and the body temperature varied throughout the day, with its nadir at 8 AM and its zenith at 11 PM. Figure 2 shows the fever detection rate by each hour. Within 24 hours, 38.3% (23/60) fever was detected by taking measures at 7 PM and 8 PM, and only 3.3% (2/60) fever was detected by taking measures at 1 PM.

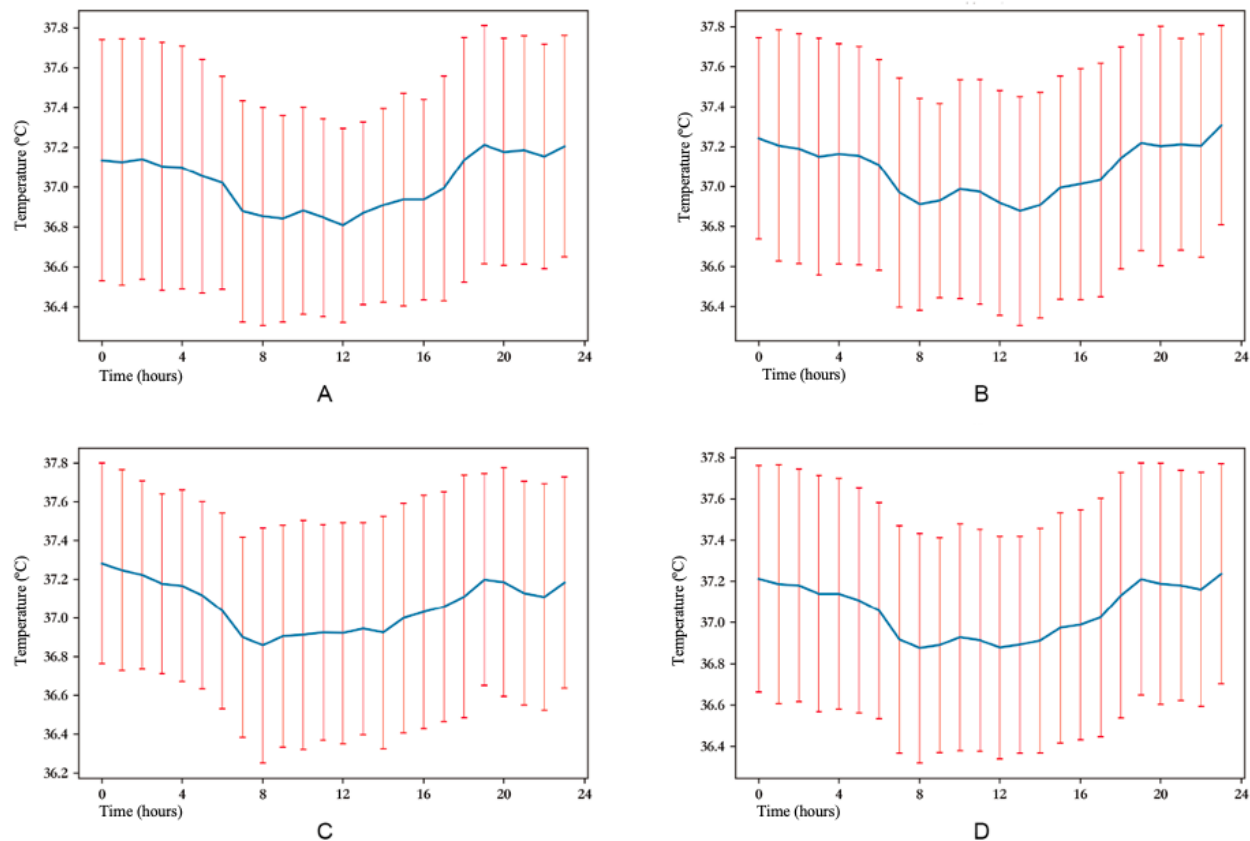
Figure 1. Body temperature curve after gastrointestinal surgery. Body temperature fluctuations on the (A) first, (B) second, and (C) third days after surgery. The average body temperatures in the first 3 days after surgery were 37.02 °C, 37.08 °C, and 37.06 °C, respectively. (D) Average body temperature within 24 hours. The average body temperature bottomed out at 8 AM and peaked at 11 PM.


Figure 2. Fever detection rate on each hour. The vertical axis represents the fever detection rate, and the abscissa axis represents the hours. The fever detection rate peaked at 38.3% at 7 PM and 8 PM and reached a nadir of 3.3% at 1 PM.
Fever Detection Rate and Measurement Times

Using intermittently collected temperature data on the hour, varied measurement plans were constructed and demonstrated. The highest and lowest detection rates and the measurement timings for the highest detection rate are shown in Table 2. For the 1–time point model C (24, 1), meaning fever was diagnosed by the temperature data at 1 time point per day, the fever detection rate ranged from 3.3% (2/60) to 38.3% (23/60). In the 2–time point model C (24, 2), meaning fever was diagnosed by the temperature data at 2 time points per day, the fever detection rate ranged from 6.7% (4/60) to 56.7% (34/60). For the C (24, 3), C (24, 4), and C (24, 6) models, the fever detection rate ranged from 6.7% (4/60) to 65% (39/60), from 8.3% (5/60) to 70% (42/60), and from 11.7% (7/60) to 76.7% (46/60), respectively. When the measurement frequency was increased to hourly, the detection rate gradually reached a plateau of 85% (51/60) (Figure 3A).

Figure 3. Correlation between fever detection rate and measurement times. The vertical axis represents the fever detection rate, and the abscissa axis represents the measurement times. The blue (D1), orange (D2), and green (D3) lines show the fever detection rates on the first, second, and third days after surgery, respectively. The red line (D1-3) shows the fever detection rate within 3 days. (A) The averaged fever detection rates with varied time points. (B) The highest detection rates with varied time points.
Table 2. Fever detection rates of body temperature measurement plans with varied measurement timings.

Measurement timings	Fever detection rate[b] (%, 95% CI)		Measurement plans with the highest detection rate
	Lowest	Highest	
Measurement plans [a]			
C (24, 1)	3.3 (0.4-6.2)	38.3 (30.5-46.2)	7 or 8 PM
C (24, 2)	6.7 (2.6-10.7)	56.7 (48.7-64.7)	3 AM and 7 or 8 PM
C (24, 3)	6.7 (2.6-10.7)	65.0 (57.3-72.7)	3 AM, 8 PM, and 10 or11 PM
C (24, 4)	8.3 (3.9-12.8)	70.0 (62.6-77.4)	12 AM, 3 AM, 8 PM, and 11 PM
C (24, 6)	11.7 (6.5-12.9)	76.7 (69.8, 83.5)	12 AM, 3 AM, 6 AM, 4 PM, 8 PM, and 11 PM
C (24, 8)	18.3 (12.1-24.6)	80.0 (73.5-86.5)	12 AM, 1 AM, 3 AM, 5 AM, 6 AM, 4 PM, 8 PM, 11 PM, etc (n=26)
C (24,24)	85.0 (79.2-90.8)	85.0 (79.2-90.8)	__[c]
Plans in our ward			
Plan A	43.3 (40.3-56.4)	43.3 (40.3-56.4)	6 AM and 6 PM
Plan B	48.3 (40.3-56.4)	48.3 (40.3-56.4)	6 AM, 10 AM, 2 PM, and 6 PM
Plan C	58.3 (50.4-66.3)	58.3 (50.4-66.3)	6 AM, 10 AM, 2 PM, 6 PM, 10 PM, and 2 AM

[a]C (24, r), selecting r time points from the 24 hours in 1 day.

[b]Fever detection rate = (detected number of patients with fever) / (all patients with fever) within 3 days after surgery.

[c]Not applicable.

Fever Detection Rate and Measurement Timings

The detection rate of the intermittent approach is influenced by the measurement timings. Table 2 shows that the corresponding time points of the top detection rates were distributed throughout the nighttime. For example, at 7 or 8 PM for C (24, 1); 3 AM and 7 or 8 PM for C (24, 2); 3AM, 8 PM, and 10 or 11 PM for C (24, 3); and 12 AM, 3 AM, 8 PM, and 11 PM for C (24, 4), the detection rate also reached a plateau by taking measures at fewer specific time points (Figure 3B). For example, an 85% (51/60) detection rate can also be achieved by using 11 time

points: 12 AM, 1 AM, 3 AM, 5 AM, 6 AM, 8 AM, 4 PM, 5 PM, 8 PM, 9 PM, and 11 PM (see row C (24, 11) in Multimedia Appendix 2). However, this is also cumbersome in real clinical work.

In our ward, according to the nursing grade, postoperative temperature are measured with 3 plans: plan A (6 AM and 6 PM), plan B (6 AM, 10 AM, 2 PM, and 6 PM), and plan C (6 AM, 10 AM, 2 PM, 6 PM, 10 PM, and 2 AM). Based on the continuously collected data, the fever detection rate of these plans were 43.3% (26/60), 48.3% (29/60), and 58.3% (35/60), respectively. The optimal detection rate of plans with the same measurement times were 56.7% (34/60), 70% (42/60), and 76.7% (46/60), respectively (Table 2).

Discussion

Principal Findings

This is the first study to investigate fever detection rates by intermittent temperature measurements. In this study, every possible intermittent measurement plan with varied measurement timings was constructed, and the corresponding fever detection rates were calculated. The results showed that fever was less frequently detected by medical staff than by the sensors, and the upper limit of detection rates by intermittent measurement was 85% (51/60) when body temperature was measured every hour. For measurement plans with varied daily frequencies, we can improve the detection rates by adjusting the measurement timings.

Limitations

While our findings have important implications, we acknowledge several limitations to our study. First, this is a small-sample retrospective study; as such, its results may be subject to bias. Second, we included patients who had undergone gastrointestinal surgery; it remains to be verified whether patients who have undergone other types of surgery also exhibit similar postoperative body temperature characteristics, which would require validation in other patient cohorts. Third, the detection rates were calculated based on the assumption that temperature was measured on the hour. There may be better time points at which fever detection is the highest. However, for convenience, body temperature is usually measured during the hour of clinical work, and our assumption is consistent with clinical practice. Fourth, previous studies and our research both indicate that the incidence of febrile events decreases as the duration of hospitalization increases [31-33]. Given that our study had a small sample size, and febrile events became infrequent after 3 days, it was challenging to discern the differences across various temperature monitoring schedules. Therefore, we chose to analyze the time period during which the occurrence of febrile events was higher, and only body temperature within the first 3 days after surgery was recorded. Whether the selected time points that were determined in this study are applicable after 3 days remains to be determined in further studies. Fifth, like most studies, we used a fixed threshold to define fever at different times. However, considering the variability of body temperature, it might be more reasonable to use a floating threshold to determine whether a patient is having a fever at different times. For instance, whether a body

temperature exceeding 37.5 °C after waking up, or exceeding 37 °C, should also be considered an abnormal state. Nonetheless, we currently lack a more rational method to define fever. Moreover, this issue goes beyond the interpretive scope of this study and requires further exploration in future research. In addition, body temperature is influenced by age, sex, and even weather [34]. However, stratified analysis was not performed since it is not practical to do so in the ward to define fever by varied levels.

Comparison with Previous Work

Consistent with a previous study which found that the proportion of patients with fever increased 2.4 to 3.6 times from morning to evening [29], we also observed that the timings of the measurement plans with the highest detection rates were predominantly at night. Moreover, as Figure 2 illustrates, the discrepancy between fever detection rates during the day and at night was more pronounced (2/60, 38.3% at 7 or 8 PM vs 2/60, 3.3% at 1 PM). This can be explained by the circadian rhythm of human body temperature. It is well known that the body temperature fluctuates throughout the day [18], with potential fluctuations of up to 1 °C within a single day [35]. In our study, we also found that body temperature exhibited rhythmic variations in patients who underwent gastrointestinal surgery. Figure 1D demonstrates that patients' body temperatures after surgery tend to be higher at night and lower during daylight, with the minimum recorded at 8 AM and the maximum at 11 PM. Hence, assessing fevers using temperature readings taken at various times throughout the day can lead to substantial discrepancies in conclusions.

Unfortunately, the timing of temperature monitoring is often neglected in both clinical research and practical settings. Notably, even in medical students' textbooks, there is no clear protocol for monitoring body temperature during the perioperative period. Medical centers tend to formulate postoperative temperature monitoring protocols based on customary local practices rather than standardized guidelines. This study demonstrates that our hospital's long-standing protocol has failed to effectively identify postoperative fever events. As indicated by Table 2, conducting as many as 6 temperature measurements daily only detected 58.3% (35/60) of patients with fever. If we adjust the temperature measurement times to 3 AM and 7 or 8 PM, 2 daily measurements could still identify 56.7% (34/60) of the cases. Optimizing the schedule to include checks at 12 AM, 3 AM, 6 AM, 4 PM, 8 PM, and 11 PM could improve fever detection rates to 76.7% (46/60).

As with our usual practice, some studies on the clinical significance of fever are typically measured only at a few unreported times of the day [16,17,19,20], while other studies do not show the timing of measurement [6,9,17,21-25]. Assuming body temperature is measured per hour, there would be 24 time points per day, resulting in a vast array of measurement schedules. Given the wide range of detection rates among the numerous measurement schedules, many patients with fever might go unidentified when measurements are taken at randomly selected times. Since fevers cannot be accurately detected, the interpretation of the clinical significance of postoperative fever may also be biased. In addition, we also see

some clinical studies that consider fever as an outcome of the intervention, especially those related to ERAS strategies for perioperative stress control [8-14]. In these studies, the timing and frequency of temperature measurements are not reported either. If consistency of the timing of temperature measurements is not considered when assessing fever, biases are likely to occur when evaluating the efficacy of the respective clinical interventions. Therefore, we may consider including recommendations on the timing of temperature measurements in ERAS-related guidelines.

Multimedia Appendix 2 lists the optimal measurement schedules that achieve the highest detection rates, varying from once to 23 times per day. By aligning these schedules with the routine practices of local hospitals, clinicians can formulate more precise thermometric protocols. For instance, a tridaily measurement regimen might entail taking temperatures at 3 AM, 8 PM, and 10 or 11 PM, as specified in row C (24, 3) in Table 2. It is essential to recognize, however, that these proposed times are flexible rather than absolute mandates for fever surveillance. In clinical practice, temperatures will also be measured at any necessary time. Given the symptoms that accompany fever, it is reasonable to measure temperature at suggested times as well as when needed.

What is the clinical significance of detecting postoperative fever, especially fever that occurs in the early days following surgery? Many studies have investigated the correlation between postoperative fever and infection. Most have found that postoperative fever is a marker of infection with very low specificity and sensitivity [2,5]. Some researchers have reported that among patients who developed fever after abdominal surgery, only 2% had positive blood cultures [5]. Among patients with fever following orthopedic surgeries, the positive finding rates for chest x-rays, urinalysis, urine cultures, and blood cultures were 0.3%, 28.5%, 10.9%, and 3.5%, respectively. Such low cost-effectiveness has led some researchers to question the use of postoperative temperature measurement [36]. One study even instructed the clinical team responsible for patient care to remain unaware of the patient's body temperature and required clinical decisions to be made without looking at temperature data. This study reported a positive predictive value of merely 8% for fever as an indicator of infection, suggesting the potential abandonment of routine temperature measurements [17]. Our findings align with these observations, demonstrating an insignificant link between fevers within the first 3 postoperative days and the onset of complications.

Although the prevalence of postoperative fever may not require immediate imaging or bacteriological assessments, it is inadvisable to ignore it and leave patients to manage the condition without support. The risks posed by postoperative fever extend beyond infection. Postoperative fever is also associated with the release of inflammatory mediators in the absence of infection. This study indicates that fever during the early postoperative days has a positive correlation with prolonged hospital stays (with a median of 7, IQR 6-9 days, compared with a median of 6, IQR 5-7 days). The longer hospitalization might be attributable to surgical stress, as a fever following surgery may arise from inflammation and tissue damage [37], suggesting that patients enduring pronounced surgical stress may need additional recovery time. Monitoring for postoperative fever is crucial in evaluating the magnitude of surgical stress and the efficacy of interventions to mitigate it. Fever, as a surgical stressor, constitutes a postoperative adverse event and an unpleasant experience that necessitates closer nursing attention. Considering the benign nature of early fever, there might be 2 approaches, refraining from intervention and allowing the fever to subside on its own, or providing necessary medical care, such as pain management [38], physical cooling, physical examinations, and psychological comfort, to facilitate the recovery process. If we opt to take some action, routine ward rounds could be considered during peak fever times, such as between 7 PM and 8 PM.

Conclusions

In conclusion, reliance on traditional, arbitrary temperature measurement can lead to the oversight of numerous febrile episodes. From the standpoint of both clinical safety concerning fevers and the interpretability of clinical research, it is necessary to improve the detection rate of postoperative febrile events. Even in medical settings where continuous temperature monitoring sensors are unavailable, adjusting the timing for measuring temperatures to the nighttime can substantially improve the detection of febrile events. Postoperative body temperature monitoring protocols can be revised in accordance with the working habits of local hospitals. In addition, to facilitate more precise assessments of study outcomes, future research examining postoperative fevers should consider detailing the timing of temperature recordings in their reports.

Abstract

Background: Chronically elevated inflammation is implicated in many conditions, including obesity, metabolic syndrome, and cardiovascular disease, and has been associated with increased mortality risk. Whole-body cryotherapy (W-BC) is a promising modality to treat inflammation with demonstrated benefits for clinical subpopulations including those with arthritis, obesity, and type 2 diabetes. However, it is unclear whether the benefit from W-BC extends to healthy individuals prior to chronic disease–related inflammation. In addition, the long-term durability of W-BC effect is unknown.

Objective: This study investigates the inflammatory response to W-BC in healthy adults with a biomarker of inflammation, high-sensitivity C-reactive protein (hsCRP), and clinical biomarkers of metabolism including fasting glucose, hemoglobin A_{1c} (HbA$_{1c}$), low-density lipoprotein (LDL) and high-density lipoprotein (HDL), and triglycerides.

Methods: Fifteen individuals (n=9 female) participated in frequent recreational W-BC (3 minutes of cold exposure at –110 ℃) over approximately 9 months and had blood draws at baseline plus follow-up visits. Biomarkers were modeled as linear functions of W-BC sessions received in the month prior to blood draw.

Results: The mean amount of W-BC received was 6.78 (SD 4.26) times per month with the cumulative total ranging from 13 to 157 W-BC sessions over the course of the study. On average, participants completed 1-2 sessions per week throughout the intervention. The number of W-BC sessions were associated with decreased hsCRP (–0.14 mg/L in hsCRP per W-BC session; $P<.01$) and with durability of up to 9 months. Increased W-BC was also associated with a downward trend in fasting glucose. This trend failed to reach significance at 1 month (–0.73 mg/dL in fasting glucose per W-BC session; $P<.10$) but was significant for 2- and 3-month windows ($P<.05$). HbA$_{1c}$ was increased significantly after 9 months ($P<.01$); however, the change occurred within normal ranges (difference=0.13% and <5.7%) and was not clinically significant. There was no association between W-BC and LDL cholesterol, HDL cholesterol, or triglycerides ($P>.10$), although LDL trended lower over the time period examined ($P=.07$).

Conclusions: These results suggest that W-BC beneficially impacts systemic inflammation by lowering hsCRP levels in healthy individuals and may also have some modulating effect on fasting glucose.

Introduction

Chronic systemic inflammation is associated with aging [1] and aging-related diseases [2] including increased cardiovascular disease, cancer, and overall mortality [3,4]. Systemic inflammation is also implicated in metabolic conditions such as diabetes, overweight, and the cluster of conditions collectively known as metabolic syndromes [5]. As populations age and chronic conditions increase worldwide [2], identifying nonpharmacologic therapies to proactively treat inflammation in healthy individuals has become paramount.

One potential approach is cold therapy, which has been examined for acute and disease-specific inflammation [6]. While cold therapy has historically involved either localized treatment or cold water immersion, in recent years cryotherapy machines use air chambers that reach below –100 ℃ [7]. Multiple forms of cryotherapy exist, one of which is whole-body cryotherapy (W-BC) in which a person is completely enclosed in a cryotherapy chamber. In sports medicine, W-BC has been shown to reduce inflammation markers including interleukin-6 (IL-6) and C-reactive protein (CRP) [8]. Separately, in inflammatory diseases such as rheumatoid arthritis, W-BC has been used to reduce pain and disease activity [9]. W-BC has been shown to decrease CRP [10] and proinflammatory cytokines IL-6 and resistin, while increasing the anti-inflammatory cytokine IL-10 in men with obesity [11]. W-BC has also demonstrated reductions in CRP in postmenopausal women with type 2 diabetes [12]. Although these results are promising, there remains a crucial gap in long-term study of inflammation specifically in healthy individuals as further value could be extracted if benefits extend prior to disease onset. Moreover, the chronic, rather than acute, impact of W-BC on inflammation is insufficiently studied as most literature focuses on the time frame immediately following treatment [7]. Thus, the durability of such an effect is not well established. This study aimed to analyze the impact of W-BC on systemic inflammation and related markers of metabolism in healthy adults within a free-living environment. To understand the longer-term effect, durability analysis was also performed. It was hypothesized that W-BC would have a beneficial impact on inflammation in healthy adults, possibly mediated via an anti-inflammatory effect of lowering blood glucose.

Methods

Participants

The study cohort was composed of healthy adults older than 18 years whose deidentified data were abstracted from client records for research analysis. Data were collected from individuals who had been screened for contraindications and exclusion criteria as previously reported [13]. Briefly, participants were excluded if they reported a diagnosed chronic disease, had untreated high or low blood pressure, or were pregnant or breastfeeding. All participants completed a consent that allowed data to be used for research purposes.

Ethical Considerations

Data were examined retrospectively and determined to be exempt by the Norwich University institutional review board and research ethics committee and informed consent was waived (HHS IORG #0004914; institutional review board no. 00005859; date of registration: April 30, 2023).

Intervention Protocol

Participants were followed for an average of 8.55 months (SD 3.13; median 6.77, IQR 6.77-9.73), with total follow-up duration ranging from 5 to 13 months for those who had at least 1 follow-up visit. During this time, they frequently participated in recreational W-BC at a commercially operated studio (Restore Hyper Wellness). The mean amount of W-BC received was 6.78 (SD 4.26) times per month with the cumulative total ranging from 13 to 157 W-BC sessions over the course of the study. On average, participants completed 1-2 sessions per week throughout the intervention. Participants were encouraged to engage in regular physical activity and received guidance on healthy dietary patterns, although these behaviors were not monitored.

Whole-Body Cryotherapy Protocol

Participants were escorted to a private changing room where they removed personal clothing and put on a provided hat, socks, slippers, mask, and gloves, as well as a towel or robe. Once changed, they were escorted to the cryotherapy chamber for 3 minutes of cold exposure at –110 ℃. Chambers were electrically cooled using a main cooling unit in a full body chamber (Zimno Tech). Participants were observed by an employee trained in administering the protocol and could exit the chamber at any time. At the completion of 3 minutes, the chamber door was opened and the participants exited, returned to the private changing room, and redressed in their own clothing.

Blood Biomarkers

Blood was drawn at baseline and then incrementally at follow-up visits. Participants were asked to fast for 8-12 hours prior to blood draw. On average, there were 2.13 (SD 2.59) follow-up visits with a mean time of 170 (SD 84) days between blood draws. The minimum time between blood draws was 17 days, and the maximum was 292 days. Blood biomarkers measured include serum high-sensitivity C-reactive protein (hsCRP), fasting glucose, hemoglobin A_{1c} (HbA$_{1c}$), low-density lipoprotein (LDL) and high-density lipoprotein (HDL), and triglycerides. All blood was drawn from the median cubital vein with a 20-gauge intravenous catheter needle. Drawn samples were sent to Quest Diagnostics for analysis. hsCRP was analyzed with an immunoturbidimetric assay (test code 10124); fasting glucose, serum lipids, and triglycerides were analyzed with spectrophotometry (test codes 6881 and 7600, respectively); and HbA$_{1c}$ was analyzed with an enzymatic assay (test code 496). For hsCRP, the reporting range by Quest Diagnostics was 0.3-10 mg/L, with values outside the range being listed as <0.3 or >10 mg/L. There were no identified thresholds for fasting glucose, HbA$_{1c}$, or lipids.

Statistical Analysis

All data analysis and statistical modeling were carried out in R (version 4.3.1) [14]. Data processing was performed using tidyverse packages including readr and readxl for file opening; dplyr, hms, lubridate, tibble, and stringr for wrangling; and ggplot2 for visualizations [15]. Two data points were missing a parsable date and those records were removed. Out of range hsCRP measurements were included as their threshold value, that is, <0.3 was included as 0.3.

Statistical significance was defined as a $P<.05$ threshold while anything failing to meet that threshold but with $P<.10$ was noted as being mild association and of possible interest. Paired t tests on all complete pairs for a given analyte were used to compare start and end measurements for all biomarkers in Table 1.

Table 1. Summary of study cohort—demographics and blood biomarkers.

Variable	Start mean (SD)	End mean (SD)	P value[a]
N	15	13	N/A[b]
Sex (female/male)	9 females/6 males	8 females/5 males	N/A
Age (years)	48.60 (8.50)	48.50 (8.31)	N/A
HbA$_{1c}$ (%)	5.12 (0.27)	5.25 (0.29)	.008[c]
Fasting glucose (mg/dL)	96.00 (15.96)	98.31 (12.87)	.93
hsCRP[d] (mg/L)	3.39 (3.31)	1.88 (1.88)	.03[c]
LDL[e] (mg/dL)	121.07 (30.22)	112.00 (37.05)	.07
HDL[f] (mg/dL)	57.87 (12.35)	58.92 (13.47)	.76
Triglycerides (mg/dL)	113.47 (54.58)	119.92 (63.46)	.81

[a]P values calculated using paired 2-tailed t tests on all complete pairs for a given analyte.

[b]N/A: not applicable.

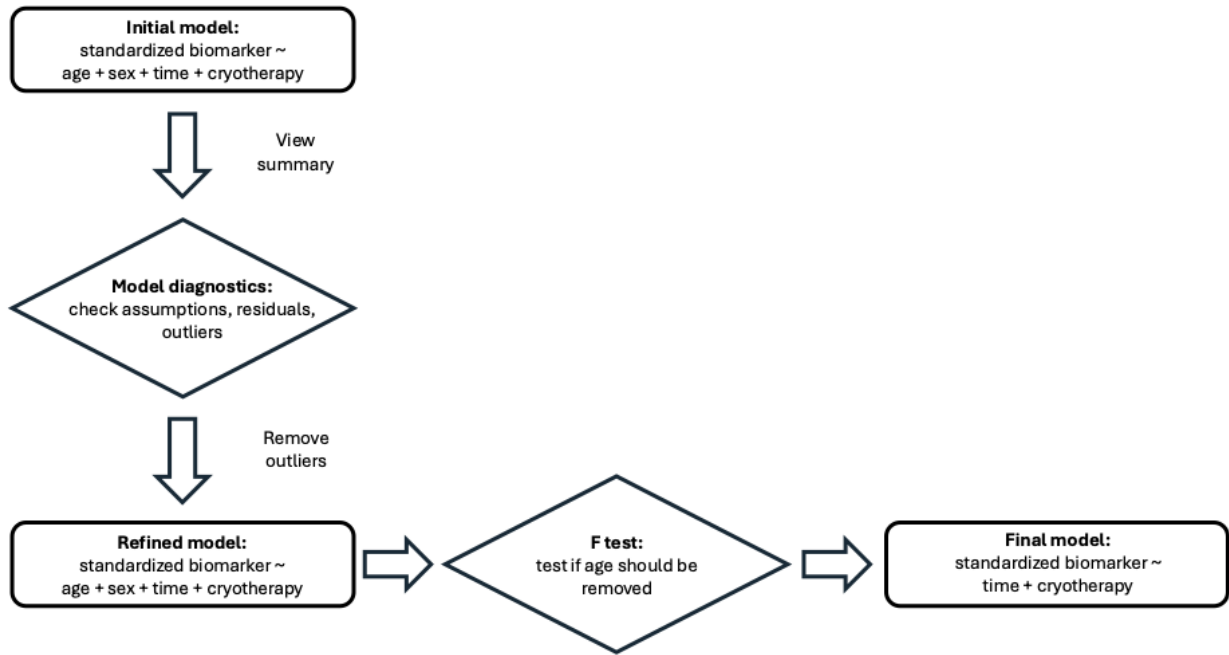
[c]$P<.05$.

[d]hsCRP: high-sensitivity C-reactive protein.

[e]LDL: low-density lipoprotein.

[f]HDL: high-density lipoprotein.

For both the primary analysis (W-BC impact on hsCRP) and the secondary analysis (W-BC impact on biomarkers of metabolism) multiple linear regression models were constructed. An initial model was fit with the analyte of interest standardized by the participant-specific mean as the response, and the predictors were age, sex, days from study start, and number of W-BC sessions in the past 30 days (1 month). After inspection of model diagnostics for violations of the linear modeling assumptions, outliers were removed based on a Cook's distance threshold of 4/n where n is the sample size. A refined model was then fit without outliers and inspected again for model diagnostics. Finally, the reduction method F test was used to determine whether a reduced model that removed age and sex was preferred. This was done because age and sex were not found to be significant in any of the initial models. Based on the F test results, the final model was chosen (Figure 1).

Figure 1. Statistical analysis flowchart. Diagram of study statistical methods showing each modeling step. For durability testing, the final model structure, namely, analyte regressed on days from study start and number of W-BC sessions, was used to fit models on different time windows. In particular, 1- to 3-week, 1- to 3-month, 6-month, and 9-month windows were tested. The false discovery rate method was used to correct for multiple testing.


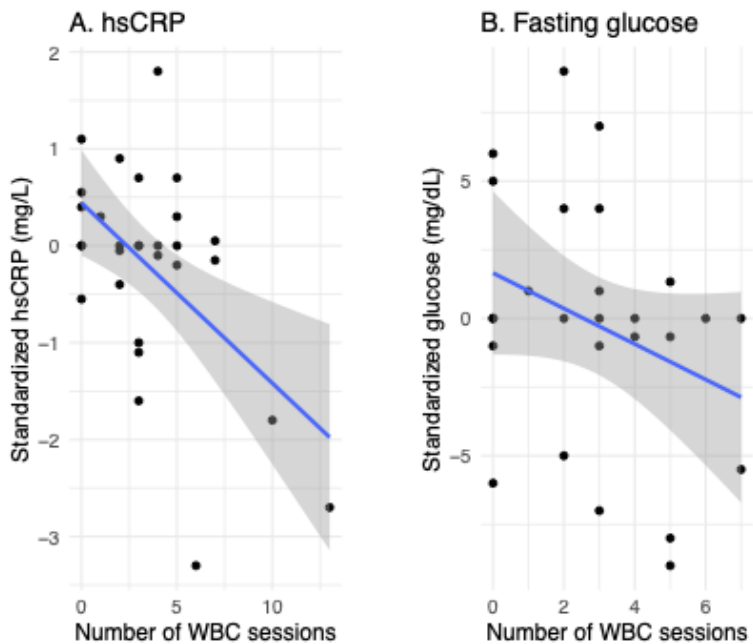
Results

Participants

Fifteen participants (female: n=9) were included in the analysis (Table 1). Ages ranged from 32 to 59 years. Average weight at baseline was 84.97 (SD 14.61) kg. Ethnicity or race and height were not recorded. Two were lost to follow-up and an intention-to-treat statistical model was used.

Inflammation and hsCRP

The number of W-BC sessions in the month prior to blood measurement was associated with a statistically significant decrease in hsCRP ($P<.01$). The final linear model for hsCRP was fit on 29 observations from 15 participants. Neither age nor sex was associated with changes in hsCRP and was not included in the final model (Figure 2A). The effect size was –0.1413 mg/L in hsCRP per W-BC session (95% CI –0.2289 to –0.0537).

Figure 2. Model results. (A) Impact of W-BC on hsCRP counting W-BC sessions in the month prior to serum measurement. The y-axis shows hsCRP values standardized by subtracting subject specific means, while the x-axis is the number of W-BC sessions. The final linear regression was fit on 29 observations from 15 subjects (9 females/6 males); $P<.01$. (B) Impact of W-BC on fasting glucose modeled in the same fashion as hsCRP in (A). The final linear regression was fit on 26 observations from 14 subjects (9 females/5 males); $P=.07$. hsCRP: high-sensitivity C-reactive protein; W-BC: whole-body cryotherapy.


To account for possible time-related confounding, time was adjusted for by including days since baseline launch day. Time was found to be a significant predictor of hsCRP although with a very small effect size ($P<.01$; effect size=–0.0047 mg/L, 95% CI –0.0066 to –0.0028). Importantly, even with time in the model, the number of W-BC sessions was still strongly significant. In addition, W-BC sessions had a larger effect size being –0.1413 mg/L as compared with –0.0047 mg/L for time.

If scaled to 1-month windows, the effect of W-BC was still larger than time. Namely, multiplying days by 30 and W-BC sessions by the monthly average of 6.78 gives monthly effects sizes of –0.9579 mg/L and –0.1409 mg/L for W-BC and time, respectively. Thus W-BC sessions have a statistically significant impact on reducing hsCRP while also having a larger effect as compared with time (Table 2).

Table 2. Results for primary (hsCRP) and secondary (fasting glucose) analyses.

Response metric and predictor	Effect size[a]	95% CI	Scaled effect size[b]	P value
hsCRP [c] (mg/L)				
W-BC[d]	–0.1413	–0.2289 to –0.0537	–0.9579	.0027[e]
Time	–0.0047	–0.0066 to –0.0028	–0.1409	.00004[e]
Fasting glucose (mg/dL)				
W-BC	–0.7337	–1.5236 to 0.0562	–4.9743	.0672
Time	0.0114	–0.0008 to 0.0237	0.3423	.0663

[a]Effect size given as units of analyte per W-BC session (W-BC) or day (time), for example, for hsCRP, the effect size is –0.1413 mg/L in hsCRP per W-BC session.

[b]Scaled to 1 month by multiplying coefficients by 30 days for time and 6.78 for W-BC (mean amount of W-BC received per month).

[c]hsCRP: high-sensitivity C-reactive protein.

[d]W-BC: whole-body cryotherapy.

[e]$P<.05$.

To elucidate the durability of the observed effect, sequential time windows were tested (Figure 3A). Windows less than 3 weeks were not associated ($P>.10$) with hsCRP. At 3 weeks, a mild association appeared ($P>.10$), and at 1 month the association was significant even after adjusting for the multiple testing windows ($P<.05$). For windows of 2 months or longer, the association remained, though only mildly ($P>.10$). Because participants were tracked only for around 9 months on average, longer windows were not constructed.

Figure 3. Durability testing. (A) Durability of whole-body cryotherapy (W-BC) effect on hsCRP measured by fitting linear models on a range of window sizes: 1-3 weeks, 1-3 months, 6 months, and 9 months. Models first reached mild association ($P<.1$) at 3 weeks which persisted up to the 9-month window. (B) Durability of W-BC effect on fasting glucose modeled in the same fashion as hsCRP in (A). Only 2- and 3-month models were significant ($P<.05$). Overall trend suggests an association that takes time to appear and tails off for very long windows. hsCRP: high-sensitivity C-reactive protein.

Biomarkers of Metabolism

The number of W-BC sessions in the prior 1 month failed to reach the threshold for statistical significance ($P=.07$). The final linear model was fit on 26 observations of fasting glucose from 14 participants. Neither age nor sex was associated with fasting glucose and was not included. The estimated effect size was –0.7337 mg/dL in fasting glucose per W-BC session (95% CI
–1.5236 to 0.0562) meaning more W-BC was mildly associated with a small decrease in fasting glucose (Figure 2B). Time indicated a possible small increase in fasting glucose over time although failed to reach significance (P=.06; effect size=0.0114, 95% CI –0.0008 to 0.0237). HbA_{1c} did increase slightly after 9 months (P<.01); however, the change was quite minimal and within normal ranges (difference=0.13% and <5.7% at both time points). Only hsCRP was reduced significantly (P=.03) in before versus after measurements.

Durability results revealed that slightly longer time windows may be more appropriate for studying fasting glucose. After correction for multiple testing using the false discovery rate method, the shorter 1-month window was not statistically significant (adjusted P>.05). However, windows of 2 and 3 months (60 and 90 days) showed a significant association between W-BC and decreased fasting glucose (adjusted P<.05; Figure 3B).

For the lipid biomarkers, namely, LDL cholesterol, HDL cholesterol, and triglycerides, no association with W-BC was found (P>.10), although LDL trended lower over the time period examined (P=.07).

Discussion

Principal Findings

This study investigated long-term physiologic effects associated with inflammation and aging in healthy adults by examining hsCRP and biomarkers of metabolism as a function of W-BC. Overall, W-BC showed beneficial impacts for inflammation and fasting glucose but not serum lipids. The effect with hsCRP appears time dependent and indicated that the impact of W-BC on inflammatory markers may take up to 3 weeks to manifest, with the effect significant and durable for up to 9 months with continued use.

The results of this study agree with, and extend, prior research on W-BC related to inflammation. Studies in patients with arthritis showed that W-BC helped reduce inflammatory markers such as IL-6, tumor necrosis factor, and serum CRP [16-18]. Similar anti-inflammatory benefits from W-BC have been observed in studies of men with overweight and obesity, as well as postmenopausal women with type 2 diabetes [10-12]. While prior studies provided a groundwork for the acute anti-inflammatory effect of W-BC in populations who already suffer from chronic inflammation, this study sought to extend the generalizability of such an anti-inflammatory effect to healthy individuals without specific disease conditions.

To the best of our knowledge, there is only 1 other study that specifically examined healthy individuals and long-term durability of the anti-inflammatory effect with W-BC. Lubkowska et al [19] measured cytokine levels in healthy men for up to 6 weeks after W-BC and found a beneficial association between W-BC and serum cytokines. Their results, along with the current findings, demonstrate that W-BC can decrease inflammation in healthy adults, both in the short term (ie, 6 weeks) and the long term (ie, up to 9 months).

The current findings also add a durable clinical marker of systemic inflammation associated with future disease risk (hsCRP) to the cytokines previously studied. This is key because cytokines alone may be less accurate biomarkers than CRP for disease risk due to issues with stability, half-life, and serum variability. For example, IL-6, one of the main cytokines analyzed by Lubkowska et al [19, shows distinct diurnal variation and therefore time of day can be a confounder [20,21]. In contrast, CRP shows no diurnal variations lending it stability and reproducibility for comparison [22]. CRP may also be a better overall marker of disease risk by not only showing acute inflammation but also having persistence and stability in plasma. Research in cardiovascular disease indicates that hsCRP may be a better marker for future diagnoses of hypertension, myocardial infarction, and coronary heart disease [23,24]. Together, the current findings and prior outcomes elucidate potential mechanistic and clinical implications of short- and long-term W-BC.

Fasting glucose was also beneficially impacted by W-BC in this study, though the exact relationship is less clear. At 1 month, the association between W-BC and fasting glucose trended downward (P<.10). Durability analysis then revealed significant associations between W-BC and decreased fasting glucose for 2- and 3-month windows (adjusted P<.05). After 3 months, no linear relationship was found. Thus, the effect of W-BC on fasting glucose may be more time-constrained such that some benefits are seen for intermediate time windows but may not be durable chronic adaptations. This time-dependent interpretation is further supported in light of the lack of change seen in fasting glucose from the start to the end of the 9-month study. Interestingly, a very small increase in HbA_{1c} was noted at the final follow-up period (P<.01). However, the change was quite minimal (difference=0.13%) and within normal ranges at both time points (5.12 [0.27%] and 5.25 [0.29%], respectively) and not considered clinically significant.

From a clinical perspective, the current results extend inflammatory effects of W-BC to known markers of metabolic dysregulation. Specifically, decreases in blood glucose are known to modulate inflammation [25]. Thus, the beneficial impact on inflammation seen from W-BC may be achieved at least in part due to reductions in blood glucose. Indeed, the study by Wiecek et al [12] noted decreases in both blood glucose and CRP. While the previous study specifically examined women with type 2 diabetes and therefore elevated glycemia, the participants in this study were healthy, nondiabetic individuals. Thus, these results further extend the beneficial impact of W-BC on fasting glucose to those without an existing hyperglycemic diagnosis. Further targeted research would be needed to establish a definitive connection between the glucose modulating effects of W-BC and its anti-inflammatory benefits.

No significant effect from W-BC was found for the lipid markers of metabolism in either the comparison of study start to end or the linear modeling for specific time windows. This result slightly contradicts prior research finding a benefit of W-BC for lipids. In particular, Lubkowska et al [26] found that W-BC combined with exercise as a program to treat overweight resulted in improved lipid metabolism including decreased LDL and

triglycerides and increased HDL. However, this study included exercise in a protocol targeted at treating overweight, thus applicability for W-BC specifically is less clear. A more recent study investigating lipid metabolism in healthy adults demonstrated that daily W-BC was associated with decreased LDL and triglycerides and increased HDL [27]. However, this study was analyzing acute effects immediately after daily application of W-BC while the present study, which found no significant effect on lipid metabolism, is focused on longer-term impacts. Thus, it is plausible that W-BC could impact lipid metabolism in the short term while not having a lasting durable benefit. It is also possible that a true effect exists, but this study was simply underpowered to discern it.

Limitations

One major limitation of this study is sample size. Both the number of participants and the number of follow-up visits were small. To correct for any time-based confounding, time has been included in the models; however, other possible sources of confounding could exist. In addition, there was no control group. In general, control groups for W-BC are difficult since a participant cannot be blinded to whether they receive cryotherapy. In addition, this study was conducted in a free-living real-world environment rather than a controlled clinical setting. Such a design lends both benefits and drawbacks. The main drawback of this free-living environment is that external factors could lead to possible confounding. For example, weight loss in individuals with obesity has been linked to a decrease in inflammatory markers including CRP [28,29]. As weight loss information was not available, time was included as a proxy for any weight loss or other baseline improvements in health that participants may have experienced. However, time

alone likely does not capture all confounding effects and thus the impact of external uncontrolled factors cannot be ignored.

In spite of the limitations, a free-living study also has unique benefits. In particular, such a design enables immediate applicability of results to real-world environments. This study did not involve a clinical protocol necessitating strict compliance, yet the results still demonstrated a significant benefit from recreationally participating in cryotherapy. Thus, the takeaways from these results may be applied more generally to the public in that individuals can simply incorporate cryotherapy into their daily lives.

Future directions of study could include analysis of dosage for optimal effect. For example, if the benefit of increased W-BC sessions plateaus at some point, then individuals can limit unnecessary time, expense, and exposure by participating in only an optimal number of W-BC sessions. Dosage could also be dependent on the durability of the effect. Given the rapidly rising popularity of cryotherapy, high-quality randomized controlled trials are needed to investigate these more specific outcomes.

Conclusions

This study explores the impact of W-BC on healthy participants outside of any specific exercise protocol or disease state. In doing so, W-BC has been demonstrated to be potentially beneficial to the general population as an anti-inflammatory treatment. Furthermore, the anti-inflammatory effects show lasting durability for impact on future chronic inflammation. Finally, this study demonstrated that W-BC may have a beneficial, though time-constrained, impact on glucose.

Short Paper

Validation and Refinement of the Sense of Coherence Scale for a French Population: Observational Study

Abstract

Background: Salutogenesis focuses on understanding the factors that contribute to positive health outcomes. At the core of the model lies the sense of coherence (SOC), which plays a crucial role in promoting well-being and resilience.

Objective: Using the *validscale* Stata command, we aimed to assess the psychometric properties of the French version of the 3-dimension 13-item SOC questionnaire (SOC-13), encompassing the comprehensibility, manageability, and meaningfulness dimensions. We also aimed to determine if a refined scale, assessed through this method, exhibits superior psychometric properties compared to the SOC-13.

Methods: A sample of 880 consecutive primary care patients recruited from 35 French practices were asked to complete the SOC-13. We tested for internal consistency and scalability using the Cronbach α and Loevinger H coefficients, respectively, and we tested for construct validity using confirmatory factor analysis and goodness-of-fit indices (root mean square error of approximation [RMSEA] and comparative fit index [CFI]).

Results: Of the 880 eligible patients, 804 (91.4%) agreed to participate (n=527, 65.6% women; median age 51 years). Cronbach α and Loevinger H coefficients for the SOC-13 were all <0.70 and <0.30, respectively, indicating poor internal consistency and poor scalability (0.64 and 0.29 for comprehensibility, 0.56 and 0.26 for manageability, and 0.46 and 0.17 for meaningfulness, respectively). The RMSEA and CFI were >0.06 (0.09) and <0.90 (0.83), respectively, indicating a poor fit. By contrast, the psychometric properties of a unidimensional 8-item version of the SOC questionnaire (SOC-8) were excellent (Cronbach α=0.82, Loevinger H=0.38, RMSEA=0.05, and CFI=0.97).

Conclusions: The psychometric properties of the 3-dimension SOC-13 were poor, unlike the unidimensional SOC-8. A questionnaire built only with these 8 items could be a good candidate to measure the SOC. However, further validation studies are needed before recommending its use in research.

Introduction

Salutogenesis, a concept developed by Aaron Antonovsky, represents a paradigm shift in health research as an approach focusing on understanding the factors contributing to positive health outcomes rather than merely concentrating on disease prevention [1,2]. At the core of Antonovsky's salutogenic model lies the concept of the sense of coherence (SOC), a multifaceted concept reflecting an individual's capacity to comprehend, manage, and find meaning in the world around them, influencing

their ability to cope with stressors and maintain positive well-being [3]. The three interrelated dimensions of SOC include comprehensibility (perceiving the world as ordered/predictable), manageability (belief in coping effectively with stressors), and meaningfulness (finding purpose/motivation in life). A strong SOC fosters a cognitive orientation that enables individuals to perceive their environment as structured/predictable, facilitating a greater understanding of the challenges they encounter. Moreover, the belief in one's ability to manage stressors effectively empowers individuals to approach difficulties with confidence/resilience. The sense of meaningfulness, derived from finding purpose/motivation in life, further contributes to an individual's adaptive capacity in the face of stressors. The SOC theory also introduces a unidimensional model that provides a consolidated measure, aiding in a quicker clinical assessment of an individual's overall SOC. The choice between the 3-dimension and unidimensional models depends on assessment goals and the required depth of information.

The SOC theory has gained considerable attention in health research, with numerous studies exploring its applicability/implications [3,4]. Researchers typically use the 13-item questionnaire (SOC-13) to assess an individual's level of coherence and its association with various health-related outcomes [4,5]. The questionnaire has been translated into several languages, including French. However, to our knowledge, the French version did not go through validation procedures. A relatively old population-based study evaluated a French version of the SOC-13 scale modified by the authors [6]. This questionnaire (not provided in their article) showed satisfactory internal consistency but only for the unidimensional model, whereas the validity was insufficient.

Given the lack of information on the validity/reliability of the French SOC-13, we aimed to assess its psychometric properties in primary care patients, ensuring its appropriateness/effectiveness for assessing SOC in French-speaking patients. If the psychometric properties of this scale were found to be insufficient, a secondary objective was to develop an alternative version that would be more valid/reliable than the SOC-13. By selecting primary care patients as the target, we explored the SOC concept in a real-world, patient-centered setting, recognizing implications for interventions and the broader relevance to salutogenesis.

Methods

Study Setting

This observational study was performed with primary care patients in France during 2023. We used a professional register of primary care physicians in the Rhône-Alpes region of France and randomly selected 200 physicians using computer-generated random numbers. Five research assistants contacted each selected physician via email until the target number of physicians (n=35) was attained. In case of refusal or no response after 3 reminders, the next practice on the list was contacted. A sample of 880 consecutive patients recruited from these practices (20-25 patients per practice) were asked to complete the French SOC-13 in the waiting room. Eligible participants were nonurgent, French-speaking, adult patients capable of understanding the study.

Ethical Considerations

The study was approved by the Research Ethics Committee of the University College of General Practice (Lyon) (project ID IRB 2023-01-03-01). Informed consent was obtained from all participants and their ability to opt out was ensured. Privacy/confidentiality were maintained through anonymized data.

SOC-13 Scale

The SOC-13 questionnaire has three components: items 2, 6, 8, 9, and 11 are related to comprehensibility; items 3, 5, 10, and 13 are related to manageability; and items 1, 4, 7, and 12 are related to meaningfulness. The questions are rated on a 7-point Likert scale so that the total score ranges from 13 to 91. The coding for items 1, 2, 3, and 7 is reversed. We summarized the 3 subscores and the total score using the median (IQR).

Validation of the French Version of the 3-Dimension SOC-13 and Development of the Unidimensional 8-Item SOC Questionnaire

We used the *validscale* command [7] in Stata to assess the psychometric properties of the SOC-13 using classical test theory [8]. We assessed both the 3-dimension and unidimensional models with this approach. We tested for internal consistency and scalability using the Cronbach α and Loevinger H coefficients, respectively. A minimum value of 0.70 for Cronbach α and of 0.30 for Loevinger H were considered acceptable [9,10]. We tested for construct validity using confirmatory factor analysis and goodness-of-fit indices. To assess the adequacy of the statistical model, we used the root mean square error of approximation (RMSEA) and the comparative fit index (CFI). These indices evaluate the agreement between the observed and expected data according to the specified model. An RMSEA<0.06 and a CFI>0.90 are generally considered to indicate that the model is a good fit [11]. We used the *convdiv* option to assess convergent/divergent validities through examination of a correlation matrix [7].

We also developed a shorter questionnaire in French that is potentially more reliable/valid and easier to use in primary care than the SOC-13. We removed all problematic items from the SOC-13 by examining the Cronbach α values obtained for each removed item, while keeping at least 2 questions per dimension. This questionnaire consisted of 8 items (items 6, 8, 9, and 11 for comprehensibility; items 10 and 13 for manageability; and items 4 and 12 for meaningfulness).

The French versions of the SOC-13 and the new unidimensional 8-item SOC scale (SOC-8) are provided in Multimedia Appendix 1. Following published guidelines, we targeted a minimum of 500 participants, achieving a "very good" sample size, with a responder-to-item ratio exceeding 20:1 [12]. All analyses were performed with Stata 15.1.

Results

A total of 804 participants agreed to take part in the study (participation rate=91.4%), 65.6% of whom were women (n=527). The median age of the participants was 51 (IQR 30, range 20-93) years. Depending on the item, between 787 and 793 participants responded to the SOC-13 questions. The median score was 23 (IQR 8, range 5-35) for comprehensibility, 18 (IQR 6, range 4-28) for manageability, 21 (IQR 6, range 8-28) for meaningfulness, and 62 (IQR 16, range 30-89) for the total score.

Internal consistency and scalability were not sufficient for the 3-dimension model. Cronbach α and Loevinger H coefficients were all <0.70 and <0.30, respectively (0.64 and 0.29 for comprehensibility, 0.56 and 0.26 for manageability, and 0.46 and 0.17 for meaningfulness, respectively). Table 1 shows the proportion of missing data for each item, the distribution of item responses, and the Loevinger H and Cronbach α coefficients obtained by omitting each item. Loevinger H coefficients were <0.30 for 9 of the 13 items.

The confirmatory factor analysis, goodness-of-fit indices, and correlation matrix are shown in Table 2. The RMSEA and CFI were 0.09 and 0.83, respectively, indicating a poor fit. Only 4 items had a correlation coefficient with the score of their own dimension >0.40 (indicating lack of convergent validity) and only 5 items had a correlation coefficient with the score of their own dimension greater than those computed with other scores (indicating lack of divergent validity).

Table 1. Distribution of item responses, internal consistency, and scalability of the French versions of the 3-dimension 13-item and unidimensional 8-item sense of coherence (SOC) scales.

[a]Cronbach α is calculated if the item is removed; for example, if item 2 of SOC-13 were removed, the Cronbach α for comprehensibility (ie, Dimension 1) would increase from 0.64 to 0.71.

Table 2. Confirmatory factor analysis for the French versions of the 3-dimension 13-item and unidimensional 8-item sense of coherence (SOC) scales, and the correlation matrix for convergent and divergent validity for the French version of the 3-dimension scale.

Scales and items	Factor loading (SE)	Intercept (SE)	Error variance	Correlation matrix

[a]SOC-13 scale: χ^2_{62}=436.36, χ^2/df=7.0, root mean square error of approximation=0.088, standardized root mean square residual=0.067, comparative fit index=0.831; convergent validity: 4/13 items (30.8%) have a correlation coefficient with the score of their own dimension greater than 0.400; divergent validity: 5/13 items (38.5%) have a correlation coefficient with the score of their own dimension greater than those computed with other scores.

[b]Unidimensional SOC-8 scale: χ^2_{20}=61.90, χ^2/df=3.1, root mean square error of approximation=0.052, standardized root mean square residual=0.030, comparative fit index=0.973.

[c]Not applicable; the dimensions are only relevant to the SOC-13 scale.

The results were similar for the unidimensional SOC-13, except that Cronbach α was higher than that found for the 3-dimension model (Cronbach α=0.79, Loevinger H=0.24, RMSEA=0.09, CFI=0.82). By contrast, the psychometric properties of the unidimensional SOC-8 were excellent, as shown in Tables 1 and 2 (Cronbach α=0.82, Loevinger H=0.38, RMSEA=0.05, CFI=0.97). The median score was 41 (IQR 13, range 8-56). The 3-dimension SOC-8 produced similar results, except that the Cronbach α values were lower (0.71 for comprehensibility, 0.55 for manageability, and 0.50 for meaningfulness; Loevinger H=0.39, 0.39, and 0.36, respectively; RMSEA=0.06; CFI=0.98).

Discussion

We assessed the psychometric properties of the SOC scale within the framework of classical test theory. In a French primary care patient population, the validity/reliability of the French version of the 3-dimesion and unidimensional SOC-13 scale were poor. By contrast, the psychometric properties of the unidimensional SOC-8 were excellent. The properties of the 3-dimension SOC-8 scale were not better than those of the unidimensional model.

XSL•FO
RenderX

Despite the lack of validation studies (the general population study published in 2001 was based on a version of the questionnaire modified by the authors [6]), the SOC-13 has already been used in several studies in French-speaking populations, including in France [13] and Belgium [14]. However, our study findings indicate that the French questionnaire lacks validity and reliability, possibly influenced by language-specific nuances affecting the scale's psychometric properties.

Researchers interested in assessing the SOC could perhaps use the unidimensional SOC-8 in the future, which showed excellent psychometric properties in our study, although further validation studies are still needed. All three dimensions (comprehensibility, meaningfulness, and manageability) are represented in the 8 questions of the SOC-8. This confirms that they adequately represent the SOC in reality. The difference in psychometric properties between the SOC-8 and the SOC-13 can be explained by the fact that the 5 items excluded in the SOC-8 are perhaps less clear in French and could potentially lead to different interpretations among respondents.

Our study has several limitations. As this study was limited to patients in France, it raises questions about generalizability to other French-speaking populations. Additionally, reproducibility was not assessed and external validation of the SOC-8 is crucial before widespread adoption.

In conclusion, our study suggests that the psychometric properties of the French version of the 3-dimension SOC-13 are poor, unlike the unidimensional SOC-8. A questionnaire built only with these 8 items could be a good candidate to measure SOC. However, further validation studies are needed before recommending its use in research.

Abstract

Background: Health and health behaviors in midlife are important determinants of healthy aging. There is evidence of unmet needs for health-promoting information for women from culturally and linguistically diverse backgrounds and women with low literacy.

Objective: This study aimed to (1) develop accessible short, animated videos viewable and downloadable from YouTube aimed at promoting positive health behaviors in women in midlife and (2) evaluate their accessibility, acceptability, understanding, and usability and whether this was influenced by the level of education or socioeconomic disadvantage.

Methods: In collaboration with a video production company, a multidisciplinary team of academics and health professionals developed 2 short, animated videos on self-management of menopause health and 2 promoting joint health. Their accessibility, acceptability, understanding, and usability to women were evaluated in an anonymous web-based survey.

Results: A total of 490 women viewed the videos and responded to the survey. Of these, 353 (72%) completed all questions. Almost all (from 321/353, 91% to 334/363, 92%) agreed that the information in the videos was "very easy to understand." The proportions reporting that all or some of the information in the video was new to them varied between videos from 36% (137/386) to 66% (233/353), the reported likelihood of using the practical tips offered in the videos varied from 70% (271/386) to 89% (331/373), and between 61% (235/386) and 70% (263/373) of respondents stated that they would recommend the videos to others. Education-level group comparisons revealed few differences in opinions about the videos, except that women with lower education were more likely than those with higher education to state that they would recommend the 2 joint health videos to others (36/45, 80% vs 208/318, 65%; P=.051 for video 3; and 36/44, 80% vs 197/309, 64%; P=.04 for video 4). There were no differences between women living in the least advantaged areas (Socioeconomic Indexes for Areas quintile areas 1 and 2) and those living in the most advantaged areas (Socioeconomic Indexes for Areas quintile areas 3, 4, and 5) in their responses to any of the questions about the 4 videos.

Conclusions: Most women found the videos easy to understand, learned something new from watching them, planned to use the practical tips they offered, and were likely to recommend them to other women. This suggests that short, animated videos about health self-management strategies in midlife to improve the chance of healthy aging are perceived as accessible, acceptable, easy to understand, and useful by women.

Introduction

Recent years have seen a shift in public discourse relating to menopause, which has moved from the portrayal of menopause as a debilitating and unwelcome life phase characterized by endocrine deficiency to viewing it as a biological transition that women can manage with the right support. Hickey et al [1] advocate for an empowerment model to support women transitioning into menopause and beyond, where empowerment is defined as an active process of gaining knowledge, confidence, and self-determination to self-manage health and make informed decisions about care.

In high-income countries, women's life expectancy is now around 85 years [2] and women over the age of 50 years are one of the fastest-growing demographic groups [3]. It is well established that health and health behaviors in midlife are important determinants of healthy aging [4]. In women, midlife usually coincides with the menopausal transition, a life stage when physiologic changes occur that are linked to bone, cardiovascular, cognitive, and musculoskeletal health [4]. Furthermore, as populations globally are aging, the proportion of people with osteoarthritis is increasing [5]. The joint pain caused by osteoarthritis can be debilitating, and studies show that anxiety and depression are common among patients with this condition [6]. Postmenopausal weight gain is common, and a recent systematic review concluded that weight gain in adults is associated with an increased risk of knee osteoarthritis [7].

Healthy aging is governed by complex interactions between biological, environmental, socioeconomic, and cultural factors [8-10]. Some of these factors are beyond personal control. Others, including smoking, poor nutrition, weight gain, and lack of physical activity, are potentially modifiable. Because these factors are associated with the development of chronic conditions such as type 2 diabetes, joint pain, and cardiovascular disease, it is important to improve health literacy relating to self-care strategies for optimizing health in midlife to increase the chance of healthy aging [9,11].

Health literacy is the capacity "to obtain, process, and understand health information and services needed to make appropriate health decisions" [12]. Socioeconomic disadvantages, including having a low income, low educational attainment, and low literacy and being a nonnative English speaker, are associated with lower health literacy and poorer health [13,14].

The internet is increasingly used to access health information. While access to the internet has been shown to reduce health inequalities [15], the readability of web-based health information is mostly above the average reading level [16,17], making it inaccessible to people with low literacy and those with English as a second language [18].

We used content analysis to assess the accessibility of the information on 16 Australian websites with health information for women in midlife and found that most offered written factsheets with content above the average adult reading ability, only 4 included written resources in languages other than English, and only 2 had information in audiovisual format in languages other than English. We concluded that more accessible information resources for health self-management to reduce the risk of chronic disease are needed for women in midlife for whom English is not their first language and those with low literacy [19].

Digital health promotion resources have the potential to reach many people from diverse backgrounds with health-promoting messages [20]. Based on the evidence of unmet needs for health-promoting information for women from culturally and linguistically diverse backgrounds and women with low literacy, this study aimed to (1) develop accessible short, animated videos viewable and downloadable from YouTube aimed at promoting positive health behaviors in women in midlife and (2) evaluate their accessibility, acceptability, understanding, and usability and whether this was influenced by level of education or socioeconomic disadvantage.

Methods

Video Development

A multidisciplinary team of academics and health professionals with extensive research, professional, and personal experience of menopause and healthy aging developed the template for short, explanatory, animated videos with practical evidence-informed tips about maintaining good health in midlife. In addition to their research experience, team members have clinical expertise in psychology, rheumatology, health promotion, gynecology, and women's health nursing.

The decision to use narrated animated videos was based on a review of 38 trials demonstrating the efficacy of this medium in improving knowledge about medical procedures, management of chronic conditions, health promotion, and disease prevention [21]. In addition, evidence from a study of colorectal cancer screening found that people with low health literacy recalled as much information as their more health-literate counterparts when given the opportunity to watch spoken videos [22].

After reviewing the evidence about menopause and potentially modifiable factors in midlife that can affect women's future health trajectory, the team decided to create four 2-minute videos covering (1) explanation of the physiology of menopause, common menopause-related symptoms and how they can be managed, positive aspects of menopause, and a recommendation to seek medical advice if symptoms are severe ("What is menopause?"); (2) practical steps women can take to optimize their health during the menopausal transition and in later life ("How to stay healthy after menopause"); (3) practical advice on managing joint and back pain ("Slowing weight gain to reduce joint pain"); and (4) simple strategies to reduce joint

pain by avoiding weight gain ("Maintaining weight for joint health").

The development of the video content was informed by a review of the literature, which identified "...focus on enjoyment, health benefits including healthy aging, social support, clear messages, and integration of behaviors into lifestyle" as facilitators for the uptake and maintenance of positive health behaviors by people in midlife [23].

After expert advice from an animated explanatory video production agency, Punchy Digital Media [24], that videos should ideally be up to only 2 minutes long and have fewer than 300 spoken words, draft scripts were developed with particular attention to simple language (Australian education year 8 readability) and short sentences, framing messages in a clear and positive way and offering advice about health behaviors that can be integrated into daily life [23]. The scripts were then edited by the agency's experts, and after several rounds of feedback from researchers, a final script was agreed on. Using these scripts, the agency developed a storyboard for the narration of each video in consultation with the research team. The storyboards underwent multiple iterations in response to the researchers' comments until a consensus was reached. The animations were then created in an iterative process where feedback from the researchers was integrated until a final version was agreed on. The videos were produced using traditional 2D motion graphics. This style uses flat 2D illustrations, icons, typography, shapes, and container elements brought to life through motion and transitions. Animated characters guide viewers through concepts step-by-step as infographics pop on screen to visually illustrate spoken messages. The final animations had images of women with different body shapes, ages, skin color, and clothing conveying ethnic and cultural diversity.

As the target populations included women from culturally and linguistically diverse backgrounds, the services of Ethnolink [25], an expert multicultural and multilingual communications agency used by government and health organizations across Australia, were sought. They translated the scripts into Vietnamese and Simplified Chinese, the 2 most commonly spoken non-English languages in Australia, and tested the translations and animations with women from these language backgrounds. Some changes in the captions and voice-over were made in response to their feedback.

Evaluation of the English-Language Version of the Videos

In this study, data were collected through an anonymous web-based survey.

Materials

The English versions of the educational videos were embedded in an anonymous web-based survey to ascertain women's perspectives on the accessibility, acceptability, understanding, and usability of the videos. The participants were asked to view the four videos sequentially and answer four questions after each: (1) How easy was it to understand the information in the video? (very easy, quite easy, quite hard, and very hard); (2) How new was the information in the video to you? (the

information was completely new, some of the information was new, a bit of the information was new, and none of the information was new); (3) How likely are you to use some of the tips from the video? (very likely, quite likely, not very likely, and not likely at all); and (4) Would you recommend this video to others? (yes, maybe, and no). After viewing the 4 videos and answering the questions, respondents were asked to state their age, highest level of completed education (no formal education, primary school [years 1-6], secondary school [years 7-12], and postschool qualification), state of residence, postcode, and main language. The survey was administered using Qualtrics software [26].

Participants and Recruitment

Women aged 18 years or older were eligible to participate. They were recruited through advertising on social media platforms (Facebook [Meta] and Twitter [rebranded as X]) and Jean Hailes for Women's Health's newsletter [27]. Jean Hailes for Women's Health is the national digital gateway for women's health funded by the Australian Government. The advertisement included detailed participant information and links to the videos and survey questions.

Data Management and Analysis

Responses entered by respondents in Qualtrics were downloaded into SPSS version 28 (IBM Corp) [28]. Responses to the questions about the videos were dichotomized: (1) ease of understanding information: very easy vs quite easy, quite hard, and very hard; (2) how much of the information was new: the information was completely new and some of the information was new vs a bit of the information was new and none of the information was new; (3) likelihood of using the tips from the videos: very likely and quite likely vs not very likely and not likely at all; and (4) likelihood of recommending videos to others: yes vs maybe and no. Postcodes were used to determine Socio-Economic Indexes for Areas (SEIFA) quintile. SEIFA is a ranking of areas in Australia according to relative socioeconomic advantage and disadvantage. SEIFA quintile 1 represents the most disadvantaged and quintile 5 the most advantaged areas. Respondents were grouped by level of education (primary and secondary school vs postschool qualification) and socioeconomic advantage (SEIFA 1 and 2 vs SEIFA 3, 4, and 5). The cutoff points for dichotomized variables were chosen to provide as equal-sized groups as possible. Data were analyzed using descriptive statistics and chi-square test for group differences between those with low versus high levels of education and those in the more (SEIFA 1 and 2) and less (SEIFA 3, 4, and 5) socioeconomically disadvantaged groups. Not all respondents answered all questions; the numbers who did are shown for each question in the tables.

Ethical Considerations

The study was approved by Monash University's Human Research and Ethics Committee (2023-39025-93342). Participant information about the purpose of the study and the anonymous nature of the survey was provided before potential participants were directed to the survey. The participant information also stated that completion of the survey questions was taken as consent to participate in the study. In recognition

of their time, women who completed the survey were offered the opportunity to enter a draw for 1 of 10 Aus $40 (Aus $1=US $0.64) gift cards. Those who wanted to participate in the draw were asked to provide an email address in a file not linked to their survey responses.

Results

In all 490 women responded. Of these, 353 (72%) completed all questions. Respondent characteristics are shown in Table 1.

Table 1. Respondent characteristics.

Characteristics	Value
Age (years; n=452), mean (SD)	53.5 (8.8)
Level of education (n=446), n (%)	
Primary or secondary school	60 (13.5)
Postschool qualification	386 (86.5)
Main language (n=433), n (%)	
English	421 (97.2)
Other	12 (2.8)
Socio-Economic Indexes for Areas (n=434), n (%)	
Quintiles 1-2	104 (24)
Quintiles 3-5	330 (76)

Respondents' mean age was around the age when most women experience menopause [29]. Compared with the general Australian population, the proportions with postschool qualifications (386/446, 86.5% vs 63%) and living in the 3 most advantaged SEIFA quintile areas (330/434, 76% vs 60%) were much higher [30] suggesting that most respondents were well educated and living in relatively advantaged areas. Almost all (421/433, 97.2%) reported that English was their main language.

Responses to the questions about the videos are shown in Table 2.

Table 2. Respondents' views about the videos.

Responses	Video 1[a] (n=386), n (%)	Video 2[b] (n=373), n (%)	Video 3[c] (n=363), n (%)	Video 4[d] (n=353), n (%)
Information was very easy to understand	355 (92)	341 (91)	334 (92)	321 (91)
All or some information was new	137 (36)	213 (57)	154 (42)	233 (66)
Very or quite likely to use the tips	271 (70)	331 (89)	307 (85)	298 (84)
Would recommend the video to others	235 (61)	263 (70)	244 (67)	232 (66)

[a]What is menopause?

[b]How to stay healthy after menopause?

[c]Slowing weight gain to reduce joint pain.

[d]Maintaining weight for joint health.

Almost all respondents (from 321/353, 91% to 334/363, 92%) agreed that the information in the videos was "very easy to understand." The proportions of respondents reporting that all or some of the information provided in the video was new to them varied between one-third (137/386, 36%) for the video explaining menopause and two-thirds (233/353, 66%) for the video explaining how maintaining weight benefits joint health. The reported likelihood of using the practical tips offered in the videos was lowest for the video explaining menopause. For the other 3 videos, the vast majority (from 271/386, 70% to 331/373, 89%) stated that they were very or quite likely to use the tips. Around two-thirds (between 235/386, 61% and 263/373, 70%) of respondents stated that they would recommend the videos to others.

Education-level group comparisons revealed few differences in opinions about the videos, except that women with lower education were more likely than those with higher education to state that they would recommend the 2 joint health videos to others (36/45, 80% vs 208/318, 65%; *P*=.051 for video 3; and 36/44, 80% vs 197/309, 64%; *P*=.04 for video 4). There were no differences between women living in the least advantaged areas (SEIFA quintile areas 1 and 2) and those living in the most advantaged areas (SEIFA quintile areas 3, 4 and 5) in their responses to any of the questions about the 4 videos.

Discussion

Principal Findings

Menopause is ubiquitous at midlife, and weight gain and joint pain are common in women as they age [31,32]. High-quality, accessible, and evidence-based information is important to allow women to optimize their health in midlife and improve their

chances of healthy aging. However, accessing evidence-based and practical information about strategies in midlife to optimize health in older age can be difficult, especially for those with low literacy or from culturally and linguistically diverse backgrounds. To bridge this gap, we developed short, animated videos with practical tips on self-management of menopausal symptoms and joint pain. Evaluation of these videos showed that most women found them easy to understand, learned something new from watching them, planned to use the practical tips they offered, and were likely to recommend them to other women.

Socioeconomic disadvantage is known to be linked to poor health literacy, that is, the capacity to access, understand, appraise, and apply health information [33]. The videos were developed specifically to meet the needs of women who may have limited health literacy and who therefore may not be reached by health-promoting messages on existing websites [19]. However, since most survey respondents were well educated and living in socioeconomically advantaged areas, they were not representative of the target population. This likely reflects the known challenges of selection bias in survey research where people with higher social status and healthier lifestyles are overrepresented [34].

Despite this potential selection bias, the finding that there were no significant differences between the more or less educated groups or between those living in more or less socioeconomically advantaged areas in the proportions reporting that they learned something new from watching the videos suggests that health promotion messages delivered in short video format may benefit a cross-section of women in midlife. This supports the conclusion of a systematic review comparing the impact of video animations with other formats of information delivery on patient knowledge, attitudes, and behaviors, that "video animations show promise as patient information tools, particularly for effects on knowledge" [21].

Health behaviors occur in the context of complex interactions between social, cultural, and economic factors. Most respondents stated that they acquired new knowledge from the videos and intended to use the tips in the videos. While increased knowledge alone might have a limited effect on health behaviors, motivation, and intention are known to be powerful drivers of behavior change [35,36]. The new knowledge respondents reported acquiring from the videos combined with their intention to use the tips in the videos suggest that they may contribute to positive health behavior change among women in midlife.

A limitation of this study was that the proportions of respondents with postschool qualifications and living in the 3 most advantaged SEIFA quintile areas were much higher than in the general population, suggesting selection bias. This may in part be because of the method of recruitment, which included posts on social media and in a women's health organization's web-based newsletter that is distributed to women who have opted to receive it. Self-selection and lack of representation of people with limited or no access to the internet are known to contribute to selection bias in web-based surveys, including this survey [37]. A systematic review of strategies to reach hard-to-reach populations in medical research, including socially disadvantaged groups, concluded that they should include researchers and research institutions acknowledging the need for extended timeframes, planning for higher resourcing costs, and recruiting via community partnerships [38]. Another limitation of the study was that some details may have been lost by dichotomizing data.

The videos are available in English, Vietnamese, and Simplified Chinese and currently reside on the website of the Centre for Research Excellence Women and Non-communicable Diseases [39]. Based on the positive findings from this evaluation study, a multipronged dissemination strategy is used to make these and other videos that are currently being developed accessible to as many women as possible. They include publishing a piece in a web-based publication that reaches more than 60,000 medical practitioners in Australia [40]. In this piece, we describe the videos and explain how they can be used as a tool for general practitioners to empower midlife women with knowledge to help them stay healthy for longer, especially those with limited health literacy. We are also making the videos available on government-funded health information websites including Health Translations [41], which has a free library of multilingual health and well-being information. Pending funding, we are also planning to evaluate the videos among Vietnamese- and Chinese-speaking women through interpreter-assisted focus groups.

Conclusion

This study suggests that short, animated explanatory videos about health self-management strategies in midlife to improve the chance of healthy aging are perceived as accessible, acceptable, easy to understand, and useful by women and associated with high rates of intention to change health behaviors. Future research is needed to determine if and for whom this is followed by more positive health behaviors.

Abstract

Background: Homestay accommodations aim to support a smoother transition for refugees; yet, the intricate nature of relationships between refugees and their hosting families can make this process complex, which, in turn, can affect their health and well-being. It is crucial to grasp the experiences of both refugees and their host families in order to foster effective settlement, integration, and well-being.

Objective: The purpose of this scoping review is to explore the dynamics of homestay or hosting with a focus on understanding the experiences of both refugees and their hosting families to identify gaps in the literature and propose directions for future research.

Methods: We used the Joanna Briggs Institute methodology and followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist to guide this scoping review. Searches were conducted in MEDLINE via EBSCO, Scopus via OVID, CINAHL, SOCIndex, Web of Science Core Collection, ProQuest Dissertations and Theses, the SciELO Citation Index, and APA PsycInfo. Literature written in English and published from 2011 to 2024 that focused on homestay hosting contexts for refugees was included.

Results: The results of this review illuminate the multifaceted and dynamic nature of homestay hosting for refugees. The findings include motivations and barriers for homestay hosting, factors influencing host-refugee relations, and psychological and social outcomes of homestay hosting.

Conclusions: The results of this scoping review demonstrated the need for tailored support for refugees to improve homestay programs for the benefit of both refugees and host families and highlighted the need of more inclusive, supportive, and effective strategies for the hosting, resettlement, and integration of refugees.

Introduction

Background

Refugee hosting encompasses a range of arrangements, such as permitting a displaced family to construct a shelter on the host family's land, providing a portion of the home for a family's use, cohabitating with a family in the same house or room, offering an outbuilding on the host's premises for occupancy, and granting access to another property owned by the host for use by individuals [1,2]. Refugee homestay encompasses offering temporary shelter within the personal residences or

properties of citizens and permanent residents of the host country and providing refugees with safety, shelter, and basic needs until they achieve independence or secure long-term accommodation [3-5]. This concept covers a spectrum of hosting options, from brief stays to longer-term arrangements, facilitated by grassroots volunteers, nonprofits, or governmental bodies [4] to address the social isolation and housing challenges refugees face upon arrival [4-6]. Hosting within the context of refugee resettlement frequently denotes an institutionalized social practice that appears to be embedded within a wider policy or humanitarian framework. Homestay extends the realm of private hospitality by functioning beyond migration networks, engaging primarily citizens of the host country who initially have no personal relationship with the refugees [4]. Refugee homestays, therefore, offer tailored support that eases refugees into their new environment, with host families being instrumental in facilitating refugees' adaptation to local practices and integration into local communities within a nurturing, family-like atmosphere [4,7]. Within these contexts, refugees can take on roles that involve organization and collaboration with local residents, which can instill a strong sense of ownership and autonomy over their living conditions [8]. Thus, refugee homestays can also build social capital among refugees in their host communities [8,9].

Refugee homestays stand out as an economical approach that benefits both refugees and host community members [4,10]. This shared living setup offers a supportive environment for refugees, facilitating not only language learning but also the development of social networks that can provide essential support for refugees where they can leverage their cultural backgrounds [8]. Homestays provide a unique opportunity for deep cultural immersion, promoting intercultural dialogue [4]. This exchange enriches both refugees and hosts by sharing cultures, traditions, and values, thereby enhancing communal diversity and understanding [5]. Moreover, these housing arrangements open avenues for both refugees and local residents to learn and acquire new competencies through shared activities and interactions [4,10]. Understanding the dynamics of homestay hosting for refugees is vital for grasping its public health implications [11]. These living arrangements directly influence refugees' access to health care, psychological support, and social integration, factors that are critical for maintaining physical and mental well-being [11]. By examining how homestays can shape health outcomes, we can better appreciate the necessity for supportive and informed health care policies tailored to the unique needs of refugees. Additionally, exploring health service accessibility and addressing the specific challenges faced by refugees in homestay environments could improve public health systems and outcomes.

Refugee homestay programs in Europe enhance refugee well-being through personal connections, diverse housing setups, and interactions with political landscapes, showcasing evolving solidarity amid immigration policies [4]. Refugee cohabitation and homestay programs play a critical role in improving the health and well-being of refugees by providing stable, supportive, and integrated living environments [12]. These arrangements foster a sense of belonging and community, which is crucial for mental health, reducing feelings of isolation and stress [12]. Access to shared resources and knowledge within these households can also improve refugee's health by facilitating better nutrition and health care practices [13]. Moreover, the interpersonal relationships developed in homestays can offer emotional support and practical assistance, helping refugees navigate their new surroundings and the challenges of resettlement more effectively [12,13]. Hosting refugees can increase depression and mental health issues in hosts, possibly triggered by hearing refugees' traumatic stories. This, combined with the stress of sharing living spaces and resources, can impact hosts' mental health despite the altruistic benefits [14].

However, the informal nature of many homestay programs often results in power imbalances, with refugees seen as dependents on their hosts for a range of things [4]. Hosts' well-intentioned support can also limit refugees' interests and efforts at self-sufficiency [15], underscoring the delicate balance between assistance and independence within homestay interactions. In other words, homestay arrangements require considerable adjustments by both hosts and refugees, extending beyond mere accommodation to forming a domestic bond that encourages mutual respect and support [4,5]. However, intimate living situations can restrict refugees' control over their personal space and privacy [15].

An initial search of the literature using review registries such as Joanna Briggs Institute (JBI) Evidence Synthesis and the Open Science Framework did not uncover any existing or ongoing scoping reviews on homestay or hosting dynamics and refugee well-being. The available literature reviews generally address the political issues that homestay accommodation for refugees raises in Europe [4] and the impacts of hosting forced migrants in lower-income countries [16]. In our study, we explicitly defined key terms such as "refugees" and "asylum seekers" to delineate the scope of our analysis. Refugees are "individuals forced to flee their country due to conflict or persecution," while asylum seekers are "those seeking international protection but whose refugee status is yet to be determined" [17]. The concepts of "health" and "well-being" were explored in relation to physical, mental, and social factors, as outlined by World Health Organization guidelines [18]. Our review specifically targets the experiences of refugees in homestay settings, a focus chosen to uncover how these living arrangements impact health outcomes and integration processes. This approach can assist in exploring the unique challenges and supports that influence refugee well-being in nontraditional housing situations, addressing a significant gap in current public health research.

Aim or Research Question

This scoping review aims to delve into the interactions between refugees and their host families. Scoping reviews allow for the collection, organization, and summarization of evidence [19] to identify trends, patterns, and differences and similarities on a phenomenon of interest. This scoping review aimed to answer the following research question: "What is known from the existing literature about the experiences of both refugees and their hosts within homestay or hosting dynamics that shape their health and well-being?"

Methods

Study Design

This scoping review was conducted following the JBI methodology for such reviews [19] and according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews)

checklist [19,20] (Multimedia Appendix 1). The protocol for this review has been registered with the Open Science Framework and has been published in *JMIR Research Protocols* [21].

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria are present in Textbox 1.

Textbox 1. Criteria for inclusion and exclusion of sources.

Inclusion criteria

- Population: Records involving refugees, displaced individuals, or asylum seekers.

- Concept: Records on refugee homestay or hosting experience, homestay hosting practices, host-refugee relationship, and cohabitation.

- Context: Records related to refugee hosting across various host nations and geographical environments where homestay or hosting is practiced.

- Types of sources: Primary research papers, review papers, editorials, thesis and dissertations, reports, gray literature, conference presentations, and opinion pieces.

- Language: English.

- Publication date: Publications after 2011.

Exclusion criteria

- Population: Records involving a population other than refugees, displaced persons, or asylum seekers such as immigrants.

- Concept: Records on various hosting setups or focusing on hosting within a host nation or country that address different types of hosting experience.

- Context: Records on various hosting setups or focusing on hosting within a host nation or country.

- Types of sources: Incomplete and unrelated records that fall outside the review's focus.

- Language: Language other than English.

- Publication date: Publication prior to 2011.

Search Strategy

The search strategy was developed in collaboration with a research librarian based on seed papers provided by the lead researcher (AA-H) and an early search of various databases using fundamental terms. This strategy, incorporating all relevant keywords and index terms, was first applied to create a comprehensive search strategy for CINAHL, detailed in Multimedia Appendix 2. For other databases, the strategy was adjusted according to the specific Boolean operators, truncation, and wildcards. Additionally, our search strategy underwent peer review by another librarian using the PRESS (Peer Review of Electronic Search Strategies) Peer Review Strategy [22].

The review focused on studies published in English since 2011, and the reference lists of all selected sources were examined for further studies. The 2011 cutoff was selected because it marks a period of significant policy shifts and an increase in global displacement, leading to a surge in relevant literature on refugee health care needs and practices. This time frame ensures the inclusion of the most current and applicable findings since the Syrian refugee crisis. The databases searched encompassed Academic Search Complete, CINAHL, MEDLINE, SOCIndex via the EBSCO interface, APA PsycInfo via the OVID interface, the Web of Science Core Collection, ProQuest Dissertations and Theses, SciELO Citation Index via the Web of Science interface, and Scopus via their respective interfaces. Further search was performed using Google Scholar and a reference list of the selected papers. This approach considers the inclusion of

gray literature, such as conference proceedings and opinion papers, to ensure the gathering of all relevant information related to the aim of this review and offer a comprehensive search and review.

Study Selection and Extraction

Following the search, all identified citations were gathered and uploaded into EndNote (version 21; Clarivate), and the duplicates were removed. Titles and abstracts of the remaining sources were screened by 2 independent reviewers (AA-H and GJ) to assess their alignment with the review's inclusion criteria. All relevant studies were retrieved, and their citation details were imported into the JBI System for the Unified Management of the Assessment and Review of Information for unified management, assessment, and review of information [23]. Two independent reviewers (AA-H and GJ) screened each title and abstract against the inclusion criteria. The full texts of selected citations were then assessed against the inclusion criteria by the 2 independent reviewers (AA-H and GJ). Reasons for exclusion of papers at the full-text stage, which did not meet the inclusion criteria, were recorded and reported. Any disagreements that arose between the reviewers at each stage of the selection process were resolved through discussion or with an additional reviewer (YMY). The outcomes of the search and the study inclusion process were reported and presented in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. Data were extracted from studies included in the review by the 2 reviewers (AA-H and GJ) using

a data extraction table tailored to the content relevant to the review question (refer to Multimedia Appendix 3 [1-3,6,9,11,14,15,24-38]). The standardized data extraction tool from the JBI System for the Unified Management of the Assessment and Review of Information was used in this process, with minor adjustments made to align with the objectives of this review. The extracted data encompassed specific details about the participants, concept, context, study methods, and key findings pertinent to the review question. Any disagreements that arose between the 2 reviewers were resolved through discussion or with the third reviewer (KM). The team reached out to authors for further details or clarifications in cases of missing or ambiguous data.

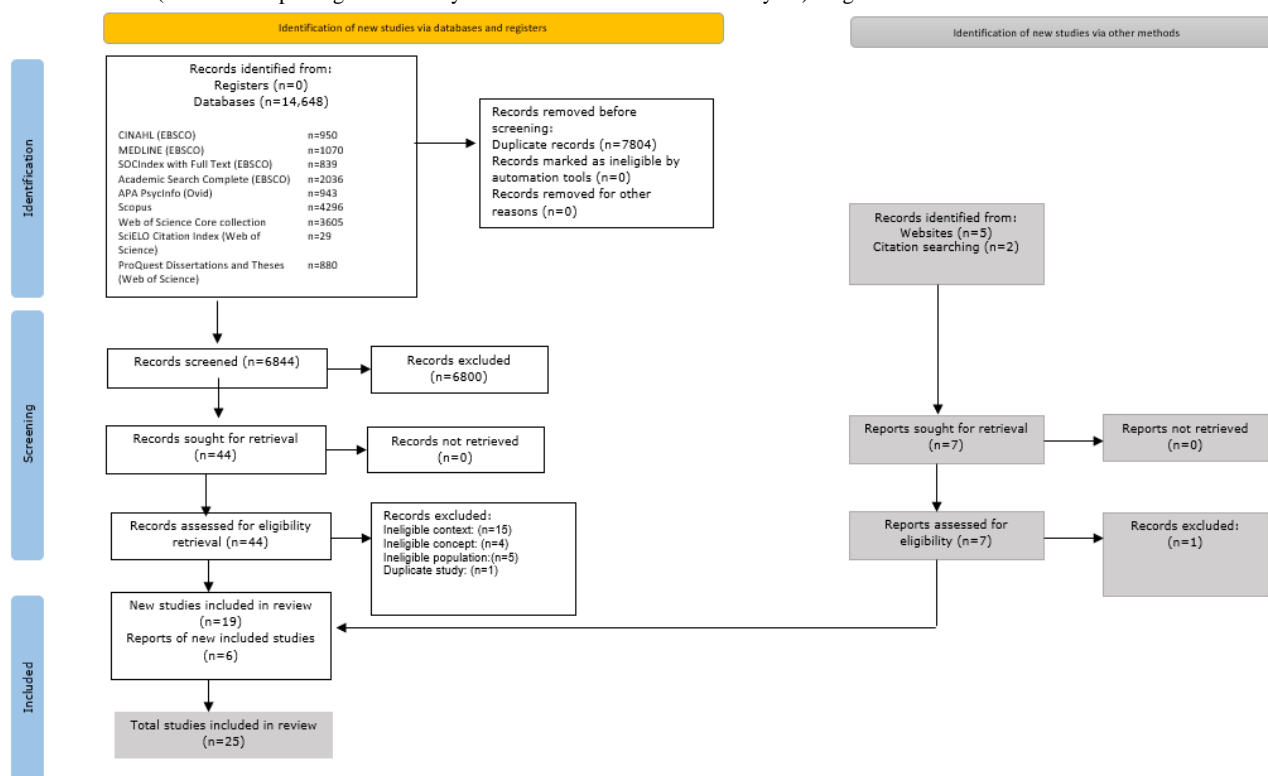
Data Analysis

The data analysis method used basic inductive content analysis, with 2 independent reviewers (AA-H and GJ) responsible for cataloging the characteristics of reports and the frequency of papers discussing refugee homestay arrangements, including the challenges, motivations, and outcomes identified. They then conducted a thorough review of the collected data (such as academic papers, reports, and other pertinent materials from a scoping review) to pinpoint significant codes pertinent to the paper's population, concept, and context. These identified codes were then categorized into themes based on emerging trends, patterns, similarities, or differences. This coding process was both iterative and dynamic, allowing for the continual refinement and adjustment of codes, as additional data were reviewed [39]. To guarantee the reliability and precision of the coded information, a comparative method was used among team members to address any discrepancies either through team consensus or by consulting the third reviewer (KM) for resolution (see Multimedia Appendix 3 for the extraction table).

Results

Overview

The initial search resulted in 14,648 records for potential inclusion. Of these, 7804 duplicates were eliminated, along with 5 records that were identified as retracted (by Retraction Watch), leaving 6844 records for the first round of review, during which, the titles and abstracts were assessed for their relevance to the research aim, narrowing the field to 44 records for a detailed assessment of the full text. Of these, 15 were later excluded due to not fitting the context, 4 not aligning with the study's concept, 5 not aligning with the study's population, and 1 duplicate record. Following a specific search on Google Scholar and a manual check of references in the selected papers, an additional 6 records were added. In total, 25 records were deemed suitable for the final scoping review (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram for selected studies.


Included Studies

The papers included in this scoping review were published between January 2011 and January 2024. This scoping review included contributions from various geographical locations (see Figure 2 for the summary of the included studies) and spans a global array of research, encapsulating studies from across continents, including individual contributions from Ghana [24], the United Kingdom [25], Germany [26], the United States [14], Australia [27,28,40], Belgium [9,29], Finland [30-32], Slovakia [33,34], the Netherlands [11,35], Spain [6], Uganda [36], Italy [3], and a broader European perspective [37]. Alongside these studies, the review is enriched by 2 opinion papers [1,38] and 2 literature reviews [2,4]. This scoping review consists of

blending empirical data from 4 quantitative studies [11,14,29,34], 15 qualitative studies [3,6,9,15,24-27,30-32,35-37,40], and 2 mixed methods studies [28,33]. The findings of this scoping review were categorized into (1) motivations and barriers for refugee homestay hosting, (2) factors influencing host-refugee relations in homestay hosting, and (3) psychological and social outcomes of refugee homestay hosting.

Figure 2. Geographical locations and years of publications for the included studies.
The sociopolitical contexts from which refugees emerge and the countries they migrate to play a pivotal role in shaping their homestay experiences. In Ghana, Liberian refugees encounter strained relationships with host communities due to resource allocation issues, land use, and perceived neglect by humanitarian organizations [24]. Similarly, in the Netherlands, displaced Ukrainian refugees experience variations in mental health outcomes based on the degree of their contact with host nationals, with factors like perceived discrimination paradoxically reinforcing their ethnic identity and, at times, improving their mental health in uncertain times like war and displacement [11]. In Slovakia, the hosting of Ukrainian refugees by local families demonstrates the role of hospitality in fostering social inclusion and building emotional ties, which in turn enhances societal cohesion [33]. However, the impact of such hospitality varies, with psychological resilience playing a crucial role in how well refugees can integrate and benefit from these arrangements. The Netherlands provides another illustrative example with the "TakeCareBnB" initiative, which has been effective in enhancing the integration of Syrian refugees by facilitating cultural and language learning and promoting deeper emotional and practical engagements with host families [35]. In the United Kingdom, the foster care system offers a range of relational dynamics from familial-like bonds to more formal guest-like interactions with young Afghan refugees, which significantly influence their sense of belonging and integration [25]. In Finland, hosts who live with asylum seekers from Syria, Iraq, and Afghanistan often experience deep emotional and sensory impacts. These interactions frequently go beyond simple hosting, drawing hosts into the refugees' ongoing struggles and conflicts. As a result, the hosts' own emotional landscapes are significantly influenced by the intense experiences and stories shared by the asylum seekers [30]. In France, the study on family hosting of refugees from Syria, Tibet, Bangladesh, and Zimbabwe shows improved language skills, cultural understanding, and overall well-being. However, it also points out issues like diminished independence and privacy concerns [15].

Motivations and Barriers for Refugee Homestay Hosting

This theme aims to provide a comprehensive overview of the foundational elements that contribute to successful or strained homestay experiences, offering insights into how these factors can be managed or leveraged to promote better health outcomes within these unique settings. The theme examines the factors that influence the decision-making processes of both hosts and refugees as they enter homestay arrangements. The analysis

delves into the complex motivations, such as cultural exchange alongside the perceived stability and safety for refugees. Concurrently, it explores barriers like cultural mismatches, language difficulties, and the psychological strains of adaptation that can impact these dynamics. Understanding these motivations and barriers is crucial, as they directly affect the health and well-being of refugees by shaping their living environments, social interactions, and access to community and health care services. Motivations for refugee hosting are often rooted in a deep sense of empathy, sympathy, compassion, opposition to the detention of refugees [27], social change, critique of government refugee policies and a desire to provide support to individuals in need [37], and volunteering [32]. Agblorti [24] illustrates that the Ghanaian hosts, despite facing significant sacrifices, express a sense of duty toward their refugee "brothers and sisters." This sentiment of humanitarian concern is echoed in studies across different contexts, including the Netherlands [11] and Slovakia [33,34], where the social inclusion of refugees and the personal satisfaction from offering assistance are highlighted as key motivators. Furthermore, initiatives like TakeCareBnB in the Netherlands showcase how structured programs can facilitate these motivations, enhancing integration and fostering cultural and emotional support [35]. Overall, hosts' motivation for hosting refugees often centers on compatibility, shared values, class, gender, cultural differences,

and specific guest profiles such as "woman with a small child" [32]. People are often motivated to host due to a moral awakening sparked by media reports, prompting them to welcome refugees into their homes [30]. The role of social innovation and policy interventions emerges as a pivotal factor in mitigating barriers and enhancing motivations [4]. Media coverage significantly influences public views on refugees and homestay hosting, often casting refugees in a negative light through sensationalism and inaccuracies [40]. Such portrayals can foster hesitation about and resistance to welcoming refugees into their homes [40].

Barriers to hosting, on the other hand, introduce challenges that can deter or complicate the hosting experience. Caron [1] identifies the uncertainty regarding the duration of stay and the potential for overstaying as significant concerns for hosts, reflecting the anxiety associated with sharing living spaces over indefinite periods. The presence of children and economic constraints can create tensions among children or the strain of sharing resources leading to unsustainable relationships [2]. Studies from Australia [40] and Belgium [29], for example, highlight the challenges posed by cultural and language barriers as well as the psychological distress experienced by refugees, which can impede social integration and strain host-guest relationships (Table 1).

Table 1. Key motivations and barriers associated with refugee homestay hosting.

Aspect	Motivations	Barriers
Cultural exchange	Hosts motivated by the opportunity to engage in cultural exchange, providing stability and safety for refugees.	Cultural mismatches and language difficulties can create challenges, leading to strained interactions between hosts and refugees.
Empathy and compassion	Deep sense of empathy, compassion, and opposition to the detention of refugees. Motivations include social change, critique of government policies, and volunteering.	Psychological strains of adaptation, including stress and anxiety from living in a new environment, can impact refugees' well-being and social integration.
Humanitarian concern	Sense of duty toward refugees, as seen in contexts like Ghana, where hosts make sacrifices out of humanitarian concern. Similar sentiments are echoed in the Netherlands and Slovakia, where social inclusion and personal satisfaction motivate hosts.	Uncertainty regarding the duration of stay and the potential for overstaying can cause anxiety and strain relationships. Economic constraints, especially in households with children, can exacerbate tensions and make hosting unsustainable.
Structured programs	Programs like TakeCareBnB in the Netherlands enhance motivation by facilitating integration and offering cultural and emotional support.	Media portrayal of refugees, often negative and sensationalized, can influence public opinion, leading to resistance or hesitation in hosting refugees.
Moral awakening	Moral awakening, often triggered by media reports, prompts individuals to welcome refugees into their homes.	Psychological distress experienced by refugees, such as trauma and stress, can impede their social integration and strain relationship with hosts.
Social innovation	Social innovation and policy interventions play a key role in mitigating barriers and enhancing motivations.	Challenges in sharing resources, especially in families with children, can create tensions and lead to unsustainable hosting arrangements.

Factors Influencing Host-Refugee Relations in Homestay or Hosting

The theme "factors influencing host-refugee relations in homestay or hosting" focuses on identifying and analyzing the key elements that shape the dynamics between hosts and refugees in homestay settings. It explores how factors such as empathy, communication styles, expectations, and cultural sensitivity impact the relationship quality and, subsequently, the integration experiences of refugees. These relational

dynamics are critical, as they directly influence refugees' psychological comfort, sense of belonging, and overall mental health. By examining these factors, the theme aims to highlight practical ways in which host-refugee interactions can be improved to foster a supportive environment that enhances the health and well-being of refugees. The dynamics of host-refugee relationships are deeply influenced by factors such as cultural proximity, gender, and shared interests, and the sociopolitical context can significantly affect the overall experiences and outcomes of refugee homestay hosting. These significantly

influence the outcomes of these arrangements. For example, Al-Saqaff [11] highlighted how the amount and type of host interaction affect displaced Ukrainian refugees, showing differences in integration shaped by gender and discrimination and enhancing the understanding of host-refugee dynamics. Additional factors that affect homestay accommodation include the unpredictability of how long guests will stay, the dimensions and placement of the hosting environment, the expenses related to accommodation, the risk of overcrowding due to family size, the impact of children's presence and actions, and the financial standing of the host family [1,2].

Bassoli and Luccioni [4] offer critical insights into the factors shaping hosting experiences and the political implications of homestay accommodation such as the allocation of shared spaces and resources and participation in group activities. Alrawadieh et al [33] concluded that the direct contact between hosts and refugees allowed for a deeper understanding of the refugees' backgrounds, facilitating a genuine connection and empathy. Moreover, factors like common interests, religious ties, cultural proximity, and gender play a significant role in influencing hosting behavior [33]. For example, shared religious beliefs or cultural practices can provide common ground, fostering a sense of connection and belonging [33]. Refugees faced difficulties adjusting to homestay arrangements and felt isolated without cultural connections, while hosts dealt with skepticism and disapproval from their social circles, complicating the hosting dynamic [27]. This aligns with findings from other studies [1,40] that have identified potential barriers including economic constraints, hosts' uncertainty about the length of stay for accommodated refugees, cultural clashes, and the emotional toll of hosting, which can impact the durability of these relationships. Participation in household culture and the development of trusting and reciprocal relationships between hosts and refugees play a significant role in the dynamics of homestay hosting [25].

The close connection between refugees and their hosts is deepened by technology and the emotional toll of global conflicts [30]. Technology helps forge deep bonds and understanding by linking refugees' past and current situations [30]. However, the risk of deportation introduces emotional and psychological challenges, impacting the safety and stability of the hosting environment [30]. Brinker [6] commented that intermediaries perceived by refugees as key facilitators in the hosting arrangement offer personalized support and easing coliving adjustments. However, intermediaries' actions could sometimes exacerbate power imbalances and affect their neutrality due to close ties with hosts. Intermediaries also often stepped back once they deemed their assistance unnecessary, affecting the dynamics between hosts and refugees [6]. Radical cosmopolitanism transforms the host-refugee relationship from hierarchy to equality, focusing on mutual experiences and engagement rather than charity. It contests traditional divides, promotes equitable interactions, and fosters unity, thereby dismantling exclusionary barriers and enriching the host-refugee connection (Table 2) [26].

Table 2. Key factors influencing host-refugee relations in homestay settings.

Factor	Description	Impact on host-refugee relations
Empathy and communication	Effective communication styles and empathy are crucial for fostering supportive host-refugee relationships.	Enhances psychological comfort, sense of belonging, and overall mental health of refugees.
Cultural proximity	Similar cultural backgrounds, shared religious beliefs, or common interests between hosts and refugees.	Facilitates genuine connections, fosters a sense of belonging, and eases integration into the host environment.
Gender dynamics	Gender roles and expectations can vary significantly between hosts and refugees.	Affects integration experiences, with gender and discrimination playing a role in shaping the host-refugee dynamic.
Sociopolitical context	The broader sociopolitical environment, including the public's attitude toward refugees and government policies.	Influences the ease or difficulty of hosting, with social disapproval or skepticism potentially complicating the hosting dynamic.
Household dynamics	Participation in household culture, including allocation of shared spaces and resources, as well as group activities.	Trusting and reciprocal relationships are crucial; failure to integrate into household culture can strain relationships and impact the success of the hosting arrangement.
Financial constraints	Economic limitations of hosts, including the cost of accommodating refugees and the potential for overcrowding.	Financial strain can lead to stress and tension, making it difficult for hosts to sustain long-term hosting relationships.
Duration of stay	Uncertainty about the length of the refugee's stay.	Causes anxiety and can lead to strained relationships if the duration exceeds the host's expectations.
Technology	Use of technology to maintain connections between refugees and their past or current situations.	Technology can deepen emotional bonds and understanding but also brings challenges related to the emotional toll of global conflicts and the risk of deportation.
Intermediaries	Role of intermediaries in facilitating the hosting arrangement.	Intermediaries can provide personalized support but may also introduce power imbalances and affect the neutrality of the hosting arrangement.
Radical cosmopolitanism	A philosophical approach that transforms host-refugee relationships from hierarchical to egalitarian, focusing on mutual experiences and engagement rather than charity.	Promotes equitable interactions, dismantles exclusionary barriers, and enriches the host-refugee connection, leading to more positive and sustainable relationships.

Psychological and Social Outcomes of Refugee Homestay Hosting

The psychological and social outcomes of refugee homestay hosting are multifaceted, reflecting a complex interplay between personal interactions, societal perceptions, and individual experiences. The theme critically examines the mental health and social integration outcomes for refugees living in homestay arrangements. This theme explores how these living situations affect refugees' psychological well-being, including aspects of stress, anxiety, and depression, as well as their social outcomes, such as community integration, social networks, and cultural adaptation. By assessing both the positive impacts, such as increased social support and cultural understanding, and the challenges, like isolation or cultural clashes, this theme provides a nuanced view of how homestay settings can influence refugees' overall health and social well-being. The intent is to offer insights into how homestay environments can be structured and supported to promote better mental health and social integration, crucial for the long-term success and well-being of refugees.

The depth and quality of contact between refugees and hosts play a significant role in mental health outcomes, with increased contact generally correlating with better mental health, especially among female refugees [11]. The role of hospitableness in promoting refugee social inclusion cannot be overstated. Creating a welcoming environment that fosters emotional and cultural connections is essential for integrating refugees into society and improving their well-being [33,34]. Employment opportunities, in particular, have been highlighted as beneficial for refugees' self-esteem and overall mental health, pointing to the critical need for access to work as part of the integration process [34]. The research by both Alrawadieh et al [33] and Altinay et al [34] underscores the importance of a welcoming atmosphere and emotional ties between hosts and refugees, highlighting the significant yet nuanced role of hospitableness in fostering societal cohesion and integration. van Dijk et al [35] in the Netherlands and Sirriyeh [25] in the United Kingdom explored innovative integration models and fostered care arrangements that emphasize the mutual process of integration, revealing the potential of such arrangements to enhance social connections, cultural understanding, and emotional support. Homestay hosting often hinges on overcoming prejudices and the ability of young refugees to integrate into household cultures [25].

Host-refugee relationships that are rooted in equality, everyday practices, and the breaking down of traditional barriers can potentially advocate for a society that values protection and support for refugees as a fundamental obligation, fostering a sense of togetherness and community integration [26]. Despite the positive aspects of homestay hosting, challenges, such as mental health risks for refugees and hosts, the potential for strained relationships, and issues of dependency and gratitude among refugees point to the need for comprehensive support mechanisms [27,40]. These mechanisms should aim to balance the benefits of homestay accommodation with the challenges it presents, ensuring that both hosts and refugees can navigate their relationships positively and productively [27,40].

The concept "asylumscapes" redefines the host-refugee relationship by highlighting the emotional labor and complex interactions involved, which significantly affect both psychological well-being and social cohesion [38]. Advocating for a better grasp of these relationships and hosting practices can nurture mutual support and improve social interactions, boosting both the resilience and inclusiveness of the communities involved [38]. Hosting asylum seekers offers an opportunity for compassionate engagement but also poses potential mental health risks for the hosts. The challenges of sharing limited spaces and resources, coupled with exposure to refugees' traumatic stories, can contribute to increased stress and a heightened risk of depression and other mental health issues among hosts [14]. Finally, Bassoli and Campomori [3] emphasized the intercultural conversations that support the independence of guests to facilitate societal transformation while ensuring the integration of refugees, offering mutual advantages to both hosts and guests (Table 3).

Table 3. Key psychological and social outcomes of refugee homestay hosting.

Outcome type	Description	Impact on refugees and hosts
Mental health	The quality of contact between refugees and hosts significantly influences mental health outcomes. Increased contact generally leads to better mental health, especially for female refugees.	Positive interactions reduce stress, anxiety, and depression, while challenges such as dependency and shared space pressures can exacerbate mental health issues.
Social integration	Homestay hosting fosters social networks, cultural understanding, and community integration by creating emotional and cultural connections.	A welcoming environment promotes societal cohesion and integration, enhancing the well-being of refugees. Cultural clashes or isolation can hinder these benefits.
Employment opportunities	Access to employment boosts refugees' self-esteem and overall mental health, making it a critical part of their integration process.	Employment provides a sense of purpose and belonging, improving mental health and facilitating social integration. Lack of employment opportunities can lead to frustration and social exclusion.
Hospitableness	Creating a welcoming and emotionally supportive environment is essential for integrating refugees and improving their well-being.	Hospitableness fosters positive relationships and societal cohesion, but the emotional labor involved can strain hosts, particularly when dealing with refugees' traumatic experiences.
Cultural adaptation	The ability of young refugees to integrate into household cultures is crucial for the success of homestay arrangements.	Successful cultural adaptation leads to better social and emotional outcomes, while failure to adapt can result in isolation and strained relationships.
Equality and everyday practices	Relationships rooted in equality and mutual respect can break down traditional barriers, advocating for a society that values refugee protection and support.	Equality in host-refugee relationships fosters a sense of togetherness and community integration, promoting social cohesion and reducing feelings of dependency among refugees.
Dependency and gratitude	Feelings of dependency and gratitude among refugees can complicate relationships, leading to potential strain and mental health risks.	While gratitude can strengthen bonds, excessive dependency can create power imbalances and strain the relationship, highlighting the need for support mechanisms to manage these dynamics.
Asylumscapes	The emotional labor and complex interactions involved in homestay hosting redefine the host-refugee relationship, affecting both psychological well-being and social cohesion.	Understanding the emotional and social dynamics of asylumscapes can improve mutual support, resilience, and inclusiveness within host communities, benefiting both refugees and hosts.
Intercultural conversations	Intercultural conversations within homestay settings support the independence of guests and facilitate societal transformation, offering mutual advantages to both hosts and guests.	These conversations enhance cultural understanding and promote the integration of refugees, leading to positive social outcomes and reducing the potential for cultural clashes.
Mental health risks for hosts	Hosts may experience mental health risks due to the pressures of shared spaces and resources as well as the emotional toll of dealing with refugees' traumatic experiences.	Hosts may develop symptoms of depression or other mental health issues, underlining the importance of providing support to manage the emotional challenges of hosting.

Discussion

Principal Findings

This scoping review included 25 papers that were published between 2011 and 2024 that met the inclusion criteria. As the world continues to adapt to the persistent refugee crises, comprehending the nuances of shared living arrangements is crucial for creating efficient and enduring solutions [41]. Collaborative efforts involving humanitarian organizations, nongovernmental agencies, and host countries are essential in providing displaced populations with protection, vital services, and opportunities for rebuilding their lives [42] in support and leaving many refugees in precarious housing situations [43]. The review concluded that refugee homestay or hosting presents a unique opportunity to foster societal cohesion, cultural exchange, and mutual support between hosts and refugees. This finding is consistent with other studies, where refugee homestay and shared living spaces not only serve as a practical solution to resource limitations but also create a distinctive chance for refugees to exchange cultural experiences, combine their methods of coping, and collaboratively deal with the complexities of resettling [44,45]. By providing sustained support to hosting families and communities, stakeholders can contribute to the creation of a connected and resilient global network [46]. Such international collaboration mitigates the risk of individuals feeling isolated or disconnected, fostering an environment where refugee resilience can flourish as a collective outcome [47].

The sociopolitical context of the countries involved in the reviewed literature plays a crucial role in shaping the experiences of both refugees and hosts in homestay arrangements. In countries like Germany [26], the United Kingdom [25], and the Netherlands [11], the political discourse surrounding immigration and refugee policies has been highly polarized, often influenced by media narratives that oscillate between humanitarian empathy and security concerns. For instance, media representations in these countries may

emphasize either the vulnerabilities of refugees or the potential risks they pose, thereby influencing public perceptions and, consequently, the experiences of both hosts and refugees in homestay settings. In countries like Slovakia [33] and Finland [30], where sociopolitical contexts may be less diverse, the experiences of refugees in homestay arrangements might be shaped by a stronger emphasis on cultural assimilation, with hosts potentially feeling a greater responsibility to "integrate" their guests into the local way of life [43]. Conversely, in countries such as Uganda [36] and Ghana [24], where communities may have a history of displacement and resilience, the sociopolitical environment may foster a more community-oriented approach to hosting, although economic constraints often pose significant challenges. The sociopolitical climate in the United States [14] and Australia [28], where immigration is a contentious issue, can lead to highly varied experiences, with some hosts motivated by a strong sense of social justice and others influenced by more conservative, security-focused narratives. These media-driven narratives and public perceptions inevitably impact the dynamics of homestay arrangements, shaping the motivations, interactions, and outcomes for both refugees and hosts [27,31].

Nevertheless, the sustainability of positive host-refugee relationships demands ongoing support to navigate the complex dynamics and challenges that arise over time. The psychological and social impacts of hosting are multifaceted, reflecting the need for comprehensive support mechanisms to balance the benefits and challenges of homestay accommodation. This finding is coherent with the findings of Baggio [48] that highlight the profound loss of homes and disruption of social structures amplifying the psychological distress experienced by refugees and underscoring the need for comprehensive support mechanisms. In addition, the resulting state of refugees' constant unfamiliarity and instability exacerbates the psychological distress stemming from the original conflicts that forced them to flee [15,32]. Through a deeper exploration of these challenges and stressors, scholars and policy makers can contribute to refining coliving as a viable pathway for displaced individuals to not only survive but thrive in their pursuit of a secure and settled life [49].

Recognizing that the responsibility for successful settlement extends beyond borders, international stakeholders, organizations, and agencies directly engaged in these matters must spearhead a concerted effort to ensure that homestay refugee hosting emerges not just as a plausible but as a widely adopted and effective solution on a global scale [42,46]. By acknowledging the complexities inherent in these shared living spaces, policy makers, humanitarian organizations, and host communities can work together to create environments that foster dignity, inclusivity, and hope for those rebuilding their lives in the wake of displacement [49]. Our study's findings shed light on key aspects of homestay hosting for refugees, offering actionable insights for enhancing public health strategies and interventions. By illustrating the direct impacts of homestay environments on refugee health outcomes, these insights encourage the development of tailored health services that address the unique needs of refugees in such settings. However, the research also highlights significant gaps in the

literature, particularly around safe and secure service practice guidelines for homestay hosting, the long-term psychological effects of homestay arrangements, and the sociocultural dynamics between hosts and refugees. Future research should focus on these areas to refine understanding and inform more effective policy formulation. This deeper exploration is crucial for crafting interventions that not only support refugee health in the immediate but also contribute to their long-term well-being and integration into new communities.

Our review explicitly details the cultural and adjustment challenges faced by refugees, underscoring how these factors significantly influence their health and well-being. By examining the nuanced interactions between refugees and their host environments, we highlight the critical role of cultural congruence and social support in the adjustment process. These elements are pivotal in shaping refugees' mental health and overall well-being, as they navigate the complexities of integrating into new societies. Understanding these dynamics can inform the development of targeted interventions that address specific cultural and adjustment needs, ultimately improving health outcomes and facilitating smoother transitions for refugees in their host countries.

Implications

The insights from this review are intended to guide the development of more inclusive, supportive, and effective approaches to refugee hosting, resettlement, and integration, with a strong emphasis on public health implications. The findings extend beyond academic discussion, offering practical guidance for policy makers, public health practitioners, and researchers. From a public health perspective, service providers and health care professionals working with refugees can leverage our findings to implement more inclusive and supportive strategies that address the unique health and well-being needs of refugees and their host families [50]. For example, social workers and community organizers can develop tailored programs that promote cultural exchange, language learning, and social integration, all of which are crucial for mental health and social cohesion. The review underscores the necessity of developing customized support mechanisms that mitigate the health challenges inherent in homestay arrangements. Public health practitioners should focus on creating environments that empower refugees, fostering a sense of belonging and community, which are essential for overall well-being [4]. Ultimately, our aspiration is that our findings will inform the establishment of more individualized and compassionate support practices within public health frameworks, ensuring that both refugees and their host families can thrive together in a healthy and supportive environment.

From a policy perspective, policy makers are encouraged to develop clear, actionable policy guidelines that support the creation of more effective and compassionate refugee homestay hosting models. These policies should aim to streamline the resettlement and integration process, ensuring that refugees and their host families have the necessary resources and support. Additionally, further investigation into the long-term impacts of homestay arrangements on refugees and their hosts highlights the need for policies that are not only responsive but also

sustainable to ensure support for refugees and host communities alike [3,51]. By advocating for customized support mechanisms, explicit policy directives, and further investigation into the enduring impacts of homestay arrangements, our review laid the groundwork for the conduct of subsequent studies to expand upon our findings.

From a research perspective, the review serves as a foundation for future research in the field, encouraging scholars to explore the nuanced dynamics of refugee hosting. By identifying gaps in the current literature, the review invites further exploration of how homestay arrangements affect the well-being of refugees as well as hosts over time. We also recommend that future research investigates the effectiveness of different hosting models, with the goal of informing best practices for refugee support. This includes studying the impact of various support mechanisms on the integration process and identifying strategies that facilitate positive outcomes for both refugees and host families.

Strengths and Limitations

To the best of our knowledge, this review is the first to explore the dynamics of homestay or hosting and refugee well-being, offering valuable insights to inform the development of refugee homestay hosting models and practices across different host countries and geographical contexts. Employing the JBI framework as the methodological backbone of this scoping review represents a significant strength, ensuring rigor, transparency, and replicability in our approach [19,52]. The JBI framework is renowned for its comprehensive guidelines that facilitate the systematic identification, selection, and synthesis of a wide range of research evidence [19,52]. By adhering to this framework, we ensure that our review process is both methodical and inclusive, enabling us to encompass a broad spectrum of studies and thereby capture the multifaceted nature of the subject matter. Furthermore, the JBI framework's emphasis on aligning the review objectives with the methodology used enhances the relevance and applicability of our findings. This approach not only strengthens the credibility of our review but also maximizes its potential to inform policy,

practice, and future research, contributing valuable insights into the complex dynamics under investigation. One of the limitations is the potential exclusion of relevant studies due to language constraints and publication date. The decision to limit the review to English-language sources was made to ensure accessibility and relevance. While this constraint may exclude significant work in other languages, English is the dominant language in global academic discourse on refugee health, which minimizes potential bias. However, we acknowledge that non–English-language sources might offer additional perspectives, and this is a limitation that was added to the limitation section. As is the case in most scoping reviews, we did not aim to assess the quality of the selected sources. This underscores the need for a focused, in-depth examination of the selected studies in order to help expand on the preliminary insights provided in this scoping review. Additionally, the variability of studies across diverse cultural and geographical contexts might require context-specific research to grasp the intricacies of homestay or hosting and its impact on refugee well-being.

Conclusions

This scoping review highlighted the complex relationship between homestay hosting and refugee well-being, uncovering the potential benefits, challenges, psychological and social impact, and factors that influence such arrangements. By examining the existing state of research, it illuminated the multifaceted nature of these hosting setups and their impact on both refugees and their host families. Our findings underscored the critical need for policies and practices that are deeply informed by an understanding of these intricate dynamics, aiming to effectively support the well-being of both refugees and their hosts. Grasping the intricate dynamics of homestay hosting arrangements is crucial for developing policies and programs that bolster the well-being of refugees and their host families. The review sheds light on the current knowledge landscape, identifying research gaps and potential ways to improve the homestay hosting experience for all parties involved.

Abstract

Background: Oral health is a determinant of overall well-being and quality of life. Individual behaviors, such as oral hygiene and dietary habits, play a central role in oral health. Motivation is a crucial factor in promoting behavior change, and gamification offers a means to boost health-related knowledge and encourage positive health behaviors.

Objective: This study aims to evaluate the impact of gamification and its mechanisms on oral health care of children and adolescents.

Methods: A systematic search covered multiple databases: PubMed/MEDLINE, PsycINFO, the Cochrane Library, ScienceDirect, and LILACS. Gray literature, conference proceedings, and WHOQOL internet resources were considered. Studies from January 2013 to December 2022 were included, except for PubMed/MEDLINE, which was searched until January 2023. A total of 15 studies were selected following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. The eligibility criteria were peer-reviewed, full-text, and empirical research related to gamification in oral health care, reports of impact, and oral health care outcomes. The exclusion criteria encompassed duplicate articles; unavailable full texts; nonoriginal articles; and non–digital game–related, non–oral health–related, and protocol studies. Selected studies were scrutinized for gamification mechanisms and outcomes. Two main questions were raised: "Does gamification in oral health care impact oral health?" and "Does oral health care gamification enhance health promotion and literacy?" The PICO (Patient, Intervention, Comparison, Outcome) framework guided the scoping review.

Results: Initially, 617 records were obtained from 5 databases and gray literature sources. After applying exclusion criteria, 15 records were selected. Sample size in the selected studies ranged from 34 to 190 children and adolescents. A substantial portion (11/15, 73%) of the studies discussed oral self-care apps supported by evidence-based oral health. The most clearly defined data in the apps were "brushing time" (11/11, 100%) and "daily amount brushing" (10/11, 91%). Most studies (11/15, 73%) mentioned oral health care behavior change techniques and included "prompt intention formation" (11/26, 42%), "providing instructions" (11/26, 42%), "providing information on the behavior-health link" (10/26, 38%), "providing information on consequences" (9/26, 35%), "modeling or demonstrating behavior" (9/26, 35%), "providing feedback on performance" (8/26, 31%), and "providing contingent rewards" (8/26, 31%). Furthermore, 80% (12/15) of the studies identified game design elements incorporating

gamification features in oral hygiene applications. The most prevalent gamification features were "ideological incentives" (10/12, 83%) and "goals" (9/16, 56%), which were found in user-specific and challenge categories, respectively.

Conclusions: Gamification in oral health care shows potential as an innovative approach to promote positive health behaviors. Most studies reported evidence-based oral health and incorporated oral health care behavior change techniques.

Introduction

People's health behaviors, such as physical activity, diet, tobacco and alcohol use, recreational drug consumption, and adherence to chronic medications, directly influence their health risks and consequent diseases. To decrease the burden of preventable chronic diseases and enhance well-being in society, it is essential to bring about a change in behavior [1-4]. According to the World Health Organization, oral health is a strong indicator of general health, well-being, and quality of life. The treatment of oral pathologies is expensive and usually not covered under universal health care, accounting for 5% of health care expenditures and 20% of out-of-pocket expenses in wealthy countries [5-11]. Health care systems have limited resources, and making informed decisions based on data collection, focusing on individuals, can provide better health outcomes without incurring additional costs; this approach can deliver better value and at the same time reduce costs [12,13].

Motivation is a core target of a wide range of established behavior change techniques [1,14-17]. Computer games can be used to increase health-related knowledge and promote desirable health behaviors in children [18]. Games are designed to provide enjoyment, engagement, and satisfaction [1,19-22]. Mobile phones and mobile health technologies can address these issues at low costs [1,23,24]. Mobile devices are useful for delivering health interventions due to their widespread adoption, powerful technical capabilities, and portability [25]. The positive emotional attachment with the user may increase the benefit of health promotion via mobile devices, allowing health interventions to be delivered immediately, anytime, and anywhere [26]. The use of health care apps provides easy access to information and has the potential to improve patient engagement and treatment compliance [27]. Indeed, the number of health care apps available has been growing year after year, with over 200 billion app downloads worldwide from the Apple App Store and Google Play in 2020 [28].

Bohn et al [29] found that educational applications are valuable tools for enhancing patient-provider communication in dental settings. Studies have pointed out that the traditional educational approach, which relies mainly on reading and listening to standardized content, should be replaced with customizable and interactive involvement, using communication tools that are familiar to newer generations [30]. Gamification is a possible response to overcoming the challenges of communication and motivation in health care [31], as it can track individual behaviors and involve users in goal-chasing activities while displaying progress and feedback through personalized information apps [1,32].

Deterding et al [33] define gamification as the integration of game design elements into nongame contexts [34]. This process enriches products, services, and information systems with game design features to positively influence the motivation, productivity, and behavior of users [33,35,36]. Gamified systems commonly use motivational features such as immediate success feedback (reward mechanism), continuous progress feedback, and goal setting. These systems work through interface elements such as point-scoring systems, badges, levels, challenges, competitions, relatedness support, social feedback (engagement loops), recognition, comparison through leaderboards, teams, communication functions, autonomized support through customizable avatars and environments, and narratives providing emotional and value-based rationales for certain activities (customization) [1,34,37,38]. Users receive badges that represent success and can be shared in social networks and displayed in a digital trophy cabinet when new milestones are achieved [35]. Recently, the self-determination theory has become a key framework for health behavior interventions and research [1,39-43]. According to this theory, gamification induces 4 main intrinsic motivators: user satisfaction, conveyance of optimism, provision of meaning [35,44], and facilitation of social interactions [45,46].

Apart from financial aspects, extrinsic motivators systematically activate intrinsic motivators, such as social recognition, support of learning processes, and behavioral change. The evidence suggests that positive outcomes are stronger when gamification is used to target behavioral outcomes [1,23,24,47-50]. However, critics have pointed out the lack of high-quality effect studies on gamification [22,38,51,52]. Nevertheless, clinicians have an opportunity to promote engagement in health promotion through a motivating, fulfilling, and fun activity [53]. Therefore, this study aims to analyze the impact of gamification and its mechanisms on oral health care.

The objective of this scoping review was to analyze the impact of gamification and its mechanisms on oral health care in children and adolescents. We assessed the effectiveness of gamification in promoting changes in oral health behavior and enhancing oral health care outcomes for its users. Furthermore, we investigated the role of gamification in oral health care, including the integration of evidence-based oral health care concepts and gamification design elements in application design.

Methods

Objective

This scoping review aims to analyze the impact and efficiency of gamification mechanisms on oral health care, with a focus on promoting user engagement to expand oral health literacy and support oral health care policies, in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [54,55].

Scoping Review

This review used a systematic methodology to identify gamification on oral health care apps, evaluate their features, identify their gamification mechanisms, and follow their outcomes.

We did not apply any restrictions related to population samples or oral health care systems, but we excluded contexts outside oral health.

The following main questions guided our analysis:

- Does gamification in oral health care impact oral health?
- Does oral health care gamification enhance health promotion and literacy?

On the basis of these questions, we searched several domains, including oral health care outcomes, gamification design elements, evidence-based oral health care concepts used in app development, and oral health behavior changes related to gamification. We use the PICO (Patient, Intervention, Comparison, Outcome) framework to elucidate the systematic review questions:

- P (Patient, Population, or Problem): the population under investigation included children and adolescents: mother-preschooler (3-6 years old) dyads and adolescents (younger than 16 years).
- I (Intervention): the intervention under investigation was the gamification strategy and its usefulness for oral health promotion and literacy.
- C (Comparison): gamification was compared with its alternative, traditional learning methods.
- (Outcome): the outcome assessed was divided into 2 main sections: behavior change techniques and gamification mechanisms.

Search Strategy

The search was conducted across several electronic bibliographic databases, including PubMed/MEDLINE, PsycINFO, the Cochrane Library, ScienceDirect, and LILACS. In addition, gray literature, conference proceedings, and WHOQOL internet resources were assessed. The search strategy included terms related to gamification and oral health care such as gamification, oral health care, policies, games, digital, apps, and outcomes. The authors used a controlled and hierarchically organized vocabulary produced by the National Library of Medicine called the Medical Subject Headings to ensure that the search results accurately reflected the subject content of journal articles as they are published. The search strategy enabled us to identify both published and unpublished studies. All sources were last searched until July 2023, except for PubMed/MEDLINE, which was searched until January 2023. The references to gamification date back to nearly 2010, and articles exploring gamification in oral health were only mentioned or studied in the last decade. There were no language restrictions, and studies published between January 2013 and December 2022 (10 years) were included.

The search string used on PubMed was "Gamification" [mh] OR "oral healthcare" [tiab] OR "gamification" [tiab] OR ad [tiab] OR "applications" [tiab] OR "gamification" [tiab] OR "digital" [tiab] OR "games" [tiab] OR "outcomes" [mh] OR policies [tiab] OR gamification [tiab] OR "oral health" [mh:noexp] (see Multimedia Appendix 1).

Initially, all types of articles were considered eligible, including systematic reviews, research articles, and prospective and retrospective studies, as long as they met the following criteria: (1) peer-reviewed, (2) full-text papers, (3) empirical research (qualitative and quantitative), (4) explained research methods, (5) gamification as a research subject, (6) effect reported in terms of impact (affect, behavior, and cognition) and user experience, and (7) oral health care outcomes. Criteria 1 to 4 were implemented to ensure focus on high-quality work reporting original research. Criteria 3, 4, and 7 were also included to enable assessment of the quality of evidence. Criterion 5 admitted papers that studied gamification in a broader concept, even if it did not elicit game elements. Criteria 6 and 7 were chosen to assess reported health and well-being outcomes and potential mediators, with user experience being included given its prevalence as an outcome.

However, studies were excluded if they (1) were duplicated; (2) had full text not available; (3) were not the original article; (4) did not refer to a game; (5) were nondigital, such as conventional games like cards or board games; (6) did not concern oral health; and (7) were study protocols without outcomes to report.

Study Quality Assessment, Data Extraction, and Analysis Plan

All searched articles were filtered using broad selection criteria framed as questions:

- Does gamification in oral health care impact oral health?
- Does oral health care gamification enhance health promotion and literacy?

The study selection and data extraction were performed blindly. After the search, all references were imported into a reference management system (Mendeley), and duplicates were removed. The remaining articles' titles and abstracts were assessed to identify eligible studies. To determine eligibility, three additional questions were asked and answered: (1) Is the topic relevant to the defined scope? (2) Does it meet the inclusion and exclusion criteria? and (3) Is the methodology appropriate? To ensure a comprehensive, transparent, and objective extraction process, a standardized prepiloted form was used to extract data from the included studies. Two reviewers independently extracted the data, and any discrepancies were resolved through discussion with a third author. Additionally, the third reviewer further scrutinized the data to verify the consistency of the extraction

process and resolved any remaining discrepancies. In case of missing or additional data, other researchers were contacted [56,57].

The eligibility assessment of each full-text paper was conducted by 2 independent raters. In cases where discrepancies arose, they were resolved through discussion and comparison of our evaluations. Articles were excluded from our review when both investigators unanimously concurred on their ineligibility due to inappropriate methodology or results that did not address the key research questions at hand. This rigorous and collaborative approach to eligibility assessment ensured the quality and relevance of the articles included in our study.

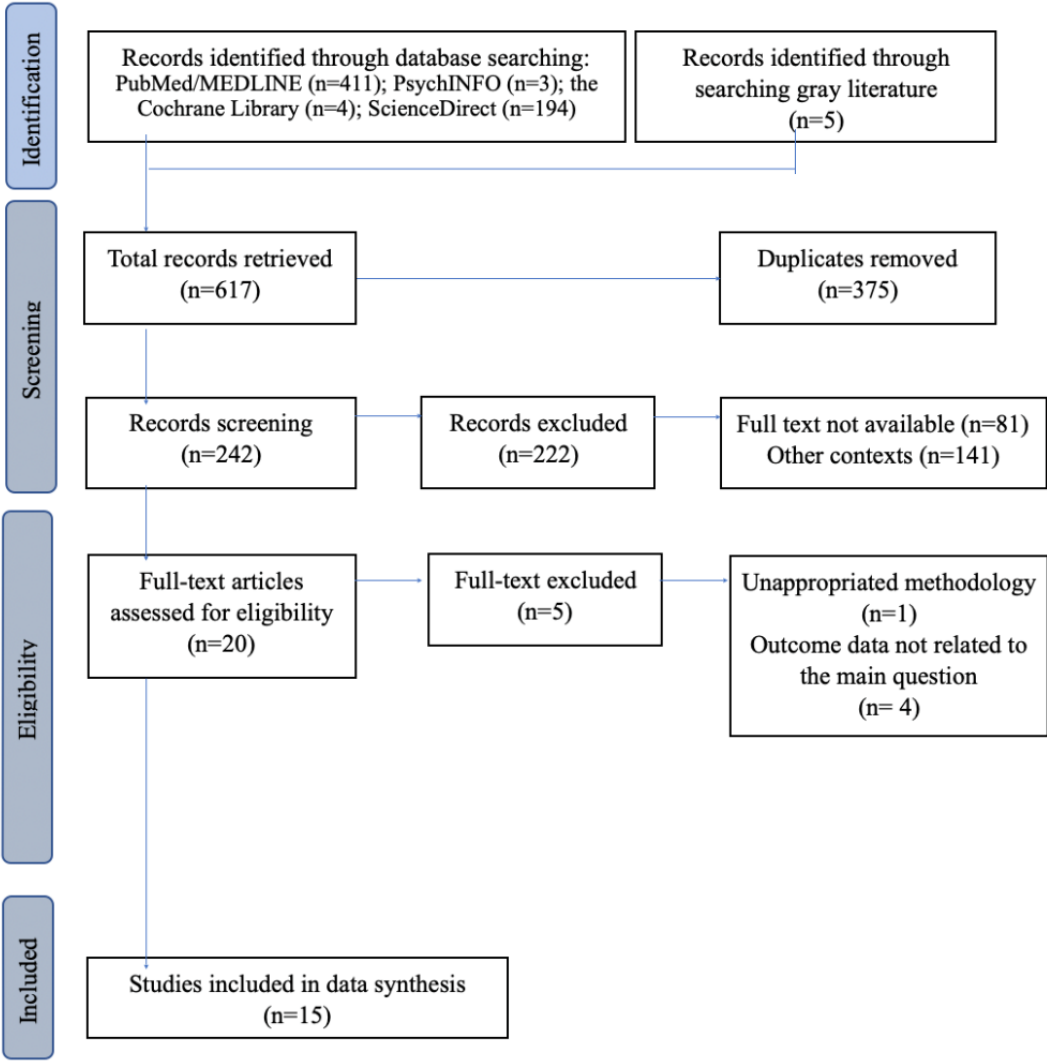
Each article was classified as having low, moderate, or high relevance. Articles were deemed highly relevant if they effectively demonstrated an impact on the considered items, whereas moderate relevance was attributed to those that projected such items. Low relevance was assigned to manuscripts that did not present any conclusions or perspectives in these domains.

Data from the scoping literature were extracted into an Excel (Microsoft Corp) data sheet using a support checklist. The data sheet was divided into sections dedicated to a theory, area, concept, theme, or element from the framework of gamification and oral health care, including game mode, population sample, gamification components, behavior change techniques, and outcomes. After synthesizing the data and assessing the quality of the evidence, the writing of the scoping review article began.

Results

Process Selection

Figure 1 shows the PRISMA flowchart outlining the process of record identification, selection, eligibility, and inclusion. Initially, 617 records were retrieved from 5 databases and gray literature sources. After removing duplicates and records that did not meet the inclusion criteria, 15 records were selected for analysis.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.


Sample Characteristics

Of the 15 studies available (see Multimedia Appendix 2 [9,18,26,27,30,58-67]), the majority (n=8, 53%) collected data at multiple time points (2 or more) from various points or conditions [18,30,58-62,68]. Of these 8 studies, 7 were blind, randomized control trials [18,30,58,59,61-63]. A content analysis of the applications for behavior change was adopted in 7 studies [9,27,60-62,64,65]. One-time cross-sectional questionnaires were applied in 3 studies [26,66,67].

The sample size in the selected studies ranged from 34 to 190 individuals. All participants were children younger than 13 years, except for 4 studies that also included adults [26,61,62,65]. Mobile apps were the predominant modality used to change oral health care behavior in the studies (n=12), with 3 exceptions based on computer games. One of the games was available on a tablet and DVD for PC [63], whereas the other 2 apps were associated with a toothbrush sensor [58,59].

Oral Hygiene Evidence-Based Categories

The oral self-care applications supported by evidence-based oral health were mentioned in 73% (11/15) of the selected studies. The group categories and archetypes of evidence-based content related to oral hygiene were identified by analyzing the selected studies, as illustrated in Figure 2.

We found that the most clearly defined types of information in the applications were "brushing time" for at least 2 minutes (11/11, 100%) and "daily amount brushing" at least twice a day (10/11, 91%). However, "toothpaste spit out after" brushing was only found in 1 application (1/12, 8%), and "cleaning the tongue" and "toothbrush grip" were never mentioned.

Figure 2. Evidence-based content related to group categories and archetypes of oral hygiene, as recognized in the chosen studies. The y-axis displays the listed group categories and archetypes, whereas the x-axis signifies the frequency of their occurrence within the studies. The accompanying legend elucidates the color-coding system denoting distinct group categories and archetypes. TB: toothbrush; TP: toothpaste.
Behavior Change Techniques

Behavior change techniques for oral health care resulted from mechanisms of gamification, either implicit or explicit. Oral health care behavior change techniques were mentioned in 73% (11/15) of the studies. The data collected from these studies were used to create a behavior change score with 26 items [9]. The studies were analyzed to determine the frequency of behavior change techniques used in oral health applications, as shown in Table 1.

Among the behavior change techniques scrutinized, a set of 7 distinct components emerged as the most prevalently used across the array of surveyed studies. These components, along with their respective frequencies of use, are outlined as follows: "prompt intention formation" (11/26, 42%), "provide instructions" (11/26, 42%), "provide information on behavior-health link" (10/26, 38%), "provide information on consequences" (9/26, 35%), "model or demonstrate behavior" (9/26, 35%), "provide feedback on performance" (8/26, 31%), and "provide contingent rewards" (8/26, 31%).

Table 1. Frequency distribution of behavior change techniques observed in oral health applications identified in the selected studies (N=137).

Behavior change techniques	Value, n (%)
1. Provide information behavior health link	10 (7.3)
2. Provide information on consequences	8 (6.6)
3. Provide information seeking others' approval	1 (0.7)
4. Prompt intention formation	11 (8)
5. Prompt barrier identification	3 (2.2)
6. Provide general encouragement	7 (5.1)
7. Set graded tasks	2 (1.5)
8. Provide instruction	11 (8)
9. Model or demonstrate behavior	9 (6.6)
10. Prompt specific goal setting	4 (2.9)
11. Prompt review of the behavioral goals	5 (3.6)
12. Prompt self-monitoring behavior	2 (1.5)
13. Provide feedback on performance	8 (5.8)
14. Provide contingent rewards	8 (5.8)
15. Teach to use prompts or cues	4 (2.9)
16. Agree on behavioral contract	7 (5.1)
17. Prompt practice	7 (5.1)
18. Use follow-up prompts	4 (2.9)
19. Provide social comparison	2 (1.5)
20. Plan social support or change	2 (1.5)
21. Prompt identification as a role model	2 (1.5)
22. Prompt self-talk	2 (1.5)
23. Relapse prevention	4 (2.9)
24. Stress management	1 (0.7)
25. Motivational interviewing	5 (3.6)
26. Time management	7 (5.1)

Gamification Mechanisms

The game design elements based on the gamification features rating criteria for oral hygiene applications were recognized in 12 (80%) of the 15 studies. Table 2 illustrates the 26 gamification features [9] that were considered, along with the number of times each element was identified.

On average, the applications included in the study possessed an average of 10.6 of 31 potential gamification features. Notably, specific game design elements were prevalently used within various categories. Among the system design features, "meaning" (10/36, 28%) stood out prominently. Within the challenges category, "goals" (9/16, 56%) emerged as the most frequently incorporated element. For rewards, "ownership" (9/22, 41%) was notably prevalent. Among social influences, both "collaboration" and "reputation" (both 3/19, 16%) were prominent. Additionally, within the user-specific category, "ideological incentives" (10/12, 83%) exhibited a substantial presence. Interestingly, none of the applications used "badges," "conforming behavior," "virtual goods," or "self-expression" (Table 2).

Table 2. Frequency distribution of game design elements detected in the surveyed studies.

Game design elements	Value, n (%)
System design (n=36)	
Visual feedback	9 (25)
Audible feedback	4 (11)
Reminder	5 (14)
Meaning	10 (28)
Integration concepts	3 (8)
Visually resembling games	1 (3)
Fantasy	4 (11)
Challenges (n=16)	
Goals	9 (56)
Time pressure	4 (25)
Progressive disclosure	3 (19)
Rewards (n=22)	
Ownership	9 (41)
Achievement	5 (23)
Point system	4 (18)
Badges	0 (0)
Bonus	4 (18)
Social influences (n=19)	
Loss aversion	2 (11)
Status	2 (11)
Collaboration	3 (16)
Reputation	3 (16)
Competition	1 (5)
Envy	1 (5)
Shadowing	2 (11)
Social facilitation	2 (11)
Conforming behavior	0 (0)
Leaderboards	2 (11)
Altruism	1 (5)
Virtual goods	0 (0)
User specifics (n=12)	
User levels	1 (8)
Ideological incentives	10 (83)
Virtual characters	1 (8)
Self-expression	0 (0)

Discussion

Principal Findings

The oral health outcomes related to gamification interventions highlighted the role of gamification in promoting oral health care and literacy. This scoping review also highlights the

limitations of currently available oral health care apps and points out the main areas to invest in for the future. A total of 11 (73%) of the 15 articles found positive impacts of using oral health apps, especially in children and adolescents. They facilitate the responsiveness of oral preventive care [66]; improve knowledge in high-risk populations; encourage dietary changes [63]; and promote a reduction of clinical plaque, gingival, and caries

indexes [26]. Additionally, they show a statistically significant improvement in health care indices [58], tooth brushing quality (duration and distribution) [60], and motivation to brush teeth for longer [26] and seem effective in adolescents with fixed orthodontic appliances by self-reported behavior and psychosocial factors [59]. Gamification structures augment oral health literacy, facilitate user alertness for oral health care themes and professional feedback, and engage commitment. A greater improvement in gingival status is commonly reported [27,61,62,69].

The feedback provided by participants showed a higher level of satisfaction in learning about oral health care through games rather than traditional noninteractive methods. Most studies reported a positive impact of gamification, particularly in children and adolescents, who are considered the main target audience of these apps [18,26,30,58-66].

The studied apps contained educational content with evidence-based dentistry and high-quality teaching for oral self-care. Some of these also feature gamification elements and behavior change techniques. The results of the studies demonstrate that these apps have excellent functionality, effectiveness, efficiency, and user satisfaction [9,64,66]. Several studies evaluating multiple oral hygiene apps have found evidence-based content, such as brushing time and daily amount of brushing. Fijačko et al [9], Parker et al [27], and Hotwani et al [64] all reported on these elements.

The health behavior change techniques found in the analyzed apps included prompt intention formation, shaping and demonstrating behavior, providing information about the link between behavior and health consequences, instructions, and contingent rewards [26,30,58,63,66,67]. A set of 7 distinct components emerged as the most prevalently employed across the array of surveyed studies. These components, along with their respective frequencies of use, are outlined as follows: "prompt intention formation," "provide instructions," "provide information on behavior-health link," "provide information on consequences," "model or demonstrate behavior," "provide feedback on performance," and "provide contingent rewards." These components collectively represent the core elements of behavior change techniques that were consistently integrated into the analyzed oral health applications, aiming to enhance engagement and promote positive behavior change.

Regarding game design elements, these applications emphasized feedback, goal attainment, sense of ownership, and ideological incentives [27,61,65-67]. Parker et al [27] identified some recurring game design elements among 20 apps analyzed, such as knowledge provision, self-monitoring of frequency, and duration of toothbrushing. Hotwani et al [64] found that information provision, goal setting, feedback, progressive disclosure, and time pressure were frequently used in the 6 apps evaluated. Fijačko et al [9] analyzed 17 apps and identified time pressure, digital characters, and fantasy as key game design elements.

Comparison With Prior Work

Delivering trustworthy information to users is essential for promoting healthy habits. Health care apps should undergo validation by health care institutions and professionals before becoming public to ensure their accuracy and reliability. However, there is a risk of users becoming overly dependent, potentially compromising the need for regular appointments with oral health care professionals in real life [27,70].

Considering evidence-based oral health care, most apps emphasize brushing for at least 2 minutes and twice a day. Although this is an important core of oral hygiene recommendations, there is still room for improvement. To achieve holistic oral care, it would be advisable to incorporate other aspects such as oral hygiene techniques, the use of devices, dietary advice, sugar intake control, guidance on early childhood caries, baby oral hygiene, the effects of fluoride, the use of fluoride toothpaste, toothbrushing training videos, and regular dental visits. The development of apps should be based on theoretical models when designing educational content, and the accuracy of the content should be a priority to bring about real behavior change [61,64,70]. Sharif and Alkadhimi [65] went beyond the basics and included interdental cleaning, spitting out after brushing, avoiding mouth rinsing after brushing, characteristics of the toothbrush, and the quantity of fluoride content in toothpaste and mouthwash. Other advisable strategies include reporting about others' approval, social interactions with oral health professionals and other application users, identifying barriers to oral hygiene and potential overcoming strategies, providing encouragement, setting graded tasks and goals, displaying tracked data and objectives, feedback on performance, setting a behavioral contract with oral health professionals, social comparison, and social support [1,9,27,35,63,65,71].

Patient adherence to a smartphone app is more effective because of the ability to customize reminders and prompts, constant accessibility, adjustability to the user, ability to provide tailored feedback, widespread use, and interactive features [63,72,73].

Strengths and Limitations

Despite the proven efficiency of gamification in health care promotion and prevention, it remains an unexplored territory in oral health, mainly applied to specific educational purposes and oral health promotion [74]. This scoping review highlights the limitations of currently available oral health care applications and points out the main areas to invest in for the future. Two major limitations were found in this study. The first is the limited availability of articles related to the main topics. Gamification, within the context of health care, is not a recent concept. However, its quantitative assessment, particularly in the field of oral health, remains relatively uncommon. To address such limitation and ensure a comprehensive review, we diligently accessed and explored 5 databases, along with incorporating gray literature sources. This approach was essential to include as many relevant studies as possible, aligning with our predefined inclusion criteria. Considering the diverse nature of our search strategy, we believe that we have made every effort to provide a reliable representation of the existing literature in the field of gamification in oral health care.

The second limitation is the heterogeneous studies with varying focus and dispersing attention. The diversity of approaches makes a rigorous comparison more challenging.

Taking into account the multiple aspects involved in gamification strategies and by transparently outlining these parameters, we believe that our work can serve as a valuable reference for future researchers seeking to design studies that address and overcome these challenges. Our hope is that this will pave the way for a more effective understanding of the underlying mechanisms behind the implementation of gamification in oral health context.

Future Directions

Future studies could focus on other age groups as well, such as the study by Zolfaghari et al [61], which developed applications for mothers of children, improving their oral health literacy and practice and promoting plaque control in children within just 1 month of use [61,74,75].

There is potential for future optimization of key gamification features, such as badges, encouragement of correct behavior, digital goods, self-expression, reminders, fantasy themes, time pressure, disclosure of progress, achievements, points systems, bonuses, loss aversion, status, collaboration, reputation, competition, shadowing, social facilitation, leaderboards, altruism, user levels, and digital characters [26,27,30,66,71,76].

Conclusions

Gamification in oral health care does have an impact; it enhances oral health promotion and literacy. It represents a potential new approach for oral health care providers to change people's oral health behavior. The most frequent game design mechanisms adopted were meaning, ideological incentives, feedback, goals, and ownership. Some authors have highlighted several factors for gamification success, including engagement strategy, applications aesthetics, evidence-based information content, behavioral change taxonomies, attention to psychological needs, evaluation, validation, quality assessment, and professional regulation standards for oral health care applications. More studies are needed to better understand the clinical, psychological, and social processes involved in selecting the most efficient gamification mechanisms. The process of mobile health in oral health care is in the initial stage, but gamification is crucial for improving individual health-related practices.

Abstract

Background: Edentulism impacts the physical health and quality of life of older individuals. The prevalence, influencing factors, and differences in terms of edentulism in urban and rural areas of China are unclear.

Objective: This study investigated the denture-wearing conditions and causes affecting older patients with edentulism in urban and rural areas of China and analyzed the differences.

Methods: This cross-sectional study included the data of 5139 older individuals (age>65 years) with edentulism obtained from 23 Chinese provinces in 2018. Participants were divided into urban and rural groups based on their household registration. Factors influencing denture use in both groups were explored using binary logistic regression, while factors influencing differences in denture wearing in both groups were explored using the Fairlie decomposition model.

Results: Of the 5139 participants, 67.05% (808/1205) from urban areas and 51.12% (2011/3934) from rural areas wore dentures. In the urban group, participants with a higher level of education (1-6 years: odds ratio [OR] 2.093, 95% CI 1.488-2.945; ≥7 years: OR 2.187, 95% CI 1.565-3.055) or who exercised (OR 2.840, 95% CI 2.016-3.999) preferred wearing dentures, but individuals with BMI<18.5 kg/m2 (OR 0.558, 95% CI 0.408-0.762) or widowed (OR 0.618, 95% CI 0.414-0.921) did not. In the rural group, a higher level of education (1-6 years: OR 1.742, 95% CI 1.429-2.123; ≥7 years: OR 1.498, 95% CI 1.246-1.802), living alone (OR 1.372, 95% CI 1.313-1.663), exercise (OR 1.612, 95% CI 1.340-1.940), high economic status (OR 1.234, 95% CI 1.035-1.472), residence in the eastern area (OR 2.045, 95% CI 1.723-2.427), presence of chronic diseases (1 disease: OR 1.534, 95% CI 1.313-1.793; ≥2 diseases: OR 1.500, 95% CI 1.195-1.882) were positively associated and age≥80 years (OR 0.318, 95% CI 0.247-0.408), BMI<18.5 kg/m2 (OR 0.692, 95% CI 0.590-0.813), and widowed (OR 0.566, 95% CI 0.464-0.690) or other marital status (OR 0.600, 95% CI 0.392-0.918) were negatively associated with denture use. The Fairlie decomposition model revealed that the number of chronic diseases (16.34%), education level (11.94%), region of residence (11.00%), annual income (10.55%), exercise (6.81%), and age (–0.92%) were the main factors responsible for differences between urban and rural edentulism and could explain the difference in the denture-wearing rate (58.48%) between both groups.

Conclusions: Older individuals with edentulism with a higher education level and who exercise are more willing to wear dentures, while those with BMI<18.5 kg/m2 show a decreased willingness to wear dentures in both urban and rural areas in China. Controlling the number of chronic diseases, improving the education level and annual income, cultivating good exercise habits,

XSL•FO
RenderX

and bridging the gap between the economic status of the east and west can narrow the differences in denture wearing among urban and rural older individuals with edentulism.

oral health; older adults with edentulism; edentulism; denture; decomposition analysis; China

Introduction

Oral diseases have become a public health concern worldwide [1], affecting 64.6% of the Chinese older adult population in varying degrees [2,3]. Oral diseases particularly affect older individuals and are majorly responsible for the disease burden [4,5]. Edentulism is the loss of all natural teeth, and it is 1 of the most serious oral diseases [6]. Patients with edentulism face serious oral health risks, adversely affecting their health and quality of life [7]. The absolute disease burden due to edentulism is increasing in many countries [8].

According to current research, patients with edentulism are more prone to chronic diseases (eg, hypertension [9], diabetes, chronic kidney disease, cardiovascular disease, and asthma) [10], psychological abnormalities (eg, sleep disorders) [11], and increased cognitive impairment [12]. Reportedly, edentulism increases the risk of all-cause mortality [13] and a poorer quality of life [14].

Several surveys have reported that the prevalence of edentulism among middle-aged and older Chinese individuals ranges from approximately 8% to 28% [15-19]. China is experiencing a crisis of rapid population aging. According to the Seventh National Population Census Data released by the State Council of China, in 2021, the older adult population (age>65 years) accounted for 190 million (approximately 13.5% of the total population), which is >14% in some provinces [20]. By 2050, the older adult population in China will be nearly 487 million, accounting for 34.9% of the total population. This gradual aging phenomenon indicates that the older adult population in China will suffer from serious oral health problems, such as edentulism.

Replacing missing teeth is the most effective treatment for edentulism, while dentures are the main treatment modality [21]. Particularly, older individuals with edentulism are more likely to wear dentures. Wearing dentures can effectively help restore masticatory function [22], prevent malnutrition [23], improve oral health [12], lower the incidence of cognitive impairment and mental illness [24], lower all-cause mortality [13], and improve the overall physical health of the older [12,22,25].

To the best of our knowledge, there exists a limited body of research that has reported on the use of dentures among older individuals with edentulism in China. This prevailing circumstance is regrettably unfavorable and undermines the comprehensive exploration of oral health services and the formulation of pertinent policies in the Chinese context. China, as a geographically expansive and densely populated nation, has been the subject of numerous investigations revealing an escalating pattern of health disparities between urban and rural

residents in response to the nation's burgeoning economic growth [26]. This discernible phenomenon has been substantiated in domains encompassing psychological well-being, the incidence of chronic ailments, and atmospheric pollution levels [27-29]. Curiously, the realm of oral hygiene, acknowledged as a pivotal determinant influencing the health of the older populace [30,31], has regrettably remained marginalized in the academic endeavors of Chinese scholars. Notably absent is a substantive examination of the urban-rural dichotomy in denture adoption rates among geriatric cohorts with edentulism, an omission that represents a conspicuous deficiency within China's public health research landscape. The prevailing lacuna necessitates the exploration of causative factors underpinning the incongruities in denture usage rates among older individuals with edentulism in China. This imperative investigation can furnish the Chinese governmental apparatus with actionable policy recommendations tailored to the augmentation of oral public health endeavors. These recommendations are envisaged to play a catalytic role in ameliorating the existing health disparities between China's urban and rural spheres, thereby aligning harmoniously with the overarching objective of mitigating health inequalities on a broader societal canvas.

To address these scholarly exigencies, this study embarked on an in-depth inquiry into the unmet requirements for denture use within the edentulous older demographic in China, as well as its main influencing factors. Furthermore, it is pertinent to acknowledge the salient socioeconomic and health differentials existing between the urban and rural populace of China [26,32-34], an observation that affects the realm of oral health. There is evidence of the complex interactions of socioeconomic inequalities, urban-rural economic differentials, and the socioenvironmental milieu across different life stages shaping inconsistent oral health outcomes [35-37].

Considering these findings, this study conducted a comparative analysis of denture use among urban and rural older individuals with edentulism in China. We analyzed the differences in denture use among urban and rural older individuals with edentulism and further identified the factors influencing those differences in order to inhibit the prevailing inconsistencies in oral health outcomes between urban and rural areas. Our aim was to provide key insights into the calibration of oral health service policies and the enhancement of the oral and holistic well-being of the older adult population in China.

Methods

Data Sources

This was a cross-sectional study to analyze the prevalence of denture use between rural and urban older individuals with

XSL•FO

RenderX

edentulism. Data were obtained from a survey conducted by the Chinese Longitudinal Healthy Longevity Survey project team in 2018, covering 23 Chinese provinces. Multistage cluster sampling was used, and about 50% of counties, county-level cities, and municipal districts in all survey provinces were randomly selected as survey areas. These areas were divided into large and small "sample counties" for the survey. Data were collected by centralized trained investigators who were assessed to be qualified for duty.

Ethical Considerations

The study was approved by the Research Ethics Committee of Peking University and Duke University. Written informed consent was obtained from all participants during the face-to-face interview. Data collection was approved by the Research Ethics Committee of Peking University. The data were made public after anonymous processing, and detailed design reports are available on the university's website [38-40]. As the data analyzed are available in the public domain, separate ethical approval was not required for this study.

A total of 15,874 participants were surveyed, approved by the Research Ethics Committee of Peking University (IRB00001052-13074).

Sample Selection

Participants needed to meet the following inclusion criteria: (1) be ≥65 years old, (2) have edentulism, and (3) answer the questionnaire completely. A total of 10,641 (67.03%) participants without edentulism were excluded from our study; 22 (0.14%) participants were excluded because they did not respond to the indicator of whether dentures should be worn; 3 (0.02%) participants aged <65 years and 69 (0.43%) participants who did not respond to basic information were also excluded. Finally, 5139 (32.37%) participants were included in this study.

Edentulism and Denture Use Assessments

Participants with edentulism were assessed by asking the question "How many teeth do you have (excluding dentures)?" Participants who answered 0 were considered edentulous, while those who answered anything other than 0 were excluded from this study.

Participants were asked the question "Do you wear dentures?", with "yes" or "no" as a response.

Variables

Participants were divided into urban and rural groups based on China's household registration classification (*hukou*).

With similar other studies as references, the covariates included in this study comprised 4 indicator types: demographic characteristics, lifestyle characteristics, economic status, and health status. The demographic characteristics included age,

sex, education level, and marital status; the lifestyle characteristics included the residential status, any history of smoking, alcohol consumption, and exercise; the economic status included the annual income and residential region; and the health status included the BMI and chronic disease status. The variable and reference group settings for all indicators are described in detail in Table S1 in Multimedia Appendix 1.

Statistical Analysis

The basic information was analyzed using descriptive statistical methods. Wearing dentures was used as the outcome variable, 1-way ANOVA was performed using the chi-square test, and binary logistic regression was conducted to explore the factors influencing denture use in the urban and rural groups. All factors were entered into the logistic regression analysis, and forward stepwise regression was performed.

The Fairlie decomposition model was used to perform decomposition analysis. It decomposed the difference between the urban and rural groups with edentulism and without dentures into 2 based on the difference in the observation of characteristic factors and coefficients [26,41]. Specific application examples from several studies exist [42-45]. The decomposition equation used in this study was as follows:

where are the average probabilities of binary outcomes for denture wearing in the urban and rural groups, respectively; F is the cumulative distribution function of the logical distribution; represents the total difference due to group differences; and are the sample sizes of the 2 groups of the comparator.

The first term in parentheses in the equation represents the part of the gap due to the difference in the group of observed characteristics and the part attributable to the difference in the estimated coefficient, while the second term represents the part due to the difference in the Y level [43].

Results

Participant Characteristics

The participant selection process is presented in Figure 1. Table 1 presents the results of the chi-square test for the basic participant characteristics of denture wearers and nonwearers among older individuals with edentulism in the urban and rural groups. Participants from the urban area constituted 23.45% (1205/5139) of the study population. The results revealed that except for the marital status, there were significant differences in the distribution characteristics of other factors between urban and rural participants (*P*<.05).

Assessment of the Proportion of Denture Wearing Across Provinces

Table S2 in Multimedia Appendix 2 shows the results of the chi-square test for the proportion of denture wearing among older individuals with edentulism by region (central, western, and eastern) and by *hukou* (urban and rural). The results revealed that 67.05% (808/1205) of participants in the urban group used dentures (95% CI 64.40-69.71), while 51.12% (2011/3934) of participants in the rural group used dentures (95% CI 49.56-52.67), and the difference was statistically significant (χ^2_1=94.591, *P*<.001). The prevalence of denture use across the various regions of China was as follows: central region, 45.26% (535/1182; 95% CI 42.42-48.10); western region, 47.92% (623/1300; 95% CI 45.20-50.64); and eastern region, 62.51% (1661/2657; 95% CI 60.67-64.36). The regional differences were statistically significant (χ^2_2=132.086, *P*<.001).

Based on the survey results, we mapped the proportion of denture use among older individuals with edentulism across 23 Chinese provinces (Figure 2 and Table S3 in Multimedia Appendix 3). We observed that the highest proportion was in Liaoning (81.36%, 95% CI 74.23-88.49), while the lowest proportion was in Hunan (21.91%, 95% CI 15.57-28.05) among the provinces surveyed.

Figure 2. Proportion of denture use among older individuals with edentulism across 23 Chinese provinces.

Distribution of Denture Wearers and Nonwearers Among Older Individuals With Edentulism

Table 2 reveals the results of the chi-square test for the distribution characteristics of denture wearers and nonwearers among older participants with edentulism in the urban and rural groups. The results revealed that the distribution of certain factors among participants with dentures in urban and rural groups was significantly different; certain differences were also observed in those without dentures. Age, marital status, alcohol consumption, and exercise were significantly different among participants in urban and rural groups who were denture wearers; however, no differences were observed in denture nonwearers.

Table 2. Distribution of characteristics of denture wearers and nonwearers among older individuals with edentulism in urban and rural areas in China.

Characteristics	Denture wearers		Denture nonwearers	
	Urban group (n=808), n (%)	Rural group (n=2011), n (%)	Urban group (n=397), n (%)	Rural group (n=1923), n (%)

Logistic Regression Results

The results of binary logistic regression for the multivariate analysis of older individuals with edentulism in the urban and rural groups who were denture wearers are presented in Table 3. The results revealed that in the urban group, a higher level of education (1-6 years: odds ratio [OR] 2.093, 95% CI 1.488-2.945; ≥7 years: OR 2.187, 95% CI 1.565-3.055) and who exercised (OR 2.840, 95% CI 2.016-3.999) were protective factors for denture use in older individuals with edentulism, while BMI<18.5 kg/m² (OR 0.558, 95% CI 0.408-0.762) and a widowed marital status (OR 0.618, 95% CI 0.414-0.921) were risk factors for denture use in older individuals with edentulism. In the rural group, a higher level of education (1-6 years: OR 1.742, 95% CI 1.429-2.123; ≥7 years: OR 1.498, 95% CI 1.246-1.802), living alone (OR 1.372, 95% CI 1.313-1.663), exercise (OR 1.612, 95% CI 1.340-1.940), a high economic status (OR 1.234, 95% CI 1.035-1.472), residence in the eastern area (OR 2.045, 95% CI 1.723-2.427), the presence of chronic diseases (1 disease: OR 1.534, 95% CI 1.313-1.793; ≥2 diseases: OR 1.500, 95% CI 1.195-1.882) were protective factors for denture use in older individuals with edentulism, while age ≥80 years (OR 0.318, 95% CI 0.247-0.408), BMI <18.5 kg/m² (OR 0.692, 95% CI 0.590-0.813), and widowed (OR 0.566, 95% CI 0.464-0.690) or other marital status (OR 0.600, 95% CI 0.392-0.918) were risk factors for dentures in older individuals with edentulism.

Decomposition Analysis Results

Tables 4 and 5 reveal the differential decomposition of denture-wearing prevalence among older individuals with edentulism in the urban and rural groups. The results revealed that the explanatory degree of the model was 58.48%, indicating that this study could explain 58.48% of the difference in the denture-wearing rate between urban and rural older individuals with edentulism, and the remaining 41.52% accounted for urban and rural characteristics and unincluded observation indicators. The explainable part reveals that the main factors contributing to this difference were the number of chronic diseases (16.34%), education level (11.94%), residence region (11.00%), annual income (10.55%), exercise (6.81%), and age (–0.92%).

Discussion

Principal Findings

Our study revealed that 54.86% of Chinese older individuals with edentulism wear dentures, among which the denture-wearing rate of individuals with edentulism in urban areas is higher than that in rural areas, indicating that older individuals with edentulism in urban areas focus on their oral problems. In terms of regional distribution, the denture-wearing rate in the eastern region was the highest, followed by the

western and central regions. Studies have reported that this is probably due to the higher health literacy level among older individuals in the eastern region and their active awareness and behavior in promoting oral health. Additionally, the higher economic level of residents in the eastern region provide a certain economic basis for the residents to obtain good oral health care. Thus, more adequate educational and medical resources help provide better access to denture-related treatment services for older individuals [46-49].

Our study revealed that age, sex, the BMI, and the education level are significant factors affecting the urban-rural distribution of older patients with edentulism ($P<.05$). Sex, the BMI, and the education level mainly affect the urban-rural distribution of older patients with edentulism, although the urban-rural distribution factors influencing denture-wearing older patients with edentulism are mainly age, the education level, and the marital status. Further analysis revealed that the education level is a protective factor for denture wearing among older patients with edentulism in urban and rural areas and that a higher education level could improve health literacy, the awareness of health maintenance, and the promotion of healthy behavior, leading to better use of medical resources, such as oral health clinics and oral health care aids, to promote their oral health [48,50]. Previous studies [51-53] have reported that the number of teeth can affect an individual's choice of food and nutrient intake, and individuals without teeth are more likely to have a lean physique. In this study, a BMI of <18.5 kg/m^2 was a relevant factor for denture wearing in older individuals with edentulism (urban areas: OR 0.558, 95% CI 0.408-0.762, $P<.001$; rural areas: OR 0.692, 95% CI 0.590-0.813, $P<.001$), which might be because denture use can improve the oral health of patients with edentulism, prompting them to choose more food varieties and have a more comprehensive nutritional intake, while denture nonwearers will be malnourished due to poor oral health, limited food options, and aggravated leanness.

Lifestyle habits, such as smoking and alcohol consumption, influence the use of dentures among patients with edentulism [54-56] and significantly impact the urban-rural distribution of older patients with edentulism and older patients wearing dentures ($P<.05$); the effects of the living status and exercise on the urban-rural distribution of older patients with edentulism and older patients wearing dentures are also significant ($P<.05$). However, the effects of alcohol consumption and exercise on the urban-rural distribution differences among older individuals with edentulism who do not wear dentures are not significant. Although previous studies have reported that smoking and alcohol consumption affect an individual's oral health literacy and healthy behavior, this study did not demonstrate significant healthy behaviors among urban and rural patients with edentulism who wore dentures. Furthermore, exercise was a protective factor for denture use in older patients with edentulism (urban areas: OR 2.840, 95% CI 2.016-3.999, $P<.001$; rural areas: OR 1.61295% CI 1.340-1.940, $P<.001$). Older individuals who exercise regularly are more aware of health maintenance, have higher health requirements, and are more willing to wear dentures to maintain their quality of life and health status.

According to the provisions of the Basic Medical Insurance System for Chinese Residents, the cost of a denture for patients with edentulism is not fully reimbursed, with most of the expense being borne by the patient. Similar to previous studies [57-59], we found that the socioeconomic status and household economic status have a significant impact on dental service use. Our results revealed that the economic status and area of residence are strongly associated with the inequality of the urban-rural distribution of older patients with edentulism in China and that their impact on the difference in the urban-rural distribution of older patients with edentulism in China is significant regardless of whether the patients are denture wearers. For older patients with edentulism from rural areas, a high annual family income and residence in the eastern region were protective factors for wearing a denture. Older individuals living in urban areas have a higher and more stable financial income after retirement compared to older individuals from rural areas. Additionally, urban residents have a higher percentage of commercial health insurance than rural residents, thereby providing favorable financial support to urban patients with edentulism to obtain dentures [60,61]. In recent years, the centralized procurement policy of medical consumables has been implemented in China, and regarding oral equipment, this can significantly lower the medical burden of providing dentures to patients with edentulism and increase the proportion of dentures provided to older patients with edentulism from rural areas, thus reducing the urban-rural inequality in denture use.

Islas-Granillo et al [62] reported that chronic diseases severely impact the oral health of older adults and that older adults with multiple moderate chronic diseases are more likely to experience edentulism [54,62,63]. This study reported that regardless of whether dentures are worn, the number of chronic diseases significantly impacts the urban-rural distribution differences in older patients with edentulism. The number of chronic diseases had no significant impact on denture wearing in older patients with edentulism from urban areas but was a protective factor for older patients with edentulism from rural areas who wore dentures. The reason probably is that older patients with edentulism with chronic diseases frequently visit medical institutions, their health literacy and willingness for health maintenance are stronger, and they are in a position to maintain their oral health more actively. Wu et al [63] reported that because of behaviors, such as frequent physical examinations or hospital visits, older adults with chronic diseases have better access to health resources, including dental examinations and treatment, than those without chronic diseases.

We performed a decomposition analysis using the Fairlie model to investigate factors influencing the urban-rural differences in denture wearing among older patients with edentulism in China, which revealed that age, education level, exercise, annual household income, area of residence, and number of chronic diseases are associated with urban-rural differences in denture wearing.

Recommendations

Based on the differences in the denture-wearing rate between older patients with edentulism from urban and rural areas, this study proposed targeted policy recommendations to improve

the denture-wearing rate and to promote equity in urban and rural oral health. First, we need to focus on patients with aphthous ulcers who have poor oral health literacy and a low education level. It is recommended that Chinese family physicians give full play to health education and guidance to create oral health awareness and motivate such patients to develop good oral health habits. Second, due to the differences in family income and regional economic development, it is necessary to focus on older patients with edentulism from rural or underdeveloped areas. The government should increase the investment in health care to lower the cost of dentures for patients with edentulism, thereby facilitating patients to easily avail of denture treatment. Finally, we recommend actively improving oral health education, maintaining oral hygiene, and encouraging residents to develop an exercise routine to maintain oral health. In summary, the oral health situation of older individuals with edentulism in China is serious, and the denture-wearing rate needs to be improved. The government should adopt measures to promote oral health, increase oral health medical funding, expand basic social medical coverage, and implement a centralized procurement policy for oral medical materials to reduce the medical burden of older patients with edentulism who require dentures, thereby improving their denture-wearing rate and promoting their oral health.

Limitations

This study has several limitations. First, older patients with edentulism are widely distributed across China; however, this study only investigated a small number of individuals in certain provinces of the country and did not cover the entire older adult population. Second, denture use among older patients with edentulism is influenced by several factors, only some of which were analyzed in this study. Third, even though the self-reported number of teeth and denture use in this study were credible, in the follow-up studies, clinical diagnosis could be made with professional instruments. Fourth, as a cross-sectional study, the causal relationship could not be elucidated, and it is suggested that a follow-up study be conducted prospectively.

Conclusion

Herein, we analyzed the rate of denture wear and explored the existence and causes of the differences in the denture-wearing rate among older individuals with edentulism in urban and rural China. Studies have demonstrated that the proportion of denture wearers among older patients with edentulism in rural areas is significantly lower than that in urban areas. The government needs to formulate corresponding measures in terms of the number of chronic diseases, annual household income, region of residence, education level, and exercise to bridge the gap in the denture-wearing rates among older patients with edentulism in rural and urban China. The findings of this study can provide a theoretical basis for developing relevant health policies to minimize the difference in denture-wearing rates between older patients with edentulism in urban and rural areas.

Abstract

Background: Surveys of internet panels such as Amazon's Mechanical Turk (MTurk) are common in health research. Nonresponse in longitudinal studies can limit inferences about change over time.

Objective: This study aimed to (1) describe the patterns of survey responses and nonresponse among MTurk members with back pain, (2) identify factors associated with survey response over time, (3) assess the impact of nonresponse on sample characteristics, and (4) assess how well inverse probability weighting can account for differences in sample composition.

Methods: We surveyed adult MTurk workers who identified as having back pain. We report participation trends over 3 survey waves and use stepwise logistic regression to identify factors related to survey participation in successive waves.

Results: A total of 1678 adults participated in wave 1. Of those, 983 (59%) participated in wave 2 and 703 (42%) in wave 3. Participants who did not drop out took less time to complete previous surveys (30 min vs 35 min in wave 1, $P<.001$; 24 min vs 26 min in wave 2, $P=.02$) and reported having fewer health conditions (5.88 vs 6.6, $P<.001$). In multivariate models predicting responding at wave 2, lower odds of participation were associated with more time to complete the baseline survey (odds ratio [OR] 0.98, 95% CI 0.97-0.99), being Hispanic (compared with non-Hispanic, OR 0.69, 95% CI 0.49-0.96), having a bachelor's degree as their terminal degree (compared with all other levels of education, OR 0.58, 95% CI 0.46-0.73), having more pain interference and intensity (OR 0.75, 95% CI 0.64-0.89), and having more health conditions. In contrast, older respondents (older than 45 years age compared with 18-24 years age) were more likely to respond to the wave 2 survey (OR 2.63 and 3.79, respectively) and those whose marital status was divorced (OR 1.81) and separated (OR 1.77) were also more likely to respond to the wave 2 survey. Weighted analysis showed slight differences in sample demographics and conditions and larger differences in pain assessments, particularly for those who responded to wave 2.

Conclusions: Longitudinal studies on MTurk have large, differential dropouts between waves. This study provided information about the individuals more likely to drop out over time, which can help researchers prepare for future surveys.

Introduction

Background

Conducting surveys on platforms such as Amazon Mechanical Turk (MTurk) have proliferated as a cost-effective and fast way of collecting data about health [1-3]. The number of studies using MTurk for social science research has been steadily increasing due in part to the ease of use, existing tools to support research activities, and quick turnaround for data collection [4]. In addition to the relatively low costs of conducting survey research with MTurk [5], another potential benefit is being able

to reach participants and retain them in longitudinal studies [6]. If the goals of a research study involve having a representative sample of participants, it is important to assess how well MTurk can meet that need.

MTurk is one of many ways to collect nonprobability survey samples that are defined and created by researchers from a pool of available participants [7,8]. Previous research has found differences between the characteristics of MTurk respondents and the US general population. MTurk participants are generally younger, more likely to be female, White, have lower income, and have higher education levels compared with the US general population, differences that have persisted over time [9-14].

Previous Work

Collecting a nonprobability versus a probability-based sample may depend on the research question. While "statistical sampling theory suggests that any estimate of a parameter will be more accurate when that parameter is estimated using data from a random sample" [7], adjustment approaches after sample collection may improve the comparability of a nonprobability sample to the general population [15]. However, nonresponse bias due to attrition in samples can significantly impact inferences drawn from either a probability or a nonprobability panel [16,17]. Attrition over time can reduce sample size, which lowers the power of any statistical analysis, while differential attrition can bias inference in less predictable ways [7]. Several methods exist to control for bias introduced by nonresponse, including sample weighting, that reduce the impact of nonresponse on inferences. Survey attrition has been noted as a critical concern with using MTurk [4]. Still, there is limited information about the effects of survey attrition in longitudinal studies using MTurk and the extent to which it limits the inferences that can be drawn [18].

Previous research has shown that nonresponse patterns vary by survey population and survey type in MTurk. In a 3-wave longitudinal study fielded from April 2020 to March 2021, MTurk respondents who were younger, Hispanic, and had self-rated difficulty with the survey were more likely to drop out in subsequent survey waves [19]. Rates of nonresponse for short-term studies (ie, a few days to a few weeks) tend to be lower than for long-term studies (ie, a month or more) [20]. Factors related to nonresponse vary by survey type, time between survey waves, and the underlying population [21-23]. Surveys that are longer and with greater response burden produce higher rates of nonresponse [24] in all types of longitudinal surveys [25,26], including internet survey panels [22,23]. Most of these studies have focused primarily on samples of the general population [19] rather than on subgroups with clinical conditions.

We use the Mercer et al [27] framework to assess the impact of nonresponse on estimation and bias in a longitudinal study of individuals with back pain. The authors propose a 3-element assessment to assess the impact of selection bias in survey estimates. We adapt this framework to and evaluate nonresponse, assuming the baseline data reflect the population and that nonresponse bias is similar to selection bias when assessing longitudinal surveys. The 3 elements proposed by Mercer et al [27] include "exchangeability" (whether all confounding variables are known and measured), "positivity" (whether the sample includes all necessary kinds of units in the target population), and "composition" (does the sample distribution match the target population concerning confounders, or can it be adjusted to match the target population). Assessing and addressing issues with exchangeability, positivity, and composition have been shown to improve inference in causal analysis and survey analysis to deal with selection bias issues. In this article, we use the same framework to improve inference from nonresponse bias in MTurk studies.

It is essential to understand the factors associated with attrition in longitudinal studies with internet panels, given their widespread use. To improve exchangeability, it is also important to understand and assess what factors could confound inference due to nonresponse. While studies have previously examined these issues among general populations, the factors associated with attrition may vary among populations with different health conditions. It is estimated that 39% of the US adult population has back pain [28]; back pain accounts for the largest share of years lived with disability in the United States [29]. Healthier individuals are more likely to respond to surveys, and longitudinal surveys risk losing an increasing number of less healthy participants in successive survey waves [30,31]. Given that health and pain are multidimensional, multiple measures of health and pain may be necessary to capture the confounding due to poorer health and increased pain. As more studies use surveys to assess back pain, nonresponse due to poorer health can significantly impact inference drawn from analyses, even longitudinal analyses, if differential attrition by pain status is observed. In addition, MTurk workers are known to have a high turnover rate [32]. The inability to follow up could be another important source of attrition.

Goals of the Study

As a part of a more extensive study, we collected survey data on MTurk from individuals who self-identify as having back pain. To improve sample quality, we implemented a range of tactics to screen out poor-quality data, requiring that participants had completed several previous tasks and met an approval threshold, as well as postsurvey data cleaning to screen out those who reported having one or both of 2 fake health conditions included on the survey. What was left was a sample of self-selected, higher-quality participants who were surveyed 3 times over 6 months.

Because of the prevalence of individuals with back pain, attention to them, and the use of survey methods to assess their back pain, we analyzed data from a 6-month 3-wave longitudinal panel survey to (1) describe the patterns of survey responses and nonresponse among MTurk members with back pain, (2) identify factors associated with survey response over time (to assess "exchangeability"), (3) assess the impact of nonresponse on sample characteristics (to assess "positivity"), and (4) assess how well inverse probability weighting can account for differences in sample composition (to assess "composition"). We hypothesize that those with poorer health, more pain symptoms or severity, specific pain, and nonchronic pain will be least likely to respond to follow-up surveys. Weighting may

be able to adjust to correct for nonresponse, but whether the sample is sufficiently varied is unclear.

Methods

Recruitment

We developed web-based surveys to collect data from MTurk participants and used the platform CloudResearch (formerly TurkPrime; Amazon) to field the survey in 2021 [33]. Individuals who reported having back pain at baseline (wave 1) were provided the opportunity to complete follow-up surveys after 3 months (wave 2) and 6 months (wave 3). We did not note in the wave 1 survey instructions that this was a longitudinal study because only those who met the inclusion criteria for the longitudinal study were asked if they wanted to participate in follow-up surveys. At the beginning of wave 2 and wave 3 recruitment, all eligible participants who consented to participate in follow-up survey waves were sent a recruitment email telling them the follow-up survey was available, that it would take approximately 25 minutes to complete, the payment for completing it, and that they had up to 5 weeks to return it. Weekly reminder emails (1-4 weeks after the recruitment email) were sent to all nonparticipants reiterating the timeline for survey completion, the approximate time to complete it, and the payment for completion.

Based on previous data collection efforts, we recruited individuals to have a final wave 1 sample of about 1500 individuals with back pain [9]. Those invited to participate at baseline had to have completed a minimum of 500 previous human intelligence tasks (HITs) on MTurk with a successful completion rate of at least 95%. No additional requirements were given to participate in the wave 1 survey. These threshold values were selected to enhance data quality. Previous research [34] and pilot tests of the survey found a 95% approval threshold and at least 500 completed HITs improve data quality and that limiting samples to ensure data quality does not limit the pool of available workers enough to restrict the sample to below the 1500-participant target [35]. While more recent studies [36] have shown that the approval rate is insufficient to ensure high-quality responses, we used a range of steps to ensure high-quality responses, including reputation, number of previous tasks, and attention checks (described in the Measures section). Given the structure of the MTurk interface, we are unable to determine the impact of the approval and completed HIT thresholds have on the sample profile (ie, we cannot quantify the number of individuals who tried to complete the survey but could not because of the thresholds for participation, as those individuals would not see the survey). Additional detail on data collection of wave 1 data is described by Qureshi et al [13].

Ethical Considerations

All participants provided electronic consent at the beginning of the survey. Those who completed general health and back pain surveys at wave 1 were offered US $3.50 for their participation. Participants were offered an additional US $5 per subsequent completed survey (wave 2 and wave 3). All baseline participants (even those who did not participate in wave 2) were asked to participate in wave 3. Data were deidentified and are stored online [37]. All procedures were reviewed and approved by the research team's institutional review board (RAND Human Subjects Research Committee FWA00003425; IRB00000051) and conforming to the Declaration of Helsinki principles. The study was funded by the National Institutes of Health or the National Center for Complementary and Integrative Health (Grant 1R01AT010402).

Measures

The main outcome variable was participation in wave 2 and waves 2 and 3, defined as a binary outcome (0 if no participation and 1 if participation). We used several exposure variables, including self-reported demographic variables, self-reported health conditions, and self-reported back pain assessments.

Each survey asked about demographic characteristics (age, sex, race or ethnicity, employment status, income, education, and marital status) and health conditions. Health conditions were assessed in 2 forms. First, we asked "Have you EVER been told by a doctor or other health professional that you had…" for each of the following conditions: hypertension, high cholesterol, heart disease, angina, heart attack, stroke, asthma, cancer, diabetes, chronic obstructive pulmonary disease, arthritis, anxiety disorder, and depression. Then, we asked "Do you currently have…" for each of the following conditions: allergies or sinus trouble, back pain, sciatica, neck pain, trouble seeing, dermatitis, stomach trouble, trouble hearing, and trouble sleeping. We included these various measures of health to allow for the examination across various dimensions of health to support "exchangeability" for inference.

We also included 2 fake conditions in the survey that were used to screen out low-quality respondents. Individuals who endorsed one or both fake conditions were not asked to participate in the back pain follow-up survey if they endorsed having back pain. Overall, 15% (996/6832) of respondents endorsed one of these fake conditions, and their responses were believed to be dishonest or careless. Those reporting fake conditions were more likely to identify as male, non-White, to be younger, report more health conditions, and take longer to complete the survey. Their responses had less internal consistency reliability on several health measures than those who did not endorse a fake condition (Hays et al [38]).

Those who reported having back pain were asked to participate in a follow-up survey that included additional questions related to their back pain. If an individual opted not to continue, they would be paid for completing the first part of the survey and were not included in further analysis. The survey included questions about whether the respondent's back pain was "chronic" according to 1 of 4 definitions (either that their back pain persisted for least 3 months, that their back pain persisted for at least 3 months, and they had pain at least half the days in the past 6 months, that a health provider told them that their pain is chronic, or that they believe their back pain is chronic). We also asked whether their back pain was due to a "specific" medical condition. We categorized individuals with back pain into 4 groups [39]—those with specific chronic back pain, those with specific nonchronic back pain, those with nonspecific chronic back pain, and those with nonspecific nonchronic pain. The survey also included the Impact Stratification Score (ISS) [40], Oswestry Disability Index (ODI) [41], Roland Morris

Disability Questionnaire (RMDQ) [42], the Pain, Enjoyment of Life and General Activity scale (PEG) [43], and the Keele STarT Back Screening Tool (SBST) [44].

Statistical Analysis

We report response rates to the wave 2 and 3 surveys among those responding to the wave 1 survey to assess the "positivity" of samples for inference. In addition, we report descriptive statistics on age, sex, race or ethnicity, income, education, marital status, self-reported health conditions, the proportion who endorsed back pain types, and back pain measure scores for those who participated in each survey wave. We report differences for those who did and did not complete the wave 2 survey and both the wave 2 and wave 3 surveys using *t* tests for continuous and chi-square tests for categorical variables.

Next, we report estimates from stepwise logistic regression models predicting response to wave 2 (model 1) and both waves 2 and 3 (model 2). We used a backward elimination with a selection criterion of α=.157 and a forward selection criterion of α=.05 to select the variables to include in the models [45]. These selection criteria determine whether a variable is included in the final model. Using a backward elimination with a selection criterion of α=.157 rather than α=.05 is meant to reduce overfitting of the final model, a common issue associated with stepwise models [46]. We report the odds of completing the subsequent surveys. Based on previous studies, age, sex, race, and ethnicity were included in the regression models [19,47]. We also examined education, marital status, income categories, employment, health conditions, type of pain, pain impact, and time to complete the questionnaire as predictor variables.

Finally, we used inverse probability score weighting to examine sample characteristics in waves 2 and 3 based on model 1 and model 2 results to assess how well the sample weights correct for nonresponse from in later waves to assess "composition." Model weights are derived from estimated probabilities of completion using the aforementioned stepwise logistic regression models. By using inverse probability weights, we overweight respondents like those who drop out, approximating how the original sample would have looked if everyone responded to both follow-up waves. We included all candidate variables without backward elimination as a sensitivity analysis to derive inverse probability weights. Similar baseline characteristics between the full sample at baseline and weighted estimates for those who participated in later waves is an indication that observed variables can account for the level of bias introduced by sample attrition. All analyses were conducted using Stata software version MP17 (StataCorp) [48]. The study confirms to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist for cohort studies (Table S1 in Multimedia Appendix 1).

Results

Sample Characteristics

A total of 1678 adults who responded in wave 1 qualified to take subsequent surveys, that is, did not endorse a fake condition on the wave 1 survey and consented to participate in a future survey [13]. Of those who qualified to participate from the total sample in wave 1, 983 (59%) responded in wave 2. Of the 983 who responded in wave 2, a total of 703 (42% of wave 1 respondents) also responded in wave 3. The 8 respondents who only responded in waves 1 and 3 (ie, not in wave 2) were excluded from further analyses. Compared with those who did not respond, respondents in wave 2 were older, with higher income, more likely to never have been married, less likely to be Hispanic, less educated, and less likely to be employed full-time. We saw similar trends for those who responded in both waves 2 and 3 versus those who did not (Table 1).

Table 2 shows the overall sample distribution at wave 1 and response rates in waves 2 and 3. Generally, those who were older, those who were female, non-Hispanics, not married or living with a partner, and those at low (ie, US $0-US $39,999) and high income (more than US $60,000) were more likely to respond during waves 2 and 3 than their counterparts. These differences were more apparent when comparing wave 1 with wave 3. However, when comparing wave 3 response among those who responded in wave 2, response rates were generally 65%-75% and not systematically different by characteristic. In addition, the sample prevalence of health conditions was similar between the unweighted samples of those who participated in wave 2 only and those who participated in waves 2 and 3 (Table 2).

Those who responded in wave 2 completed the wave 1 survey in less time than those who did not respond in wave 2 (30 min vs 35 min, *P*<.001). Those who responded to the wave 3 survey also reported less time completing the wave 2 survey than those who did not respond (24 min vs 26 min, *P*=.02), similar to the time advertised to complete the survey. We found no differences in the time of day (morning, afternoon, evening, or nighttime) when the baseline survey was completed between the responders and nonresponders to the wave 2 survey and the waves 2 and 3 surveys.

Respondents in wave 2 had fewer reported health conditions than those who did not respond (5.8 vs 6.6, *P*<.001). A similar trend was observed for those who responded versus those who did not respond to both waves 2 and 3, though the effect was not significant (5.7 vs 6.0, *P*=.08). There were differences between responders and nonresponders in wave 2 for 15 conditions, with nearly all being less common for responders than nonresponders, except for arthritis, anxiety, and allergies. There were also differences between responders and nonresponders in waves 2 and 3, but for fewer (11) conditions (Table 3).

Respondents to wave 2 were less likely to have nonspecific low back pain and more likely to have chronic low back pain than those who did not respond, with similar patterns for those who did and did not respond to both the waves 2 and 3 surveys. Participants in wave 2 and in both waves 2 and 3 reported less pain intensity and pain interference, and better health on the ISS, ODI, RMDQ, PEG, and SBST measures (Table 4).

Table 1. Characteristics of those participating in wave 1 only versus those who also responded in wave 2 (at 3 months) and in waves 2 and 3 (at both 3 and 6 months).

Characteristic	Responded in wave 1 only (N=695), n (%)	Responded in wave 1 and 2 only (N=983), n (%)	P value (wave 1 vs wave 1 and 2)	Responded in all 3 waves (N=703), n (%)	P value (wave 1 vs all 3 waves)

Response Patterns in Wave 2

Table 5 presents the odds ratios (ORs) based on the logistic regression results after stepwise selection. The models identified the factors most related to responding in the wave 2 survey (Table 5; Model 1).

Respondents with longer response times (minutes) in wave 1 were less likely to respond to the wave 2 survey than those with longer response times in wave 1 (OR 0.98, 95% CI 0.97-0.99). Respondents who were Hispanic or Latino were also less likely to participate (compared with those who were not Hispanic or Latino, OR 0.69, 95% CI 0.49-0.96). In addition, those with a bachelor's degree as their terminal degree (compared with all other education groups, OR 0.58) were less likely to respond in the following survey. Those with angina (OR 0.56), diabetes (OR 0.68), and sciatica (OR 0.72) compared with those without those conditions were less likely to respond to the wave 2 survey. Finally, those with greater pain intensity and interference (mean of the *z* scores for these measures; OR 0.75), and those with any specific back pain (OR 0.36-0.71) compared with those with nonspecific pain were less likely to respond to the following survey.

In contrast, older respondents (older than 45 years compared with 18-24 years old) were more likely to respond to the wave 2 survey (OR 2.63-3.79) and those whose marital status was divorced (OR 1.81) and separated (OR 1.77) were also more likely to respond the wave 2 survey. Those with allergies (OR 1.30) and trouble sleeping (OR 1.33) compared with those without those conditions were more likely to respond to the wave 2 survey.

Table 5. Results of models predicting response for wave 2 (3 months) and for waves 2 and 3 (3 and 6 months).

Response Patterns in Waves 2 and 3

We found that factors related to response in wave 2 were similar to those that related to response in waves 2 and 3 (Table 5; Model 2): time to complete, age, race, ethnicity, education, marital status, pain type, pain impact, and certain chronic conditions were associated with participation in both waves 2 and 3 of the survey.

In contrast to the model predicting response in the wave 2 survey (Model 1), those who identified as Asian (OR 2.04, 95% CI 1.23-3.41) were more likely to complete the waves 2 and 3 surveys than those who identified as White. Income was no longer significant, but being a student was associated with lower odds of responding (OR 0.40, 95% CI 0.20-0.83). Similarly, having diabetes or sciatica was no longer associated with response, but hypertension was associated with lower odds of responding (OR 0.77) compared with those without the condition.

Description of Sample With Weighting by Nonresponse

Weights were created using the final stepwise logistic regression models shown in Table 5. To derive weights for responses in wave 2, the final model included age, sex, race, ethnicity, marital status (being divorced or never married), mean pain intensity and pain interference score, type of pain (specific and chronic pain or specific and nonchronic pain), and health conditions (angina, diabetes, allergies, sciatica, and trouble sleeping). To derive weights for response in waves 2 and 3, the final model included age, sex, race, ethnicity, marital status (being divorced or never married), employment (student or not student), mean pain intensity and pain interference score, type of pain (specific and chronic pain or specific and nonchronic pain), and health conditions (hypertension, angina, allergies, and trouble sleeping).

The inverse probability weighted samples of those completing wave 2 only and those completing waves 2 and 3 were similar demographically to the sample of all individuals who completed wave 1 for all categories except for income (Table S2 in Multimedia Appendix 1) [49]. Income was similar for the unweighted data and sample weights produced differences in the estimate of some income categories like the US $30,000-US $39,999 income range [50]. Estimated sample weights and weighted sample distributions did not vary between the

backward elimination estimation–derived weights and those not using backward elimination estimation and were robust to model specification.

The greatest differences observed between the baseline and the weighted samples were in income, where the weighted sample had approximately US $5000 more in annual income than the baseline population. In addition, the wave 2 and 3 weighted samples had lower measured scores on the ISS, the ODI, the RMDQ, the PEG, and the SBST compared with the weighted participants in waves 2 only and the unweighted baseline sample (Table S3 and S4 in Multimedia Appendix 1). These differences were less than those between the unweighted samples (Table 4).

Respondents were generally older, less Hispanic, less likely to have a bachelor's degree, less likely to be married, lower income, and less likely to be employed full-time when comparing unweighted and weighted wave 2 responses (Table S2 in Multimedia Appendix 1). Unweighted respondents had fewer health conditions and were less likely to have all health conditions except arthritis, anxiety, allergies, and trouble sleeping than weighted respondents in Wave 2 (Table S3 and S4 in Multimedia Appendix 1). The largest difference between unweighted and weighted respondents in wave 2 was in pain assessments. Unweighted respondents were much less likely to have nonspecific pain (0.55 vs 0.74), more likely to have chronic pain (0.92 vs 0.88) and have lower pain intensity and pain interference than weighted respondents. Unweighted respondents also scored systematically lower on the ISS, the ODI, the RMDQ, the PEG, and the SBST.

Discussion

Principal Results and Comparison With Previous Work

Comparisons of MTurk samples with the general US population have shown that MTurk participants tend to be younger, more educated, and less racially and ethnically diverse than the general population [11]. The characteristics of our baseline sample are consistent with this literature. This study extends the existing literature by describing nonresponse rates and predictors of nonresponse in a longitudinal study of MTurk participants with back pain, a population increasingly studied

using survey methods to assess severity and changes over time [30,31].

We found that overall nonresponse was larger from wave 1 to wave 2 than between waves 2 and 3, even with a sample that was screened for higher quality respondents and those with lower quality responses were removed; however, it should be noted that since participants already responded in wave 2, there is selection bias as they have already participated in a follow-up survey wave. Previous research has shown that the majority of MTurk workers are frequent users of MTurk [51], participating in many tasks and using the platform regularly. Despite this, we found that even with regular outreach about the follow-up survey, response rates declined. While our survey focused on patients with back pain, our retention rate is on par with longitudinal studies that included more general samples of MTurk respondents [52], and greater than the average internet survey response rate of 40%-50% [53].

In addition, we found differential response rates by participant characteristics. Response rates were generally over 40% for all categories except those with relatively small sample sizes (ie, <2% of the overall sample). In this study, we have sample coverage for subgroups that reflect the larger population, indicating higher "positivity" as per Mercer et al [27]. Persistent respondents in our survey were older with higher income, less likely to be Hispanic, less educated, less likely to be employed full-time, and more likely to never have been married, all broadly consistent with previous nonresponse studies in MTurk [19]. In comparing response rates from wave 2 to wave 3, we also found less differential nonresponse than when comparing wave 2 with wave 1 and waves 2 and 3 with wave 1.

Participants who continued to respond in survey waves completed their previous surveys faster than those who did not respond and reported fewer health conditions. Our multivariate models largely supported these findings. Factors associated with increased response across survey waves were completing our previous survey faster, being divorced or never marrying, and having allergies or trouble sleeping, while factors negatively associated with response were being Hispanic or Latino, younger, having a bachelor's degree, and having more reported pain intensity and interference. Our backward estimation specification allowed for individual categorical responses (ie, income, education, and employment) to be assessed independently, leading to instances where only specific subsets of a category are included in the model. The reference groups in these cases are any individuals not included in that category, sometimes making model interpretation unintuitive (ie, having an income of US $40,000-US $59,999). However, categories with the lowest response rates compared with wave 1 were included in the models, further supporting the model for the prediction of nonresponse. The effect of the inverse probability weights was robust to whether the subset of significant variables or all candidate variables were used to derive them. All of this mitigated "composition" issues that limit the ability to draw inferences as per Mercer et al [27].

The inverse probability weighted sample analysis produced sample demographics and condition prevalence rates that were similar between baseline respondents and those responding at subsequent waves except for pain assessments, which is most likely driven by changes in pain assessments over time rather than bias introduced by nonresponse. Average pain, according to different measures, was higher in the weighted sample than the unweighted samples, indicating that those with higher pain are more likely to be due to dropout and less likely to be due to a reduction in pain over time. Given the weighting was able to recreate wave 1 characteristic distributions even though the wave 2 and waves 2 and 3 samples were not similar to wave 1, we ensure that the composition of the weighted sample reflects our starting sample and would minimize inferential bias. These results were consistent with descriptive analysis of the survey waves, highlighting a potential issue with longitudinal analyses on those who report pain.

In each successive wave, those with more, nonchronic, and specific pain had a higher likelihood of nonresponse, potentially biasing analyses that do not account for differences in panel composition over time. Analyses using convenience panels need to account for changes in sample composition, particularly the loss of those with more severe and specific pain, and worse health. Estimates of impacts on pain may be biased if those with the most pain and the more specific pain are differentially dropping out of the panel. Hence, evaluating whether attrition impacts inferences about change in outcome measures such as pain is important.

Platforms like MTurk will continue to be used to collect survey data inexpensively and rapidly. Results from this nonresponse analysis should be considered in the context of general trends for MTurk workers. First, researchers should consider the underlying population that completes surveys on MTurk. Generally, the population who responds is younger, so higher nonresponse rates among younger individuals may be less concerning as that subgroup is already providing a higher proportion of responses than the general US population [13]. In addition, those with back pain tend to be older on average and come from predominantly non-White racial and ethnic groups [28]. However, high nonresponse rates among Hispanic or Latino participants may bias inferences as they represent smaller proportions of the base sample. In addition, analyses that account for specific populations like those with back pain should account for differences in sample composition over time, particularly around variables that may impact response rates and potential outcomes such as pain intensity or severity.

Regular outreach and follow-up have already been shown to increase response rates in longitudinal studies with MTurk. Inverse probability weighting can be used to correct for participant nonresponse. Given patterns of nonresponse, targeted surveys to populations that are either underrepresented or are more likely to drop out of surveys with MTurk can avoid issues with weighting small samples, especially when multiple successive survey waves exist.

Limitations

This study had several limitations. First, since it focused on patients with back pain, its results should be interpreted with care and may not generalize to those without back pain. In addition, all data collection occurred during the COVID-19 pandemic. Response behavior may have differed during this

time compared with before or after the pandemic. Finally, all data related to health conditions and pain assessments were self-reported. However, we applied various approaches to limit our sample to high-quality and truthful responses.

Conclusions

Longitudinal studies on MTurk, particularly those exploring specific issues like the impacts of pain on health, should carefully consider how nonresponse will affect their study samples and whether samples drawn from these studies reflect the population of interest.

Acknowledgments

Data Availability

The dataset analyzed for the current study is not publicly available yet due to the project still being in progress, but the data are available from the first author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Cardiovascular disease (CVD) represents the greatest burden of mortality worldwide, and statins are the most commonly prescribed drug in its management. A wealth of information pertaining to statins and their side effects is on the internet; however, to date, no assessment of the accuracy, credibility, and readability of this information has been undertaken.

Objective: This study aimed to evaluate the quality (accuracy, credibility, and readability) of websites likely to be visited by the general public undertaking a Google search of the side effects and use of statin medications.

Methods: Following a Google web search, we reviewed the top 20 consumer-focused websites with statin information. Website accuracy, credibility, and readability were assessed based on website category (commercial, not-for-profit, and media), website rank, and the presence or absence of the Health on the Net Code of Conduct (HONcode) seal. Accuracy and credibility were assessed following the development of checklists (with 20 and 13 items, respectively). Readability was assessed using the Simple Measure of Gobbledegook scores.

Results: Overall, the accuracy score was low (mean 14.35 out of 20). While side effects were comprehensively covered by 18 websites, there was little information about statin use in primary and secondary prevention. None of the websites met all criteria on the credibility checklist (mean 7.8 out of 13). The median Simple Measure of Gobbledegook score was 9.65 (IQR 8.825-10.85), with none of the websites meeting the recommended reading grade of 6, even the media websites. A website bearing the HONcode seal did not mean that the website was more comprehensive or readable.

Conclusions: The quality of statin-related websites tended to be poor. Although the information contained was accurate, it was not comprehensive and was presented at a reading level that was too difficult for an average reader to fully comprehend. As such, consumers risk being uninformed about this pharmacotherapy.

Introduction

Background

Cardiovascular diseases (CVDs) are the primary cause of death globally, with an estimated 17.9 million people dying of CVDs in 2021. This represents 31% of all global deaths. Of these deaths, 85% are due to heart attack and stroke, whose most common etiology is atherosclerosis [1]—the development of fatty plaque within artery walls. A key pharmacological treatment for atherosclerosis is statin therapy. It has a role in the primary and secondary prevention of vascular events, with a lowering of low-density lipoprotein cholesterol leading by 2 mmol/L, typically giving a 10% absolute benefit (the reduction in the probability of an event's occurrence within a population receiving treatment) for those diagnosed with vascular disease and a 5% absolute benefit for those with risk factors yet without having experienced a vascular event [2]. This creates issues when we consider that patients may be biochemically abnormal (with hypercholesterolemia) but asymptomatic. Such patients may doubt the use of the prescribed statin therapy as they determine the cost-benefit balance between tangible adverse effects and theoretical benefits. This may prompt the consultation of alternative sources of knowledge to aid decision-making. In this era of shared decision-making, where patients participate in the medical decisions that affect their health [3], it is essential that the information they access is high quality and easily understood.

Use of the Internet for Health Information Seeking

In this milieu, the internet has risen as a key source of health-related information, with 79% of adults seeking web-based health information in America and 79% to 86% in China, the Philippines, Hong Kong, Indonesia, and Vietnam [4,5]. Comparatively, seeking web-based health information is as popular as playing games or downloading music from the web [6]. Notably, the COVID-19 pandemic has presented unprecedented challenges, catapulting society further into a future dependence on telehealth and internet-assisted health care [7,8]. As such, traditional in-clinic and leaflet modes of health information delivery are being supplemented, and in some cases supplanted, by internet searches. With this dramatic change in the terrain upon which patients and their families are attaining information, it is crucial to determine the quality of web-based health information put forth to them.

Health literacy is defined as "the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions" [9]. It requires a complex group of skills such as reading, listening, analyzing, and decision-making, as well as the ability to apply the aforementioned skills to health situations [10]. Those with poor health literacy are vulnerable to undertaking unnecessary tests and treatments or, conversely, refusing beneficial tests and treatments. In part, they may be misled into assessing the quality of web-based health information based on its search result ranking, image quality, celebrity endorsement, and website authorship rather than relying on the criteria of established quality guidelines [11,12].

Health literacy–related knowledge and skills are particularly deficient among vulnerable populations, who are also more likely to experience CVD [12,13]. Unfortunately, those with poor health literacy are susceptible to the influence of mass media and emotionally persuasive texts. This may explain the response to the television program "Catalyst" in Australia [14], whose criticism of statins resulted in 11% of patients (in a survey by the Australian National Heart Foundation of 1094 patients) who watched the program ceasing to take their cholesterol-lowering medication and significant and sustained changes in statin usage, with 2.6% fewer statins (equivalent to 14,005 dispensing) each week [15].

Internet Standards

There is considerable heterogeneity in the quality of web-based health information [16]. The quality of information can be examined in 3 domains: accuracy, credibility, and readability [17]. Each is defined as follows: accuracy is the intent to be evidence based and safe by adequately offering a complete, unbiased picture and its relevance [17]; credibility is the attribution of source and authorship and the disclosure of conflicts of interest for the presented information [18]; and readability is the ease of understanding due to the style of writing, describing the reading comprehension level a layperson requires to understand a text [19,20]. Complex wording reduces engagement with, and application of, content [21]. This leaves patients vulnerable to becoming ill-informed and at risk of adverse health outcomes [22]. The quality of web-based health information is, therefore, a pressing issue, which the Health on the Net Foundation aims to address by providing a Health on the Net Code of Conduct (HONcode) seal, an internet-based certification of medical and health websites that adheres to a set of publishing principles regarding the source and purpose of medical information. However, few consumers are aware of Health on the Net or the HONcode.

While there have been assessments of the quality of websites on many key areas of health care, such as diabetes [23], obesity [24], and hypertension [25], and on surgical interventions [26,27], there is a dearth of assessment about the quality of web-based information pertaining to medications. Such assessments are necessary to inform clinicians of the quality of content likely to be accessed by their patients, who are particularly interested in the likelihood and nature of adverse side effects. We aimed to assess the quality of consumer health information on websites about statins through consideration of accuracy, credibility, and readability.

Methods

Study Design

Overview

Through this cross-sectional study, we analyzed the accuracy, credibility, and readability of websites that were most commonly presented to patients searching for the keywords "statin" and "statin side effects." We determined each website's search engine ranking, category (commercial, not-for-profit, or media), and the presence or absence of the HONcode seal. Furthermore,

we determined the relationship between the accuracy, credibility, and readability of the websites found.

In selecting websites on statins to analyze, we aimed to emulate a typical consumer's search for web-based health information. A web search was conducted using Google, in keeping with evidence that it accounts for more than half of all web traffic [28-30] and is an increasingly preferred search engine by the general public [31]: 91% of American adults using the internet use a search engine, and of those, 83% use Google more often than other search engines [4,32]. To conduct the search, location filters, user information, search history, cached data, and cookies were disabled, and sponsored results were excluded to avoid inadvertent search bias. The search terms used were "statin" and "statin side effects," following the advice of our lipidologist coauthor (SL) that the generic term "statin," rather than specific medication names, was commonly used in discussion with patients in clinical practice and that "statin side effects" were a key concern of patients.

The first 20 ranked websites in the Google search results page were analyzed (after removing any duplication from search results of the 2 search terms). We did not identify further websites in the search results, given that, in general, websites returned on the first Google search results page generate 92% of all traffic from an average search [16,33]. This drops by 95% for the second page and by 78% and 58% for subsequent pages [31]. Thus, we did not aim to identify all websites on statins but rather to emulate an authentic consumer search.

Website Search Rank

The effect of the association between search result ranking and accuracy, credibility, and readability was considered. Given that engagement is highest with the first 5 websites in search results, garnering 67% of all clicks from a search results page [31,34], the websites were divided into 4 sets of 5 websites, each according to their ranking as per Google search result. Thus, websites ranked 1-5 were called quartile 1, websites 6-10 were called quartile 2, and so forth.

Website Categorization

In the interest of determining whether the nature of the authorship of the websites had a bearing on their accuracy, credibility, and readability, each of the 20 chosen websites was categorized into 3 types: commercial (defined as a website that generates revenue or cash and is not affiliated with the government), not-for-profit (a website that garners support for a cause rather than revenue, including government and charities), and media (a website that reports new findings or stories, with the primary purpose of the website being news reporting).

Presence of HONcode Seal

We assessed whether the quality of the websites was associated with the presence or absence of the HONcode seal.

Measures

Overview

In assessing the accuracy, credibility, and readability of the websites, we considered existing tools and developed study-specific tools where necessary.

Accuracy

For accuracy, we developed a statin-specific tool that took into account medical guidelines. The checklist (Table 1) was designed after referring to other studies purporting to assess the quality of web-based health information [17]. A key difference here was that we were looking at a specific treatment. Three features were considered: (1) the intent to be evidence based; (2) safety, in that a website should adequately offer users a complete, unbiased picture of statin treatment; and (3) relevance, in that it is reasonable to expect a website to address the criteria in the checklist [17]. The checklist was intrinsically linked to a website's comprehensiveness, consistent with other studies that have evaluated completeness as an integral part of accuracy [16].

To meet these features, guidelines from the American College of Cardiology and the Australian Heart Foundation [37] were synthesized into short statements, which formed the accuracy criteria. These statements formed a checklist that each website was required to address to be considered "accurate." The development of the statements was further informed and determined by a review of the treatment of cholesterol in light of its evidence base [38], as well as criteria from the treatment section of the validated DISCERN tool [39]. This section (items 9-16 of the DISCERN tool) addresses issues of risk, benefit, and how the website guides decision-making surrounding treatment options [39]. Combining these sources ensured that a higher score would be awarded to websites providing the most evidence-based information. In total, 20 equally weighted criteria were devised, and a score of 20 was arbitrarily defined as a minimum acceptable standard.

Each accuracy item was scored as: "present and complete" (2), "present but incomplete" (1), "absent" (0), or "inaccurate" (*). A maximum score of 40 could be awarded to each website assessed. "Incompleteness" was defined as a nonexact or indirect mention of a topic outlined in a criterion rather than an explicit statement. Two reviewers (DdP and E loh) completed the assessment.

Any hyperlinks that navigated to information within a website were followed and the data were included in the final assessment; links leading to external websites were not followed. Embedded videos were analyzed. Once each reviewer concluded their analysis, the results were compared. Discrepancies were resolved through discussion until reaching a consensus.

Table 1. Website accuracy checklist.

Accuracy criteria	Descriptor
1	Mentions that cholesterol is a modifiable risk factor for cardiovascular disease [35]
2	Mentions that consultation with a doctor is essential before and while taking statins and when ceasing them [36]
3	Lists conditions for which statins are used [36]
4	Defines the target population for statin therapy [37]
5	Mentions the importance of adherence to statin therapy [36]
6	Addresses the subtleties of primary prevention [38]
7	Mentions that statins are about reducing complications of high cholesterol rather than achieving a specific (low-density lipoprotein) cholesterol [38]
8	Describes or at least lists the benefits of statin therapy [39]
9	Describes or at least lists the side effects or risks of statin therapy [39]
10	Describes how treatment affects the overall quality of life [39]
11	Mentions low to moderate dose statin therapy is recommended in primary prevention [37]
12	Specifically addresses rhabdomyolysis [36]
13	Describes the approximate financial burden to the patient [36]
14	Describes the duration of treatment before an effect is measurable [39]
15	Describes how statins work or at least what they do [39]
16	Describes what may happen without treatment [39]
17	Explores the possibility of using alternative therapies to statins [39]
18	Mentions that statins must not be used during pregnancy [37]
19	Describes drug interactions or at least lists them [39]
20	Mentions that statins do not replace a healthy lifestyle [36]

Credibility

In developing the criteria to be included in the assessment of credibility (Table 2), DISCERN was chosen as a reference, as well as other studies that used DISCERN or another available tool for website assessment. However, as the 5-point Likert scale used in DISCERN can be subject to response style bias [40], a present (1) or absent (0) scale was adopted as it has been shown to improve the objectivity of data collection [41-43].

Table 2. Website credibility checklist.

Item	Criteria	Score criteria
1	Referencing or citations obtained from peer-reviewed journals	1 point if the articles for which the references are obtained are published in peer-reviewed journals [16,44]
2	Website updated within last 24 months	The latest update should be within the past 24 months [45]
3	Avoids anecdotal evidence for making claims	Does not use anecdotal evidence as a basis for claims; quoting a case study without using claims is acceptable [46]
4	Mailing address present	Physical contact address of the website clearly stated [45]
5	Contact information available	Contact information including name, position, telephone number, address, and email [47]
6	Sponsorship stated	Any sponsorship should be clearly stated
7	Organizational privacy policy stated	Organization privacy policy should be clearly stated [47]
8	Declaration of the author's qualification	Author's qualification should be health care related [16,44]
9	Paid access tab present	If paid access is available, the difference in the information obtained from paid vs unpaid access should be clearly stated [48]
10	Disclosure of funding or conflicts of interest	Conflicts of interest and funding disclosure should be clearly stated [44]
11	The presence of an HONcode seal or third-party certification	Presence of a HONcode[a] seal or any other third-party certification [16]
12	Advertisement neutral	Advertisements should steer clear from the website information (eg, no pop-ups related to the website content) [16]
13	Disclaimer regarding web-based health information	A disclaimer should be clearly stated that web-based health information does not replace a practitioner's advice [44]

[a]HONcode: Health on the Net Code of Conduct.

Each website was appraised according to this list. A score was allocated for each website's front page, with internal links explored only if relevant. Data (credibility scores) were undertaken as independent assessments by 2 assessors (E Loh and DdP). The results were compared, and if discrepancies arose, discussions were held to clarify the score, with external input from advisors (HM, SL, and KS) obtained where appropriate.

Readability

For readability, various tools are available, including the Flesch Kincaid Reading Ease, Flesch Kincaid Grade Level, Simple Measure of Gobbledygook (SMOG), and Average Grade Level. We used SMOG as it is considered the gold standard for assessing the readability of health care material and has a high correlation with the other scoring systems [24,49]. Importantly, the outcome measure is easy to understand as, for example, an SMOG readability grade of 6 represents a text comprehensible to all individuals with sixth-grade reading skills and above [50-53]. This grade level was set as the basis of readability, given that the available literature sets this as the standard for "superior" readability. To use this tool, texts from the 20 selected websites were copied and saved as separate Microsoft Word (Microsoft Corp) and plain text documents for analysis, deleting text unrelated to the health information topic (eg, author information or disclaimers) to prevent this from confounding

the scoring. A single web-based readability calculator [54] was used to generate the scores.

Data Analysis

The website category and ranking findings were compared by ANOVA, and differences between websites with and without the HONcode seal were analyzed with 2-tailed *t* tests. In addition, the relationship between credibility and readability with accuracy was assessed by Pearson correlation.

Ethical Considerations

As the research was not conducted on human subjects, no ethics review was required.

Results

Selected Websites

The top 20 websites returned by the search are listed in Multimedia Appendix 1 [55-74]. Of the 20 websites chosen from the search, 45% (n=9) were categorized as commercial, 45% (n=9) not-for-profit, and 10% (n=2) media (Table 3). There was an even distribution of commercial and not-for-profit websites across the 4 quartiles, with both media websites found in the fourth quartile. Eight of the websites bore the HONcode seal.

Table 3. Top 20 statin websites' category, HONcode[a] presence or absence, accuracy, credibility, and readability.

Website rank	Category	HONcode Seal	Accuracy	Credibility	Readability (SMOG[b] score)
1	Commercial	Yes	20	6	10.7
2	Not-for-profit	Yes	9	11	11.3
3	Not-for-profit	No	23	9	12.5
4	Commercial	Yes	16	6	13
5	Commercial	No	10	4	7.7
6	Not-for-profit	No	15	7	13
7	Commercial	No	14	10	9.6
8	Not-for-profit	No	13	5	10.8
9	Not-for-profit	No	16	11	10.2
10	Commercial	Yes	11	10	8.6
11	Commercial	Yes	16	9	9.4
12	Commercial	No	13	6	11
13	Not-for-profit	No	17	9	8.9
14	Not-for-profit	No	8	7	9
15	Not-for-profit	No	8	7	10.3
16	Media	No	8	4	7.8
17	Not-for-profit	Yes	16	11	6.7
18	Commercial	Yes	19	8	9.7
19	Commercial	Yes	21	7	9.2
20	Media	No	14	2	8.1

[a]HONcode: Health on the Net Code of Conduct.

[b]SMOG: Simple Measure of Gobbledegook.

Accuracy

The mean website accuracy score was 14.35 (SD 4.43). In terms of accuracy, the 3 highest-scoring websites were Wikipedia (score of 23), Drugs.com (score of 21), and Medicine.net (score of 20). These were the only websites to achieve a score of 20 or above. No website contradicted any checklist criterion. The top 3 performing checklist criteria were related to side effects and statin mechanism of action (criteria 9, 12, and 15), with a score of "present and complete" for each of these criteria achieved by 18, 14, and 12 websites, respectively. Although side effects were covered to some degree in all websites, criteria about drug safety (criteria 18 and 19) were complete in only 8 and 7 websites, respectively. Other poorly performing criteria reflected the lack of detail about primary prevention (criteria 11 and 6), with a score of "absent" assigned to 19 and 17 of the websites, respectively.

Credibility

None of the sampled websites met all credibility criteria for a perfect score of 13. The mean score overall was 7.45, with a range of 2-11. Importantly, 12 websites referenced peer-reviewed journal articles as a source of information, and 15 avoided anecdotal evidence for making claims. Media and some commercial websites reported personal opinions. While only 6 websites provided an organization's contact details, the others provided an email address or feedback form for contact purposes. Sponsorship was explicitly stated in 12 websites, with reference to either government or private organizations. All websites declared their organization's privacy policy, including websites with lower overall credibility scores. Only 8 websites declared author qualifications, which were primarily health related. None of the websites required paid access. Funding sources were fully disclosed in 11 websites, with the remaining 9 not reporting their source of funding or conflicts of interest. Twelve websites either had no advertisements or non–health care advertisements; the 8 websites that did not meet this criterion were commercial or media websites. Only 5 websites did not include a disclaimer that web-based health information does not replace a practitioner's advice: all of these websites were commercial or media websites.

Readability

Overall, for SMOG readability, the median was 9.65 (IQR 8.825-10.85) and the average was 9.875 (SD 1.75), that is, above the ninth-grade level. None of the websites met the recommended grade level of 6; even the media websites required an eighth-grade level of comprehension.

XSL•FO

RenderX

Correlation Between Accuracy, Credibility, and Readability

No significant correlation was evident between the correlation between credibilty and accuracy (P=.23) (Figure 1).

Figure 1. Relationship between website credibility (black triangles) and correlation readability (blue squares) with accuracy (P=.23).
Website Search Rank

Websites that featured prominently in search results were not necessarily the most accurate, with no significant difference between the quartiles (P=.64). Indeed, of the 20 websites reviewed, the second highest scoring website for accuracy was ranked in the 19th position on search results. Similarly, there was no difference in credibility (P=.63) or readability (P=.06) between the quartiles.

Website Categorization

Comparing commercial with not-for-profit websites, 2-tailed *t* tests revealed there was no significant difference in terms of accuracy (P=.275), credibility (P=.83), or readability (P=.452). As there were only 2 media websites, a comparison with them was not made. Notably, they had the lowest scores for credibility, but both scored among the most readable.

Presence of HONcode Seal

Of the 20 websites, 8 were HONcode certified, with 6 of these categorized as commercial websites and 2 as not-for-profit. The mean accuracy scores for websites with and without the HONcode seal were 16 (SD 4.2) and 13.25 (SD 4.4), respectively, but this was not significantly different (P=.18). The presence or absence of the HONcode seal did not preclude a website from scoring at either end of the accuracy scale. Although the 8 websites with the HONcode seal scored higher in credibility (mean 8.5, SD 2) than websites that were not HONcode certified (mean 6.75, SD 2.7), this was not significantly different (P=.139). There was no significant difference in readability scores (P=.92) when comparing websites with HONcode seal status or lack thereof (mean 9.83, SD 1.9 and mean 9.91, SD 1.7, respectively).

Discussion

This study found that overall, the quality of websites with statin-related information tended to be poor. The website content was not sufficiently comprehensive, and the reading level was too difficult for the average reader to fully comprehend. The credibility of the websites varied, although overall websites bearing the HONcode seal had higher credibility than those without.

Here, we formally assessed the quality of websites addressing statins and their side effects. The finding that the quality of information is of variable caliber is consistent with studies investigating web-based health information on other topics [4,17,75]. Although the criteria used by Google's ranking algorithm is confidential, Google's guidelines state that it uses a series of algorithms that account for the words of the query, relevance and usability of web pages, the expertise of sources, ease of use on mobile device interfaces, as well as location and settings to determine the results displayed [76,77]. However, this study demonstrates that the most prominent websites in the Google search ranking are not necessarily of high quality.

The lack of correlation between accuracy and credibility or readability is a concern if patients are using the information to understand their condition and take action related to it. Patients with poor health literacy may use inaccurate and untrustworthy information in deciding whether to see a health professional following the onset of symptoms or whether to undertake tests and treatments that may be unnecessary or recommended by health professionals [12]. Vulnerable populations are at higher risk of having poor health literacy and experiencing CVD

[12,13], making them especially vulnerable to inaccurate, untrustworthy, and unreadable websites on statins.

While most websites analyzed as part of this study scored low in accuracy, this tended to be attributed to a lack of completeness of information rather than a lack of factual information. While the checklist developed here may be stringent, it would be reasonable to expect that websites dedicated to statins would be comprehensive. The lack of comprehensiveness in the information provided on the websites could result in consumers overlooking important details unless they browse through multiple websites. Furthermore, visits to multiple websites may not generate clarity but confusion. This is due to the increased likelihood of encountering inconsistent information, particularly as websites have different agendas based on the website type. That said, the commercial websites scored, on average, just as well as the not-for-profit websites, indicating that they can be a valuable source of information for consumers. It also indicates that government and other not-for-profit websites will be required to at least match the accuracy of commercial websites if they are to remain relevant in Google's search algorithm, as having information-rich content is a factor that contributes to higher search rankings [78].

When browsing the internet, one would expect government and other not-for-profit websites to provide credible information. However, some of these websites returned relatively low credibility scores and overall were not significantly more credible than commercial websites. Over half of the 20 websites analyzed provided evidence-based information and avoided anecdotal evidence, increasing their credibility rating [16,44]; however, it was concerning that 5 websites provided information based on anecdotal evidence. As expected, media websites received low credibility scores as news articles about statins contained personal views and anecdotes. Other indicators of credibility were lacking by a large proportion of websites, in particular author qualifications and details about sponsorship, funding, and conflicts of interest [16,44]. Furthermore, many of the commercial and media websites included advertisements, including health-related advertisements [16], and 5 of them did not include the disclaimer that web-based health information does not replace a practitioner's advice [44]. Thus, even patients with a degree of health literacy would find it difficult to accurately appraise the credibility of many of these websites on statins.

Given that the general public is unlikely to be fully equipped to gauge the credibility of web-based health information presented [12], clinicians could advise that patients identify the presence of the HONcode seal as this merits some confidence in the information presented [16]. However, the code does not necessarily imply that websites are comprehensive. Additionally, website developer application for the HONcode seal is voluntary, so high-quality websites may not bear the HONcode seal. The finding that the readability of the websites with the HONcode seal was not at a suitable level means that such websites may not represent digestible patient health information.

Furthermore, a practical issue is that the HONcode seal is at the bottom of the web page and is thus not necessarily evident at first glance.

Many patient demographic groups have been found to read at a level more than 3 years below their completed educational years [79]. Thus, the study results may not be indicative of the severity of the problem posed by websites with high readability scores in terms of the general public's understanding of web-based information [79]. Those with limited literacy skills tend to have poorer health status due to a lack of knowledge and understanding of health care issues and a diminished ability to participate in shared decision-making in the clinical context [80]. They also tend to have poorer compliance with treatment recommendations and subsequent disease progression, as well as a higher risk for seeking emergency care and more frequent and longer inpatient admissions [27].

Additionally, other factors besides readability play into the way a text is received, including logical and sequential presentation of information. Additionally, alternative media such as images and graphs provide a well-documented "picture superiority" effect that boosts understanding of and engagement with a text [81], although some of these may also require interpretation by consumers.

A limitation of this study of these websites is that the internet is dynamic, with websites updated at any time. The search used in undertaking the study is constrained temporally in its noniterative nature, as well as its method, which used only the major search engine Google. While a metasearch capturing results from multiple search engines would provide a more comprehensive view of the information about statins on the internet, it is unlikely to represent the behavior of the public [82]. Additionally, only 8 of the websites in the study were updated in some way after completion of this study, and the information on some websites is dated as more than 10 years old.

Overall, this study has demonstrated that within the surfeit of information available on the internet regarding statin therapy, the quality of websites is of mixed caliber. The content of information is generally accurate but incomplete, while credibility is variable. Readability is generally of a level too difficult for the general public to comprehend. This suggests a need for guidance to website developers of health care websites in order to capitalize on the vast potential of the internet to equip patients with the empowerment of improved health information and health literacy. It also highlights that clinicians will need to be educated themselves about what is on the internet and what constitutes accuracy, credibility, and readability in order to impart this knowledge to their patients. During the COVID-19 pandemic, the methods through which patients seek information about their health have shifted toward increasingly internet-based means, making the quality of information on the internet of particular significance in the current climate and for the foreseeable future.

Acknowledgments

Authors' Contributions

E Ling attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted. The project was planned by HM with input from all authors. Checklists were developed by E Loh and DdP with the assistance of SL and KS. Data were collected by E Ling, E Loh, and DdP. Data analysis was done by E Ling, E Loh, and DdP with assistance from HM. Data interpretation and manuscript review were done by all authors.

Abstract

Background: Quality and accuracy of online scientific data are crucial, given that the internet and social media serve nowadays as primary sources of medical knowledge.

Objective: This study aims to analyze the relationship between scientific relevance and online visibility of strabismus research to answer the following questions: (1) Are the most popular strabismus papers scientifically relevant? (2) Are the most high-impact strabismus studies shared enough online?

Methods: The Altmetric Attention Score (AAS) was used as a proxy for online visibility, whereas citations and the journal's impact factor (IF) served as a metric for scientific relevance. Using "strabismus" as a keyword, 100 papers with the highest AAS and 100 papers with the highest number of citations were identified. Statistical analyses, including the Spearman rank test, linear regression, and factor analysis, were performed to assess the relationship between AAS, citations, a journal's IF, and mentions across 18 individual Web 2.0 platforms.

Results: A weak, positive, statistically significant correlation was observed between normalized AAS and normalized citations ($P<.001$; $r=0.27$) for papers with high visibility. Only Twitter mentions and Mendeley readers correlated significantly with normalized citations ($P=.02$ and $P<.001$, respectively) and IF ($P=.04$ and $P=.009$, respectively), with Twitter being the strongest significant predictor of citation numbers ($r=0.53$). For high-impact papers, no correlation was found between normalized citations and normalized AAS ($P=.12$) or the IF of the journal ($P=.55$).

Conclusions: While clinical relevance influences online attention, most high-impact research related to strabismus is not sufficiently shared on the web. Therefore, researchers should make a greater effort to share high-impact papers related to strabismus on online media platforms to improve accessibility and quality of evidence-based knowledge for patients.

Introduction

Patients, health care professionals, and researchers increasingly use social media and online platforms as a source of knowledge, health care news, and scientific research [1]. Despite the worldwide prevalence of strabismus remaining stable at around 2% [2], the public's online interest in the topic has been rising, a trend reflected by the increasing popularity of queries related to the disease over the past 2 decades according to Google Trends. Due to this increasing reliance on online platforms, it is essential to ensure the quality and relevance of scientific data that are commonly accessed on the web, especially for lay members of the public who may lack the skills or time to assess that themselves.

To quantify the relevance of research within the field of medical science, the number of citations and impact factor (IF) of the

journal are used most frequently [3]. The dissemination of the same academic information through platforms used by the general public, on the other hand, can be most reliably quantified by the Altmetric Attention Score (AAS), a real-time weighted measure of mentions across all Web 2.0 social media platforms [4,5].

Bibliometric analyses using altmetrics and other scientometrics have been conducted previously in the field of ophthalmic research to evaluate publication trends [6], disruptiveness of papers [7], or research productivity [8]. To date, however, there have been no such analyses within the subspecialty of strabismus, despite the pervasiveness of the disease.

Therefore, we decided to analyze the relationship between the scientific relevance of strabismus research and its contributions to the online sphere, in order to answer the following questions: (1) Are the most popular strabismus papers scientifically relevant? (2) Are the most high-impact strabismus studies shared online enough?

Methods

In line with the best practice of literature searching [9], a thesaurus synonym search was performed to identify appropriate keywords for database search. As of January 2023, the thesaurus does not identify synonyms for "strabismus," and the *Cambridge Dictionary* confirms it is the only medical term to describe the condition [10]. No morphological variation of the term has been identified, eliminating the need for the use of truncation in keyword searches.

Therefore, a list of research papers including the keyword "strabismus" was generated on January 27, 2023, with Altmetric Explorer with no other restrictions (search period: January 2011 to January 2023). The keyword search engine in Altmetric Explorer yields comprehensive results including outputs that match the keyword across publication title, author name, or journal title [11]. Hence, the pooled list was then filtered by a consultant ophthalmologist according to relevance to include 100 papers with the highest AAS (a total of 255 titles and abstracts were analyzed to compile 100 relevant publications). Additional preliminary searches using lay synonyms of strabismus, including "squint" and "cross-eye," were performed but yielded no relevant or sufficiently high AAS results for inclusion, proving the keyword "strabismus" captures the bona fide core of publications in the field.

On the same day (January 27, 2023), for each of the papers, Web of Science (WoS) was used to add information on the number of citations, time since publication, and IF of the journal at the time of publication; other metrics traditionally used to assess the quality and relevance of scientific research [12]. Additional data on the source of AAS, including mentions across (1) news, (2) blogs, (3) Twitter, (4) peer review, (5) Facebook, (6) Wikipedia, (7) LinkedIn, (8) Weibo, (9) Google+, (10) Reddit, (11) Pinterest, (12) F100, (13) Q&A, (14) policy, (15) patent, (16) video, (17) syllabi, and (18) Mendeley, were pooled from Altmetric website and evaluated to characterize the field.

For systematic comparison, the same approach to searching was implemented to yield a list of papers with the highest number of citations: on January 27, 2023, WoS was used to generate a list of 100 papers including the keyword "strabismus" with the highest number of citations, excluding papers published before 2011, and the year Altmetric Explorer was founded and started tracking the AAS (search period: January 2011 to January 2023). No other filters were applied to the search. On the same day, the AAS for each of the papers was manually pooled from Altmetric website. Data on time since publication and the journal's IF at the time of publication were extracted from WoS. To account for temporal differences [13], the values for AAS and citations for both groups have been then normalized per year since publication.

Kolmogorov-Smirnov test was used to verify that the distribution of the data does not follow a normal distribution, and Spearman rank correlation coefficient was used to test for correlation between all variables. Following correlational calculations, linear regression analysis and factor analysis were performed to explain patterns among correlated variables, both of which are statistical techniques commonly used in altmetric research [14,15]. SPSS (IBM Corp) was used for all statistical calculations. Statistical significance was defined as $P<.05$.

Ethical Considerations

No ethics board approval was required, as the study did not involve any human participants.

Results

Correlation Analysis

The normalized AASs of the 100 papers with the highest online visibility (median AAS 11, IQR 6-16) correlated significantly with normalized citations ($P<.001$) but demonstrated a weak strength of the relationship ($r=0.27$) for papers with AAS <150. To achieve this result, we excluded 3 outlier papers with significantly higher AASs (922, 413, and 169, respectively, compared to median 11, IQR 6-16; z score>3), which would otherwise skew the statistical analysis. Spearman rank test demonstrated no correlation between the normalized AAS and the IF of the journal ($P=.15$) or time ($P=.37$).

For the 100 papers with the highest number of citations (median 30, IQR 15-45), no statistically significant correlation was found between normalized citations and the normalized AAS ($P=.12$) or IF of the journal ($P=.55$), but as expected, they correlated significantly with time ($P=.01$).

Upon analysis of AAS sources, we found a weak, positive, statistically significant correlation between normalized citations and Twitter mentions ($P=.02$; $r=0.27$), normalized citations and Mendeley readers ($P<.001$; $r=0.40$), and normalized citations and policy mentions ($P=.02$; $r=0.24$) for the 100 papers with highest AAS. The same variables showed a weak, positive, statistically significant correlation with the IF of the journal at the time of publication: Twitter and IF ($P=.04$; $r=0.25$), Mendeley readers and IF ($P=.009$; $r=0.32$), and policy mentions and IF ($P=.04$; $r=0.26$).

Correlations between the number of mentions in the news, on blogs, in peer-reviews, on Facebook, Wikipedia, LinkedIn, Reddit, Google+, Weibo, Pinterest, syllabi, or video and

normalized citations or IF were not significant at $P<.05$ (Multimedia Appendix 1).

Multivariate Analysis

To better understand variance among the correlated variables, a linear regression model was run with normalized citations as the dependent variable and Twitter mentions, Mendeley readers, and policy mentions as covariates. ANOVA test showed significant variance within the sample, confirming the suitability of the test ($P<.001$). We obtained an R^2 value of 0.31, indicating that 31% of the variance within citations can be explained cumulatively by the 3 AAS sources. Only Twitter and policy mentions, however, were significant predictors ($P<.001$ and $P=.004$ respectively), with Twitter mentions being the most important predictor as indicated by the highest standardized coefficient ($r=0.53$).

Factor Analysis

Factor analysis was performed on metrics with adequate data for the papers with the top 100 AAS normalized citations, normalized AAS, IF, time since publication (months), Twitter mentions, Mendeley readers, and policy documents. Bartlett test of sphericity indicated an approximate chi-square value of $\chi^2_{93}=124.4$ ($P<.001$) and a Kaiser-Meyer-Olkin adequacy value of 0.607, together indicating the suitability of the data set for factor analysis. Three factors were identified across these variables: factor 1 between Twitter, Mendeley, AAS, and citations; factor 2 between Mendeley, policy, and citations; and factor 3 between IF and time.

Discussion

Principal Findings

The significant, yet, weak correlation of AAS with citations for papers with the highest online visibility shows that the clinical relevance of strabismus-related publications (as measured by citations) can contribute to increased online popularity but is not the sole determining factor. Furthermore, the lack of correlation between AAS and IF demonstrates that the relative importance of a journal in the field (and consequently the paper) does not determine its online popularity, which raises questions about the quality of strabismus research receiving the most online attention.

Through correlational and multivariate analysis of mentions across individual Web 2.0 platforms, we have demonstrated Twitter mentions to be a significant and strong predictor of citations for the most popular strabismus papers. Although prior studies demonstrated a more significant, causative impact of tweets on citation numbers [16], the relationship can differ between fields [17] and seems to be statistically significant for strabismus research, albeit moderate compared with other research domains. Overall, our findings imply that dissemination of strabismus research through Twitter can have an impact on scholarly visibility and subsequently citation rates.

Furthermore, we demonstrated a lack of statistically significant correlations between traditional scientometrics (citations and IF) and mentions across other social or media platforms, which has been also observed in other fields of research [17]. This reveals existing gaps that require more references to research papers on strabismus, including social media platforms like Facebook or LinkedIn, as well as critical, knowledge-oriented pages such as Wikipedia.

Furthermore, in terms of factor analysis, factor 1 linking AAS, citations, Mendeley, and Twitter likely suggests that for strabismus research, there is a degree of overlap regarding the user bases or networks between Mendeley and Twitter, despite the former being considered a platform largely used by academic professionals as opposed to the more widely public microblogging service [18]. It may also indicate that highly cited papers are receiving engagement and being discussed in both academic and general public networks indicating that such papers may have a wider social impact. Factor 2 linking Mendeley, policy documents, and citations may suggest that for highly cited papers, there is increased interest and readership on Mendeley—a proportion of which may be faculty and departmental figures. This in turn may lead to policy mentions for impactful research papers. Therefore, this suggests that papers with high citation counts and academic impact may be influencing policies and organizational standards [19]. Factor 3 linking IF and time could be due to the overall increase and growth of the cited strabismus literature over time; however, this is less relevant to our research question.

For the 100 papers with the highest number of citations, the lack of correlation between citations or IF and the AAS suggests that clinical relevance or perceived prestige related to the publishing journal does not affect the online visibility of strabismus papers. Researchers publishing in the strabismus realm should, therefore, make a greater effort to share their high-impact papers on social media. In turn, this could increase the visibility and accessibility of their research, especially for the lay public who rarely browses journals for medical knowledge, enhance collaboration, and further enhance the overall impact of their research.

Strengths and Limitations

AAS itself is a useful tool for authors to get quick, up-to-date insight into the performance of their papers on the web. It is crucial, however, to bear in mind the inherent limitations of AAS due to the fact that it is ultimately only a metric of "mentions" or "posts" and is not an indicator of research quality or legitimacy [20]. In isolation, it may be deemed unreliable, as "viral" papers that do not exhibit robust research methodology or present sensible conclusions may still acquire a high AAS. Furthermore, the AAS does not account for following or website traffic, therefore providing no information on the actual number of viewers. As a result, a frequently mentioned paper can effectively have low visibility and reception, despite a high AAS. Although Twitter mentions and Mendeley readership seem to have some impact on citation numbers of the most popular strabismus papers, they only account for a small proportion of the variance within citation data (31%). Thus, using alternative metrics, like tweets, as predictors of scientific contribution and success does not constitute a comprehensive and precise appraisal method, as demonstrated before across several other fields [16,17].

Furthermore, citations take a longer time to accumulate, whereas AAS is updated almost in real time, so even when a new paper is published that can have high publicity in social media and among the scientific community, the citation numbers will lag months or sometimes years behind. Due to this phenomenon, there may be weaker or no association between citations and AAS for the latest research papers, which could skew the results of our 12-year view. Further statistical testing would be necessary to confirm that.

Additionally, in the case of strabismus research, both the AAS and citation numbers are characteristically low, which raises questions about the reliability of the data set, as it is analogical to having a small sample size. Various scientifically irrelevant factors can cause a high AAS, such as the topic of the paper, sensationalism, how easily it is understood by the general public, or the number of intersections of the topic with other branches of medicine. A good example of the effect of those confounding factors is a publication included in our data set entitled "Evidence That Leonardo da Vinci Had Strabismus," which had the highest AAS of 922 (over 83 times the median score) but only 6 citations. This demonstrates that especially for papers with high AAS scores, the virality of the topic can have a higher impact on the AAS than its scientific significance.

Conclusions and Future Directions

We have demonstrated that the clinical relevance of strabismus research contributes to the amount of online attention it receives. However, the most high-impact strabismus research is not sufficiently shared across online platforms. Therefore, we recommend that researchers make a greater effort to share high-impact studies on social media platforms to improve the quality of evidence-based information about strabismus and improve the accessibility of this knowledge. To maximize the societal impact of research, it is important to interact with both academic and general audiences, as shown by the overlap between Mendeley and Twitter engagement of strabismus publications.

Furthermore, we revealed Twitter mentions to be the strongest predictor of citation numbers for strabismus papers, highlighting the potential impact of social media on scholarly visibility. Our findings also highlight the need for engagement of strabismus researchers across a broader range of platforms, including Facebook, LinkedIn, or Wikipedia. However, due to its inherent biases and limitations, the AAS itself or mentions across specific platforms should only complement traditional metrics, such as IF and citations, to provide a broader picture of the publicity of the paper but should not act as a stand-alone metrics for assessing the quality and relevance of strabismus papers.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic led to several surges in the mass hospitalization rate. Extreme increases in hospital admissions without adequate medical resources may increase mortality. No study has addressed the impact of daily census of ventilated patients on mortality in the context of the pandemic in a nationwide setting.

Objective: This study aimed to determine whether daily census of ventilated patients affected COVID-19 mortality rates nationwide in Israel.

Methods: We conducted a cohort study using nationwide, public-domain, population-based COVID-19 data of hospitalized patients from an Israeli database from March 11, 2020, until February 11, 2021. We included all COVID-19 hospital admissions, classified as mild to severe per the Centers for Diseases Control and Prevention classification irrespective of whether they were mechanically ventilated. Outcome measures were daily death rates and death rates expressed as a percentage of ventilated patients.

Results: During the study period (338 days from March 11, 2020, to February 11, 2021), 715,743 patients contracted and were clinically confirmed as having COVID-19. Among them, 5577 (0.78%) patients died. In total, 3398 patients were ventilated because of severe COVID-19. Daily mortality correlated with daily census of ventilated patients (R^2=0.828, P<.001). The daily percent mortality of ventilated patients also correlated with the daily census of ventilated patients (R^2=0.365, P<.001)—backward multiple regression analysis demonstrated that this positive correlation was still highly significant even when correcting for the average age or gender of ventilated patients (R^2=0.4328, P<.001) or for the surge in their number. Overall, 40% of the variation in mortality was explained by variations in the daily census of ventilated patients. ANOVA revealed that at less than 50 ventilated patients per day, the daily mortality of ventilated patients was slightly above 5%, and it nearly doubled (10%) with 50-149 patients; moreover, in all categories of ≥200 patients ventilated per day, it more than tripled at ≥15% (P<.001).

Conclusions: Daily mortality rates per ventilated patient increased with an increase in the number of ventilated patients, suggesting the saturation of medical resources. Policy makers should be aware that expanding medical services without adequate resources may increase mortality. Governments should perform similar analyses to provide indicators of system saturation, although further validation of these results might be needed to use this indicator to drive public policy.

Introduction

SARS-CoV-2, the causative agent of COVID-19, was first identified on November 17, 2019, and was declared a pandemic by the World Health Organization on March 11, 2020 [1]. The virus is extremely contagious and the emergence of multiple mutated strains increased its contagiousness [2]. The disease's severity, as observed in a small percentage of patients, warrants complex intensive care facilities [2]. At the onset of the pandemic, medical systems worldwide have been tremendously challenged by COVID-19, leading to major disruptions in routine hospital services, leading to chaos and exhausting reserve medical supplies [3-6]. Excess mortality beyond expected rates has been observed in many countries, including Israel [7]. Possibly, many potentially curable patients might have died because medical services were overwhelmed [6-8]. However, the extent of the impact of the saturation of medical services on a country's COVID-19 mortality has not been systematically studied, and no study has addressed the impact of census on mortality in the context of the pandemics in a nationwide setting. The existence of such a relationship may be suggested by the strong correlation reported between the number of hospital beds per population size and COVID-19–specific mortality both in the United States [9] and worldwide [10]. In Israel, the number of intensive care units (ICU) beds is much lower than that in other high-income countries such as Germany or the United States [11,12].

We analyzed the national database of the Israeli Ministry of Health (MOH), systematically collected and reported since March 11, 2020, until February 11, 2021, that is, prior to mass vaccination conducted in Israel.

We hypothesize that daily COVID-19 mortality rates would be directly related to the daily national census of ventilated patients, increasing each time with an increase in the number of ventilated patients. Alternatively, it was also possible that because of routine experience in treating ventilated patients in regular wards, there would be no discernable effect of workload on mortality.

Methods

Study Design

In this retrospective cohort study, data were extracted from a nationwide, official, open-access COVID-19 database of Israel [13] and the MOH [14], specifically constructed for the purpose of reporting and research.

Setting

We used a national, public repository database, which was curated and made available on a government website to the general public for free use.

We collected data from all 31 general public hospitals in Israel, whereby clinical data were reported to the MOH 3 times daily. Data were uploaded automatically through a dedicated interface. After processing and quality control testing, it became possible to obtain a nationwide perspective of hospitalized patients. Simultaneously, with automatic transfer of information, manual reports were also transmitted from hospitals for the purpose of

quality control, as described below. Data for a particular data were finalized, and updated data were uploaded into the system by midnight of any particular day. These databases were updated every weekday, 3 times daily. The data included the daily cumulative number of patients having tested positive for COVID-19, new laboratory-proven cases, vaccinated people (newly and cumulative), hospitalized patients (with mild, moderate, or severe COVID-19), mechanically ventilated patients with their average age and gender, and COVID-19–related deaths.

In addition to hospital-generated data, laboratory data of all new patients were regularly uploaded to the database through specific interfaces between testing laboratories and MOH computers. In Israel, SARS-CoV-2 positivity was confirmed via polymerase chain reaction–based swab tests using samples obtained from both the throat and one nostril in each patient. Testing was conducted at designated testing sites, such as task-specific health maintenance organizations' clinics converted to testing sites, task-specific testing tents, mobile vans, and Home Front Command run testing compounds, in association with Magen David Adom (the Israeli "Red Cross") and health maintenance organizations. In addition, patients in isolation or those who were unable to reach the testing site for medical reasons were tested at home. These laboratories reached a peak of >120,000 tests per day, while the Israeli population is approximately 9,300,000 [13].

To fully understand the settings of this study, one must be aware of how the pandemic was handled in Israel. The Israeli national health system is highly centralized and is under strict MOH regulation. During the pandemic, and in view of the chaos publicized in many countries whose medical systems were overwhelmed, the MOH took the following measures (among others): (1) throughout the whole pandemic, it facilitated the redirection of critically ill patients among medical centers to distribute the patient burden evenly; (2) all elective surgeries were canceled to focus hospital activities on patients with COVID-19—the latter requirement was strictly followed during the first peak of the pandemic, and was thereafter canceled to prevent potential harm; and (3) during surges in the number of hospitalized patients, care of critical patients (both ventilated and nonventilated) was provided by additional physicians and nurses who are not related to anesthesiology or ICU departments but have previous experience of handling ventilated patients in non-ICU wards; indeed, there are not enough ICU beds in Israel to take care of all ventilated patients, and many of them are cared for in non-ICU wards [15]. Owing to the scarcity of experienced physicians and nurses (some of whom were in quarantine due to unprotected, inadvertent exposure to SARS-CoV-2) during peaks of the COVID-19 pandemic, additional medical personnel were assigned to coronavirus wards after receiving a "crash" course on ventilator management. In Israel, ICU beds are usually occupied at a rate of approximately 100%, and the overflow is taken care of on regular wards. During the pandemic, most critically ill patients with COVID-19 ended up being cared for in satellite units (designated coronavirus wards) because of 100% occupancy rates of formal ICUs, and to facilitate the isolation of these patients. Importantly, in Israel, there are no hospitals such as the so-called

"community hospitals" (level 1 hospitals) present in the United States, which do not contain ICUs; thus, all hospitals contributing to this database are regional, tertiary care centers.

The period of data collection in this study was from March 11, 2020, when the database was implemented, until February 11, 2021. All hospitalized patients were followed up from exposure and until death or discharge from the hospital (hereinafter the "follow-up period"). As part of quality control processes, a comparison was made between automatic and manual reports. Gaps were checked manually and corrected as needed. Additional checks were carried out for deceased patients, and hospital reports and death certificates were additionally compared to verify that the main cause of death was COVID-19–related.

Participants

The participants in this study were all the patients who tested positive for COVID-19 at some point during the study period. They were selected in accordance with a laboratory-confirmed diagnosis as described above. The patients were classified by the severity of symptoms: mild, moderate, and severe. Initially, each hospital report used its own criteria for levels of severity. From July 12, 2020 (day 123 of the study period since the implementation of the database on March 11, 2020), the MOH issued specific definitions established by the National Institutes of Health [16,17]: ventilated patients were those requiring invasive mechanical ventilation (with an endotracheal or tracheostomy tube). Mild disease was defined as laboratory confirmation in combination with mild symptoms (fever, cough, weakness, and loss of taste and smell). Moderate disease was defined as laboratory confirmation together with pneumonia (clinical or through imaging). Severe disease was defined as laboratory confirmation with one or more of the following: a respiratory rate of >30 breaths per minute, oxygen requirement of >30%; oxygen saturation in arterial blood of ≤93% in ambient air, and a ratio of arterial oxygen pressure and oxygen requirement of <300.

Follow-Up Methods

The number of deaths was updated daily. The overwhelming majority of patients who died were invasively ventilated prior to dying, and several of them were even placed on mechanical ventilation during transport to the hospital. We cannot, however, rule out that some patients died prior to arriving at the hospital; nonetheless, they were customarily ventilated by paramedics en route to the hospital unless they belong to the very small group of "do not resuscitate" patients because they have an incurable disease that would potentially lead to their death within less than 6 months (according to the Israeli "Dying Patient Law").

Assessments

The main outcomes of interest were whether the patient died or not, was ventilated or not, their length of stay (LOS) in the hospital, and the duration for which they received mechanical ventilation. Potential confounders, predictors, and effect modifiers were the only variables that were prospectively collected from this database, namely gender, patients' age, and the daily census of ventilated patients in Israel.

Data Source

The data source is the Israeli MOH's National COVID-19 Database, systematically collected and reported since March 11, 2020, until February 11, 2021, that is, prior to mass vaccination that occurred in Israel.

Ethical Considerations

The website we used is a public repository, available free of charge to the public. It is completely anonymized and deidentified; therefore, it was appropriate to not apply for approval from an ethics review board. Under the federal regulations for human subjects research (45 CFR Part 46), research involving publicly available data sets would not require review by an institutional review board—no application is required—as long as the data are obtained from sources that are publicly available and are deidentified and uncoded as in this study [18]. Nevertheless, since the data were collected in Israel, the National Committee for Human Medical Research of the Israeli MOH provided its full approval for the study and waived the requirement for obtaining informed consent. The Israeli National Committee for Human Medical Research deemed this study exempt from ethical approval since this study involves public data processing for the purposes of policy making and reflecting on the national system's dealings with the epidemic; therefore, it does not require to adhere to the tenets of the declaration of Helsinki.

Statistical Analysis

The Minitab Statistical Package (version 16; Minitab, LLC) was used for analyses. Data were tested for normality and expressed as mean (SD) or median (IQR) values as requested. Stepwise backward multiple regression analysis was carried out to determine the correlation between daily percent mortality per group of ventilated patients (dependent variable) and the daily census of ventilated patients (independent variable), while taking into account potential confounding variables that may affect daily percent mortality, such as mean patient age, gender, and COVID-19 surge (surges 1, 2, or 3). This method places all the independent variables at once in the equation, and eliminates those found to be insignificant sequentially step by step, repeating the operation each time until only the significant variables remain in the final equation. This method allows for results that are not influenced by the order of introduction of the independent variables. Daily percent mortality per group of ventilated patients was calculated as the daily mortality rate in Israel divided by the census of ventilated patients on the same day. Independent variables entered in the regression equation were only those found to influence (in univariate analysis) the daily percent mortality of ventilated patients at an α value of <.10.

Analysis of means using ANOVA was carried out to determine differences in the mortality rates of ventilated patients by group based on their number in the daily census. We arbitrarily analyzed daily census according to 8 groups of increasing census size: group 1 containing 1-49 ventilated patients, group 2 containing 50-99 ventilated patients, group 3 containing 100-149 ventilated patients, group 4 containing 150-199 ventilated patients, group 5 containing 200-249 ventilated patients, group

6 containing 250-299 ventilated patients, group 7 containing 300-349 ventilated patients, and group 8 containing 350-399 ventilated patients.

No sample size calculation was carried out as we used all the available numbers nationwide.

Results

During the study period (338 days from March 11, 2020, to February 11, 2021) 715,743 patients contracted and had a laboratory-confirmed diagnosis of COVID-19. They constitute the study population. Among them, 5577 (0.78%) patients died.

In total, 3398 patients were ventilated because of severe COVID-19. We retrieved complete data (including outcomes, gender, age, and LOS in hospital) for 3373 of them (as of this writing, there was no determined outcome for 25 patients who are still ventilated). These data are presented in Table 1. Briefly, patients who died were older, and there were many more men ventilated than women, but mortality among ventilated men and women was similar (approximately one-third of patients). LOS in hospital was much shorter among patients who died than among those who survived. The LOS to ventilation (from hospital admission to the end of hospital stay) was shorter for patients who died, and the LOS from ventilation to outcome (discharge or death) was much longer for survivors.

Table 1. Demographic data for ventilated patients (N=3373).

	Age[a] (years), mean (SD; median; IQR)	Gender[b] (male:female), n:n (% males)	Length of stay to outcome (days)[a], mean (SD; median; IQR)	Length of stay to ventilation (days)[a], mean (SD; median; IQR)	Length of stay from ventilation to outcome (days)[a], mean (SD; median; IQR)
Alive (n=1128; 33.44%)	60.3 (16.3; 62; 51-71)	721:407 (63.9%)	35.7 (29.4; 27; 15-47)	4.9 (5.9; 3; 1.6)	30.8 (28.4; 22; 11-42)
Dead (n=2245; 66.56%)	72.2 (13.0; 74; 65-82)	1487:758 (66.2%)	18.7 (16.5; 15; 8-25)	6.0 (6.6; 4; 1-8)	12.8 (15.1; 8; 3-17)

[a]$P<.001$.

[b]$P=.18$.

Figure 1 depicts the daily number of patients hospitalized every day of the study for severe disease and the number of ventilated patients, showing 3 surges of frequencies. Figure 2 depicts the daily mortality per day of the study, which also shows 3 surges of daily death rates, parallel to the surges in the number of patients with severe disease and ventilated patients. Figure 3 shows the daily percent mortality of ventilated patients over time, which also follows a similar pattern to the 3 peaks.

Daily mortality correlated with the daily census of ventilated patients ($R^2=0.828$, $P<.001$; Figure 4). The daily percent mortality of ventilated patients also correlated with the daily census of ventilated patients ($R^2=0.365$, $P<.001$; Figure 5). Backward multiple regression analysis revealed that the latter positive correlation was still highly significant even when correcting for the average age or gender of ventilated patients ($R^2=0.4328$, $P<.001$) or for the wave number ($P>.05$). Both average age and gender remained significant ($P<.001$) in the final analysis (older age and a higher percentage of females contributing to higher mortality; Table 2). The R^2 value of the correlation equation predicting the percentage mortality per ventilated patient was at best 0.4, implying that 40% of the variation in mortality can be explained by variations in the daily census of ventilated patients. Obviously, the rest or the variability (60%) was explained by other factors that were probably patient-dependent (such as BMI, diabetes, or other chronic diseases), which were not retrievable from this database.

Figure 1. Daily rates of patients with severe COVID-19 (black dots) and those ventilated (red dots) over time.
Figure 2. Daily mortality over time.
Figure 3. Daily percent mortality of ventilated patients over time.
Figure 4. Daily mortality rates versus the daily census of ventilated patients.
Figure 5. Daily percent mortality of ventilated patients versus daily census of ventilated patients.
Table 2. Multiple regression analysis results showing the relative contribution of the daily census of ventilated patients, gender, and age (independent variables) on the daily percent mortality of ventilated patients (dependent variable).

	Daily census of ventilated patients[a]	Gender[a]	Age[a]	Model summary
Partial R^2	0.3574	0.0275	0.0005	0.3915
Effect size (adjusted sum of squares)	3772.7	290.7	68.6	5012.5
P value	<.001	<.001	.09	<.001

[a]All variables here refer to the dependent variable, that is, daily percent mortality of ventilated patients.

ANOVA (Figure 6) revealed that with <50 ventilated patients per day, the daily mortality of ventilated patients was slightly above 5%; with 50-149 patients, it nearly doubled (10%); and in all 3 categories of 200 and more patients, it more than tripled at ≥15%.

Figure 6. Analysis of the mean percent mortality of ventilated patients by ventilated patients' groups (group 1: 1-49; group 2: 50-99; group 3: 100-149; group 4: 150-199; group 5: 200-249; group 5: 250-299; group 6: 300-349; group 7: 350-399).
We investigated whether an increase in the number of ventilated patients during a specific surge may have been related to an accumulation of mechanically ventilated patients from previous surges. In fact, LOS or length of ventilation did not differ among patients who were admitted during surges 1, 2, or 3 (ANOVA P>.05). Moreover, among 11 of 164 patients admitted to hospital during surge 1 died during surge 2, and none died during surge 3; 65 of the 1088 patients admitted to hospital during surge 2

died during surge 3 (together with 993 patients admitted to hospital during surge 3)—among them, the vast majority (n=63) were admitted within the last 20 days of surge 2.

Discussion

Principal Findings

This is the first nationwide study demonstrating increasing mortality with increasing demand for health care resources during the COVID-19 pandemic. Indeed, daily mortality rates expressed as a percentage of ventilated patients correlated with the daily census of ventilated patients. We do not believe that this increase in percent mortality rates during surges was due to the accumulation of mechanically ventilated patients who stayed alive until but died during the following surge because the LOS or length of ventilation until death did not differ among patients who were admitted during surges 1, 2, or 3, and also because such "leftovers" were much less than 10% of a given surge.

In China, higher mortality was recorded in Wuhan than in other Chinese provinces, which is related to the rapid escalation in the number of infected patients with insufficient access to health care resources [19]. In the United States, a retrospective cohort study of a 26-hospital–integrated delivery system showed an association between a greater percentage of COVID-19–related admissions of hospital capacity and a lower survival rate [20]. There are multiple examples in the news media describing "accidental deaths" due to improper care of patients with COVID-19 [21]. To limit the dimensions of this catastrophe, many countries had imposed lockdowns and quarantines, leading to consecutive peaks of the pandemic [21].

Israel is generally considered to be technologically sophisticated [22], but its medical system is greatly stretched [23]. In a 2020 report from the 37 nations belonging to the OECD (Organisation for Economic Co-operation and Development), Israel features among the bottom 4 nations in terms of acute hospital care beds (2.2 per 1000 population), which is well below countries such as Japan (7.8 per 1000 population) [23]. Israel also features among the 11 countries with the lowest numbers of both physicians and nurses per 1000 population [23]. The Israeli system considers itself efficient, reporting daily occupancy rates among the highest worldwide, at 93.3% on average, second only to Ireland among the 37 OECD countries [23]. In Israel, the number of ICU beds is 4.6 per 100,000 population and 2.2 ICU beds per 100 hospital beds (reported in 2007) [11], which is much lower than that in other high-income countries such as Germany (24.6 hospital beds per 100,000 population and 4.1 ICU beds per 100 hospital beds), or the United States (20 hospital beds /100,000 and 9 ICU beds per 100 hospital beds) [12]. In Israel, every winter, many patients are ventilated in internal medicine wards because of the unavailability of ICU beds [15]. However, in non–COVID-19 times, the mortality of ventilated patients in non-ICU wards was higher than that of formal ICU beds, proving that the system might be "cheaper" but not necessarily better [15]. There is a strong correlation between the number of hospital beds per population size and COVID-19–specific mortality both in the United States [9] and globally [10]. This does not imply that *more* is necessarily

better. Indeed, case-mix and ICU organization are important to consider. Strategies for how to use ICU beds, the proportions of mechanically ventilated versus nonventilated patients, the availability of intermediary care, and other factors are important to consider. For instance, if a country has a policy of admitting nonventilated patients to high- or medium-care departments instead of ICUs or transferring extubated patients to intermediary care units immediately, such a country will need fewer ICU beds than those that do the opposite.

Daily mortality expressed as a percentage of ventilated patients correlated with the daily census of ventilated patients. This was true even after taking into account the average age of ventilated patients and their gender or surge number. We suggest that the medical system reached saturation, that is, its inability to adequately handle complex ventilated patients. The reasons for this saturation are multiple. We cannot currently determine whether or not there was a shortage of specific drugs, mechanical ventilators, oxygen, or other supplies, or a shortage of personnel, higher patient-nurse ratios, lack of ICU beds, etc, but these have been reported anecdotally in the general nonmedical literature [24]. In fact, it is highly possible that whenever the census of ventilated patients increased, some patients died because they could not receive proper care and not because their disease was incurable. These data should be considered within the context of the quasi-heroic behavior of exhausted, overworked teams of caretakers that performed their duties throughout the pandemic under perilous circumstances. Furthermore, it is highly possible that parallel increases in the mortality of mechanically ventilated patients without COVID-19 occurred during the same periods. Unfortunately, no similar database for was maintained for patients without COVID-19, and we were not able to verify if this occurred.

In this study, mortality was observed among approximately two-third of patients—a number difficult to compare to that of other countries since reported death rates of ventilated patients with COVID-19 is also dependent upon case-mix, varying from 48% among younger patients (younger than 40 years) to 84% among older ones (>80 years of age) [25]. It has recently been shown that for instance, the physical manifestations of frailty and comorbidity, particularly a history of cognitive impairment and falls, may be useful in identifying patients with COVID-19 who need additional support during hospitalization and may be at a higher mortality risk [26]. This may also be dependent on noninvasive and invasive ventilation strategies. A recent meta-analysis by Lim et al [26] estimated the mortality rate among such patients to reach 45% on average, which is lower than that reported in this study. In our study, the effect of the census of ventilated patients census on daily mortality was nearly identical during the 3 different surges, which suggests that the SARS-CoV-2 variants, likely to differ among the various waves, affected mortality in a similar manner.

Worldwide, there have been reports of "spontaneous" reductions in critical care admissions, such as those related to stroke and cerebral emergencies [27], accidents, emergency surgery, and acute coronary events [28-30], which may have reduced the ICU burden. We suspect that it may have existed in Israel as well in particular during the first surge, but it did not reduce the ICU burden to a point that prevented an increase in mortality

rates reported here. A recent study reported that the management of critically ill patients with COVID-19 in the United Kingdom was far from ideal in numerous cases, with systematic errors in the measurement of height and derived ideal body weight and delayed applications or nonimplementation of evidence-based interventions for acute respiratory distress syndrome (in particular, prone positioning) [31].

Our findings may not be exclusive to the COVID-19 pandemic. For instance, Israel has not yet achieved peace with all its neighbors, and a large-scale increase in hostilities may have led to a number of casualties that the Israeli medical system might not be able to handle. Israel is also located on The Great Syria-African Rift and is at risk of major and potentially deadly earthquakes to occur.

The major strengths of this study are the use of a national large database, a long study period for most part of the pandemic, and the measures undertaken for quality control. A limitation of this study relates to changes in some definitions in the middle of data collection. These changes are unlikely to influence our main findings, in that mortality rates (regardless of severity staging) correlated with the workload of ventilating patients. Another limitation of this study is that the data set did not evaluate workload in individual hospitals and individual ICUs (occupancy rates, staffing patterns, and hours of nursing care per patient per day) relative to resource availability, which somewhat limits drawing causal inferences. It is unclear whether our findings are universal or change when examined in accordance with a hospital's geographic location or size; however, of note, during each surge, the Israeli MOH frequently intervened and helped individual hospitals to move patients between hospitals to prevent maldistribution. We also provide no data on ventilated patients in non–COVID-19 beds, whose survival might also have been affected by the shift of many medical resources from other departments to care for patients with COVID-19; hence, we were unable to provide data on noninvasive ventilation or the use of vasoactive drugs or even extracorporeal membrane oxygenation that was administered to some patients. This information would have potentially helped stratify the complexity of health care requirements but was not available in this database. Finally, outcomes noted were either discharge from hospital or death, while some patients may have died after discharge. We do not believe that withholding strategies due to lack of bed availability may have influenced survival since in Israel, since patients requiring ventilation are not dependent upon bed availability, and are ventilated in non-ICU settings. Additionally, the law in Israel does not allow extubating of a dying patient.

Recommendations to the Health Care Leadership

Recognizing the fact that the ability to provide adequate intensive care and respiratory care services is a critical and unique national resource during pandemics and other emergencies. The use of percentage mortality or the census of ventilated patients as a potential key tool for monitoring the hospital system nationwide.

An information system should be constructed such that it supports the provision of a nationwide perspective on all ICU beds in Israel so as to divert patients in emergencies where there is an unusual load while simultaneously taking advantage of the relatively short geographical distances in the country.

A multiyear program for intensive care training for medical and nursing teams should be developed, while finding solutions that enable maintaining an adequate professional level even for teams that have undergone intensive care training but do not regularly work in ICUs.

Conclusions

Since this study is a noninterventional observational study, the correlations we found (ie, an increase in the percent mortality of ventilated patients with an increase in the census of ventilated patients) are concerning, and suggest, but do not prove, causality. We speculate that the results of this study might help health policy makers to address medical capacities on a nationwide scale, determine how much their system has been affected by pandemics, and to what extent it should be strengthened by the addition or expansion of intensive care facilities. This should facilitate better preparation for future pandemics, the appearance of the next mutant of SARS-CoV-2 that may be resistant to currently available vaccines, or future events potentially resulting in a burden on the health care system. Obviously, there should be a balance between the needs of a country under extraordinary circumstances and needs during "routine" circumstances. An increase in the number of beds might not be the only way out, especially when there are no trained personnel to take care of patients. Increasing ICU training and ICU rotations of health care workers might better prepare a country to handle a large-scale catastrophe.

Authors' Contributions

JM designed the study and drafted the manuscript. FM conducted the statistical analysis and drafted the manuscript.

Abstract

Background: China has entered the era of digital health care after years of reforms in the health care system. The use of digital technologies in healthcare services is rapidly increasing, indicating the onset of a new period. The reform of health insurance has also entered a new phase.

Objective: This study aims to investigate the evolution of health care insurance within the context of telemedicine and Internet Plus Healthcare (IPHC) during the digital health care era by using scientometric methods to analyze publication patterns, influential keywords, and research hot spots. It seeks to understand how health care insurance has adapted to the growing integration of IPHC and telemedicine in health care services and the implications for policy and practice.

Methods: A total of 411 high-quality studies were curated from the China National Knowledge Infrastructure (CNKI) database in the Chinese language, scientometric analysis was conducted, and VOSviewer software was used to conduct a visualized analysis of keywords and hot spots in the literature.

Results: The number of articles in this field has increased notably from 2000 to 2022 and has increased annually based on a curve of y=0.332exp (0.4002x) with R^2=0.6788. In total, 62 institutions and 811 authors have published research articles in the Chinese language in this field. This study included 290 keywords and formulated a total of 5 hot-topic clusters of "telemedicine," "IPHC," "internet hospital," "health insurance payments," and "health insurance system."

Conclusions: Studies on the application of digital technologies in health care insurance has evolved from foundational studies to a broader scope. The emergence of internet hospitals has showcased the potential for integrating IPHC services into insurance payment systems. However, this development also highlights the necessity for enhanced interregional coordination mechanisms. The reform of health insurance payment is contingent upon ongoing advancements in digital technology and increased investment in electronic medical records and primary health care services. Future efforts should focus on integrating technology with administrative systems, advancing mobile health care solutions, and ensuring interoperability among various payment systems to improve efficiency and standardize health care services.

Introduction

The Chinese government promulgated a policy document regarding the health insurance system in the last few days of the year in 1998 [1,2] and is currently working on establishing the urban employee's basic health insurance system, which was initiated in 1999 and completed by the end of 1999, and amendment work has continued for several years thereafter [3]. Since then, China's current concept of a health insurance system has been established.

During the COVID-19 pandemic, the Chinese government has published numerous policies regarding Internet Plus Healthcare (IPHC)–related health insurance services. The policies are mostly guidance documents related to health insurance payment for IPHC services, including web-based health services and telemedicine health services.

A document aiming at promoting the payment of IPHC in health insurance [4] released by China National Healthcare Security Administration in October 2020 indicated that local governments should design and manage the signing of health insurance agreements for IPHC services. Other official arrangements include improving health insurance payment policies, expanding pilot projects, handling health insurance management, and strengthening supervision measures for newly included health insurance health care services among other measures.

As mentioned in a long-term planning official document published by the government of China in December 2022, the importance of IPHC pricing and implementing appropriate services into the health insurance payment list were addressed [5].

IPHC is a novel application of the internet in the health care industry, which includes health education, medical information queries, web-based disease consultations, electronic prescriptions, remote consultations, and various remote forms of health care services such as treatment and rehabilitation [6]. In China, IPHC is an emerging health service model with a cross-industry integration and application of ITs, such as mobile internet, cloud computing, big data, and artificial intelligence [7].

Hence, this field of study is advanced and has real-world implications. The number of studies related to IPHC and telemedicine in 2020, especially in China, has considerably increased [8]. For example, according to reports in early 2020, the number of registrations and IPHC and telemedicine users exponentially increased early during the COVID-19 pandemic; in particular, an internet-based health care platform named "WeDoctor" recorded nearly 80 million visits in early February 2020 and offered services nearly 1 million times. Furthermore, "Ping An Good Doctor," another major internet-based health care platform claimed to have received over 1 billion visits, and the number of new users has been increasing by several folds [9].

From a historical perspective, telemedicine is an early prototype of China's IPHC services, which was initiated in the 1990s when doctors in China began communicating with medical experts in other countries through emails about complex and difficult clinical cases. After that, with the increasing use of computers and telecommunications for remote medical consultations in various places, China's National Healthcare Commission issued regulations to specify the order and behavior of medical care in 1999 to regulate medical order and behavior and enable the development of health care and orderly telemedicine consultation work [6].

In addition, the Chinese government has issued the "Healthy China 2030" project in 2016 [10], which first clearly stated its attitude regarding IPHC, proposing to standardize and promote telemedicine networks and IPHC services and to innovate the IPHC services model.

However, there is no literature using bibliometrics methods, which encompasses this field of the use of health care insurance in IPHC services and telemedicine, and the descriptive study and analysis described here would potentially provide an overview of this area.

This study has 3 objectives: to observe the development of health insurance in telemedicine and IPHC and its related fields in the digital era by examining the publication patterns and key clusters of influential keywords in Chinese. We analyzed the hot spots extracted from high-quality publications and articles based on a bibliometric methodology. We also linked them with future comprehensive studies to illustrate the research frontiers and future roadmap of Chinese health insurance in telemedicine and IPHC service enhancement in the digital era.

Methods

Overview

The bibliometric methodology used in this study describes the landscape and core topics of research in the field from a perspective of health insurance in the advancement in digital health care in China from 2000 to 2022.

Bibliometrics is a method of information analysis, which measures research trends and knowledge structures in a field of research to obtain quantifiable, objective data [11]. The method has been extensively used to quantitatively analyze academic literature to describe trending topics and contributions of scholars, journals, and countries and help researchers understand the current research trends, distribution, and core topics in a given field [12,13]. VOSviewer has better visualization in network and cluster analysis than other software, and the scientometric graphs conform better to current academic research styles. VOSviewer was developed by Nees Jan van Eck and Ludo Waltman and features a powerful bibliometric maps function that can clearly visualize the network of literature, keywords, authors, etc [14]. Using VOSviewer, we generated diagrams for institutional cooperation, keyword co-occurrence, author cooperation, and author cocitation, and the Chinese-language data are all retrieved from the China National Knowledge Infrastructure (CNKI) database [15].

Sampling

All articles related to the fields of health insurance in telemedicine and IPHC published from 2000 to 2022 and written in Chinese are included (Multimedia Appendix 1). The reason

XSL•FO

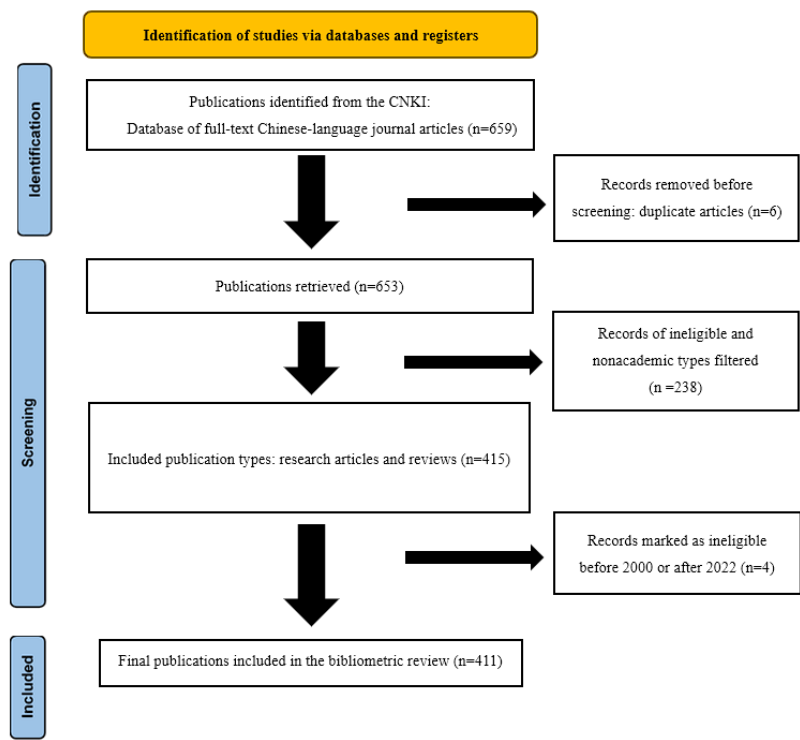
RenderX

why the beginning year was set as 2000 is that China did not formally establish its current concept of a health insurance system until 1999 [1,2].

We set the CNKI as the target database and retrieved data from "Chinese Journal Full-text Database" and "Academic Journals" (excluding dissertations, conference proceedings, and newspapers). On April 5, 2023, we selected the "Advanced Search" feature and set the search strategy as follows: "(Topic: telemedicine (exact) OR Topic: internet plus healthcare (exact)) AND (Topic: health insurance (exact) OR Topic: medical security (exact)) AND (year range 2000-2022)" to select studies from 2000 to 2022; this yielded 659 articles.

A total of 659 articles retrieved from the search were imported into Excel (Microsoft Corp) for manual checking, and we excluded 6 duplicates papers and then 238 publications belonging to other categories (such as press releases, editorial comments and short reports, nonacademic articles) and 4 publications outside of the time range of 2000-2022 to obtain a final selection of 411 articles; the refinement process is shown in Figure 1. These 411 entries were manually checked to ensure correspondence between the authors and their affiliations, especially when multiple authors are affiliated with the same institution—this step is crucial as it helps avoid potential errors.

We then exported the data and imported them into VOSviewer software (version 1.6.19) for cluster analysis. Based on cluster results, we analyzed and summarized the articles.

Figure 1. The flowchart for data collection. CNKI: China National Knowledge Infrastructure.


Results

Publication Trends

Based on the publication year in the research literature, it can be observed that between 2000 and 2015, the number of articles published in the field of IPHC, remote medical services, and health insurance services was <10 each year, and the accelerated growth started in 2015. Since the number of publications approached 14 in 2015, from 2017 to 2019, the number of articles published in this field plateaued around 30 to 40. In 2020, the number of publications in this research field increased rapidly to nearly 100 papers (around 90 a year) and remain high at about 80-90 papers in 2020 and 2021. Index regression predicts that there will still be a number of Chinese studies published in this field in the near future, while the R^2 value of

the regression model is 0.6788, indicating that the curve explains the variables relatively well.

Analysis of the Journals

Table 1 shows that journals whose scope includes health insurance focus more on this research field; *China Health Insurance Journal* accounts for 6.8% of the proportion of studies in this field. Second, journals that explore digital medicine take the lead. *China Digital Medicine* accounts for 4.8% of studies in this regard, followed by other general medical and health policy research journals. Regarding the distribution, core journals included in Chinese core journals indexed by Peking University or the Chinese Social Sciences Citation Index, both of which are top core collections of Chinese-language journals, enjoy widespread prevalence. The top 5 journals are core Chinese-language journals.

Table 1. The number of articles in the top 10 journals and their proportions in a total of 411 publications.

Rank	Journal	Articles, n (%)
1	*China Health Insurance*	28 (6.8)
2	*China Digital Medicine*	20 (4.8)
3	*Health Economics Research*	17 (4.1)
4	*Chinese Hospitals*	15 (3.6)
5	*China Social Security*	14 (3.4)
6	*Journal of Medical Informatics*	11 (2.6)
7	*Chinese Journal of Health Informatics and Management*	11 (2.6)
8	*China Health*	9 (2.1)
9	*Modern Hospital*	8 (1.9)
10	*Chinese Health Service Management*	8 (1.9)

Analysis of the Number of Citations of Articles

This field is in its infancy; hence, the top cited article in this field is a study analyzing the basis of this field. The article containing definitions came first, occupying the forefront, received 201 citations (Table 2). Then, latter research focused on currently established modules, problems faced, and future development trends. They all attempted to establish theories and models needed in this field systematically.

Table 2. The top 10 cited Chinese-language articles according to the China National Knowledge Infrastructure.

Rank	Title	Journal	Authors	Citations, n
1	Internet + Medical Mode：Contents and System Architecture	*Chinese Hospital Management*	Zhu Jinsong	201
2	Research on Development Policy of Integration of Medical Care and Pension and Institutional Pension Service for the Elderly	*Medicine and Society*	Ma Lili, Chen Na, and Tang Shaoliang	194
3	The Status Quo of Internet Medical-Based on The Analysis And Investigation on Three Hospitals	*Chinese Journal of Health Policy*	Wang Anqi and Zheng Xueqian	138
4	Analysis on the Development Model of Internet Hospitals in China	*Health Economics Research*	Zhang Mengqian, Wang Yancui, Qian Zhenguang, and Wang Dandan	59

6	Problems and Countermeasures for "Internet + Healthcare" in China	*Administration Reform*	Luan Yunbo and Tian Zhendu	52
7	Problems and Countermeasures for Medical Service Supply in Elderly Care Institutions from the Perspective of Medical-Old-Age Combination	*Chinese Journal of Gerontology*	Fan Qingmei, Chen Le, Wu Meng, Wu Jiankang, and Li Jiamin	45
8	Analysis on Problems and Countermeasures of Mobile Health Service in China	*Medicine and Philosophy*	Yang Xiaoli and Feng Xinwei	45
9	Study on Regulation System and Related Mechanism of Internet Based Medicine	*Chinese Journal of Health Informatics and Management*	Meng Qun, Yin Xin, and Dong Kenan	44
10	Analysis on Service Mode and Application Status for Network Medical Treatment in China	*Chinese Journal of Health Informatics and Management*	Liu Ning and Chen Min	42

Analysis of Authors

Analysis of the author cooperation network revealed that 811 authors had explored health insurance in IPHC and telemedicine, of whom 9 have acquired more than 12 total link strengths (Figure 2), namely total link strength (TLS), reflecting the strength of cooperation in bibliographical analysis (Table 3). Xu Hong and Lyu Dawei, who discussed the prospect of IPHC in cooperative development of the Changjiang river delta, are the most active authors in this field. The latter active authors also gained over 10 TLSs.

Figure 2. Coauthorship analysis of authors.
Table 3. Top Chinese authors ranked according to total link strength.

Rank	Author	Total link strength
1	Xu Hong	16
2	Lyu Dawei	16
3	Zheng Xueqian	14
4	Luo Li	14
5	Wang Weijun	14
6	Liu Qian	14
7	Gong Fangfang	13
8	Sun Xizhuo	13
9	Liang Zhigang	12

Analysis of Institutions

A total of 62 institutions were finally included, with a minimum limitation of more than 3 publications, whose publications were analyzed using VOSviewer (Figure 3). Moreover, the School of Health Policy & Management, Nanjing Medical University (TLS=6 times) and other 10 institutions were the top institutions with highest TLS in VOSviewer counting (Table 4). Total link strength and institution co-occurrence of publications.

Figure 3. Institution co-occurrence of publications.

Analysis of Co-Occurrence of Keywords in Chinese

Identifying trending research fields and directions through keyword co-occurrence analysis is an important indicator for monitoring the development of a discipline. Mapping of keywords is shown in Figure 4, where the size of the node represents the frequency of keyword occurrence, and the lines between the nodes reflect the co-occurrence relationships among multiple keywords. According to the mapping image generated

by VOSviewer, current hot topics in Chinese literature in this field can be visually described.

This study analyzed 290 Chinese-language keywords that appeared at least 10 times across included publications using VOSviewer. The results were grouped into 5 clusters: "Telemedicine," "Internet hospital," "Internet Plus Healthcare (IPHC)," "Health Insurance Payment," and "Health Insurance system." These clusters provide insight into the most prominent

topics related to the use of health insurance in IPHC and telemedicine (Table 5).

Figure 4. Visualization of keyword co-occurrence analysis. IPHC: Internet Plus Healthcare.

Table 5. Main keywords translated to English and their total link strength (TLS).

Keywords	TLS
Cluster 1: telemedicine	
hierarchical diagnosis and treatment	109
telemedicine	102
healthcare alliance	81
Cluster 2: IPHC[a]	
internet healthcare	129

[a]IPHC: Internet Plus Healthcare.

Primary Findings From the Co-Occurrence of Keywords

Based on the 5 keyword clusters, the hot spots in the field are described below.

Cluster 1

The primary keyword is "telemedicine" and also includes "remote consultation," "hierarchical diagnosis and treatment," "healthcare alliance," etc, focusing on doctor-to-doctor telemedicine services. Also, it includes topics such as the interactions among different health care service providers under remote conditions, remote pathological analysis, remote consultation, and other telemedicine services based on new-style intelligent communication technology [16]. There are more stakeholders in this type of health care service, demanding that health insurance policies be more detailed to take into account real-world situations.

Cluster 2

The primary keyword is "Internet plus healthcare" (IPHC). Also, it includes keywords such as "Internet healthcare," "Healthcare service," "health management," "health insurance reimbursement," and "health insurance fund." In 2019, the National Healthcare Security Administration officially launched the construction of a national unified health care security digitalization platform [17]. In 2021, the system was gradually implemented, and the number of designated medical institutions covered by the basic medical cross-provincial and interregional settlement insurance platform is increasing [17]. The construction of digitalized hospitals has better promoted the development of internet health insurance operations.

Cluster 3

The primary keyword is "internet hospital." Also, it includes keywords such as "healthcare service," "online healthcare," "smart healthcare insurance," "electronic prescriptions," and "smart healthcare." It mainly focuses on providing health management services for patients with chronic disease on the web, especially under lockdown policies for epidemic prevention and control [18]. Furthermore, as an impact of the COVID-19 epidemic, health care service units in various regions have embraced the internet and provided web-based consultation and diagnostic services. Some researchers also involved health insurance payment [17]. In the future, similar methods can be used to provide older adult–focused health care services for the aging population [19].

Cluster 4

The primary keyword is "health insurance payments," and it also includes "online payments," "health insurance payment reform," "insured population," and "health insurance files." The research and analyses are mainly policy-oriented, focusing on reducing the burden of health insurance funds and developing reasonable health care service prices and the comparison of different actual implementations of web-based insurance payments in different provinces and municipalities, as well as the future development of smart insurance [20].

Cluster 5

The primary keyword is "health insurance system" and involves keywords such as "medical service prices," "health insurance funds," and keywords such as "National Healthcare Security Administration," and "designated hospitals for health insurance." The studies and analyses mainly focus on the systematic constructions for health insurance services, the modernization and innovation of the health insurance system from a macro view in the new digital era [21], and the necessary adjustments and changes required for the system to adapt to the new pattern of health care services landscape through the digital era.

Discussion

Principal Findings

Our study shows that in the digital era, China's health care service system is facing the need for payment mechanisms and policy adjustments to support and optimize the hierarchical health care system. The practice of internet hospitals, as a part of IPHC, has demonstrated the potential for insurance payment in web-based health care services, but it has also revealed challenges in regional integration and interregional coordination. Insurance payment reform, as a key lever for driving systemic change, relies on the advancement of digitalization and informatization, as well as continuous investment in electronic medical records, IT, and primary health care services. Future research and policy making must focus on addressing the integration of technologies with administrative systems, promoting the development of mobile health care, and exploring the interoperability between health care insurance payment systems to achieve efficiency and standardization in health care services.

According to our results, there has been significant development in areas of health insurance in IPHC and telemedicine research over the past 2 decades. The number of relevant publications has steadily increased year by year, and more than 60 researching institutions and over 800 authors in China have published academic research papers in this field. Since 2017, the number of publications in this field has risen sharply from around 30 papers each year to around 90 papers each year, which means that in the near future, an increasing number of studies will focus on the use of health insurance in IPHC and telemedicine, especially in improving health insurance implementational methods and measures, and future patching policies regarding digital health care services.

In the founding stage of the research field, the most highly cited paper was an analysis of its theoretical basis, with 201 citations, occupying the top spot, having focused on established modules, current challenges, and future development trends, striving to systematically develop theories and models required for the field.

Among 62 institutions, over 10 of them had a TLS of 6 and rank at the top.

There were 62 institutions with a minimum of >3 publications; among them, 11 institutions with 6 TLSs were the top academic institutions. These research institutions include universities, hospitals, and associations in the health care industry, implying

that this research field has received widespread attention in Chinese academic fields and reflects the importance of research in this field in China. Different types of institutions engage in academic discussions from their specific perspectives.

Through bibliometric and visualization analysis, we gained a deeper understanding of the overall landscape of this research field, including prominent Chinese authors and publishing institutions, as well as their collaborative relationships and academic influence. This information provides researchers with transparent channels for selectively obtaining advanced and valuable research results. Co-occurrence analysis can also depict research trends and hot spots [22], providing researchers with assistance in proposing research topics to convince funding agencies to develop more effective funding plans.

Analysis of Research Focus

Overview

Keywords are essential in a research article and contain the most important information [23].

Based on the analysis of keyword clusters in the literature [24], this study focuses on different aspects and levels of research directions that health insurance needs to promote in implementing IPHC, as well as the problems and possible solutions reflected in the actual health care service practice [25]. From the integration of health care services and medical treatment to the connection between health insurance systems, based on the interconnection of information platforms [26], the key conflicts encountered in health care service practice are gradually being resolved and improved [27]. There are a total of 5 clusters, and based on the research results, the main research frontiers involved in these 5 clusters will be discussed below.

Cluster 1

The primary keyword is "telemedicine." By constructing a telemedicine service system between institutions in a medical treatment combination, which involves multiparty participation such as bidirectional referral and web-based consultation [28], the mechanism of health insurance payment needs to be strengthened and improved. Furthermore, to improve the hierarchical health care system, a mixed health insurance payment model should be explored [29]. In the context of combining remote health care services with health insurance, the current emerging problems such as the barriers to the generation of cross-provincial systems need to be clearly defined, and policies need to be adjusted and improved accordingly [30].

Cluster 2

The primary keyword is "Internet plus healthcare." The development of IPHC requires continuous advancement in medical digitalization [31], strong modern digital technologies such as artificial intelligence, digital twins, big data management, and remote services to realize many health care services that are currently only in their infancy, such as smart health care, which are the forefronts of current research [32]. The platform construction of electronic medical records and electronic prescriptions has been integrated with intelligent health care security platforms. However, in certain specific

implementation, there are still many practical issues such as technology advancing ahead of management models [33]. Advancing creatively through a combination of technology and policies is necessary to solve many potential new problems and conflicts. In the future, IPHC will remain an important theme for China's medical and health reforms and development [34], and there will inevitably be more academic studies on policies and management for this topic.

Cluster 3

The primary keyword is "internet hospital." Some internet hospitals have connected with local health insurance individual account payment channels to achieve health insurance reimbursement [35]. The policy enables follow-up services for chronic diseases to be included in the scope of health insurance payment, accomplishing a series of closely matched services such as web-based remote consultation [19], web-based prescription, and health insurance payment for purchasing medication [18]. Health management can also be beneficial, such as improving medication compliance and strengthening awareness of chronic disease treatment and community health management [36]. The inclusion of internet follow-up services in health insurance payment emphasizes the homogenization of offline and web-based diagnosis and treatment behaviors [37], providing a basis for health insurance pricing through the use of advanced technological assessments and other means [20], and requires further research, which is a topic of high interest.

Cluster 4

The primary keyword is "health insurance payments." The use of health insurance in internet-based medical payment is increasing, but problems and difficulties have emerged. For example, there are significant problems in the integration of regional health insurance, internet-based medical platforms, and local health insurance systems, as well as communication and coordination issues such as cross-regional medical treatment and settlement [38]. As one of the main directions for future development of internet-based health care services, the use of mobile health care through smartphones is also a current research hot spot [39].

Cluster 5

As the most powerful lever to drive reforms in the entire medical system, health care payment reforms are crucially supported by digital and information-based payment systems, so the IPHC with health insurance occupies an important position [40]. "Electronic medical records" for referral purposes and more sophisticated IT can accelerate the implementation of payment reforms [41]. Vigorous development of primary care–based internet health care [42], increasing the proportion of health insurance expenditures in this area, among other measures. Research frontiers include problems with interoperability among internet health care systems, hospital internal management platforms [43], electronic medical record systems, imaging and inspection platforms [44], and other related issues.

Strength and Limitations

To the best of our knowledge, no study has carried out bibliometric analysis in this field of research on the use of health

insurance in IPHC services, along with telemedicine. It is of noticeable significance to discuss these issues and it is now necessary for us to study the research topic and identify hot spots. The method of bibliometrics and visual analyses enable us to sort out research focuses in recent publications as well as their correlation and differentiation.

However, this study inevitably has some limitations. We only retrieved studies and reviews on research topics related to this field from the CNKI. Although the CNKI plays a significant role in academic research and literature analysis in China, there are some obvious limitations to its application in international research fields, and studies need to consider these limitations and comprehensively integrate database resources in accordance with the specific needs of the research, to ensure comprehensive evaluation and analysis. Therefore, we may have missed some publications due to database limitation, and articles related to other languages may not have been included.

Bibliometric methods provide an overall insight into the landscape of a specific research field, but researchers and policy makers should be aware that the feature is not detailed enough for the evaluation or decision-making, and this study provides no enough in-depth insight into the influential articles and authors in this field. Balanced approaches that integrate bibliometrics research with other assessment methods can provide a thorough understanding of research impact and trends.

Future Directions

Recently, many previously ignored issues have been discussed and are now at the forefront, and numerous real-world problems associated with internet-based health care services, which has been limited by the scale of services, have been pointed out and discussed. Starting from the postpandemic era, the demand for remote or IPHC services will continue to grow. The deepening support of policies for IPHC services can meet the demand for health insurance management, mobile insurance payment, and cost reduction. Future research hot spots are developing, such as those focusing on the web-based application of live broadcasting, new media, artificial intelligence technology, etc, into IPHC services. Other hot spots include chronic disease management and primary health care, as well as the community older adult care in health insurance reforms in the IPHC era. These hot spots are surely important for suggesting more reasonable policy measures, enhancing the accessibility of health care services, reducing costs, and improving the quality of health care, thus better serving the people requiring them.

In summary, this study on the application of health insurance in internet-based health care services is quite forward-looking, and it is an important frontier for future health care service research.

Significance

This study describes a bibliometric analysis of the current high-quality Chinese literature on the application of telemedicine and IPHC in health insurance in China. This study used the popular software tool VOSviewer (version 1.6.19) to analyze the literature published in the CNKI, which was involved in the development of this field, and provides an overview of all the existing high-quality Chinese research and guides future research developments to improve the application of telemedicine and IPHC in health insurance. In particular, the unique IPHC paradigm from China is of importance to health care professionals worldwide.

Conclusions

This study used bibliometric analysis to describe the current situation and trends of health insurance in IPHC and telemedicine from the literature in China. This study highlights prominent research institutions, hospital researchers, and researchers at research institutes in universities engaged in this field. More articles on health insurance in IPHC and telemedicine are expected to be published in the next few years. The use of internet hospitals has underscored the potential of health care insurance payment in IPHC services, but it also highlights challenges pertaining to regional integration and interregional coordination. As the key lever for instigating systemic change, health care insurance payment reforms hinge on the progression of digitalization and informatization, along with ongoing investment in electronic medical records, IT, and primary health care services. Future research and policy formulation are expected to focus on tackling the integration of technologies with administrative systems, fostering the advancement of mobile health care, and delving into the interoperability among health care payment systems to attain efficiency and standardization in medical health care. This research provides an invaluable reference, enhancing our grasp of the current landscape and prospective progress in the field of health insurance within the domains of IPHC and telemedicine.

Data Availability

All data and material generated or analyzed in this study are included in this published paper.

Authors' Contributions

ZH, KC, and B-LW designed the study and wrote the manuscript. XQ, RSW, Y-CC, T-HT, and Y-NH critically reviewed the manuscript. ZH, RSW, XQ, and Y-NH directed statistical analysis and helped interpret the results. Y-NH, RSW, Y-CC, T-HT, and B-LW edited the manuscript. All authors reviewed and approved the manuscript. All authors have read and agreed with the published version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Antibiotic resistance, fueled by irrational prescribing, is a global threat associated with health, social, and economic consequences. Understanding antibiotic prescribing behavior and associated factors is important to promote good prescribing practice.

Objective: This study aimed to determine the factors affecting antibiotic prescribing behaviors of physicians based on the theory of planned behavior in hospitals in northwest Ethiopia in 2022.

Methods: A cross-sectional study was conducted from September 2022 to October 2022. A total of 185 health professionals were included, and a self-administered questionnaire was used to collect data. A structural equation model based on the modified theory of planned behavior was used to determine factors affecting antibiotic prescribing behavior. The percentages of physicians' estimated prescriptions for patients with upper respiratory tract infections (URTIs) and during weekly outpatient visits were used to predict antibiotic prescribing behavior and finally linked with behavioral constructs. A P value <.05 was considered significant.

Results: Physicians estimated that they prescribed antibiotics for 54.8% (9896/18,049) of weekly outpatient encounters, and 178 (96.2%) of the 185 physicians estimated they prescribed antibiotics for patients who presented with symptoms of a URTI. Physicians aged ≤30 years were less likely to prescribe antibiotics (48/100, 48%) for patients who presented with a URTI than physicians older than 30 years (51/100, 51%; P=.004), and general practitioners were less likely to prescribe antibiotics (47/100, 47%) for patients who presented with a URTI than residents (51/100, 51%; P=.03). Similarly, during outpatient visits, physicians ≤30 years old were less likely to prescribe antibiotics (54/100, 54%) than physicians older than 30 years (57/100, 57%; P<.001), male physicians were less likely to prescribe antibiotics (53/100, 53%) than female physicians (64/100, 64%; P=.03), and general practitioners were less likely to prescribe antibiotics (53/100, 53%) than residents (57/100, 57%; P=.02). Physicians with good knowledge were less affected by perceived social pressure (mean 4.4, SD 0.6) than those with poor knowledge (mean 4.0, SD 0.9; P<.001) and felt it was easy to make rational decisions (mean 4.1, SD 1.1) compared with those with poor knowledge (mean 3.8, SD 1; P<.001). However, intentions to reduce and prescribe antibiotics were not affected by attitudes, subjective norms, or perceived behavioral control, and perceived antibiotic prescribing behavior was not related to intentions to reduce or prescribe antibiotics.

Conclusions: Antibiotic prescribing behavior was not under the volitional control of physicians. This calls for a systematic approach to change antibiotic prescribing practices in hospital.

Introduction

Antimicrobial resistance (AMR) is a natural phenomenon [1], to which overuse and misuse of antibiotics contribute and augment [1-4]. Globally, antibiotic consumption has increased (eg, by 65% from 2000 to 2015), and 30% to 50% of antibiotic prescriptions were used either inappropriately or unnecessarily [2], further resulting in increased inappropriate use [3,4] and the development of selective pressure on antibiotics [5-7]. Inappropriate prescribing is a key contributing factor to the emergence of AMR [1,8,9] and varies from 62.8% for respiratory tract infections to 78.5% in patients with skin and soft tissue infections [4]. This would strengthen the belief that antibiotics ought to be prescribed and are effective in circumstances when they are not [10]. Physicians' prescribing behaviors impact not only patient health but also medical expenses and health resources [11]. It is recommended to monitor antibiotic prescribing in hospitals to improve the quality of antibiotic prescribing through education and practice changes [12]**.** Identifying key behaviors and drivers for the behaviors that may be amenable to change and improve prescribing decisions is an important component of interventions in health care practice to mitigate the burden of AMR [1,10,11]. Antibiotic stewardship programs (ASPs), which are among the most common interventions in health facilities to optimize antibiotic use, are effective, low-cost methods to change behaviors that drive excessive prescribing of antibiotics in health facilities [1].

Human behavior is guided by beliefs about the likely consequence of the behavior (behavioral beliefs), beliefs about the normative expectations of others (normative beliefs), beliefs about the presence of factors that may facilitate or impede the performance of the behavior (control beliefs), shaping attitudes, subjective norms (SNs), and perceived behavioral control (PBC) [13]. It is reported that these behavioral beliefs (attitudes, PBC, and SN) of physicians are predictors of indiscriminate antibiotic prescribing behaviors in hospitals [9,14]; thus, campaigns that address both health service personnel and the general population should take this into account [8]. A high level of knowledge is known to be associated with a more positive attitude and behavioral intention for reducing antibiotic prescriptions and was linked with less complacency, less fear, and less ignorance, although it had indirect effects on intentions to prescribe antibiotics through the attitude of ignorance [14]. On the other hand, perceived higher patient pressure negatively affects attitudes toward the rational use of antibiotics and promotes higher use of antibiotics [15]. Thus, characterizing and designing behavior change interventions based on the behavior change wheel model and theory of planned behavior (TPB) serve as a framework for modeling the antibiotic prescribing behaviors of physicians [13,16,17]. Optimizing antibiotic consumption and reducing the rate of AMR are currently global issues [1,18]. In low- and middle-income countries, the prescribing of antibiotics is highly influenced by inadequate diagnostic facilities, lack of guidelines, difficulty monitoring patient progress, poor intensive care facilities, patient demand for quick relief, perceived patient expectations from past prescriptions, and fear of losing patients to competition [19,20]. This results in high mortality and morbidity due to inadequate regulation, limited access to diagnostic facilities, and antimicrobial over-prescription [21,22]. Based on the behavior change wheel, once a problem is identified and context is considered, functions and policies may be implemented as interventions to understand and change prescribing behavior and improve antibiotic consumption [13,17]. This requires the design and implementation of sustained awareness campaigns to change behaviors and improve health outcomes [9].

In sub-Saharan Africa, physicians still prescribe antibiotics based only on a simple assessment of patients' symptoms, just as they used to when antibiotics first became commonly used in the 1950s [9], due to a lack of diagnostic and antibiotic susceptibility tests, resulting in up to 95% of antibiotic prescriptions as unnecessary [23]. Prescribing antibiotics requires balancing physician, patient, and facility-related factors [24]. In Ethiopia, antibiotic prescribing in hospitals may account for 52.39% of all prescriptions [25], and one-half of prescribed antibiotics might not be needed [26]. Although behavior change campaigns can be very cost-effective for changing antibiotic prescribing practices, based on identified gaps [9], in Ethiopia, to our knowledge, there have been no studies to model the antibiotic prescribing behavior of physicians other than determining the perceptions of health professionals on AMR and antibiotic use [27,28]. Modeling behavior is needed to help clinical leaders drive ASP and design educational programs to help standardize and improve antibiotic prescribing behaviors in health facilities [29]. Thus, this study assessed the determinants of antibiotic prescribing behavior among physicians serving in outpatient departments (OPDs) in hospitals in northwest Ethiopia using a structural equation modeling (SEM) approach.

Methods

Study Area and Period

A cross-sectional study was conducted from September 2022 to October 2022 in 4 hospitals: Felege Hiwot Comprehensive Specialized Hospital, Tibebe Ghion Specialized Hospital, Debre Markos Comprehensive Specialized Hospital, and Injibara General Hospital. Except for attempts to implement ASPs in inpatient wards in some of the hospitals, there is currently no system to monitor antibiotic prescribing or enabling factors for prescribing antibiotics in OPDs. This survey assessed the knowledge, attitudes, SN, and PBC of physicians and their intention to prescribe antibiotics as possible factors for antibiotic prescribing behaviors to provide insights into the driving forces of antibiotic prescribing as a complementary factor for antibiotic

XSL•FO

RenderX

consumption, which together constitute baseline information to design effective ASPs to tackle AMR.

Study Participants, Sample Size Determination, and Sampling Procedures

Physicians (general practitioners and residents) working in OPDs of internal medicine, pediatrics, gynecology and obstetrics, and surgical departments were included in the study. The sample size for health professionals was determined based on the following formula for a finite population:

$$n = \chi^2 NP (1-P)/ (d^2 (N-1) + \chi^2 P (1-P))$$

where n is the sample size and χ^2 is the table value of the chi square for 1 degree of freedom at the desired confidence level ($1.96 \times 1.96 = 3.84$), *N* is the total population, *P* is the population proportion (27%), and *d* is the degree of accuracy expressed as a proportion (0.05). According to Gebretekle et al [27], physicians estimate that they prescribe antibiotics to about 27% of their patients. Thus, a prevalence of 27% was used to calculate the sample size in this study. Accordingly, n was calculated as follows:

n=(1.96×1.96) × 487 × 0.27(1–.27)/((0.05×0.05) × (487–1) + (1.96×1.96) × 0.27(1–0.27))

n=181.26 or ~182

To account for the nonresponse rate, 10% was added; thus, the total sample size was 200.

Data Collection Instruments and Processes

Data collection was based on the study by Liu et al [14,15] and customized to local scenarios in Ethiopian hospital settings. Questionnaires consisted of 4 behavioral aspects leading to antibiotic prescribing based on the TPB, namely attitudes (the degree to which a prescriber is in favor of the use of antibiotics), SN (perceived social pressure to which a prescriber is subject to prescribe antibiotics), PBC (the ease or difficulty of making a rational decision on antibiotic prescriptions), and intentions (the degree to which a prescriber is willing to prescribe or reduce antibiotics). The questionnaire for professionals was designed on a Likert scale with a 5-point response format, ranging from 1 (strongly disagree) to 5 (strongly agree) for attitudes about and intention to prescribe antibiotics, and a 5-point response format (from always to never) for SN and PBC. In addition, physicians were asked to estimate the number of patients who receive antibiotics from their weekly encounters that involve prescriptions and the number of patients for whom they prescribe antibiotics from 10 encounters with patients with symptoms of upper respiratory tract infections (URTIs) to assess their antibiotic prescribing behavior or practices. To assess physicians' knowledge, 11 questions were used, attitude was assessed using 7 questions, SN was assessed using 8 questions, PBC was assessed using 5 questions, and there were 3 questions each to measure intentions to reduce and prescribe antibiotics.

Physicians (general practitioners and residents) working in internal medicine, pediatrics, gynecology and obstetrics, and surgical OPDs in the hospital were approached to participate in the study. The questionnaire was distributed while they were on duty. The completeness of the data was monitored on a daily basis. Finally, the data were compiled, and the behavioral

constructs were linked with the percentages of physicians' perceived antibiotic prescribing behaviors and practices using SEM based on modified TPB (MTPB).

The Theoretical Framework for Structural Equation Modeling

Attitude, SN, and PBC were shown to be related to appropriate sets of salient behavioral, normative, and control beliefs about a behavior. PBC, together with behavioral intention, can be used directly to predict behavioral achievement. Attitude is defined as the degree to which a prescriber is in favor of the use of antibiotics in outpatient encounters, whereas SN and PBC measure the perceived social pressure to which a prescriber is subject to prescribe antibiotics and the perceived ease or difficulty of making a rational decision during antibiotic prescriptions, respectively. A behavioral intention that is intermediate measures the degree to which a prescriber is willing to prescribe antibiotics [13]. Thus, the theoretical framework was adopted from the TPB model [13], and links between knowledge and attitude, SN, and PBC were explored. However, since the comparative fit indexes (CFIs) were low, knowledge was linked to SN and PBC in relation to antibiotic use, and attitude, SN, and PBC were linked to intentions to prescribe antibiotics and finally to behaviors influencing antibiotic prescribing.

Statistical Analysis

Data were coded, entered, cleaned, and transferred to STATA version 14.0 (Stata Corp) for SEM analyses, but descriptive statistics were analyzed using SPSS version 23 (IBM Corp). ANOVA and chi-squared tests were performed to determine the difference in the mean measuring knowledge, attitudes, SN, PBC, and behavioral intentions of the participants according to age, gender, city, professional status, workplace, and duration of clinical practice. For knowledge, the percentage of respondents who answered correctly and the total number of correct answers per respondent were calculated. In addition, correct answers were coded as 1, and incorrect answers were coded as 0 for the SEM. Each attitude item was coded using a 5-point Likert scale (1=strongly agree, 5=strongly disagree), then recoded (–2=strongly disagree, 2=strongly agree), with a negative score indicating disagreements and a positive score indicating agreement with the average scores (ranging from –2 to 2). Intentions to reduce and prescribe antibiotics were coded similarly as the attitude measurements, with a negative score indicating refusal and a positive score indicating support for reducing antibiotic prescriptions (from –2 to 2). SN and PBC were measured from 1 to 5, with 1 indicating always and 5 indicating never, then recoded from 0 to 4, where 0 denotes never and 4 represents always. Behaviors around antibiotic prescriptions were measured using the percentage of antibiotic prescriptions for URTIs, per every 10 patients, and the percentage of antibiotic prescriptions among the estimated weekly visits.

Each variable was modeled separately to exclude factor loadings <0.3. Finally, SEM was applied to establish the associations between knowledge, attitudes, and practices. Standardized path coefficients with statistical significance (*P*<.05) were used. The maximum likelihood method was used to estimate the

parameters. The fitness of the data in the SEM model was assessed using model fitness indexes based on recommended level acceptances such as $P > \chi^2$ ($P > .05$), standardized root mean squared residual <0.09, and root mean squared error of approximation <0.08; Tucker-Lewis index >0.90; CFI>0.90; and coefficient of determination ≥0.7. In addition, descriptive analysis was used.

Operational Definitions

We considered attitude to be the degree to which a participant had a positive or negative evaluation of indiscriminate antibiotic use. SNs were participants' beliefs about whether significant others would approve or disapprove of indiscriminate antibiotic use (ie, the perceived social pressure to which a prescriber is subject to prescribe antibiotics). PBC was the participant's beliefs regarding the ease or difficulty of making a rational decision about antibiotic prescriptions. Knowledge was considered participants' understanding and awareness regarding indiscriminate antibiotic use and AMR. The level of knowledge was determined based on the average score for all the questions (ie, physicians who answered at least or above the average score were considered to have good knowledge). Behavioral intentions around antibiotic prescriptions were the degree to which a prescriber was willing to prescribe antibiotics. Behaviors were documented as physicians' self-reported antibiotic prescribing behaviors.

Ethical Considerations

Ethical approval was obtained from the College of Health Sciences (protocol code: 106/22/SoP) and the School of Pharmacy (protocol code: ERB/SOP/472/14/2022) of Addis Ababa University. A support letter to the hospitals was obtained from the Amhara Public Health Institute. During data collection, physicians' names were deidentified. All participants provided informed consent prior to participating in this study. The information obtained was kept confidential and used only for research purposes. Ethical issues like privacy and confidentiality were considered during data collection in order not to disclose information about people outside the research.

Results

Among 200 planned respondents, 185 completed the questionnaires. Thus, the overall response rate was 92.5%.

General Characteristics of Study Participants

The majority of physicians (153/185, 82.7%) were men, and their average age was 30.3 (3.9) years. Overall, physicians had been in their current roles an average of 3.0 (2.2) years and had worked at their current hospital for an average of 2.0 (1.8) years. The majority of physicians (149/185, 80.5%) had worked in their current roles for <5 years; 87 (87/185, 47%) and 55 (55/185, 29.9%) were from Tibebe Ghion Specialized Hospital and the gynecology and obstetrics department, respectively. Of the patients who visited the OPDs, the physicians estimated that 9896 (9896/18,049 54.8%) had received at least one antibiotic (Table 1).

Knowledge of Physicians About Antibiotic Prescription

The majority of physicians agreed that amoxicillin is safe for pregnant patients (169/185, 91.4%), metronidazole has the best activity against anaerobes (166/185, 89.7%), and antibiotics should not be prescribed for nonfebrile diarrhea (151/185, 81.6%). However, none of the physicians answered, "Aminoglycosides are very active if they are administered parenterally once daily." Physicians answered 5 of 11 (46%) questions correctly. Based on this, 121 (65.4%) of the 185 physicians had good knowledge, based on the cutoff of a mean ≥5; however, for 64 (34%) of the 185 physicians, knowledge was poor (Table 2).

Table 2. Knowledge about antibiotic prescriptions of 185 physicians in hospital outpatient departments in 2022.

Code	Items to assess knowledge levels	Response		Factor loading	*P* value
	Correct, n (%)	Incorrect, n (%)			
q35	Antibiotic treatment is not needed for non-febrile diarrhea.	151 (81.6)	34 (19.4)	0.43	<.001
q36	Antibiotics are not prescribed for upper respiratory tract infections.	19 (10.3)	166 (89.7)	–0.14	.11
q37	Dosage reduction for ceftriaxone and clindamycin is needed for renal failure.	37 (20)	148 (80)	–0.11	.22
q38	Amoxicillin is a safe antibiotic product for pregnant patients.	169 (91.4)	16 (9.9)	0.55	<.001
q39	Metronidazole has the best activity against anaerobes.	166 (89.7)	19 (10.3)	0.82	<.001

q43	Bacterial pneumonia (with symptoms of fast breathing, chest in-drawing, or stridor) requires antibiotic treatment.	90 (48.6)	95 (48.6)	0.14	.15
q44	Antibiotics do not reduce the duration and the occurrence of complications of upper respiratory tract infections.	37 (20)	148 (80)	0.17	.07
q45	The average number of patients taking antibiotics should be below 30% in a primary care facility.	36 (19.5)	149 (80.5)	0.063	.47

Attitudes and Intentions of Physicians Toward Antibiotic Prescriptions

The mean response for attitude questions was 2.5 (0.4). Of the 185 physicians, 88 (47.6%) perceived that microbiology results are important for treating infectious diseases, 95 (51.4%) believed that over-prescribing of antibiotics contributes to the generation of antibiotic resistance, and 89 (48.1%) believed that over-prescription of antibiotics leads to the development of resistance. Regarding intention to prescribe antibiotics, the mean score for intention to reduce antibiotics was 2.4 (0.9), whereas the mean score for intention to prescribe antibiotics 2.5 (0.8). Of the 185 physicians, 133 (71.9%) wanted to reduce antibiotic consumption, 132 (71.4%) expected to reduce antibiotic consumption, and 117 (63.2%) planned to reduce antibiotic consumption for outpatients; however, 107 (57.8%) wanted to prescribe antibiotics, 103 (55.6%) expected to prescribe antibiotics, and 102 (55.1%) planned to prescribe antibiotics to their patients (Table 3).

Table 3. Physicians' (n=185) responses to individual items about attitudes and behavioral intentions about antibiotic prescribing in hospital outpatient departments in 2022.

Measurement and items	Code	Response score, mean (SD)	Responses, n (%)					Factor loading	P value
			Strongly agree 1)	Agree (2)	Neutral (3)	Disagree (4)	Strongly disagree (5)		
Attitude[a]									
In primary care, microbiology results are useful when treating infectious diseases.	Q1	1.8 (1)	88 (47.6)	73 (39.5)	8 (4.3)	11 (5.9)	5 (2.7)	0.34	<.001
The prescription of an antibiotic to a patient does not influence the development of resistance.	Q2	4.2 (0.9)	0	16 (8.6)	12 (6.5)	68 (36.8)	89 (48.1)	−0.09	.30
Overuse of antibiotics contributes to the generation of antibiotic resistance.	Q3	1.7 (1)	107 (57.8)	57 (30.8)	7 (3.8)	7 (3.8)	7 (3.8)	0.56	<.001
Prescribing antibiotics to patients does not cause damage even if they are not indicated.	Q4	4.2 (0.9)	1 (0.01)	13 (7.0)	10 (5.4)	77 (41.6)	84 (45.4)	−0.03	.73

[a]Overall score: mean 2.5 (SD 0.4).

[b]AMR: antimicrobial resistance.

[c]Overall score: mean 2.4 (SD 0.9).

[d]Overall score: mean 2.5 (SD 0.8).

Subjective Norms and Perceived Behavioral Control of Physicians

The mean scores for SNs and PBC were 4.3 (0.8) and 4.0 (1.1), respectively. Of the 185 physicians, 133 (71.9%), 128 (69.2%), 126 (68.1%), and 125 (67.6%) never prescribed antibiotics based on patients' expectations, based on patient pressure, based on patients' requests for antibiotics, and to make patients trust them, respectively. Similarly, 119 (64.3%) of the 185 physicians never prescribed antibiotics to avoid being perceived as doing nothing for patients. Only a limited number of physicians agreed that they prescribed antibiotics based on patients' expectations or pressure (Table 4).

Table 4. Physicians' (n=185) responses to individual items about subjective norms and perceived behavioral control for intention to prescribe antibiotics in hospital outpatient departments in 2022.

Measurement and items	Codes	Response score, mean (SD)	Responses, n (%)					Factor loading	*P* value
			Always (1)	Often (2)	Sometimes (3)	Rarely (4)	Never (5)		
Subjective norm[a]									
I prescribe antibiotics since patients expect it.	Q15	3.9 (1.2)	6 (3.2)	21 (11.4)	38 (20.5)	48 (25.9)	72 (38.9)	0.54	<.001
I prescribe antibiotics since patients require and insist on it.	Q16	3.9 (1.1)	7 (3.8)	16 (8.6)	33 (17.8)	55 (29.7)	74 (40)	0.64	<.001
I prescribe antibiotics to satisfy patients.	Q17	4.1 (1.2)	10 (5.7)	12 (6.5)	24 (13.0)	46 (24.9)	93 (50.3)	0.55	<.001
I prescribe antibiotics so patients continue to trust me.	Q18	4.4 (1.0)	5 (2.7)	11 (5.9)	12 (6.5)	32 (17.3)	125 (67.6)	0.68	<.001
Even when I know that they are not indicated, I prescribe antibiotics since patients expect it.	Q19	4.5 (0.9)	3 (1.6)	4 (2.2)	19 (10.3)	26 (14.1)	133 (71.9)	0.84	<.001
Even when I know that they are not indicated, I prescribe antibiotics since patients ask for it.	Q20	4.5 (0.8)	1 (0.1)	7 (3.8)	13 (7)	38 (20.5)	126 (68.1)	0.86	<.001
Even when I know that they are not indicated, I prescribe antibiotics since patients press me to prescribe it.	Q21	4.5 (0.9)	3 (1.6)	3 (1.6)	19 (10.3)	32 (17.3)	128 (69.2)	0.87	<.001
Even when I know that they are not indicated, I prescribe antibiotics since I do not have time to explain to the patient the reason why they are not called for.	Q22	4.3 (1.1)	4 (2.2)	16 (8.6)	10 (5.4)	40 (21.6)	115 (62.2)	0.70	<.001

[a]Overall score: mean 4.3 (SD 0.8).

[b]Overall score: mean 4.0 (SD 1.1).

Antibiotic Prescribing Practices of Physicians

Of the 18,049 patients seen in the OPDs, 9896 (54.8%), or an average of 60.1 (53.5%) patients per week, were estimated to receive at least one antibiotic. Using an estimate of 10 patients for each of the 185 physicians, for a total of 1850 patients with URTIs, about 916 (49.5%) were estimated to be prescribed at least one antibiotic. Accordingly, 178 (96.2%) of the 185 physicians estimated that they prescribed antibiotics for at least one patient out of every 10 patients who presented with symptoms of a URTI, with a mean score of 5.9 (SD 2.2); 142 (142/185, 76.8%) physicians believed they would prescribe antibiotics for >3 patients; and 43 (43/185, 23.3%) physicians estimated they would prescribe antibiotics for 0 to 3 patients. The majority of physicians (56/185, 30.3%) said they would prescribe antibiotics to 5 patients out of 10 encounters with patients with URTIs in the OPDs (Table 5).

Table 5. Estimated prescriptions of antibiotics for upper respiratory tract infections (URTIs) out of every 10 patients by 185 physicians in hospital outpatient departments.

Number of patients prescribed antibiotics per every 10 patients	Physicians who estimated they would prescribe antibiotics, n (%)
0	7 (3.8)
1	4 (2.2)
2	9 (4.9)
3	23 (12.4)
Total for ≤3 encounters (30% of patients) with a URTI	43 (23.3)
4	31 (16.8)
5	56 (30.3)
6	20 (10.8)
7	10 (5.4)
8	12 (6.5)
9	2 (1.1)
10	11 (5.9)
Total for >3 encounters with a URTI	142 (76.8)

Structural Equation Modeling

The SEM using MTPB confirmed the theoretical framework for the antibiotic prescribing behaviors of physicians with some modifications. Based on the coefficient of determination (R^2), 94.6% of the variation in antibiotic prescribing behavior could be explained by all the exogenous variables. Data in the MTPB model had good fit, with $P>\chi^2$ ($P>0.0001$), a root mean squared error of approximation of 0.049, a standardized root mean squared residual of 0.071, a CFI of 0.91, and a Tucker-Lewis index of 0.901 (Table 6).

The MTPB model indicated that only physician knowledge was associated with PBC and SN. There was covariance between SNs and PBC ($P<.001$). Attitudes, SNs, and PBC were not associated with intentions to prescribe or reduce use of antibiotics. Similarly, intentions to prescribe or reduce use of antibiotics was not associated with the estimated number of antibiotic prescriptions for URTIs or during weekly visits (Figure 1). Physician age ($P=.004$) and professional level ($P<.02$) were predictors of the number of estimated prescriptions for URTIs, and physician age ($P=.001$), sex ($P=.03$), and professional level ($P=.02$) were predictors of the estimated number of prescriptions during weekly OPD visits. Knowledge

was a direct predictor of SNs ($P<.001$) and PBC ($P<.001$). There was no indirect relationship between prescriber behaviors and knowledge, attitude, SN, and PBC (Table 7).

Based on the information in Table 7, for the 49.5% of the 1850 patients with URTIs who were estimated to be prescribed at least one antibiotic, physicians older than 30 years were more likely to prescribe antibiotics (51/100, 51%) than those ≤30 years old (48/100, 48%). Based on professional level, residents (51/100, 51%) were more likely to prescribe antibiotics than general practitioners (47/100, 47%). Similarly, for the estimated 54.8% (9896/18,049) of weekly OPD visits that had an antibiotic prescription, physicians older than 30 years were more likely to prescribe antibiotics (57/100, 57%) than those ≤30 years old (54/100, 54%). Women (63/100, 63%) and residents (57/100, 57%) were also more likely to prescribe antibiotics than men (53/100, 53%) and general practitioners (53/100, 53%), respectively. Good knowledge was a direct predictor of SNs (mean 4.4, SD 0.6) and PBC (mean 4.1, SD 1.1), both of which are in contrast for those with poor knowledge (mean 4.0, SD 0.9) and (mean 3.8, SD 1), respectively. However, intentions to reduce and prescribe antibiotics were not affected by attitudes, SNs, nor PBC, and perceived antibiotic prescribing behavior was not related to intentions to reduce or prescribe antibiotics.

[c]ITPABx: intention to prescribe antibiotics.

Discussion

AMR is a global crisis [27,29-32], calling for urgent action to resolve it. One of the important strategies for combating AMR is improving antibiotic prescribing practices by determining factors that affect physicians' prescribing behaviors [10,11,14]. Physicians' antibiotic prescribing practices are influenced by physician-related factors (knowledge, expertise, specific

prescription patterns, time constraints, and communication with patients), patient-related factors (preferences, expectations, knowledge, culture, economic status, and previous experience), and health system–related factors (guidelines, policies, regulations, and financial incentives) [24]. Thus, the TPB in its original or modified (MTPB) form provides a theoretical framework to identify the determinants of physicians' antibiotic prescribing behaviors [14,15,33]. This study, using SEM, confirmed the theoretical framework for physicians' antibiotic prescribing behaviors with some modifications. The MTPB model revealed that physician knowledge was associated with PBC and SN (*P*<.001). However, attitudes, SNs, and PBC did not influence intentions around prescriptions and perceived prescribing behaviors of physicians. Overall, the study revealed that physicians' perceived antibiotic prescribing behaviors were not affected by intentions to reduce and prescribe antibiotics.

A qualitative study in Ethiopia uncovered that "junior physicians (interns and residents) are more likely to prescribe broad-spectrum antibiotics, and they further speculate these practices are driven by poor knowledge" [27]. In this, 121 (65.4%) of the 185 physicians had good knowledge (answered 5 questions out of 11), although the respondents answered only 44.13% of the total questions about antibiotic prescriptions correctly. This was relatively low compared with the 55% to 86% for physicians in hospitals in China [14,15], Lao People's Democratic Republic, Democratic Republic of Congo, and Peru [34-36]. In this study, MTPB knowledge was directly linked with the PBC and SNs of physicians (*P*<.05). This was different than the findings of a study in China that reported a link between high knowledge and positive attitudes toward the rational use of antibiotics [14,15] but similar to a study that reported a link between high knowledge and decreased SNs to prescribe antibiotics [14]. This study revealed a lack of indirect links between knowledge and antibiotic prescribing behavior, which was similar to a study in China that reported a lack of a link between knowledge and antibiotic prescribing practices [14,15]. Knowledge helps physicians weigh the treatment options and increases the accuracy of risk perception; thus, physicians with different professional titles (such as resident physicians and general practitioners) and length of practice may have different attitudes toward antibiotics, based on findings in previous studies [37,38]. Although training can contribute to knowledge acquisition, this study revealed a lack of difference in knowledge between those who completed training on antibiotic prescribing and AMR and those who did not.

This study also revealed a lack of a link between attitudes, SNs, and PBC to prescribe antibiotics. This was different from a report in China that confirmed that "intentions to prescribe antibiotics are predicted by the attitudes, subjective norms, and sense of behavioral control of the prescribers" [33], although another study reported a lack of relationship with intentions to prescribe antibiotics [14,15]. It was reported that attitudes, SNs, and PBC were predictors of antibiotic prescribing behaviors [11,39]. However, this study did not show indirect relationships between attitudes, SNs, and PBC and prescribers' perceived antibiotic prescribing behaviors.

Of the patients seen in the OPDs weekly, 54.8% were estimated to receive at least one antibiotic, and of the 1850 estimated patients who presented with a URTI, 916 (49.5%) were estimated to be prescribed at least one antibiotic. In Ethiopia, antibiotic prescribing ranges from 56.0% in primary health care facilities [40] to 73.7% in inpatient wards in the national referral hospital [41]. The majority of the prescriptions (32.9%-39.3%) were for respiratory tract infections, although about 54.2% of all antibiotic prescriptions might not be needed [27]. This could explain the high rates of perceived antibiotic prescriptions for outpatient visits and patients with URTIs in this study. In ambulatory care facilities in Tanzania, 95% to 96.3% of presenting cases were receiving at least one antibiotic [42], which is higher than the estimated prescriptions among weekly visits and patients with URTIs in this study. Another study in the same hospital reported 66.9% of patients were treated with or prescribed at least one antibiotic among weekly visits [28], which was higher than the perceived weekly prescriptions and prescriptions for URTIs in this study. A study in China reported that physicians prescribed antibiotics to an estimated 40% of patients with URTIs [14], and actual antibiotic prescribing behavior was 44.3% [33], both of which are lower than the rates in this study.

In this study, intention to reduce antibiotic use and intention to prescribe antibiotics were not linked with perceived antibiotic prescribing behaviors. Similar findings from China supported the limited role of intentions on antibiotic prescribing behavior [33]. Intraphysician prescription variability is affected by the availability of clinical guidelines, experience, peer prescribing practices, pharmaceutical pressure, time pressure, financial considerations, individual practice patterns, practice volume, and relationships with patients [24]. Differences in these factors might explain the discrepancy in the findings from this study and those from a study in China [33], which reported that a positive attitude toward antibiotics resulted in a higher intention to prescribe antibiotics. The difference might be due to differences in the type of patients, clinical practice, and availability of structural and process controls in antibiotic prescribing. Two studies, one in Eritrea and one in Ethiopia, confirmed this by reporting that patient age (<18 years), gender (male), and the number of drugs in a prescription (≥2) were associated with the prescription of antibiotics [43,44]. Thus, physicians in different health systems may be subjected to different working environments and social pressures, which could affect their overall intention to prescribe and prescribing behavior.

In general, this study uncovered a lack of volitional control among physicians when prescribing antibiotics. This indicates the complex nature of antibiotic prescribing practices, which are influenced by various factors [24]. Thus, a campaign is needed to reduce over-prescriptions of antibiotics using a systems approach to addressing gaps in the knowledge and attitudes of prescribers [33]. Introducing educational programs and training on antibiotic prescribing practices and antibiotic resistance, preparing targeted guidelines to address gaps in antibiotic prescriptions for URTIs, and involving specialists will help address the gaps in antibiotic prescribing [24,33,45]. Providing antibiotics as a universal therapy due to gaps in knowledge and skills and financial or reputational incentives on the one hand and a lack of antibiotic and poor facility

regulations, the absence of a regulatory framework, and poor implementation of existing policies on the other hand might be drivers of inappropriate antibiotic prescriptions [46]. Thus, disease-specific prescribing guidelines like those for URTIs can facilitate the translation of intentions into practices, since the inability to make a clear diagnosis and over-prescription of antibiotics may be linked with physicians' clinical capacity rather than behavioral control intentions [24]. Despite this, self-regulation, outcome expectation, and anticipation of possible barriers may still have a considerable effect on prescribing behaviors and will help reduce inappropriate antibiotic use, since inappropriate prescribing of antibiotics in ambulatory care is known to be linked to current knowledge on antibiotics, ASPs, and AMR among prescribers [42].

Therefore, ASPs must have fiduciary responsibility for all health care institutions across the continuum of care [47]. A comprehensive approach through a hospital policy on the rational use of antibiotics is essential to developing and implementing an evidence-based antibiotic use policy and standard treatment guidelines for common infectious diseases, improving antimicrobial prescribing through educational and administrative means, and monitoring and providing feedback regarding antibiotic resistance, all of which are strategic approaches [48]. Knowledge of determinants that influence antibiotic prescription behavior is essential for the successful implementation of antimicrobial stewardship interventions [49]. In Ethiopia, at present, there are limited or no national or coordinated legislative or regulatory mandates designed to optimize the use of antimicrobial therapy through ASPs [6,26]. This research on behavioral determinants may have a substantial impact on designing policies on antibiotic prescribing behaviors and implementing effective, efficient, and evidence-based interventions. It urges strengthening efforts to improve prevention and control efforts for infectious diseases, including the adoption of ASPs in all health care facilities. Research is also needed to define the optimal elements and goals of ASPs in different health care settings; expand educational efforts on ASP; devise novel mechanisms to prevent the over-prescription of antibiotics; and implement rapid, point-of-care diagnostic tests that would enable appropriate prescription and care.

Overall, this study will help understand prescribing behaviors by applying the TPB model and will be helpful for regulating prescribing behaviors, improving clinical management, promoting physician-patient communication, and establishing a harmonious physician-patient relationship to improve rational prescribing behaviors in delivering high-quality medical services. Policymakers should also consider multiple scenarios rather than merely concentrating on creating awareness. The model can hopefully be incorporated as part of multilevel interventions designed to decrease irrational prescriptions for actual patients. Furthermore, it might help initiate a nationwide survey on factors affecting antibiotic prescribing behaviors, and more research is needed to explore the views of other stakeholders on antibiotic use. Although this study presents opportunities for future studies in the country, it does have its limitations. The sample size was relatively small, and self-administered questionnaires may not provide the possibility for respondents to verify their answers, resulting in socially desirable answers. Due to a lack of records for antibiotic prescriptions, it was not possible to determine the actual antibiotic prescribing behaviors of physicians. Another limitation might be that it did not include all comprehensive physician-related factors (expertise, knowledge, specific prescription patterns, time constraints, and communication with patients), patient-related factors (knowledge, preferences, expectations, culture, economic status, and previous experience), and health system–related factors (financial incentives, guidelines, policies, and regulations) that influence antibiotic prescribing practices. Thus, further studies using TPB with a large number of physicians are warranted.

In conclusion, there was a high level of estimated antibiotic prescriptions for URTIs and weekly outpatient visits. However, the perceived behaviors around antibiotic prescription were not affected by the intention to prescribe antibiotics or the intention to reduce antibiotic use. Although the physicians had a good level of knowledge about antibiotics, antibiotic resistance, and prescriptions, which were linked with the attitudes and SNs of physicians, intentions to reduce use and prescribe antibiotics were not significantly associated with attitudes, SNs, or PBC. This may show the complex nature of antibiotic prescriptions, which cannot be justified simply by intentions and behaviors of physicians, as determined based on TPB.

Authors' Contributions

AAA was involved in study conception, study design, study execution, acquisition of data, data analysis and interpretation, manuscript writing, and manuscript review. TGF was involved in study conception, study design, supervision, manuscript writing, and manuscript review. GYW was involved in supervision, manuscript writing, and manuscript review.

Abstract

Background: Emergency medical services have a pivotal role in giving timely and appropriate responses to emergency events caused by medical, natural, or human-caused disasters. To provide adequate resources for the emergency services, such as ambulances, it is necessary to understand the demand for such services. In Indonesia, estimates of demand for emergency services cannot be obtained easily due to a lack of published literature or official reports concerning the matter.

Objective: This study aimed to ascertain an estimate of the annual volume of hospital emergency visits and the corresponding demand for ambulance services in the city of Jakarta.

Methods: In this study, we addressed the problem of emergency services demand estimation when aggregated detailed data are not available or are not part of the routine data collection. We used survey data together with the local Office of National Statistics reports and sample data from hospital emergency departments to establish parameter estimation. This involved estimating 4 parameters: the population of each area per period (day and night), the annual per capita hospital emergency visits, the probability of an emergency taking place in each period, and the rate of ambulance need per area. Monte Carlo simulation and naïve methods were used to generate an estimation for the mean ambulance needs per area in Jakarta.

Results: The results estimated that the total annual ambulance need in Jakarta is between 83,000 and 241,000. Assuming the rate of ambulance usage in Jakarta at 9.3%, we estimated the total annual hospital emergency visits in Jakarta at around 0.9-2.6 million. The study also found that the estimation from using the simulation method was smaller than the average (naïve) methods ($P<.001$).

Conclusions: The results provide an estimation of the annual emergency services needed for the city of Jakarta. In the absence of aggregated routinely collected data on emergency medical service usage in Jakarta, our results provide insights into whether the current emergency services, such as ambulances, have been adequately provided.

Introduction

Background and Context

Demand for emergency medical services (EMS), in particular ambulance services, has been much discussed in relation to finding factors influencing the change in demand, as well as the benefits of using the ambulance services. Factors influencing the usage of ambulance services can include medical conditions [1], patients' demographic and socioeconomics [2], environmental factors [3,4], and pandemic events [5,6]. Evidence from the literature also suggests that the use of ambulances reduces prehospital delay [7], which eventually can improve patient-related outcome measures [8].

In Indonesia, natural disasters take place every year including floods, wildfires, earthquakes, landslides, windstorms, tsunamis, and extreme weather conditions [9]. These disasters can affect millions of people including deaths or losses and thousands of injuries. Concerning population health, in 2019, around 19.42% and 14.38% of deaths were caused by stroke and heart disease, respectively [10]. Stroke and ischemic heart disease were among the highest contributors to the years of life lost (6,317 combined) [11]. Trauma cases, including road injuries, contributed to around 4.5% of all deaths [10]. Both natural disasters and ill health can contribute to the demand for ambulance services.

The health care system in developing countries is characterized by scarce resources, including human and financial resources. In Indonesia, health care capacity is far from adequate in many areas and not evenly distributed [12]. The Indonesian prehospital emergency medical services are fragmented and lack standardization, which causes variation in the quality and management of prehospital care delivery. Resources such as ambulances are available, both publicly and privately run. However, lack of funding, coordination, inadequately trained paramedics, and infrastructure are among the issues faced by the emergency ambulance services in Indonesia [13].

Jakarta, the capital of Indonesia, is home to over 11 million people with an area of 664 km^2 and an annual population growth rate of 0.92% between 2010 and 2020 [14]. In Jakarta, various organizations provide ambulance services. A study found that in Asian countries, ambulance availability ranged from 0.33 to 47 per 100,000 population [15]. The ambulance service includes responding to emergency needs outside the hospitals as well as providing interhospital transportation. Access barriers to ambulance services exist. It is found that many patients, even with life-threatening conditions, travel to hospital emergency departments (EDs) without using appropriate transportation including motorcycles [16]. Factors influencing the patients' choices for transport are related to medical, socioeconomic, road, and traffic conditions. The congested areas of Jakarta at certain times of the day may suggest the preference for using small and agile transportation such as a motorcycle. The use of public transport or hired cars may be more economical compared with using a private ambulance.

The decisions on ambulance provision in Jakarta are often made without evidence-based or rigorous data analysis. Indeed, it is not easy to know the actual demand in the population. The difficulty in estimating the demand for ambulances is due to several reasons:

1. There is no unifying service that collects data from various ambulance providers. Official reports on health care usage do not cover prehospital emergency services. This could be due to fragmented services, different quality in the data collection process, and lack of resources.
2. Hospitals may collect data on people attending their EDs. However, there are no data available on how the patients arrived at the hospitals. There is no (financial) incentive in collecting such data to support the decision-making process, hence the authority and health care providers do not pay particular attention to collecting data related to transport modes used by the patients.
3. There is no data on the number of people with real emergency conditions who need ambulance services. This issue may not be exclusive to Jakarta. However, factors such as culture and a lack of medical awareness can exacerbate the reluctance to seek help or use an ambulance. For example, it is common in Indonesia for patients with conditions, such as fractures to seek help from alternative treatments, such as from a massage therapist.

Approaches to Estimating Ambulance Demand

Studies on estimating ambulance demand may have used different approaches depending on the availability of the data. Where data were collected regularly by ambulance providers and available for a long period, a time series forecasting method may be suitable for a short or relatively long period of demand forecasting [17,18]. This method is suitable for anticipating resource requirements needed in a specific time or season. The output is the call volumes for each specific time frame, for example, monthly, daily, or even hourly. This method is built based on past data to mimic the patterns observed in the data with a certain degree of variability as closely as possible. The forecast is deemed relatively accurate when the model output is very close to matching the data. Studies using time series methods will compare several models, using metrics such as mean absolute percentage error, and the best-performing model is to be used to generate the forecast.

An estimation based on different regions can give a granular picture of each region. A spatial forecasting method can be applied in this case where characteristics of each forecasted area are taken into consideration [19]. Machine learning techniques such as multilayer perceptron [20], and artificial neural network [21] can be used in addressing spatiotemporal issues. However, this requires data that capture information on the patient's location as well as the time. Patients are grouped by region, and characteristics for each region may be used if multivariate models are to be developed. In addition to spatiotemporal issues, different transportation modes can also be considered to build an optimization model for estimating ambulance demand [22].

Estimating the demand for emergency services is a challenging process, particularly when aggregated data are not available. In Indonesia, studies quantifying the demand for ambulance services are scarce. Only one recent paper has attempted to quantify the demand for ED use in Jakarta, [23], using a naïve approach, complemented by regression analyses to fill in missing

data, to estimate 2 million ED visits in 2017. We build on the work of [23], with a particular focus on ambulance usage that is missing in that study. Here we differ from that paper by using simulation to estimate variance in demand as well as overall demand level and considering commuters who do not live within the Jakarta city boundaries.

In this study, we aim to estimate the demand for emergency services, including ambulance usage, by considering regional variation at the neighborhood levels within Jakarta. The study serves 2 main purposes: first, to develop a method for estimating annual emergency service usage in the absence of aggregated data, and second, to provide an estimate of the annual usage of hospital emergency services and the need for ambulance services in Jakarta. This report contributes to the existing literature on emergency medical services in low- and middle-income countries such as Indonesia.

Methods

To estimate the annual emergency service usage, we used population estimates broken down into the smallest administrative areas. The method necessitated computing (1) an estimation of population size for daytime and nighttime; (2) an estimation of the probability of emergency calls coming from each area for daytime and nighttime; (3) an estimation of the rate of ED visits per capita; and (4) an estimation of the rate ambulance needs per area in Jakarta. The details of the 4 elements needed for the estimate will be described in the relevant subsequent section.

Data Sources

The data-informing parameters used in this study came from various sources: survey data from Brice et al [16], official data obtained from the Indonesian Office for National Statistics as well as the Public Health Office reports, and data from 10 hospital EDs across Jakarta. The key survey in question, [16], collected data such as mode, time, and duration of transport to

the hospital, as well as demographic information, for 1,964 patients arriving at five major hospitals in Jakarta in December 2019. We extracted information (from the survey) on the number of patients per unit neighborhood and the methods of transportation to go to the hospitals. The Statistical Office and the Government reports provide an estimation of the characteristics of the population in the region. These include the ratio of male and female population and the population density. We used information reported for the year 2019 (before the COVID-19 pandemic) as subsequent years' data will be affected by the pandemic. Please note that mainland Jakarta is divided into 5 municipalities. Each municipality administers several districts, and each district is further divided into neighborhoods. There are 267 neighborhoods within the whole Jakarta area. We excluded 6 neighborhoods from the Thousand Island region in northern Jakarta, as data are not always available. Table S1 in Multimedia Appendix 1 summarizes the data gathered from the Indonesian Office for National Statistics and official health reports.

The survey data provide information on whether people used ambulances to go to hospitals. A total of 1964 patients were included in the survey and around 9.3% (183/1964) have used ambulances to go to the hospital's ED [16]. Table S2 in Multimedia Appendix 2 summarizes the number of ED visits from the survey when data was aggregated by neighborhoods. It shows that around 50% of neighborhoods have used at most 1 ambulance. This is significantly low compared with the number of other transportation used by the patients. We sought information on the number of ED visits in year 2019 from 10 hospitals across Jakarta. Verbal consent was sought from each ED director; however, there was no involvement with their patients or patient-level data. The data were used to estimate the rate per capita of ED used in Jakarta. A summary of this is provided in Table 1 in the parameter estimation section. The hospitals were sampled purposely to cover all the 5 municipalities in Jakarta.

Table 1. Summary of ED[a] visits from 10 hospitals across Jakarta in 2019.

Measure	Value, n
The sum of ED visits	266,931
Minimum	1,080
First quantile	12,522
Median	24,629
Third quantile	35,730
Maximum	66,899

Ethical Considerations

The aim of this secondary analysis was covered in the project, titled "Modeling Emergency Medical Services in Indonesia," approved by the ethics committee from Sumber Waras Hospital, "Rumah Sakit Sumber Waras Komite Etik Penelitian" (001//RSSW/Kom.EP/EC/XI/2019). The element of the study reported in this article used secondary data analysis and adhered

to the ethical review and approval processes as required by the Declaration of Helsinki guidelines. The original consent provided by participants included provisions for future use of their data in secondary analyses and all data used were anonymized prior to access to ensure no identifiable information was included. There was no compensation provided to participants.

Estimation Methods

The study aims to estimate the number of emergency care needs in Jakarta, hence the number of people needing ambulances. The method of estimating the annual number of ED visits using a certain transport method can be found in Boutilier and Chan [22]. However, because of data limitations, we decided to develop a Monte Carlo simulation approach instead of creating a logistic regression model. This Monte Carlo method was used to compare the results with simple naïve models. Naïve (average) models assume that the rate of ambulance use is equal across the neighborhoods, whereas the simulation model accounts for some variation in the neighborhoods. The results will be used to estimate the need for emergency care per neighborhood in Jakarta.

The lack of published hospitals' data on the number of annual ED visits required us to estimate the following: first, the population per neighborhood for daytime and nighttime. Note that daytime is defined from 6 AM to 5:59 PM, and nighttime is defined from 6 PM to 5:59 AM. This allows us to break the estimation of emergency care needs by the time of the day. Second, the probability that the emergency call happens for each period (ie, daytime or nighttime). Third, the average annual number of ED visits per capita. Fourth, the proportion of ED visits per neighborhood arriving via ambulance. We simplify the description of the estimation model, and its modification as follows:

Let $P_{i,j}$ be the population size in neighborhood i at the period of a day j; ε_j be the probability of an emergency happening at the period of a day j; λ_i be the expected annual rate of ED visits per capita in neighborhood i; and δ_i be the proportion of ED visits from neighborhood i that arrived using an ambulance.

The total expected annual number of ED visits in the whole region is the sum of expected annual ED visits in neighborhoods. Mathematically, this is written as:

Where n is the number of neighborhoods, which in our case is Jakarta (261) and j is either daytime or nighttime. The model in reference [22] was modified to include the probability of an emergency happening in each period j, here denoted as ε_j.

Parameter Estimation

Step 1: Estimating the Population of Jakarta for Daytime ($P_{i,1}$) and Nighttime ($P_{i,2}$)

The study only concerns the area of Jakarta within the mainland (ie, excluding the Thousand Island Regency). Jakarta mainland comprises 5 municipalities or cities namely North, Central, West, South, and East. Each city administered several districts, and the total number of districts is 42. Each district is divided into several neighborhoods, totaling 261 neighborhoods within Jakarta.

The Indonesian Office for National Statistics estimated the total population in Jakarta for mid-2019 to be around 10.5 million [24]. Statistics on the number of people commuting in Jakarta in 2019 were estimated in [25], which gave a net total additional population of Jakarta due to commuting is estimated to be around 1.1 million people. It also showed that the number of commuters varies for each city or municipality in Jakarta; the highest additional daytime population is in Central Jakarta (estimated to be over 524 thousand people), followed by South Jakarta (over 418 thousand people). Therefore, it follows that the total population in Jakarta for daytime and nighttime is to be estimated at around 11.6 million and 10.5 million, respectively. The nighttime estimate used the population estimate provided by the Office for National Statistics.

Step 2: Estimating the Probability of Calls for Daytime ε_1 and Nighttime ε_2

The probability of an emergency happening at period of day j (ε_j) is needed since we use the estimation in daytime and nighttime. The probability is estimated from the hospital survey data provided by Brice et al [16], which recorded the time the emergency events happened. We classify the ambulance calls into those that happened in the daytime, between 6 AM to 5:59 PM, and those that happened in the nighttime, 6 PM to 5:59 AM. These were 1228 calls and 736 calls, respectively, giving the proportion of calls happening in daytime and nighttime as 0.625 and 0.375, respectively.

Step 3: Estimating the Average Annual Rate of ED Visits Per Capita λ_i

The Public Health Office of DKI Jakarta Province reported that the number of general hospitals in Jakarta is 143 [26]. This does not account for 315 public health clinics, 47 special hospitals, or 19 maternity hospitals. At least around 86 general hospitals have ED. Sample data from 10 hospitals with EDs across Jakarta were sought during this study. The hospitals were purposely sampled to ensure representation from each of the 5 municipalities, with a diverse mix of government, Ministry of Health, defense, and private hospitals. The inclusion of at least one general hospital from each municipality was aimed at ensuring the samples were as representative as possible, allowing us to estimate demand across all EDs. Table 1 summarizes the findings on the number of total ED visits for 2019 from the participating hospitals. Multiplying the median, the first, and the third quantiles to 86 general hospitals, we arrived at a crude estimation for the total annual number of people attending the ED in Jakarta (Table 2).

To arrive at the annual rate of ED visits per capita, we simply divide the estimated total annual ED visits by the total population of Jakarta (in our case 10.5 million). The median number of annual ED visits is 2,118,051 (IQR 1,076,892-3,072,737).

It follows that the crude estimation for the median rate per capita for ED visits is 0.20 (IQR 0.1-0.3; based on a 10.5 million population size and rounded to 1 decimal point). It suggests that the total annual ED visits in Jakarta based on 2019 data is between 1 and 3 million visits. From this, we use the assumption that the rate per capita ED visit is uniform for the whole region.

Step 4: Estimating the Yearly Rate for Ambulance Needs Within Jakarta δ_i

We used the survey results of Brice et al [16] on the usage of ambulances per neighborhood. We obtained the count per neighborhood on whether people used ambulances or not to go to the hospitals. Since generally patients are independent of each other, we assumed that people who used ambulances to go to the hospitals were independent of those who used other modes of transportation. To obtain the yearly rate for ambulance need per neighborhood, we used three approaches namely a Monte Carlo simulation [27], a naïve, and a weighted naïve approach. The description of the three approaches can be found in Multimedia Appendix 3. The implementation of the Monte Carlo simulation, together with the naïve and weighted naïve

models, and the statistical analyses of the results were done in Python.

Due to the central limit theorem, the sample means for the rate of ambulance follow a normal distribution, so confidence intervals can be calculated, and parametric t tests can be performed comparing the distribution obtained from the Monte Carlo simulation to the naïve and weighted naïve estimated. At the aggregated level, the average sample mean for the rate of using an ambulance was 0.07406 (95% CI 0.07388-0.07424). This is significantly different ($P<.001$ when performing a one-sample t test) from both the naïve and weighted naïve estimates, showing that the simulation methodology produces a different estimate from the naïve approaches. Figure 1 illustrates the distribution of the sample means for the rate of ambulance needs.

Figure 1. Distribution of the mean rate for ambulance use from simulation results compared with naïve and weighted naïve estimates.
Results

Table 2 displays the results from applying naïve, weighted naïve, and Monte Carlo simulation models using different per capita rates of annual ED visits. We calculated the annual ambulance needs for each neighborhood and aggregated the results to give the estimate for the entire region. The computation for the nighttime and the daytime was based on the assumption that

the proportions of patients attending the ED during daytime and nighttime are 62.5% and 37.5%, respectively [16].

The results indicate that the annual number of people using ambulances is between around 82,000 and 241,000. Assuming that only 9.3% of people who came to the hospital ED have used an ambulance, we can estimate the total annual ED attendance to be between 0.9 and 2.6 million.

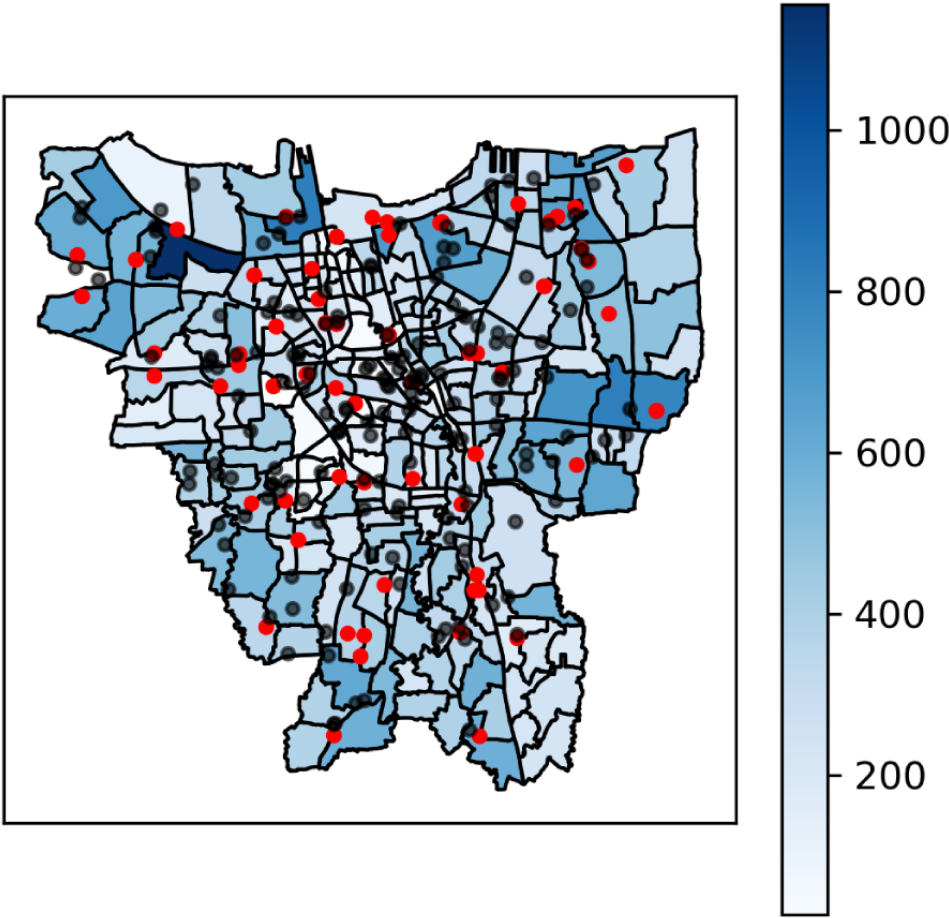
[a]ED: emergency department.

Figure 2 depicts the distribution of annual ambulance needs estimated from simulation results across the city of Jakarta. The red dots represent the geographic locations of the ambulance posts. The black dots represent the geographical location of hospitals. The vast majority of neighborhoods have no ambulance. While in a small number of neighborhoods, ambulance posts can be quite close to one another. The total number of hospitals captured is 168 with varying classifications including general and specialist hospitals, belonging to the government as well as privately funded. Hospitals with EDs are mainly located around the central region of Jakarta.

Figure 2. Distribution for annual ambulance demand and location for ambulance posts (red) and hospitals (black).


Discussion

Principal Findings

The current study estimated the annual demand for emergency services in Jakarta to be between 0.9 and 2.6 million and for ambulance services to be between 83,000 and 241,000. The estimation derived through the simulation method proved to be slightly higher than the results obtained from using the conventional averaging methods (*P*<.001). This variation could be attributed to the fact that average or naïve methods, by definition, may be affected by exceptionally small or large values within the data. Moreover, the naïve methods assumed that the rate of demand for emergency services was the same across the entire city of Jakarta, irrespective of variations in population characteristics within its neighborhoods, whereas the simulation method generated random sampling depending on the distribution of the sample values. Hence, the resultant estimates varied from one neighborhood to another. Considering the small differences in the results, the use of average models remains reasonable in this case for two reasons. First, the neighborhoods in Jakarta exhibit similar population characteristics and the Office for National Statistics in Jakarta only produces reports at aggregate levels (municipalities). Second, while patients' characteristics and medical conditions may affect the increased usage of emergency services, regional differences such as density do not [28].

The estimated demand of 2.6 million annual ED visits was based on 2019 data. A previous attempt used a survey method to estimate 2 million ED visits in Jakarta for 2017 [23], and we now estimate a higher level of demand. This could be for two reasons: first, an increase in the population of Jakarta, including an aging population [29], would result in higher demand compared with 2017; and second, our study considers daytime commuters that contribute to the demand, where the previous study does not. Like any estimation study, it cannot provide an exact measure of demand. Indeed, the true demand for health care services can never be known, even with routine data collection. Nevertheless, our study suggests two key points: first, there is a pressing need for the Indonesian government, particularly the local government in Jakarta, to collect regional and national data on emergency services usage. These data can be instrumental in studying the capacity and demand for comprehensive emergency medical services including prehospital, hospital, and ambulance services, as many capacity and planning models on the operational and strategic levels require detailed demand and variation data, while tactical planning requires a good estimate of current demand to efficiently and effectively plan for the future. Ensuring well-structured and adequately supported emergency medical services at all levels, from community to national, is essential for efficiently serving the Indonesian population [30]. Second, the study's estimated demand volume suggests a significant need for ambulance services. While government-owned ambulances in Jakarta are provided to the population free of charge, a study revealed that less than 10% of individuals seeking hospital emergency care arrived via ambulance [16]. This warrants an investigation into whether the existing ambulance capacity is sufficient to meet the needs of Jakarta's population, which exceeds 11 million people.

Comparison With Prior Work

Our study provided the first estimate of emergency services usage in Jakarta using the population estimation method considering spatial and time variation. It followed the method used by Boutilier and Chan [22] with a modification. Our formulation included the probability of emergency events happening in the nighttime and daytime. In addition, we used a Monte Carlo simulation due to limited data instead of logistic regression. When data are sufficiently large and combined with multiple variables, a machine-learning technique can be developed as implemented in Boutilier and Chan [22].

The accuracy of the simulation results depends on the underlying distribution used to generate the samples. Our samples, on the emergency medical services used, came from a cross-sectional study [16] that surveyed the usage of EMS in one month. Due to a lack of aggregated data on the use of EMS in Jakarta, the results from the current study cannot be validated.

In the absence of routinely collected data, the current study used various data sources in conjunction with survey data to parameterize the models. Previous research on health care services demand has adopted diverse methodologies to generate more precise estimations. For example, in the palliative care demand, routinely collected data can be used in an estimation model to include deaths as well as the prevalence of the disease [31]. Simple linear projection modeling can be used, complementing expert opinions and online census data [32] to project health care needs. By combining different data sources, such as hospital and census data, more detailed results can be achieved. The analyses can include the regional variation in the risk of emergency related to patients' characteristics such as age, sex, comorbidities, and socioeconomics (see an example in [33]). In Jakarta, a survey method involving many hospital EDs was used to estimate annual ED visits [23].

Limitations

Finally, the study has limitations, as mentioned above, primarily related to the absence of the routinely collected aggregated data. Other limitations are related to the construction of the model. The model did not incorporate the different transportation modes used by patients when attending the hospital EDs. Future studies could consider incorporating these modes to obtain different estimations based on transportation types. Furthermore, combining the survey data and the hospital data could be explored to investigate whether patients' choice of transportation during emergencies affects patient outcomes.

Conclusions

In this paper, we used Monte Carlo Simulation methods to estimate the annual demand for EDs and ambulance usage needed for the city of Jakarta, by extrapolating and sampling from survey data, and considering commuter behaviors that affect the daytime-nighttime population cycle of the city. This methodology includes getting an estimate of the distribution of the demand, and therefore its variability, which can be useful in downstream capacity and planning modeling. We compared

the results obtained with a naïve forecasting approach. The demand estimation is evaluated on different metrics and levels of detail and provides a breakdown into the smallest administrative areas (neighborhoods). Considering the limited resources of ambulances and the absence of routinely collected data on EMS usage in Jakarta, the results can be used to investigate further whether the current emergency services, such as ambulances, have been equally and adequately provided.

Abstract

Background: Gaming has become an integrated part of life for children and adults worldwide. Previous studies on the impact of gaming on biochemical parameters have primarily addressed the acute effects of gaming. The literature is limited, and the study designs are very diverse. The parameters that have been investigated most thoroughly are blood glucose and cortisol.

Objective: This exploratory study is the first to investigate the effects of long gaming sessions on the biochemical parameters of healthy male adults. The extensive testing allowed us to observe short-term changes (within 6 hours), long-term changes during the duration of the gaming sessions, and follow-up after 1 week to determine whether any changes were longer lasting.

Methods: In total, 9 experienced gamers completed 2 back-to-back 18-hour gaming sessions interspersed with a 6-hour rest period. All participants adhered to a structured sleep pattern due to daytime employment or attending university. Blood, saliva, and urine samples were collected from the participants every 6 hours. Linear mixed-effect models were used to analyze the repeated-measures data accumulated during the study. A total of 51 biochemical parameters were investigated.

Results: In total, 12 of the 51 biochemical parameters significantly changed during the study: alkaline phosphatase, aspartate aminotransferase, bilirubin, chloride, creatinine, glucose, hemoglobin, immature reticulocyte fraction, lactate, methemoglobin, sodium, and thrombocytes. All changes were within the normal range. The mean glucose level of the participants was 4.39 (SD 0.07) mmol/L at baseline, which increased significantly by 0.24 (SD 0.07) mmol/L per 6 hours during the first period and by 0.38 (SD 0.07) mmol/L per 6 hours in the second period ($P<.001$). The glucose levels during the second session increased even though the participants had little energy intake. Cortisol levels did not change significantly, although the cortisol pattern deviated from the typical circadian rhythm. During both gaming sessions, we observed increasing cortisol levels from 6 AM until noon. The participants were relatively dehydrated at the start of the study. The patients were asked to fast before the first blood sampling. Within the first 6 hours of the study, the participants rehydrated, followed by relative dehydration during the remainder of the study. This pattern was identified using the following parameters: albumin, creatinine, hemoglobin, erythrocytes, potassium, and platelets.

Conclusions: This study is the first of its kind, and many of the analyses in the study yielded novel results. The study was designed to emulate the behavior of gamers during the weekend and other long gaming sessions. At this point, we are not able to determine the difference between the effects of gaming and behavior during gaming. Regardless, the results of this study suggest that healthy gamers can partake in long gaming sessions, with ample amounts of unhealthy foods and little rest, without acute impacts on health.

Introduction

Video games have become a favorite pastime among children and adolescents. In the United States, 99% and 94% of boys and girls, respectively, play video games [1]. Video games are part of a larger category of sedentary activities linked to health issues such as physical inactivity, overeating, obesity, and diabetes [2-6]. Collegiate-level gamers have a comparable BMI to their nongaming peers but are less active with a higher body fat percentage, lower lean body mass, and lower bone mineral content [7]. This is particularly troublesome because studies report that children spend as much as 7-11 hours daily engaged in screen-based activities after school [8]. In addition, gaming has been linked to overeating and overconsumption of soft drinks as well as adverse health behaviors [9-12]. In a recent review, the authors found that while gaming may increase energy expenditure above baseline levels, gaming does not constitute physical activity. Energy expenditure may increase, but the activity level is comparable to that of standing or walking [13].

Previously published data from this study showed that the participants ingested an excessive number of calories from both food and drink [14]. During the study, the participants ingested an average of 6160 kcal from food and 1844 kcal from liquid sources. Additionally, the participants consumed 1354 mg of caffeine on average during the same period [14].

Previous studies of the impact of gaming on biochemical parameters have primarily addressed the acute effects of gaming. The literature is limited, and the study designs are very diverse. The parameters that have been investigated most thoroughly are blood glucose and cortisol. For blood glucose levels, gaming does not appear to increase glucose levels within the first 20 minutes of a gaming session [15,16]. Chaput et al [15] reported that gaming increased blood glucose levels after 40 minutes of a 60-minute gaming session.

Cortisol has been used as a marker of both physiological and mental stress during gaming [17-19]. Gaming may affect cortisol levels, but the nature of this relationship has yet to be elucidated. Oxford et al [17] reported that cortisol levels increase acutely when gamers compete against friends. The authors suggested that this was typical of male-male competition behavior [17].

While biochemical markers such as blood glucose and cortisol levels have been investigated during the last 2 decades, many biochemical markers pertaining to acute changes in the health of the human body have yet to be investigated. In this study, we aimed to investigate a broad array of biochemical markers to assess homeostasis, lipid metabolism, internal organ function, hematological balance, acid-base balance, and blood gases during long gaming sessions. This is the first time that most of the included parameters (except for glucose and cortisol) were investigated in gamers and during long gaming sessions. As

such, we did not know what to expect over the course of the study.

According to a recent literature review, knowledge of the effects of long video gaming sessions is minimal [13]. This exploratory study is the first of its kind in gaming. This is true for both the length of the gaming sessions, the physical setup, and the extensive testing.

A limitation of this study was the relatively small number of participants. This study was designed to realistically emulate the gaming behavior of young adults in a controlled setting in a hospital dining hall and an adjourning meeting room. The study was conducted as a local area network party for practical reasons. Four laboratory technicians worked at all times to sample, prepare, and analyze blood samples. A doctor and 2 investigators were also present throughout the gaming sessions. We tried to overcome the artificial situation of the event by discussing the setup with the participants before the study to create the most real-life–like experience (video clip [20]). The participants were asked to consume food and drink according to their wishes and what they would habitually consume [14]. The extensive testing in the study allowed us to observe short-term changes (within 6 hours), long-term changes during the duration of the gaming sessions, and follow-up after 1 week to determine whether any changes were longer lasting. The aim of this study was to investigate the effects of long gaming sessions on the biochemical parameters of healthy male adults.

Methods

Participants and Intervention

We have previously presented how the study was conducted and the physiological response to long gaming sessions [14]. In this paper, the results of an extensive collection of biochemical data are presented. We have adhered to the CONSORT (Consolidated Standards of Reporting Trials) statement regarding pilot and feasibility trials [21]. A CONSORT checklist can be found in Multimedia Appendix 1.

In brief, 9 healthy male participants older than 18 years of age with vast gaming experience were enrolled. The mean age of the participants was 25.8 (SD 2.6) years, and the mean BMI was 24.8 (SD 2.9) years. All participants were either full-time students or employees [14]. According to the protocol (EudraCT 2019-004091-19), the plan was to enroll 6-9 gamers, with at least 6 gamers engaging in gaming for 48 hours. Participants were enrolled after they had called for participants from local e-sports clubs through e-sports instructors, online message boards, and word of mouth. The participants were recruited into 2 teams of 4 and 5 members.

The intervention consisted of two 18-hour gaming sessions interspersed with a 6-hour break. During the break, the participants had approximately 4 hours of sleep. After the last

XSL•FO

RenderX

gaming period, all participants underwent both physiological and biochemical tests.

Throughout the intervention, the participants had ad libitum access to food and drink. Before the study, participants provided lists of their preferred snacks and drinks. An assortment of chips, candies, cookies, buns, cold cuts, cereal, and fruit was available throughout the study. Additionally, an evening meal was provided at 6 PM during both gaming sessions: pizza on the first evening and hamburgers on the second evening. Participants had access to tap water, soda, energy drinks, coffee, milk, and chocolate milk.

The participants were instructed to avoid strenuous physical labor, cardiovascular exercise, alcohol, and junk food for 7 days before the study. Additionally, on the day of the study, the participants were instructed to stop food intake at noon and only drink water in case of thirst.

During the study, the participants were not restricted in any way regarding gaming. Specifically, all types of games across all genres and platforms were allowed. One participant brought his PlayStation, and as a new soccer game had just been released, participants played matches in teams or head-to-head. At other times, the participants played alone in certain games or played on the web with and against players who were not participants in the study. Especially during the last 18 hours of the study, the participants played first-person shooter games against each other on teams.

Participant Involvement

After the protocol was approved by the local ethics committee in February 2018, in total, 2 meetings were held with potential participants and local e-sports instructors, discussing the content of the protocol. In particular, food monitoring and blood sampling methods were changed in accordance with the wishes of the participants.

The participants suggested a "food diary" to monitor their caloric intake. This suggestion was incorporated into the protocol. First, it was suggested by the research team that a venous catheter be inserted for blood sampling throughout the study. Instead, the participants opted for multiple venipunctures. The changes suggested at the meetings were approved by the local ethics committee in an amendment before the study started.

Ethical Considerations

The North Denmark Region Committee approved the study protocol on Health Research Ethics (N-20180011; EudraCT 2019-004091). Each participant provided informed consent in writing twice, 2 weeks prior to the study and again on the day of the study. The study used a standardized consent form that stated that participation was voluntary and that participants could withdraw from the study at any time without reason or consequence. Primary consent was obtained after approval for the secondary analysis. The data were deidentified. Except for travel expenses, participants were not compensated for their participation.

Blood Sampling and Processing

When the participants arrived at the laboratory, baseline samples were collected, including a venous blood sample, a urine sample, and a saliva swab. Blood, urine, and saliva were collected from the participants every 6 hours. After the blood was drawn by venous puncture, it was taken to the laboratory. Biochemical analyses were performed immediately using an ABL800 FLEX Blood Gas Analyzer (Radiometer); other samples were centrifuged (at 3000 rpm/1875×*g* for 10 minutes), and the plasma was frozen at –80 °C for later analysis. Blood samples were analyzed using a Cobas 8000 Modular Analyzer (Roche Applied Science) and a Sysmex XN-9000 Hematology Analyzer (Sysmex Europe, GmbH). In total, 18 parameters were analyzed on the Cobas 8000 (1 parameter is only presented in Multimedia Appendices 2 and 3), 22 parameters were analyzed on the Sysmex XN-9000 (16 parameters are only presented in Multimedia Appendices 2 and 3), and 18 parameters were analyzed using the ABL800 (11 parameters are only presented in Multimedia Appendices 2 and 3). An overview of the analyses by apparatus can be found in Multimedia Appendix 2. The complete summary of the results is provided in Multimedia Appendix 3. A total of 8 parameters were analyzed twice between the 3 machines (calcium [Ca], glucose, lactate, potassium [K], sodium [Na], bilirubin, creatinine, and hemoglobin [Hb]). All the tests were performed in accordance with the manufacturer's instructions in a nationally accredited biochemistry laboratory (Department of Clinical Biochemistry, Aalborg University Hospital).

The following 30 parameters were measured and are presented in the Results section: glucose (mmol/L), lactate (mmol/L), cortisol (nmol/L), Ca (mmol/L), albumin-corrected calcium (mmol/L), K (mmol/L), Na (mmol/L), and chloride (Cl, mmol/L) were measured to assess homeostasis. Low-density lipoprotein (LDL) cholesterol (mmol/L), high-density lipoprotein cholesterol (mmol/L), total cholesterol (mmol/L), and triglyceride (TG, mmol/L) levels were measured to assess lipid metabolism. Alanine aminotransferase (ALT, U/L), albumin (g/L), alkaline phosphatase (ALP, U/L), bilirubin (μmol/L), creatinine (μmol/L), C-reactive protein (CRP, mg/L), and ferritin (μg/L) were measured to assess organ-specific markers. sO_2 (%), pCO_2 (kPa), pO_2 (kPa), pH, and standard bicarbonate concentration (mmol/L) were measured to assess acid-base balance and blood gases. Erythrocytes (10^{12}/L), erythrocyte volume fraction (EVF), Hb (mmol/L), mean cell Hb (10^{-15}, SE 0.0018 mol), mean cell volume (10^{-15}/L, SE 0.088/L), and platelets (10^9/L) were measured to assess the hematological markers.

Statistical Analyses

Linear mixed-effects models were used to analyze participants' absolute changes in biochemical parameters throughout the study. This modeling method is a standard extension of linear regression models that controls for the random effects introduced by having paired data and is often used when analyzing studies with repeated measurements. We performed separate univariate analyses for each change in each biochemical parameter; time was the fixed effect, and participants were the random effect.

Additionally, we included an interaction term between time and period. This gave separate results for the first and second gaming periods.

We used a likelihood ratio test to test the statistical significance of the linear mixed effects models compared to a basic model, which included only random effects and thereby assumed no development over time. In total, 51 markers were analyzed (58 markers in total and 7 duplicates), and Bonferroni correction was applied by multiplying α (originally .05) by the number of tests. Statistical significance was set at α=.05 before Bonferroni correction [22]. The assumptions of linear mixed-effects models were tested and fulfilled in all the analyses. Linearity and homoscedasticity were assessed by inspecting residual plots. The normality of the residuals was assessed by inspecting histograms and quantile-quantile plots. Given that this was an exploratory study, outliers were not removed. Due to the sample size and number of tests, we did not perform post hoc tests comparing the data at individual time points.

Graphs illustrating changes over time were made for all variables, consisting of average values among participants for each sampling point, together with SEs presented as error bars from the mean. In addition, selected graphs were included to illustrate developments over time for specific parameters (Figures 1-4) that were not necessarily reflected in the linear mixed-effects models.

One participant's LDL cholesterol level decreased 3-fold below the minimum measuring range. The missing values were substituted by using the previous lowest value of the participant [23]. All the statistical analyses were performed using Microsoft Excel 2013 (Microsoft Corp) and RStudio (version 1.1.383; Posit, PBC). Linear mixed-effects models were generated using the *lme4* package [24].

Results

Overview

The linear mixed-effects models produced results with a mean baseline value at the start of the study and coefficients of change for the first and second gaming periods. Several parameters, such as albumin, Hb, EVF, and the platelet count, exhibited a pattern of high initial values, followed by a decrease after 6 hours and a continuous increase during the rest of the gaming period (Figure 1). The complete list of results of all analyses is available in Multimedia Appendix 3.

Homeostasis

The mean glucose level of the participants was 4.39 (SD 0.07) mmol/L at baseline, which increased significantly by 0.24 (SD 0.07) mmol/L per 6 hours during the first period and by 0.38 (SD 0.07) mmol/L per 6 hours in the second period (Figure 2). The mean Na level was 141.9 (SE 0.12) mmol/L at baseline and decreased by 0.31 (SD 0.1) mmol/L per 6 hours during the second period. There were no changes during the first period. The mean Cl level was 105.9 (SE 0.14) mmol/L at baseline and decreased significantly by 0.54 (SD 0.14) mmol/L per 6 hours during the second period, and there were no significant changes during the first period. Lactate, Ca, K, and albumin-corrected calcium levels did not significantly change during the study. Cortisol levels also did not change significantly. However, cortisol levels appeared to be affected by long gaming sessions and a lack of rest during the study. A deviation from this pattern is usually associated with daily fluctuations in cortisol levels (Figure 3). During a normal cortisol rhythm, cortisol levels are

at their lowest level at midnight before increasing to their peak value at 6 AM, followed by a steady decline toward midnight.

Lipid Metabolism

Total cholesterol, LDL, high-density lipoprotein, and TG did not significantly change during the study. However, the TG levels during the study showed a distinct pattern: TG levels increased after evening meals but returned to baseline after 6 hours (Figure 4).

Organ-Specific Markers

The mean ALP level was 77.2 (SE 0.63) U/L at baseline and increased during the second period by 3.8 (SD 0.63) U/L per 6 hours. There was no significant change during the first period. The mean bilirubin level was 9.9 (SE 0.22) μmol/L at baseline, decreased by 1.15 (SD 0.22) μmol/L per 6 hours during the first period and decreased by 1.05 (SD 0.22) μmol/L per 6 hours during the second period. The mean creatinine level was 93.6 (0.56) μmol/L at baseline, decreased by 2.9 (SD 0.56) μmol/L every 6 hours during the first period and decreased by 1.15 (SD 0.56) μmol/L every 6 hours during the second period. Albumin, CRP, ferritin, and ALT did not significantly change during the gaming sessions.

Acid-Base Balance and Blood Gases

sO_2, pCO_2, pO_2, pH, and standard bicarbonate concentration did not significantly change during the study.

Hematology

The mean Hb level was 9.18 (SE 0.025) mmol/L at baseline, and it decreased by 0.055 (SD 0.025) mmol/L every 6 hours during the first period. However, during the second period, Hb

increased by 0.027 (SD 0.025) mmol/L per 6 hours. The mean platelet count was $258×10^9$/L (SE $1.1×10^9$/L) at baseline and increased by $6.9×10^9$/L (SD $1.1×10^9$/L) per 6 hours during the second period. During the first session, there were no significant changes. Erythrocytes, EVF, mean cell Hb, and mean cell volume did not significantly change during the study.

Discussion

Principal Findings

This study is the first of its kind regarding the design and number of biochemical analyses in the gaming population. The fact that the study stretches over 42 hours of continuous measurements makes it unique compared to the current literature on gaming science. The study applies to recreational gamers who play with various levels of seriousness but lack a singular focus on the competition associated with e-sports. Overall, the effect of gaming on standard biochemical parameters in healthy male adults is limited. Significant changes were found in 12 of the 51 parameters. Most of the results of biochemical tests are novel findings in a gamer population [13]. It is not surprising that most parameters were unaffected by the intervention, but the high number of examined parameters added to our understanding of the effects of gaming. The participants had a large intake of calories throughout the gaming sessions (especially during the first gaming sessions) [14]. We found small changes in the levels of several biochemical and hematological biomarkers, but all the levels were within the normal range. Overall, the results of this exploratory study suggest that, from a biochemical and hematological standpoint, the health of male adults is not altered in the short term by long gaming sessions.

Dehydration

The development of several parameters, including albumin, ALP, creatinine, Ca, ferritin, Hb, erythrocytes, EVF, K, and platelets, over time suggested that the participants were relatively dehydrated at the start of the study and rehydrated within the first 6 hours, followed by relative dehydration during the remainder of the study (Figure 1). Dehydration, despite a 3-L fluid intake per 18-hour gaming session, was most likely aided by the participants' caffeine intake, as a large intake of caffeine during nonstrenuous activities can cause increased diuresis [25].

Homeostasis

Blood glucose levels increased consistently during each of the gaming sessions (Figure 2). This development agrees with the findings of Chaput et al [15], but the changes in this study occurred over a much longer period. The changes in blood glucose levels cannot be attributed to dehydration, as this pathway is under tight hormonal control [26]. The glucose levels during the second session increased even though the participants had little energy intake. This could be due to the unexpectedly high levels of cortisol present at the same time (Figure 3), triggering the release of glucose from body stores. The glucose levels never exceeded the normal range and returned to baseline levels 1 week after the second long gaming session. Short- and long-term changes in blood glucose levels in gamers who

regularly participate in long gaming sessions need further investigation.

The development of cortisol during the study differed from what would be expected (Figure 3). Cortisol is typically at its lowest level at midnight and increases sharply at 6 AM to reach a maximum between 6 and 10 AM, after which a sharp decline is expected [27]. The continued increase at noon during both sessions is surprising. Typically, the cortisol concentration decreases throughout the day and evening, reaching its nadir at midnight. The participants slept between noon (after the first session) and 6 PM. The 6 PM cortisol value could have been influenced by the waking cortisol response, which is related to the circadian rhythm [28]. Multiple factors potentially contribute to the disruption of the regular cortisol rhythm. Going into the study, the participants all adhered to a structured sleep pattern due to daytime employment or attending university classes. During both gaming sessions, we observed a rise in cortisol levels from 6 AM until noon. Gaming could be the cause of this change, as the level of alertness (or "stress") in gaming potentially requires the continuous activity of the hypothalamic-pituitary-adrenal axis [28,29]. An increase in cortisol based on light intensity has been described, and light from monitors could be a factor in the changes observed [30]. Nightshift workers who are habitually awake during the night exhibit markedly lower morning cortisol levels [31]. The sharp decrease in cortisol levels at midnight (both nights) indicated that the regular diurnal slope was not completely changed by the weekend during extreme gaming.

Lipid Metabolism

Gaming and sedentary behavior have been associated with obesity and increased cholesterol and TG levels [4], as they displace other nonsedentary activities [32]. Based on standard biochemistry, cholesterol and TG were unaffected by long gaming sessions and unrestricted food intake. However, TG levels sharply increased after mealtimes, which were normalized 6-12 hours after each meal. This increase was much greater than usual [33,34]. The sharp increase in TG was most likely the result of the high fat content of the ingested foods [14].

Organ-Specific Markers

Overall, this study does not indicate that long gaming sessions impact the kidneys or livers of gamers. Creatinine levels decreased slightly during the study, possibly because of reduced physical activity. A decrease in creatinine at this level is not known to influence health.

Bilirubin and ALP levels decreased significantly during the study. This decrease, while significant, is not associated with any known pathophysiology.

Additionally, the large amounts of caffeine ingested may have lowered the bilirubin levels [35]. In experimental models, caffeine has been shown to have antifibrogenic, anti-inflammatory, and antioxidant effects that potentially exert liver protection [36-39].

We expected an increase in ALT based on food consumption during the study [40]. Likewise, we suspected that the inflammatory parameters would change due to the large intake

of unhealthy food and drinks. As CRP, ferritin, and ALT are sensitive to changes in behavior (strenuous exercise, alcohol consumption, and excessive food intake), their lack of change during the study indicates a minor or no impact of gaming behavior.

Acid-Base Balance and Blood Gases

Our results showed that gaming did not affect the pH balance or its regulatory systems. Furthermore, the pO_2 in the venous blood did not significantly change throughout the trial. This finding agrees with the literature suggesting that sedentary gaming is not physically demanding [13].

Hematology

Hematological parameters have not previously been examined in gamers during long gaming sessions. The Hb concentration decreased significantly during the first 18 hours of gaming and increased during the second 18-hour session. These changes are in accordance with the changes in hydration status outlined earlier. Thrombocyte counts increased throughout the study, especially in the second 18-hour session. Despite the significant changes, the parameters were always within the normal range. Overall, this exploratory study does not suggest a need for further investigation into the association between hematological parameters and gaming.

Strengths and Limitations

The participants were all male individuals in their 20s, and there were only 9 participants. Based on these results, it is not possible to determine whether gaming has a different or even harmful effect on children, adolescents, or female individuals. The study was conducted in a hospital and not in the familiar environments of the participants. This may have caused participants to alter their behavior in ways we cannot determine. The easy availability of food and snacks may not relate entirely to how long gaming sessions are conducted at home or at local area network parties. We cannot rule out the possibility that overeating occurred, but the available food and drinks were only present at the behest of the participants. During the first 6-12 hours of the study, overeating was perhaps a factor, but during the second session, the participants had a markedly lower intake of calories from both food and drinks [14]. On the basis of this study, we are not able to determine whether the excessive intake of calories was due to convenience or to sustain a high level of performance during strenuous gaming.

Conclusions

This study is the first of its kind, and many of the analyses in the study yielded novel results. The study was designed to emulate the behavior of gamers during the weekend and other long gaming sessions. At this point, we are not able to determine the difference between the effects of gaming and behavior during gaming. Regardless, the results of this study suggest that healthy gamers can partake in long gaming sessions, with ample amounts of unhealthy foods and little rest, without acute impacts on health.

Data Availability

Data from this study are not available in a public repository. It can be requested from the corresponding author. The study garnered national media attention in Denmark when it was conducted, and several participants were interviewed through radio and television. The data included physical characteristics, employment status, and other personal information. Due to the low number of participants, it would potentially be possible to identify individual participants' data.

Conflicts of Interest

None declared.

Abstract

Background: Physical activity is well known to have beneficial effects on glycemic control and to reduce risk factors for cardiovascular disease in persons with type 2 diabetes. Yet, successful implementation of lifestyle interventions targeting physical activity in primary care has shown to be difficult. Smartphone apps may provide useful tools to support physical activity. The DiaCert app was specifically designed for integration into primary care and is an automated mobile health (mHealth) solution promoting daily walking.

Objective: This study aimed to investigate the effect of a 3-month-long intervention promoting physical activity through the use of the DiaCert app among persons with type 2 diabetes in Sweden. Our primary objective was to assess the effect on moderate to vigorous physical activity (MVPA) at 3 months of follow-up. Our secondary objective was to assess the effect on MVPA at 6 months of follow-up and on BMI, waist circumference, hemoglobin A_{1c}, blood lipids, and blood pressure at 3 and 6 months of follow-up.

Methods: We recruited men and women with type 2 diabetes from 5 primary health care centers and 1 specialized center. Participants were randomized 1:1 to the intervention or control group. The intervention group was administered standard care and access to the DiaCert app at baseline and 3 months onward. The control group received standard care only. Outcomes of objectively measured physical activity using accelerometers, BMI, waist circumference, biomarkers, and blood pressure were assessed at baseline and follow-ups. Linear mixed models were used to assess differences in outcomes between the groups.

Results: A total of 181 study participants, 65.7% (119/181) men and 34.3% (62/181) women, were recruited into the study and randomized to the intervention (n=93) or control group (n=88). The participants' mean age and BMI were 60.0 (SD 11.4) years and 30.4 (SD 5.3) kg/m^2, respectively. We found no significant effect of the intervention (group by time interaction) on MVPA at either the 3-month (β=1.51, 95% CI –5.53 to 8.55) or the 6-month (β=–3.53, 95% CI –10.97 to 3.92) follow-up. We found no effect on any of the secondary outcomes at follow-ups, except for a significant effect on BMI at 6 months (β=0.52, 95% CI 0.20 to 0.84). However, mean BMI did not differ between the groups at the 6-month follow-up.

Conclusions: We found no evidence that persons with type 2 diabetes being randomized to use an app promoting daily walking increased their levels of MVPA at 3 or 6 months' follow-up compared with controls receiving standard care. The effect of the

app on BMI was unclear, and we found nothing to support an effect on secondary outcomes. Further research is needed to determine what type of mHealth intervention could be effective to increase physical activity among persons with type 2 diabetes.

Introduction

Despite increased knowledge and public health initiatives, more than 460 million people, corresponding to over 6% of the world's population, are estimated to be diagnosed with type 2 diabetes today [1]. Persons with type 2 diabetes followed in primary care can be prescribed lifestyle interventions in combination with medications. Lifestyle interventions may include weight management, smoking cessation, stress reduction, and improved dietary habits or physical activity [2]. Physical activity is well known to have beneficial effects on glycemic control and to reduce risk factors for cardiovascular disease [3]. Yet, it has proven difficult to implement lifestyle interventions targeting physical activity in primary care [4]. Nevertheless, walking has been put forward as a useful therapeutic tool shown to improve glucose control, with clinically beneficial effects on blood glucose levels over time, and the potential to improve other clinical variables such as BMI and blood pressure in persons with type 2 diabetes [5].

During the past few decades, various telemonitoring, eHealth, and mobile health (mHealth) solutions targeting physical activity have been developed. Such solutions offer adaptable platforms for the delivery of self-management interventions that are easily accessible to both patients and health care practitioners, and users can engage with health information technology at their convenience. Smartphone apps may be useful in a health care setting to provide an additional tool to increase patients' engagement through the use of self-monitoring of, for example, physical activity between routine visits [6].

Today, there are many commercially developed and available smartphone apps targeting self-management of chronic conditions. Common features of available apps targeted toward persons with type 2 diabetes include self-tracking of blood glucose levels and components targeting physical activity or diet in different ways [7,8]. Nevertheless, there is a wide variety in type and number of features for diabetes management in available apps [7], making it difficult for patients to select the most appropriate one to use. There are many commercial apps targeting lifestyle among persons with type 2 diabetes; however, few solutions primarily target physical activity within this group, and even fewer have been developed specifically for implementation in primary care. Therefore, we developed a digital platform and a smartphone app specifically for targeting physical activity among persons with type 2 diabetes treated within primary care [9]. The app was built to be integrated into the existing digital infrastructure of primary care in Sweden, with the aim to provide care givers and patients with a scientifically evaluated self-care management tool.

Results from studies evaluating the effectiveness of mHealth solutions, including smartphone apps, targeting persons with type 2 diabetes, have been summarized previously [10-15]. Significant reductions in hemoglobin A_{1c} (HbA_{1c}) levels are generally shown after 3 months of follow-up. Most of the evaluated apps allowed the user to monitor their blood glucose levels and included physical activity or diet, either alone or in combination, as additional features. mHealth interventions targeting physical activity in adults in the general population have been shown to increase both minutes of physical activity and steps per day [16-18]. Nevertheless, apps primarily targeting physical activity, without including a component of glucose monitoring, in persons with type 2 diabetes are relatively uncommon. Poppe et al [19] evaluated a self-regulation–based eHealth and mHealth intervention primarily targeting physical activity in persons with type 2 diabetes and found positive results of the intervention on increased activity and decreased sedentary behavior, whereas Thorsen et al [20] found no effect of app-based interval walking on MVPA over 52 weeks compared with standard care. In summary, there is still a need to develop interventions targeting physical activity that are effective and can be implemented into primary care.

The aim of this study was to evaluate the effects of the DiaCert smartphone app promoting daily walking on moderate to vigorous physical activity (MVPA) and clinical variables in persons with type 2 diabetes. Our primary aim was to test the hypothesis that the app would lead to an increase in minutes of MVPA at 3 months compared with standard care only. Our secondary aim was to assess the effect of the app on MVPA after 6 months and on the clinical variables BMI, waist circumference, HbA_{1c}, cholesterol (total, low-density lipoprotein [LDL], and high-density lipoprotein [HDL]), triglycerides, and systolic and diastolic blood pressure at 3 and 6 months. We hypothesized that the app would lead to improvements in both MVPA and clinical variables.

Methods

Trial Design

We conducted a randomized controlled trial with 2 parallel groups between February 2017 and June 2019. The DiaCert study design [21] has been described in detail previously. Study participants were randomized 1:1 to the intervention or control group at baseline. The primary study outcome was MVPA (minutes/day) at 3 months of follow-up. Secondary outcomes included MVPA at 6 months of follow-up and the clinical variables BMI, waist circumference, HbA_{1c}, cholesterol (total, LDL, and HDL), triglycerides, and systolic and diastolic blood pressure at 3 and 6 months of follow-up. No changes to methods

were done after trial commencement. The study is reported according to the CONSORT (Consolidated Standards of Reporting Trials) statement [22] and the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile HEalth Applications and onLine TeleHealth) checklist, which is developed for eHealth or mHealth interventions [23].

Ethical Considerations

The trial was approved by the ethics committee of the regional ethical review board in Stockholm, Sweden (Dnr: 2016/2041-31/2, 2016/99-32, 2017/1406-32) and registered at ClinicalTrials.gov (NCT03053336). All participants received both oral and written information about the study and provided their written informed consent to participate. Participants received no compensation for participation in the study. After data collection, data were anonymized.

Study Participants

The inclusion criteria were (1) having a diagnosis of type 2 diabetes, (2) being 18 years of age or older, (3) being able to communicate in Swedish, and (4) having access to and being able to use a smartphone. The exclusion criterion was not being able to walk.

Patients were recruited continuously from 5 primary health care centers and 1 specialized medical center in the Stockholm area, Sweden. Patients at the participating centers received initial information about the study from their physician or diabetes nurse, and those interested in participating were contacted by study personnel and given more detailed information. Thereafter, patients either agreed to participate and were scheduled for a baseline introductory meeting, or declined participation. We did not record the number of patients who did not agree to participate. All study participants met with study personnel at baseline and after 3 and 6 months. On each occasion, study outcomes including physical activity and other lifestyle factors, as well as clinical variables, were assessed.

Interventions

Study participants randomized to the intervention group continued to receive standard care as usual but also downloaded the DiaCert app during the baseline meeting. To access the individual user account in the app, a personal 6-digit code was entered. The code was given to participants by study personnel 7 days after the baseline meeting to avoid overlap with baseline accelerometer measurements. The intervention group was encouraged to use the app daily for 3 months. At the 3-month follow-up meeting, participants deleted the app from their phones together with study personnel. Participants then received no intervention during 3 months and were offered access to the app again at the 6-month follow-up.

The DiaCert app displayed daily steps that through connection to a digital platform were shared with study personnel. An individual step goal between 1000 and 10,000 steps [24] was set at baseline based on the participant's usual activity level. Participants in the intervention group were contacted by study personnel every second week by phone. During these follow-ups, the participant could revise his or her step goal with an even 500 steps increase or decrease. The maximum goal set

at any time point was 10,000 steps. Users received automatic positive feedback messages including the user's name in the app on days when the goal was met. In addition to daily steps, information on HbA_{1c} taken during the study period was also displayed in the app.

The app design has previously been described in detail, including a presentation of the app screen by screen [9]. In brief, features of the app included a home screen displaying the daily steps in relation to an individual step goal during the past week. A circle was gradually filled as the user walked toward the step goal. It was completely filled and marked with a checkmark when the goal was reached. Through the home screen, the user was also able to access information on previous daily steps, questionnaires, and results of HbA_{1c}. The app was continuously updated to run with the current iOS and Android versions, but no changes were made to the content during the study. Users were asked to contact study personnel if they experienced malfunction of the app. The app was developed within the research project and is no longer available.

Study participants randomized to the control group received standard care, that is, continued their usual care as prescribed by their regular primary care physician and diabetes nurse, also after inclusion to the study. For ethical reasons, they were offered access to the DiaCert app at the 6-month follow-up.

Outcomes

Physical Activity

To assess the primary outcome of MVPA in this trial, physical activity was measured using the ActiGraph wGT3x-BT triaxial accelerometer (dynamic range: 8g) during 7 consecutive days. At each study meeting, the participants were asked to wear the accelerometer on their nondominant wrist day and night, starting at 4 PM the same day until 8 AM just over a week later. Participants wore the accelerometers on their wrist to increase feasibility and maximize compliance. Data were sampled at a frequency of 80 Hz.

We downloaded the collected data from each accelerometer using the manufacturer's program (ActiLife Software, version 6.13.3; ActiGraph), and thereafter, the raw data were extracted for data processing. As suggested by Migueles et al [25], processing of accelerometer data was performed using the open-source R package GGIR. GGIR version 2.0-0, R version 3.6.1, and RStudio version 1.2.5019 were used. Data collected before the first and after the last midnight were excluded in order to examine 7 complete days. As the first step of analysis, data were averaged over 5-second epochs and aggregated through application of Euclidean norm minus 1, with negative values rounded up to 0. Autocalibration was performed using local gravity to adjust for calibration errors and unreliable signals.

The default cut point for MVPA (100 milligravity) and default settings for the definition and management of nonwear time (ie, 4×15 minutes) in GGIR were applied [26]. Nonwear time was by default replaced with imputed averaged activity from the same time the other measured days. A valid day was defined as at least 16 hours of wear time and a valid week required 4 valid

days (including at least 1 weekend day) [25]. Variables were weighted 5:2 with data collected on weekdays and weekend days. For MVPA, bouts of consistent activity lasting for at least 1 minute were used, where 80% of the included epochs had to be above or equal to the cut point [27].

In addition to accelerometer measurements, we also assessed daily physical activity at baseline with 2 validated general questions used in routine health care [28]. Participants were asked to (1) report their usual time spent exercising during a week and (2) add up and report the total time estimated spent doing other types of leisure time physical activities of lower intensity in bouts of at least 10 minutes during a week. Walking, cycling, or gardening was presented to the respondent to exemplify activity level.

Clinical Variables

A detailed description of measurements has been published elsewhere [21]. In brief, HbA_{1c} (mmol/mol), total cholesterol (mmol/L), LDL cholesterol (mmol/L), HDL cholesterol (mmol/L), and triglycerides (mmol/L) were measured in fasting blood samples. HbA_{1c} was measured using the reference measurement procedure by the International Federation for Clinical Chemistry and Laboratory Medicine [29]. The enzymatic method [30] was used to measure total cholesterol and HDL cholesterol. LDL cholesterol was calculated using the Friedewald equation [31].

Height (to the nearest 0.5 cm), body weight (to the nearest 0.1 kg), and waist circumference (to the nearest 1.0 cm) were measured by study personnel who also performed 1 manual assessment of blood pressure (systolic and diastolic) after the participant had been sitting down for at least 5 minutes. BMI was calculated based on measured height and weight (kg/m^2).

Sample Size

Power calculations were performed a priori to determine the sample size need to detect a clinically significant difference of 8 minutes/day of MVPA [21]. A total of 250 participants (125 in each group) were estimated to provide 80% power at a 5% significance level. This included an expected dropout rate of 20%. Baseline data collection ended in June 2018 before reaching 250 participants because the DiaCert app was no longer compatible with the upgrades of iOS and Android.

Randomization and Blinding

A random allocation sequence list was generated by the first author (SEB) in Stata (version 14.0; StataCorp). Women and men were randomized separately in blocks of 10 within each participating primary health care center and the specialized medical center. Patients who agreed to participate in the study were continuously allocated to the next available spot on the list by study personnel (authors SEB and CA). Participants were informed about their group allocation at the end of the baseline meeting. Because of the nature of the intervention, neither participants nor study personnel were blinded to participants' group allocation.

Statistical Methods

Baseline characteristics of study participants are presented as mean (SD) or number (%) for continuous and categorical variables, respectively. Variables were checked for normality and outliers. The Student *t* test or the chi-square test was used to assess potential differences in baseline characteristics between the intervention and control group.

We used linear mixed models with fixed and random intercept and slope for the time variables to assess if there were longitudinal differences in MVPA at 3 months of follow-up (primary outcome) and secondary outcomes including MVPA at 6 months of follow-up and BMI, waist circumference, HbA_{1c}, total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides, and systolic and diastolic blood pressure at 3 and 6 months of follow-up between the intervention and control group. We have therefore included, in addition to time and group terms, a group×time interaction term to assess if any differences in the study outcomes were constant at 3 and 6 months. For outcomes that differed significantly between the study groups at baseline, that is, MVPA, additional sensitivity analysis adjusting the models for baseline levels of the outcome was performed according to the methods described by Twisk et al [32]. The analysis of intervention effect was made following the intention-to-treat approach [33]. Missing data were associated with a primary care center, with 17/25 (68%) participants with missing accelerometer data at baseline belonging to primary care center 1. Missing data were assumed to be missing at random and not depending on the study group as the degree of missing data was similar in both the intervention and control group during the intervention. Participants with complete data at baseline for each specific outcome variable were included in the analysis of intervention effect at 3 and 6 months.

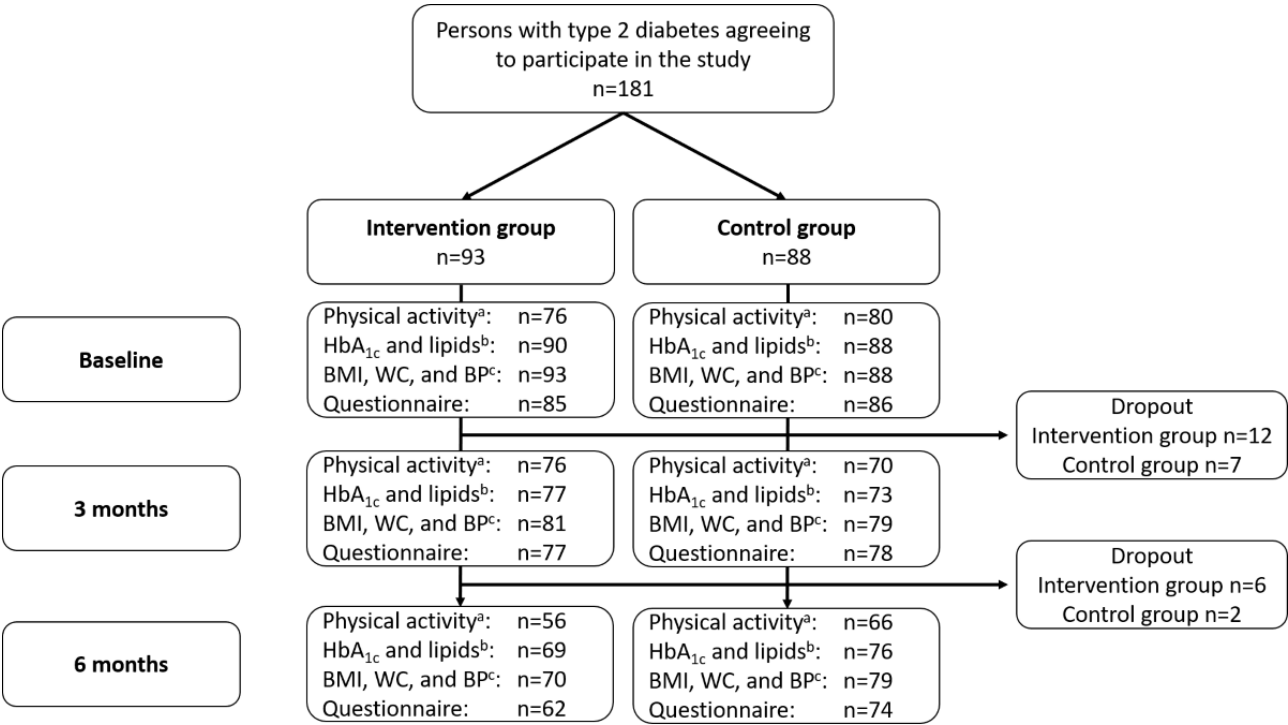
Post hoc sensitivity analyses using self-reported data on physical activity from the baseline questionnaire were carried out to deal with the unblinded nature of our study and the potential bias that may have been present during baseline accelerometer measurements. Although participants were not connected to the DiaCert app until after the completion of baseline accelerometer measurements, they were aware of which group they were randomized to during measurements. This could potentially have affected baseline levels of MVPA, which might not have represented the "true" levels of MVPA before the start of the study. Multiple imputation based on MICE (multiple imputation by chained equations) was used to address this issue [34]. We first set all baseline values of MVPA for the intervention group to missing. To predict MVPA at baseline for participants in the intervention group in the hypothetical scenario in which participants were blind to the intervention, we implemented MICE using all relevant baseline variables. The variables included in the model were age, sex, height, weight, education, household income, marital status, smoking and snuff habits, the year of diabetes diagnosis, the center of recruitment, self-reported levels of physical activity, and the number of valid accelerometer days at baseline. We compared the imputed and the observed values of MVPA at baseline using a 2-tailed *t* test. Linear mixed models, as described above, were thereafter fitted

to contrast differences in MVPA between the intervention and control group using the imputed data for MVPA at baseline.

Statistical tests were 2-sided, and the significance level was set to *P*<.05. Statistical analyses were performed using Stata (version 17; StataCorp).

Results

A total of 181 persons with type 2 diabetes were included in the trial, of whom 93 were randomized to the intervention group and 88 were randomized to the control group. At 3 months, the dropout rate was 10.5% (19/181), and at 6 months it was 14.9% (27/181). Dropout was higher among participants in the intervention group (n=12 vs n=7 at 3 months, and n=6 vs n=2 at 6 months) than among those in the control group. In total, 156 participants had valid accelerometer data on physical activity at baseline. Of these, 137 (87.8%) also had valid data at the 3-month follow-up (primary outcome). At baseline, most participants (75.6%, 118/156) had valid accelerometer data from all 7 days, 14.7% (23/156) had valid data from 6 days, and 9.6% (15/156) from 5 or 4 days. A flowchart of participants with complete data from the different assessments is presented in Figure 1.

Figure 1. Flowchart of participation and data completeness at baseline and follow-up after 3 and 6 months in the DiaCert study. [a]Number of participants with valid accelerometer data, that is, at least 16 hours of wear time and a total of 4 valid days including at least 1 weekend day; [b]Triglycerides and cholesterol (total, low-density lipoprotein, and high-density lipoprotein). BP: blood pressure; HbA_{1c}: hemoglobin A_{1c}; WC: waist circumference.


Characteristics of all 181 study participants are presented in Table 1. The majority of participants were men (119/181, 65.8%), and the mean (SD) age at baseline among all participants was 60.0 (11.4) years. The mean (SD) BMI among all participants was 30.4 (5.3) kg/m^2. Overweight and obesity was common, 85.6% (155/181) had a BMI of ≥25 kg/m^2, and 48.1% (87/181) had a BMI of ≥30 kg/m^2. Mean (SD) HbA_{1c} was 53.6 (12.8) mmol/mol. There were no statistically significant differences between the study groups regarding age distribution, primary care center belonging, sex, smoking, time since diabetes diagnosis, or clinical variables including HbA_{1c} and lipid levels. In study participants with complete accelerometer data at baseline (n=156), there was a statistically significant difference in accelerometer-measured baseline levels of physical activity between the intervention and control group, with higher MVPA (38.3 vs 29.8 minutes/day, *P*=.04) measured in the intervention group. Using the imputed data for the intervention group, the baseline MVPA was estimated to be 32.3 minutes/day, which did not differ from the measured level in the control group (*P*=.62). Additionally, self-reported levels of physical activity at baseline, that is, time spent exercising and total leisure time activity, did not differ between the groups (*P*=.20 and *P*=.20, respectively). Baseline characteristics of participants with complete accelerometer data at baseline can be found in Multimedia Appendix 1.

Effectiveness of the Intervention—MVPA

Results from between-group analysis and the intervention effect on minutes/day of MVPA are shown in Table 2. The mean change in minutes/day of MVPA from baseline to follow-ups is graphically shown in Figure 2. The statistically significant difference in minutes/day of MVPA seen between the groups at baseline, with participants in the intervention group being more active than participants in the control group, remained at the 3-month follow-up. The predicted mean difference between the groups after 3 months was 10.05 minutes (95% CI 1.66-18.44). At the 6-month follow-up, there was no statistically significant difference in MVPA between the groups (β=5.02, 95% CI –3.72 to 13.75).

Table 2. The intervention effect on the primary outcome of daily minutes of moderate to vigorous physical activity (MVPA) at 3 months of follow-up and on secondary outcomes including MVPA at 6 months of follow-up and clinical variables in the DiaCert study.

Characteristic	Group sample means				Model estimates[a]

Figure 2. Changes over time in moderate to vigorous physical activity (MVPA, minutes/day) in the intervention and control group. Predicted group means from linear mixed model analysis. Results correspond to model estimates shown in Table 2.
We found no statistically significant effect of the intervention (group by time interaction) on MVPA at either the 3- or the 6-month follow-up (Table 2). When adjusting for baseline levels of MVPA, results remained nonsignificant at both 3 (β=4.38, 95% CI –2.11 to 10.88) and 6 (β=–0.65, 95% CI –7.58 to 6.29) months. Additionally, results from sensitivity analyses using imputed baseline data also remained nonsignificant at follow-up after both 3 (β=6.86, 95% CI –4.05 to 17.78) and 6 (β=1.44, 95% CI –9.87 to 11.76) months.

Effectiveness of Intervention—Clinical Variables

Detailed results from between-group analyses and the intervention effect on clinical variables included as secondary outcomes are shown in Table 2. The mean change in outcomes from baseline to follow-ups is graphically shown in Multimedia Appendix 2. We found no statistically significant differences in any of the secondary outcomes at the 3- or 6-month follow-ups, except for in the analysis of BMI where a statistically significant effect of the intervention was seen at 6 months (group by time interaction: 0.52, 95% CI 0.20-0.84). However, there was no difference in mean BMI between the groups at the 6-month follow-up (predicted difference in mean: 0.11, 95% CI –1.45 to 1.67). Participants in the control group

had a slightly higher BMI at baseline than participants in the intervention group (30.6 vs 30.2 kg/m^2), although this difference was not statistically significant (P=.61).

Discussion

Principal Findings

In this 2-armed randomized controlled trial, we found no clear effect of the DiaCert app promoting daily walking in persons with type 2 diabetes. We found no increase in objectively measured MVPA after neither 3 (primary outcome) nor 6 months of follow-up compared with standard care when accounting for baseline levels of MVPA. This is in line with results from Thorsen et al [20]. They were not able to show an effect of app-based interval walking on MVPA over 52 weeks compared with standard care among persons with type 2 diabetes. On the contrary, Poppe et al [19] found that an eHealth and mHealth intervention that primarily targeted physical activity in persons with type 2 diabetes led to increased physical activity and decreased sedentary behavior. Participants in our study and the study by Thorsen et al [20] reported more time in MVPA at baseline compared with those in the study by Poppe et al [19]. This might have contributed to the difference in effect between

the studies, as a higher baseline level of MVPA may imply less room for improvement.

Other previous studies have also shown an effect of mHealth solutions to increase physical activity. Hochsmann et al [35] showed that an interactive smartphone game aimed at increasing daily steps in persons with type 2 diabetes had a significant effect on activity compared with a control group receiving standard lifestyle counseling. Glynn et al [36] evaluated the effect of an app that aimed to increase physical activity in primary care patients and found that the intervention group increased their number of daily steps compared with the control group. In the randomized Sophia step study, comprising persons with prediabetes or type 2 diabetes in Sweden [37], self-monitoring of daily physical activity using pedometers with registration of steps on the web in combination with counseling did not increase levels of physical activity but seemed to prevent the decrease in physical activity seen in the control group. Although our primary hypothesis was rejected and we could not show that the use of the DiaCert app led to increased MVPA among persons with type 2 diabetes, results from other studies still indicate that mHealth solutions can have positive effects on physical activity.

Although we found a statistically significant effect of the DiaCert intervention on BMI at the 6-month follow-up, there was no difference in mean BMI between the groups at any time point. Therefore, we cannot draw any conclusion regarding the effect on BMI. Not all studies evaluating interventions targeting physical activity include anthropometric outcomes, and the effect on BMI in previous studies are mixed, showing no effect or indicating a small reduction favoring the intervention group [10,12]. Thorsen et al [20] did not report BMI as an outcome, but found a nonsignificant reduction of waist circumference. Similar to the Sophia step study, our results provided no evidence for an effect on waist circumference [37].

Reviews and meta-analyses [11,13,15] provide strong evidence for a positive effect of mobile apps for lifestyle modification in persons with type 2 diabetes on HbA_{1c} levels. However, all of the evaluated apps included monitoring of blood glucose. The effects on other clinical markers including body weight, blood lipids, and blood pressure are less clear [38]. Our results are in line with the Sophia step study, where no effects on cardiometabolic variables, including HbA_{1c}, triglycerides, HDL cholesterol, and LDL cholesterol, were seen [37]. Neither our study nor the Sophia step study included a glucose-monitoring component, which may explain the lack of an effect on HbA_{1c}. Nevertheless, results from a meta-analysis by Lee et al [12] indicated that mHealth interventions in persons with type 2 diabetes >65 years of age may improve blood lipid profiles, which we found no evidence of. One explanation for the lack of an effect on cardiometabolic markers is that a changed lifestyle behavior for the better could have led to lowered medication, leaving HbA_{1c}, serum lipid levels, or blood pressure unchanged. We did not assess changes in medications during the intervention, which is a limitation of our study.

The use of different behavior change techniques may also explain differences in efficacy between apps. Fanning et al [39]

investigated the effect of a basic self-monitoring app (tracking, feedback, information) and 2 theory-based tools (goal setting and point-based feedback) on MVPA among healthy but inactive adults. Four different groups received either a basic self-monitoring app only or the basic app together with (1) goal setting, or (2) feedback, or (3) goal setting and feedback. All groups increased their MVPA, but the feedback group showed the highest increase. While the DiaCert app comprised several behavioral change techniques that previously have been included in successful interventions, such as monitoring, goal setting, and positive feedback, it did not include other features associated with effective results, for example, frequent reminders or the option to share data with peers [40]. How the included components are designed may also affect results; for example, goal setting can be personalized or generic, and a goal can be more or less challenging.

Strengths and Limitations

The design of this randomized controlled study is one of the strengths of our study. The fact that study participants were recruited from 6 different care centers located in different areas with diverse populations and levels of socioeconomic status is another strength. This likely increased generalizability of our results. However, a limitation of our study is that we did not record the number of patients who turned down participation after being contacted by study personnel. Nevertheless, the mean age in our study was slightly lower than that of the average person with type 2 diabetes in Sweden, but levels of BMI and HbA_{1c} were similar [41]. Younger persons may be more inclined to participate in an app-based intervention, although internet access and smartphone usage are high also among older age groups in Sweden [42]. Another strength of our study is that both men and women were included. Earlier studies have shown that women participate in physical activity programs more than men [43]. The larger proportion of men in our study could partly be explained by the higher prevalence of type 2 diabetes among men; almost 60% of persons with type 2 diabetes within primary care in Sweden are men [41]. It could also be speculated that older men are more interested in using technology than older women and therefore more likely to participate in an mHealth intervention.

The fact that participants were not blinded to the intervention is a limitation. While baseline information regarding the clinical variables is unlikely to have been affected by participants being aware of their group allocation, this knowledge may have had an impact on accelerometer measurements. Participants can, intentionally or unintentionally, change their physical activity behaviors during the measuring period. The statistically significant differences between the intervention and control group in accelerometer-measured MVPA at baseline were not seen for physical activity assessed in the baseline questionnaire. This could be interpreted as an immediate effect of being randomized to the intervention group and thereby feeling encouraged to become more active. Future studies should be careful not to disclose allocation information to participants until all baseline measures have been completed. It is also a limitation that personnel working in the study were not blinded during measurements. Nevertheless, objective accelerometer measurement of physical activity and clinical biomarkers

including HbA_{1c} and lipid levels represent a strength in our study design as they are less prone to biased estimates resulting from unblinded study personnel. The continuous recruitment of study participants during the whole year also reduced the risk of results being biased due to season.

We did not reach our goal of including 250 participants in the study, which is a limitation. Because a digital solution must be continuously updated to run with the current iOS and Android versions, we had to end recruitment after 2.5 years for practical reasons, before reaching the goal. However, dropout rates were lower than the estimated 20% in our power calculation [21]. Lack of data on user engagement and adherence to the app is a limitation as higher user engagement has also been associated with more favorable outcomes [44]. Decreased app engagement over time during an intervention period has been suggested as

a potential explanation for the lack of more long-term effects of physical activity promoting apps [45].

Conclusions

We found no evidence that persons with type 2 diabetes being randomized to use an app promoting daily walking increased their levels of MVPA at 3 or 6 months of follow-up compared with controls receiving standard care. Further, the effect on BMI was unclear, and we found nothing to support an effect of being randomized to use the DiaCert app on waist circumference, HbA_{1c}, total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides, and systolic or diastolic blood pressure compared with standard care. Further research is needed to determine what type of mHealth physical activity intervention could be effective to increase physical activity and improve cardiometabolic markers among persons with type 2 diabetes.

Data Availability

The data sets generated during and analyzed during this study are not publicly available due ethical restrictions but are available from the corresponding author on reasonable request.

Authors' Contributions

YTL is responsible for the DiaCert study and has designed the study together with SEB and ML. SEB, MH and CA have contributed significantly to the data collection. HE processed accelerometer data and SEB performed the statistical analysis together with GP with critical input from RB. SEB prepared the initial draft of the manuscript together with MH, which has been critically reviewed by all authors. All authors have read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The impact of missing data on individual continuous glucose monitoring (CGM) data is unknown but can influence clinical decision-making for patients.

Objective: We aimed to investigate the consequences of data loss on glucose metrics in individual patient recordings from continuous glucose monitors and assess its implications on clinical decision-making.

Methods: The CGM data were collected from patients with type 1 and 2 diabetes using the FreeStyle Libre sensor (Abbott Diabetes Care). We selected 7-28 days of 24 hours of continuous data without any missing values from each individual patient. To mimic real-world data loss, missing data ranging from 5% to 50% were introduced into the data set. From this modified data set, clinical metrics including time below range (TBR), TBR level 2 (TBR2), and other common glucose metrics were calculated in the data sets with and that without data loss. Recordings in which glucose metrics deviated relevantly due to data loss, as determined by clinical experts, were defined as expert panel boundary error (ε_{EPB}). These errors were expressed as a percentage of the total number of recordings. The errors for the recordings with glucose management indicator <53 mmol/mol were investigated.

Results: A total of 84 patients contributed to 798 recordings over 28 days. With 5%-50% data loss for 7-28 days recordings, the ε_{EPB} varied from 0 out of 798 (0.0%) to 147 out of 736 (20.0%) for TBR and 0 out of 612 (0.0%) to 22 out of 408 (5.4%) recordings for TBR2. In the case of 14-day recordings, TBR and TBR2 episodes completely disappeared due to 30% data loss in 2 out of 786 (0.3%) and 32 out of 522 (6.1%) of the cases, respectively. However, the initial values of the disappeared TBR and TBR2 were relatively small (<0.1%). In the recordings with glucose management indicator <53 mmol/mol the ε_{EPB} was 9.6% for 14 days with 30% data loss.

Conclusions: With a maximum of 30% data loss in 14-day CGM recordings, there is minimal impact of missing data on the clinical interpretation of various glucose metrics.

Introduction

Improved glucose sensing techniques have led to the increased availability of continuous glucose monitoring (CGM) technology for patients with diabetes. These minimally invasive sensors measure the glucose concentration of the interstitial fluid every 1 or 5 minutes, representing the blood glucose concentration with an average delay of 10-12 minutes [1,2]. CGM provides insights into glucose concentration fluctuations throughout the day and enables comparisons over time using predefined glucose metrics. This offers better prevention of out-of-range values compared to glycated hemoglobin (HbA$_{1c}$) measurements or traditional finger prick methods. Consequently, CGM has the potential to improve glycemic control and adherence to lifestyle and drug regimens [3-7]. Therefore, CGM devices have been included in clinical guidelines and standards of care for patients with type 1 and 2 diabetes [8].

Commonly used glucose metrics to assess glycemic control in clinical practice from CGM devices include time in range (TIR), representing the percentage of time spent within the glucose range of 70-180 mg/dL (3.9-10.0 mmol/L), time below range (TBR) in 2 levels, time above range (TAR) in 2 levels, glucose management indicator (GMI), and the coefficient of variation (CV). Although treatment targets are individualized, the general aim is to achieve a TIR of over 70% while minimizing TBR below 4% [9,10].

Incomplete data collection during CGM monitoring can affect the clinical interpretation of glucose metrics. Several factors such as loss of connectivity, sensor or reader malfunction, depleted battery, or delayed interaction with the device when data are only temporarily stored on the sensor, could lead to data loss. This data loss can introduce bias in the estimation of glucose metrics [11]. Evaluating the potential impact of data loss on clinical interpretations and determining acceptable levels of error is crucial for clinical decision-making [12].

The type and distribution characteristics of missing data are important when evaluating data loss. There are 3 types of missing data, they are, missing completely at random (MCAR), missing at random (MAR), and missing not at random (MNAR) [13-15]. MCAR implies no systematic differences between participants with complete and incomplete data. MAR occurs when missing values are independent of the missing variables, but the pattern of missing data is dependent on time. In the case of MNAR, valuable information is lost from the data and there is no general method to manage the missing data properly [16,17]. Consecutive missing data, or gaps, have a certain gap size and incidence in the data, which can be represented by a gap probability distribution. Missing data are characterized as MCAR when the gap probability follows an exponential decline, with minimal affecting analysis and outcomes. However, MAR patterns skew the research outcomes, as missing data are more prevalent at certain times than others. Therefore, insight into the gap probability distribution is essential for understanding the influence of missing data on desired outcomes [15,18-20].

Currently, the recommendation for reliable interpretation of CGM data is to evaluate either 10 consecutive days without data loss or 14 consecutive days with a maximum data loss of 30% [8,10,21]. However, these studies have not investigated the impact of deviations from missing data in common CGM metrics on clinical decisions for individual patients [12,22,23]. Furthermore, previous research has determined that at least 14-15 days of CGM data provide a good estimation of CGM metrics compared to monitoring every 3 months or HbA$_{1c}$ [21,24]. These studies primarily focused on the correlation between CGM data and HbA$_{1c}$, which does not give insight into the impact of missing data on the clinical interpretation of different CGM metrics. Additionally, it only reflects long-term glycemic control, overlooking the potential for assessing short-term variations afforded by CGM data. Therefore, this study aims to investigate the effects of data loss on glucose metrics in individual patient recordings and its influence on clinical decision-making.

Methods

Patient Inclusion and Data Collection

This study was performed in the Diabase cohort, which is a registry of adult patients with type 1 diabetes and those with type 2 diabetes who use CGM technology as part of their care. They are treated in Ziekenhuisgroep Twente (ZGT), a local hospital in the Netherlands (NCT05584293). The exclusion criteria were dependency on hemodialysis or inability to provide informed consent.

All patients included in the Diabase cohort between September 2020 and March 2022 were reported upon, which contains retrospective data from June 2016.

Ethical Considerations

The study was performed in accordance with the Declaration of Helsinki, the guidelines of good clinical practice. The Medical Research Ethics Committees United (MEC-U) in Nieuwegein, the Netherlands (registration AW23.009/W20.197), reviewed and approved the protocol. Prior to participation, patients provided informed consent to collect their (retrospective) glucose sensors and to retrieve relevant patient information from electronic patient files (age, gender, HbA$_{1c}$, and BMI).

For this study, deidentified data were provided by the Diabase cohort, ensuring the confidentiality and privacy of participant information. Participants did not receive financial compensation for their participation in this study, as it solely involved the collection of data readily available from standard practice.

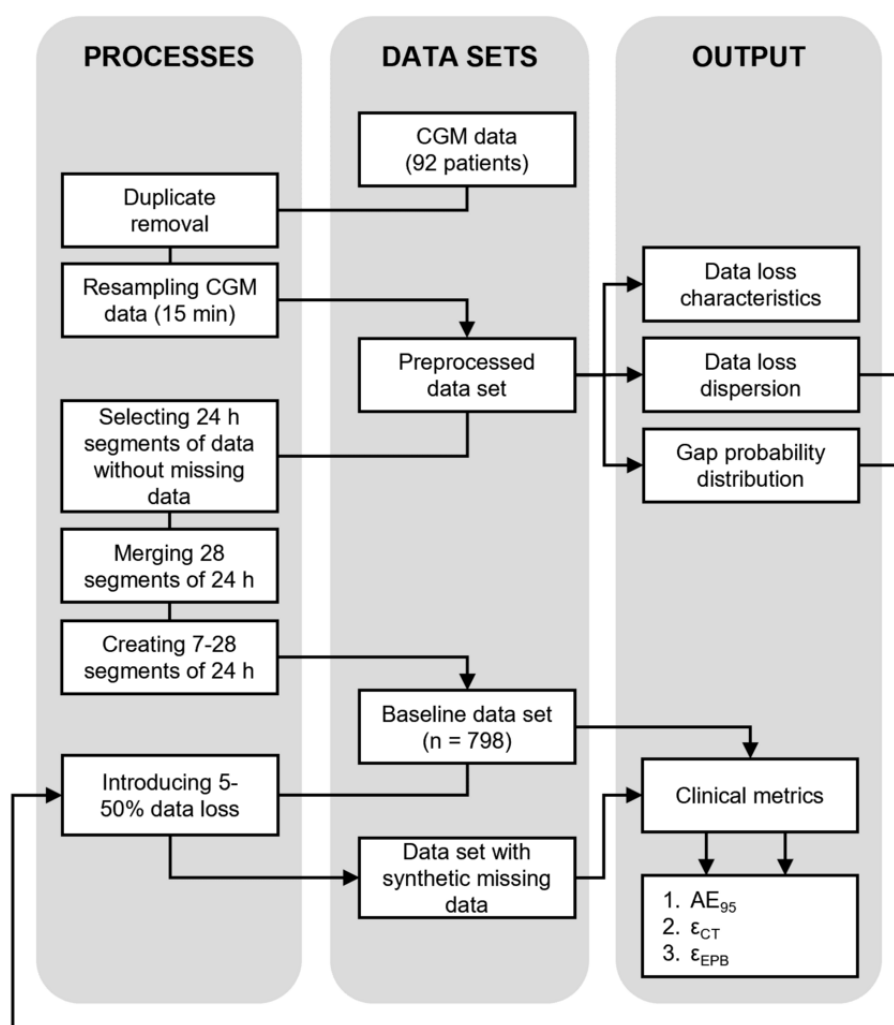
CGM Derived Clinical Metrics

We collected CGM data using FreeStyle Libre sensors, and the data were stored in LibreView (Abbott Diabetes Care). The sensors have a storage capacity of up to 8 hours of data and measure for 2 weeks.

Derived from the CGM data were the mean glucose, TIR (glucose between 70 and 180 mg/dL or 3.9 and 10.0 mmol/L; %), TBR (glucose <70 mg/dL or 3.9 mmol/L; %), TBR level 2 (TBR2; glucose <54 mg/dL or 3.0 mmol/L; %), TAR (glucose >180 mg/dL or 10.0 mmol/L; %), TAR level 2 (TAR2; glucose >250.2 mg/dL or 13.9 mmol/L; %), SD glucose (mmol/L), CV (%), GMI (mmol/mol), low blood glucose index (LBGI), high blood glucose index (HBGI), and the risk index (RI; Multimedia Appendix 1) [8,10,25-27].

Data Processing and Analysis

Data from LibreView were extracted as a CSV file and processed in Python 3.9 (extension Spyder 5.3.1; Python Software Foundation). Figure 1 illustrates the data processing steps from the original CGM data into the various outputs used in this study. Data from the FreeStyle Libre sensor were recorded at intervals of 13-19 minutes (with an average every 15 minutes). First, duplicate data and data from multiple sources within 14 minutes were removed from the data set. Subsequently, data were resampled to 1 sample per 15 minutes using linear interpolation, starting at midnight. Interpolated data points were marked as missing when the time difference between the 2 nearest original data points exceeded 19 minutes. These steps resulted in the preprocessed data set.

Figure 1. Data processing pipeline showing the data processing steps, the different data sets and the outputs. AE_{95}: 95th percentile of absolute error; CGM: continuous glucose monitoring; ε_{CT}: error clinical target; ε_{EPB}: error expert panel boundaries.


From the preprocessed data set, the data loss characteristics were determined (illustrated in Figure 1). The percentage of missing data was calculated, and we determined the percentage of time that patients adhered to the data loss guidelines outlined in prior studies. These studies indicated that maintaining >70% of CGM data over the last 14 days or 10 days out of the 14 days strongly correlates with mean glucose, estimated HbA_{1c}, TIR, and hyperglycemic metrics over a 3-month period. Consequently, our study adopts a 14-day measurement window with <30% data loss or a 10-day window with no data loss [8,21,24,28] The gap length and gap probability distribution were computed (Figure 1). To assess whether the missing data were MAR, we tested the fit of an exponential probability function to the gap probability distribution for gaps smaller than 96 samples [13]. The data loss dispersion over time was

researched by comparing the average data loss per patient of the preprocessed CGM data set between various time periods—hours within the day, days in the week, business days (Monday to Friday) versus weekends, months, seasons, and days of the year.

It is important to consider the circadian rhythm of glucose metabolism during data analysis. Numerous studies have shown diurnal variations in glucose tolerance, insulin secretion, and peripheral insulin sensitivity, with poorer glycemic control observed in the evening and at night in healthy individuals [29,30]. To account for circadian rhythm, we constructed a baseline data set for each patient by combining 28 segments of 24-hour data without missing data (Figure 1). In cases that were where available, we merged multiple periods of 28 days per patient for further analysis, excluding patients with less than 28 segments of data. From the 28-day recordings, we created shorter recordings ranging from 7 up to 28 days.

Hereafter, data loss ranging from 5% to 50% was randomly introduced into the baseline data set in accordance with the gap distribution and data loss dispersion determined from the preprocessed data set. This means the gap distribution of the synthetic missing data is as close as possible to the gap distribution found over the whole population in the preprocessed data set. Also, synthetic data have higher chance of missing following the found data loss dispersion over time. Therefore, the synthetic missing data mimics the missing data as seen in day-to-day patient care.

Absolute Errors

The CGM metrics were calculated for each recording in the baseline and synthetic missing data set, and compared for every recording. The absolute error (AE), the median AE (MedAE), and the 95th percentile of the AE (AE_{95}) as a result of missing data were calculated for all CGM metrics (Figure 1).

Clinical Target Errors (ε_{CT})

The clinical targets follow clinical guidelines—<4% TBR, <1% TBR2, >70% TIR, <25% TAR, <5% TAR2, <36% CV, and <53 mmol/mol GMI [9,10]. The percentage of recordings that surpassed the clinical target cut-off because of missing data was determined as the clinical target error (ε_{CT}). This step is illustrated in Figure 1.

Expert Panel Boundary Error (ε_{EPB})

A panel of experts consisting of a diabetes specialist nurse, a diabetes nurse, and a technical physician (a medical specialist in diabetes-related technology in health care) was interviewed. Each expert was interviewed individually to discuss clinically relevant changes in CGM metrics. During the interviews, CGM metrics TIR, TAR, TAR2, TBR, TBR2, GMI, and CV were discussed separately. The experts were instructed to consider a generic patient with diabetes and to evaluate each CGM metric separately. They were asked to identify when a change in the CGM metric would likely result in therapy alteration, indicating clinical relevance. A clinically relevant change can be dependent on the initial value of the CGM metric. For example, a change in TBR from 2% to 4% can have more impact than a change from 8% to 10%, even though the absolute change is the same. Therefore, the experts determined clinically relevant changes for various initial values of all CGM metrics (Multimedia Appendix 2). From these discussions, the strictest relevant change per CGM metric was selected as the expert panel boundary (Multimedia Appendix 2). The percentage of recordings that exceed the defined expert panel boundary due to data loss is defined as the expert panel boundary error (ε_{EPB}), this step is depicted in Figure 1. When data loss resulted in an ε_{CT} or ε_{EPB} of more than 5%, we assumed that data loss had considerable influence on the CGM metric and should be interpreted with caution, consistent with the clinically significant criterion for a 5% increase in TIR [8].

GMI Subgroup Analysis

To see whether missing data had a different influence on TBR, the recordings were divided into 3 GMI-based groups (<53, 53-64, and ≥64 mmol/mol), based on 3 commonly used HbA_{1c} categories as determined by the American Diabetes Association [31]. Hereafter, the MedAE, ε_{CT}, and ε_{EPB} were calculated for TBR in the 3 GMI groups.

Statistical Analysis

The median and IQR were calculated for the clinical and sensor data characteristics, that is, the recording length, data loss, and overall CGM metrics.

The fit between the gap distribution and the exponential probability density function was tested with a 2-sided Kolmogorov-Smirnov test and the sum of the squared error. Differences in data loss dispersion between several time periods were evaluated using the Kruskal-Wallis test with post hoc Dunn test and Bonferroni correction. Differences between the glucose metrics between the preprocessed data set and the baseline data set with 28 days were evaluated using Kruskal-Wallis test with Bonferroni correction. For these statistical analyses, the packages SciPy and scikit-posthocs in Python were used [32,33]. All data visualizations were made with the Python package Matplotlib [34].

Scatterplots were generated for CGM metrics from 14-day recordings with complete data versus those with 30% synthetic missing data. Additionally, histograms of the AE were constructed from 14-day recordings with 30% data loss in TBR and TBR2. The histogram bin widths were determined with Freedman-Diaconis rule. A P value <.01 was considered significant.

Results

Data and Patient Characteristics

Between September 2020 and March 2022, 92 patients using a FreeStyle Libre CGM device were included in the Diabase study. Descriptive statistics of the population can be found in Table 1.

Table 1. Characteristics of the population and their data used in this research.

	Values
Type 1 diabetes, n (%)	79 (95.8)
Type 2 diabetes, n (%)	13 (14.2)
Men, n (%)	47 (51)
Age (years), median (IQR)	52 (37.3-60.5)
BMI (kg/m^2), median (IQR)	26.2 (23.1-29.4)
HbA$_{1c}$[a] (%), median (IQR)	7.6 (7.0-8.3)
HbA$_{1c}$ (mmol/mol), median (IQR)	60 (53.3-67.0)
Recording length (days), median (IQR)	655 (499-925)
Data loss (%), median (IQR)	13.5 (6.3-35.6)
Time recordings had 0% data loss for 10 days (%), median (IQR)	0.0 (0.0-0.3)
Time recordings had <30% data loss for 14 days (%), median (IQR)	88.9 (63.0-98.7)

[a]HbA$_{1c}$: glycated hemoglobin.

Data Loss Statistics

The gap probability distribution of the preprocessed data set differs significantly from a fitted exponential probability density function (P=.002). This means the data loss is not completely random (Multimedia Appendix 3).

During the hours of 10-11 PM, 11 PM to midnight, and midnight to 1 AM, a higher data loss of 35.8%, 43.3%, and 35.3%, respectively, was observed compared to other hours of the day with an average data loss of 10.4% (IQR 2.7%-30.5%; P<.001). Therefore, to mimic the unequal dispersion we created synthetic missing data following the probability of missing data during the day. No significant differences in data loss were found between other time periods.

Baseline Data Set

Among the 92 patients, 84 (91%) patients had sufficient data to construct a data set of 28 segments with complete 24-hour segments of data. These 84 patients contributed to a total of 798 recordings over 28 days, forming the baseline data set. Each patient provided median of 7.0 (IQR 3.8-14.0) in 28-day recordings. The median (IQR) for TIR, TBR, TBR2, TAR, and TAR2 of all 28-day recordings were 60.3% (53.2%-67.8%), 3.3% (1.4%-5.8%), 0.3% (0.0%-1.0%), 35.4% (27.4%-43.3%), and 9.4% (5.5%-13.9%), respectively. No significant differences were found between all the clinical metrics of the preprocessed data and the 28-day baseline data set, indicating that the selected baseline data set reflects the original data.

Expert Panel

The experts unanimously agreed that the most important metrics were TBR and TBR2, resulting in strict expert panel boundaries. In the TBR range of 0%-4% and the TBR2 range of 0%-5%, a difference of 1% was deemed clinically relevant (Multimedia Appendix 2). However, as the TBR increased, the experts allowed for higher changes, accepting a maximum of 5% for TBR and 10% for TBR2 when the initial value was 100%. Expert panel boundaries for the remaining glucose metrics can be found in Multimedia Appendix 2.

CGM Metrics Without and Those With Synthetic Data Loss

In the baseline data set, 734 (92.0%), 408 (51.1%), 796 (99.8%), and 767 (96.1%) of the total (N=798) 7-day recordings contained TBR, TBR2, TAR, and TAR2, respectively. For 28-day recordings, this is 798 (100%), 611 (76.6%), 798 (100%), and 790 (99.0%) for TBR, TBR2, TAR, and TAR2, respectively.

The scatterplots of Figure 2A represent the relation between the original 14-day data of TBR and TBR2, and with 30% data loss, per individual recording. These figures show that 30% data loss in these metrics results in small deviations from the true value with data loss, as all data points are close to the identity line. More recordings fell into the ε_{EPB} area for TBR, as the expert panel boundary was stricter compared to TBR2. The histograms of Figure 2B show the AE, MedAE, and AE$_{95}$ for these CGM metrics as a result of 30% data loss in a 14-day recording. The MedAE in the histograms is small, indicating that the majority of errors are small. However, the histograms also display a long tail, indicating that there are instances where the AE is larger than the MedAE.

Figure 3 shows the values of AE$_{95}$, ε_{CT}, and ε_{EPB} for the CGM metrics TBR and TBR2, with missing data increasing from 5% to 50% over a period of 7 to 28 days. This analysis includes only the recordings that had TBR episodes. As expected, the AE$_{95}$, ε_{CT}, and ε_{EPB} increase as the percentage of data loss increases. When more days are available, the influence of data loss is reduced (Figure 3A). Applying the current guidelines of 30% data loss for a 14-day recording period, we observed an AE$_{95}$ of 1.0% for TBR and 0.5% for TBR2. The corresponding ε_{CT} values were 29 out of 786 (3.7%) recordings for TBR and 28 out of 522 (5.4%) recordings for TBR2 and the ε_{EPB} were 28 out of 786 recordings (5.0%) for TBR 1 out of 522 recordings and 0.2% for TBR2. These findings suggest that the impact of missing data on CGM metrics can vary significantly depending on the specific metric and recording period used.

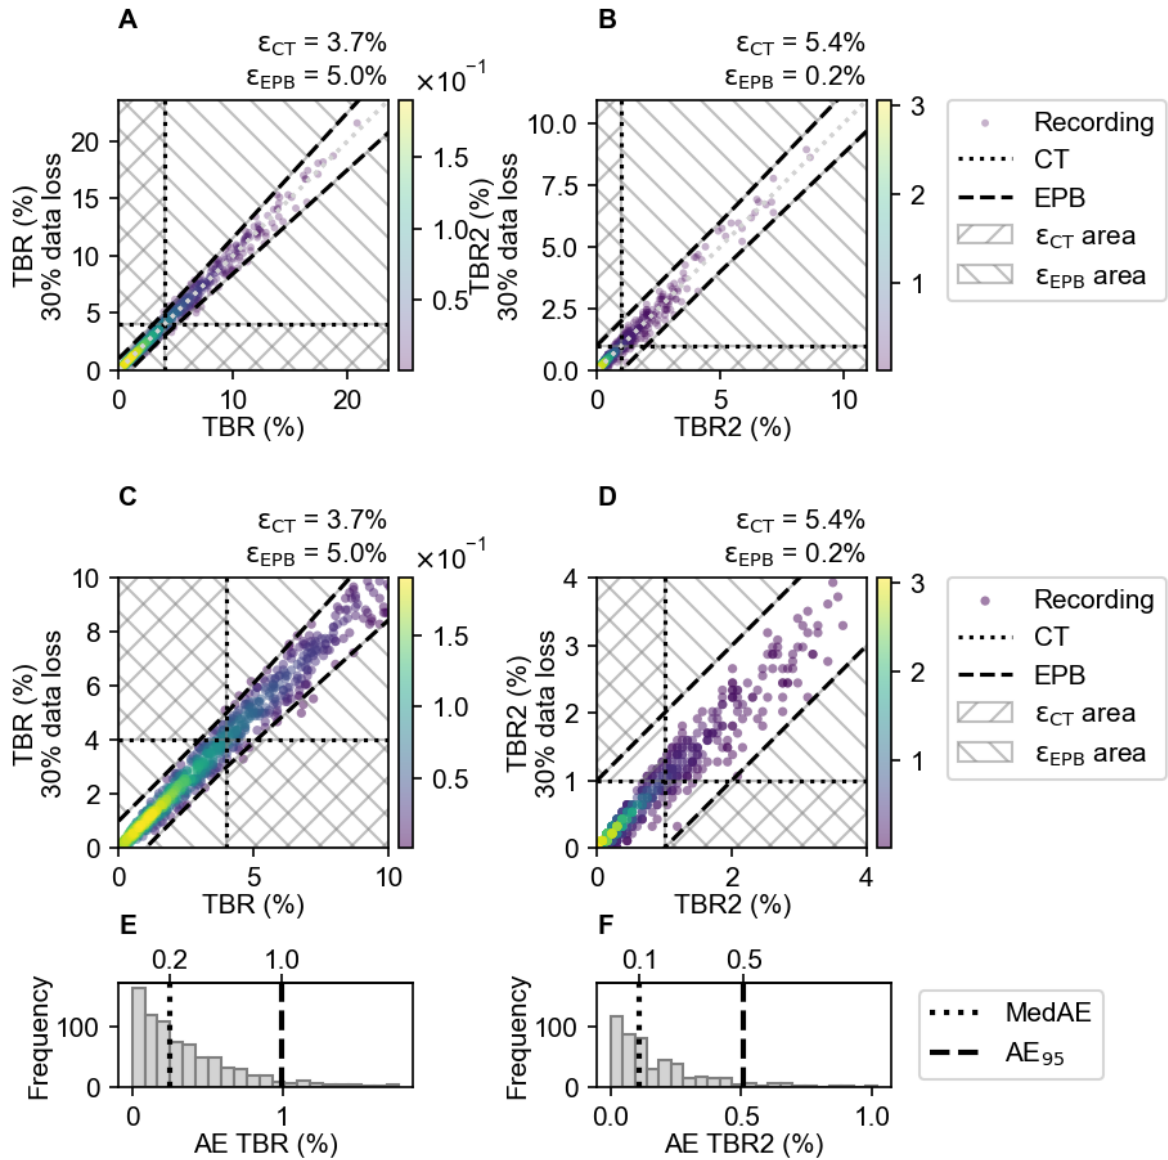
Figure 2. (A) The density scatterplots of the TBR and (B) TBR2 indicates the relation between the 14-day-long original data without missing data (horizontal axis) and the data with 30% data loss (vertical axis). More detail of the critical areas of TBR and TBR2 are illustrated in (C) and (D). The color bar indicates the Gaussian kernel-density estimate of the recordings. The black dashed lines represent the expert panel boundaries, and the horizontal and vertical black dotted lines represent the clinical targets. Values falling outside the clinical target and expert panel boundary, in the hatched areas, are labeled as errors (ϵ_{CT} and ϵ_{EPB}). (E) The histograms show the AE (%) with the median AE (MedAE) and AE_{95} as a result of 30% data loss of the TBR and (F) TBR2. AE: absolute error; AE_{95}: 95th percentile of AE; CT: clinical target; EPB: expert panel boundary; MedAE: median absolure error; TBR: time below range; TBR2: time below range level 2; ϵ_{CT}: clinical target errors; ϵ_{EPB}: expert panel boundary errors.


Figure 3. (A) The ε_{EPB} of 5%-50% data loss in recordings (horizontal axis) of 7-28 days (vertical axis) of TBR. The white line indicates the boundary where the ε_{EPB} exceeds 5%. (B,C) show the AE_{95}, (D,E) the clinical target errors (ε_{CT}), and (F,G) the ε_{EPB} of TBR and TBR2 respectively of 10%, 20%, 30%, 40%, and 50% data loss in recordings of 7, 14, 21, and 28 days. The color bar indicates the errors in percentages. AE_{95}: 95th percentile of the absolute error; TBR: time below range; TBR2: time below range level 2; ε_{EPB}: expert panel boundary errors; ε_{CT}: clinical target errors.
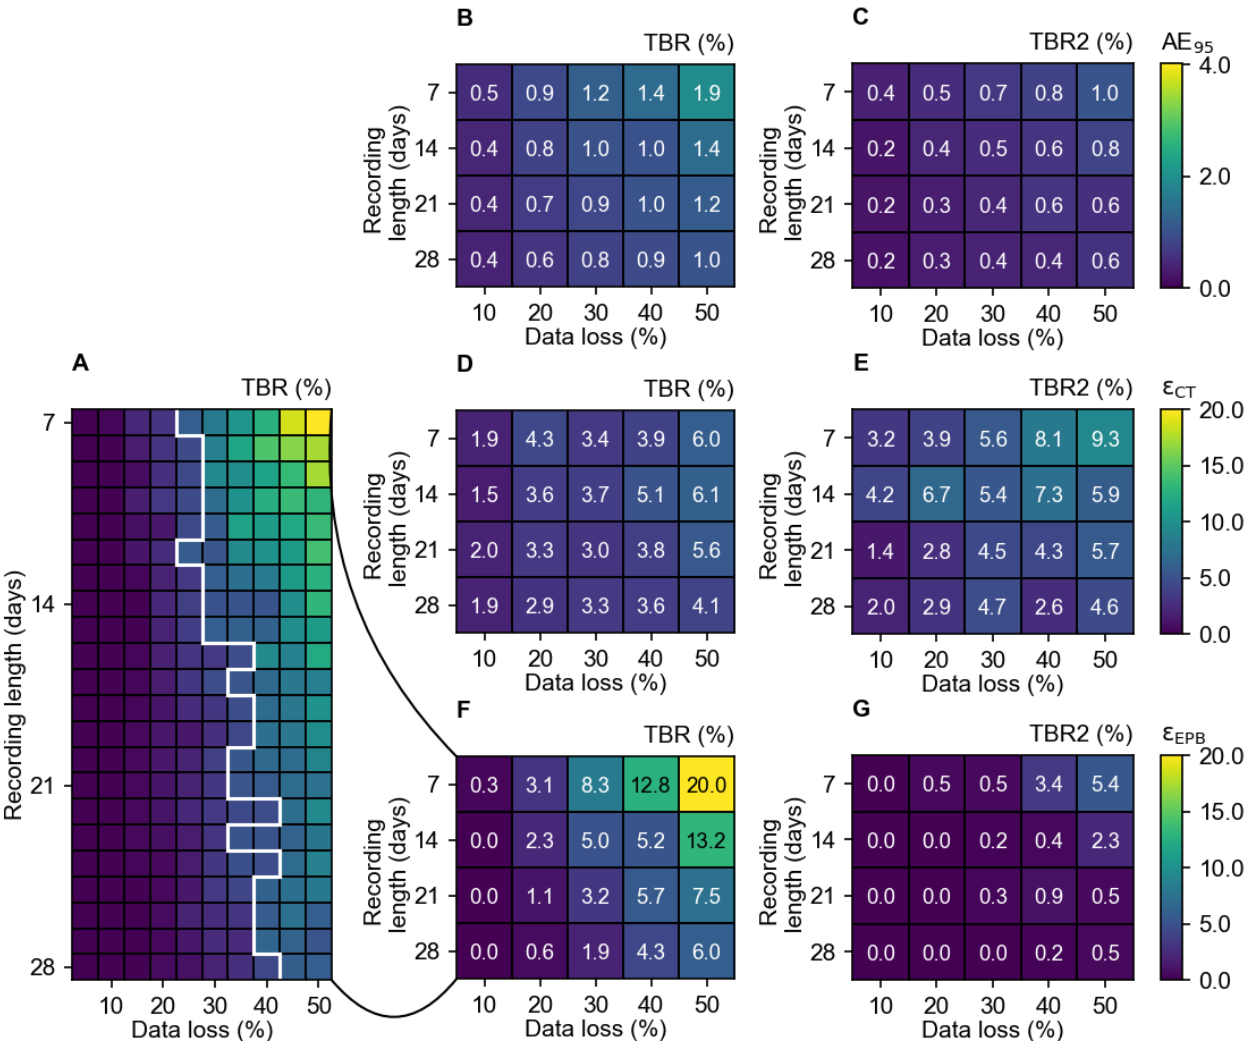


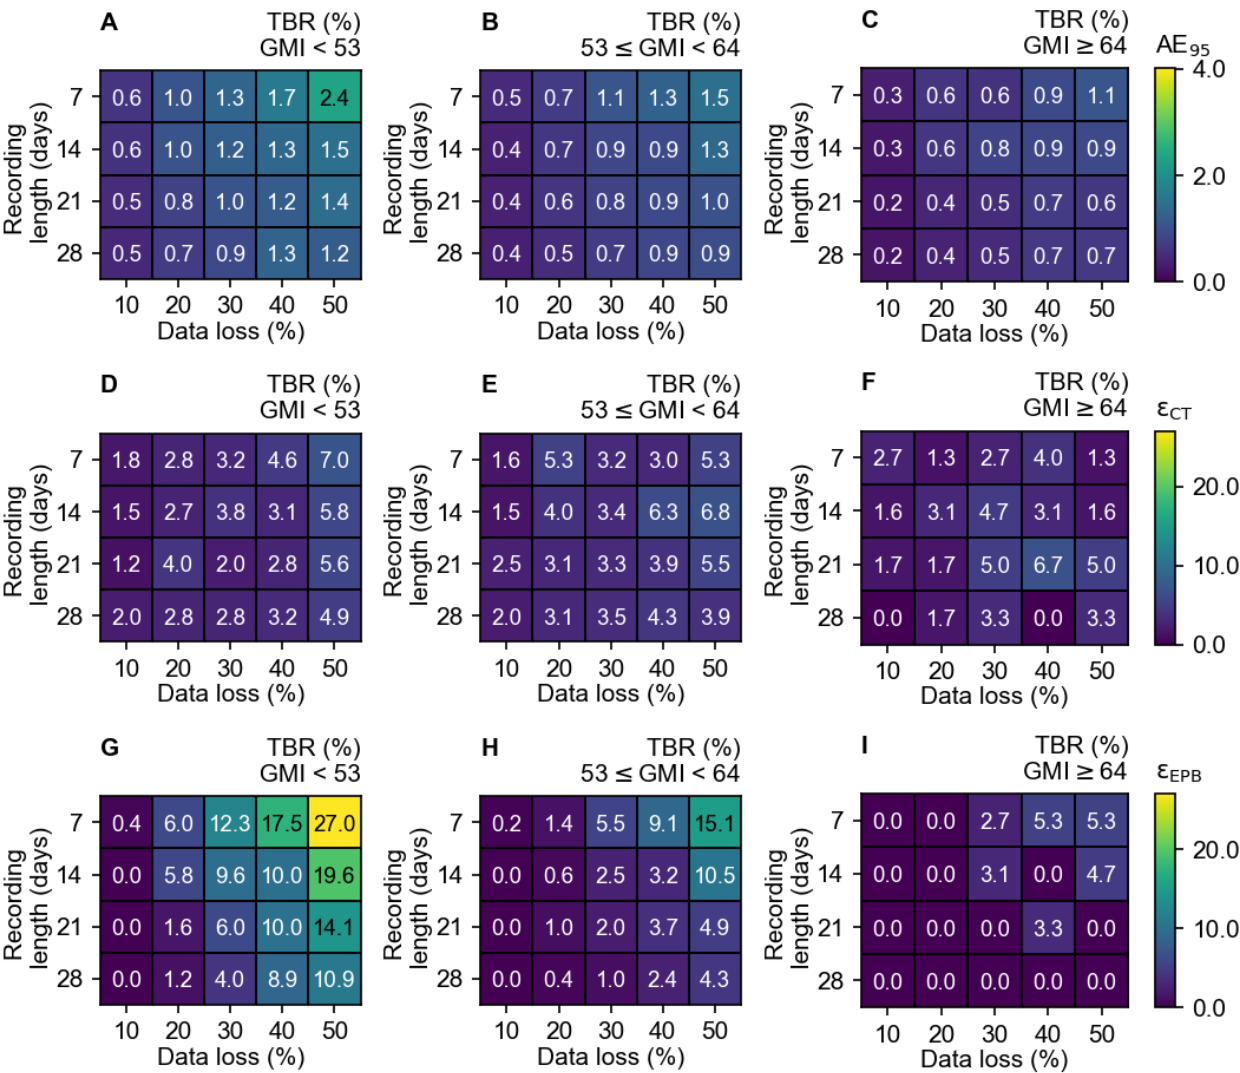
For a 14-day measurement period with 30% data loss, the AE_{95} was 2.4%, 1.3%, and 1.0%, ε_{CT} was 17 (2.1%), 23 (2.9%), and 14 (1.8%) and ε_{EPB} was 0 (0.0%), 0 (0.0%), and 0 (0.0%) for TIR, CV, and GMI, respectively (Figures S1 and S2 in Multimedia Appendix 4). For TAR and TAR2 the ε_{EPB} was 0.0% for all cases (Figure S3 in Multimedia Appendix 4).

TBR and TBR2 have the highest errors, especially with greater data loss in shorter recordings, with a maximum ε_{EPB} of 147 out of 736 (20.0%) of the recordings for TBR and 22 out of 408 (5.4%) of the recordings for TBR2, compared to a maximum of 5 out of 798 (0.6%) for TIR, CV, and GMI. In 2 (0.3%) of the 14-day recordings, the TBR value went from 0.2% to 0.0%, resulting in its disappearance due to data loss. Similarly, the TBR2 metric disappeared in 32 (6.1%) recordings in the 14-day recordings with 30% data loss. The median TBR2 value of the original recordings was 0.07% (IQR 0.07%-0.15%). No other metrics disappeared due to data loss.

For the SD, LBGI, HBGI, and RI, only the AE_{95} was available. The overall AE_{95} was low, with 0.1 for SD, 0.2 for LBGI, and 0.6 for HBGI and RI. The highest AE_{95} of 0.8% was observed for the HBGI and RI metrics in a 7-day recording with 50% data loss (Figure S4 in Multimedia Appendix 4).

GMI Subgroup Analysis

The recordings were divided into 260 (32.6%) low GMI (<54 mmol/mol), 445 (55.8%) moderately elevated (53-64 mmol/mol), and 93 (11.7%) elevated GMI recordings (≥64 mmol/mol). Figure 4 shows the values of AE_{95}, ε_{CT}, and ε_{EPB} for TBR, with missing data increasing from 5% to 50% over a period of 7 to 28 days for the GMI subgroups. The error caused by missing data is highest in the low GMI group (Figures 4A, 4D, and 4G). The AE_{95}, ε_{CT}, and ε_{EPB} are 1.2%, 10 (3.8%), and 25 out of recordings 260 (9.6%), respectively, for a recording of 14 days with 30% data loss. This means that for 9.6% of the recordings a clinical expert would see a relevant change.

Figure 4. (A-C) The AE_{95} are shown, (D-F) the ε_{CT}, and (G-I) the ε_{EPB} of TBR within 3 GMI groups of <53 mmol/mol, 53 mmol/mol≤ GMI <64 mmol/mol, and GMI ≥64 mmol/mol. These panels illustrate the impact of 10%, 20%, 30%, 40%, and 50% data loss in recordings of 7, 14, 21, and 28 days. The color bar indicates the errors in percentages. AE_{95}: 95th percentile of the absolute error; GMI: glucose management indicator; TBR: time below range; ε_{CT}: clinical target errors; ε_{EPB}: expert panel boundary errors.


Discussion

Principal Findings

This study provides a thorough analysis of missing data's impact on real-world CGM recordings for patients with diabetes. By merging data analysis and expert evaluations, it assesses the clinical implications of missing data on CGM metrics, improving our understanding of its practical effects and challenges. Findings indicate that a minimum of 14 days of glucose data collection with no more than 30% missing data suffice for clinical decision-making, ensuring adequate patient care.

The key finding of this study is that the interpretation of TBR metrics is more vulnerable to greater clinical consequences due to missing data compared to other metrics. The results indicate that up to 30% data loss in a 14-day recording results in a misinterpretation of the glucose metric in 5.0% of the time. Therefore, it should be realized that 30% data loss over a 14-day measurement will occasionally lead to false clinical

interpretations of TBR. Furthermore, when analyzing the data by GMI levels, it is notable that in 9.6% of recordings featuring low GMI levels, a clinical expert would observe a relevant change due to missing data on TBR. These findings underscore the substantial impact of missing data on TBR, emphasizing the importance of cautious interpretation in clinical practice.

Similarly, for TBR2, 14-day recordings with 30% data loss resulted in misinterpretation in 0.2% of cases, and the complete disappearance of TBR2 episodes occurred in 6.1% of the cases. One might, therefore, suggest that severe hypoglycemic episodes would be missed, which can have potentially serious clinical consequences as symptoms might not always be recognized when they occur during nighttime [35]. However, this complete loss of TBR2 episodes occurs only when the actual TBR2 value is below the clinical target of 1%, and thus, would not have required any action. In contrast, missing data had limited influence on the clinical interpretation of other glucose metrics such as TIR, CV, GMI, TAR and TAR2. This limited influence was partly caused by broader expert panel boundaries for these

metrics compared to TBR and TBR2. The expert panel accepted errors of 1%-5% for TBR2 and 1%-10% for TBR, while the accepted errors for TIR, TAR, and TAR2 ranged between 5% and 10%. When TBR is not a primary concern, 14 days of CGM data can be interpreted with 50% missing data. Even measurements shorter than 14 days could be used, but the representativeness of the data for long-term glucose values will diminish, and the correlation of the metrics with HbA_{1c} may decrease [21].

Based on the findings of this study, we propose several recommendations. First, we support the current recommendation of having a minimum of 70% data available in a CGM recording of 14 days. However, health care practitioners should be aware that there is still a chance of misinterpreting TBR. The guideline of a 10-day CGM recording with no data loss might be impractical, as the real-life CGM data analyzed in this study rarely met this criterion [8]. Therefore, our second recommendation is to use a measurement period of at least 14 days, which aligns with the durability of the current sensors. However, this result should be validated by other studies with different glucose sensors.

In this study, the expert panel boundaries are an important feature that may contribute to current clinical guidelines as they give insight into when CGM metrics result in clinically relevant changes due to data loss. The current clinical targets for most CGM metrics are valuable in the clinical setting to serve as goals for optimal glucose management. However, the targets are a limited tool for determining when a patient has a clinically relevant improvement or deterioration of their glucose management. When assessing the clinical consequences, the clinical target may not always be useful because significant changes due to data loss may not result in a different categorization if the initial value is already far from the target. However, such changes may still be clinically relevant.

In the literature, the CGM metrics SD, LBGI, HBGI, and RI are defined [21]. However, there are currently no targets defined for these metrics. Consequently, the expert panel was unable to determine such a boundary for these metrics. Nevertheless, AE_{95} can provide insight into the error size, but not indicate the impact on clinical decision-making. Previous studies investigating the influence of missing data on glycemic variability metrics reported small MedAEs [12,22]. This corresponds to our findings of small MedAEs, suggesting that even with excessive data loss, the CGM metrics would not be altered significantly. However, the AE_{95} is in some cases relatively high, indicating that in 5% of the population data loss can have quite significant clinical consequences. Therefore, we reported on AE_{95} instead of MedAE in this study.

The data loss in the real-world CGM data was MNAR, as the gap probability distribution did not follow an exponential function. Next to that, the chance of missing data during the night (10 PM-1 AM) was higher. MNAR data loss has a profound impact on the effects of missing data and synthetic data loss cannot be applied arbitrarily. Therefore, in this research, we mimicked these characteristics of data loss to create a simulation that closely resembled the actual missing data experienced by patients using CGM devices in everyday life.

Limitations

Several potential limitations of this study need to be addressed. In clinical practice, all CGM metrics are typically evaluated together rather than individually which was done to determine the clinical expert boundaries. Additionally, these metrics will be reviewed at every clinical visit, further reducing the actual risk that missing data will cause a change in treatment. Another potential limitation of our study is the small number of experts involved in defining the boundaries for CGM metrics. The subjectivity and potential biases inherent in expert input can pose challenges. Furthermore, the cut-off to accept an ε_{EPB} at 5% was chosen arbitrarily and choosing a different cut-off could influence the interpretation of the results. It is important to note that defining different boundaries than those presented in this study could influence the observed errors.

It should also be considered that this research has been performed on data measured only with the FreeStyle Libre 1 sensor, and some findings might differ for other devices. For example, the 8-hour data storage capacity may explain why more data are lost during the early night (10 PM-1 AM), which is a critical time for glucose measurements [36]. However, the presented research methodology can be easily adopted and applied to other CGM devices or populations. The results presented in our study were obtained from patients with diabetes, predominantly type 1 diabetes, who were treated in a hospital in the Netherlands. Differences in patient demographics, disease progression, and device accuracy could impact the applicability of findings across diverse populations. Therefore, caution should be exercised when extrapolating these results to other populations. However, the average HbA_{1c} value of 7.6% (IQR 7.0%-8.3%; 60.0 mmol/mol, IQR 53.3-67.0 mmol/mol) was comparable with a large cohort from Germany and Austria, with a mean HbA_{1c} of 7.8% (IQR 6.9%-8.9%; 62, IQR 52.0-74.0 mmol/mol), suggesting some level of generalizability [37]. Furthermore, the presented methodology can be applied to investigate the consequences of missing data in other diabetes populations using CGM.

Methodological Decisions

Some noteworthy methodological decisions were made in this study. First, we decided to include all the available 24-hour windows, thus including multiple 28-day recordings per patient in the data set. With this approach, there were no significant differences in CGM metrics between the preprocessed data with the baseline data set, validating the inclusion of multiple recordings. Second, not all patients used their CGM device continuously. Patients may have periods of several months where they did not use a CGM device. We marked this as missing data, which may have led to a potential overestimation of the reported data loss, compared to day-to-day CGM use. Third, we decided to create recordings of 7 to 28 days to study a range of CGM measurement lengths. The studies of Riddlesworth et al [21] and Xing et al [24] suggest that at least 14-15 days of CGM data provide a good estimation of CGM metrics compared to monitoring every 3 months or HbA_{1c}. Also,

Akturk et al [23] state that while the optimal recording length depends on the size of the gaps, duration of 14 days generally proves to be adequate. Using measurements of 7-28 days, we can ensure that an adequate measurement duration was covered.

Future Research

Future research should focus on including a heterogeneous population of patients with type 1, type 2, and other subtypes of diabetes. Next to that, more commonly used sensors should be added to the analysis to give a more generalizable result. Finally, the expert panel should be expanded and implemented similarly to the Parkes and Clarke error grids, involving a larger and more diverse panel of experts, to enhance the reliability and generalizability of the established boundaries [38,39].

Conclusions

To conclude, our aim was to examine the impact of data loss on glucose metrics within individual patient recordings from continuous glucose monitors and its implications for clinical decision-making. Through integrated data analysis and expert evaluations, we underscore the importance of comprehending missing data's clinical consequences and recommend a maximum of 30% missing data in 14-day CGM recordings to enhance accurate interpretation and glucose management, acknowledging the possibility of misinterpreting TBR even with this threshold. For reliable interpretation of TBR in recordings with a low GMI, data loss should be below10%. Further research is needed to explore the consequences of missing data in diverse populations using various CGM devices, emphasizing the importance of comprehensive data collection for optimal glucose management and clinical decision-making.

Abstract

Background: The COVID-19 pandemic impacted how people accessed health services and likely how they managed chronic conditions such as type 2 diabetes (T2D). Social media forums present a source of qualitative data to understand how adaptation might have occurred from the perspective of the patient.

Objective: Our objective is to understand how the care-seeking behaviors and attitudes of people living with T2D were impacted during the early part of the pandemic by conducting a scoping literature review. A secondary objective is to compare the findings of the scoping review to those presented on a popular social media platform Reddit.

Methods: A scoping review was conducted in 2021. Inclusion criteria were population with T2D, studies are patient-centered, and study objectives are centered around health behaviors, disease management, or mental health outcomes during the COVID-19 pandemic. Exclusion criteria were populations with other noncommunicable diseases, examining COVID-19 as a comorbidity to T2D, clinical treatments for COVID-19 among people living with T2D, genetic expressions of COVID-19 among people living with T2D, gray literature, or studies not published in English. Bias was mitigated by reviewing uncertainties with other authors. Data extracted from the studies were classified into thematic categories. These categories reflect the findings of this study as per our objective. Data from the Reddit forums related to T2D from March 2020 to early March 2021 were downloaded, and support vector machines were used to classify if a post was published in the context of the pandemic. Latent Dirichlet allocation topic modeling was performed to gather topics of discussion specific to the COVID-19 pandemic.

Results: A total of 26 studies conducted between February and September 2020, consisting of 13,673 participants, were included in this scoping literature review. The studies were qualitative and relied mostly on qualitative data from surveys or questionnaires. Themes found from the literature review were "poorer glycemic control," "increased consumption of unhealthy foods," "decreased physical activity," "inability to access medical appointments," and "increased stress and anxiety." Findings from latent Dirichlet allocation topic modeling of Reddit forums were "Coping With Poor Mental Health," "Accessing Doctor & Medications and Controlling Blood Glucose," "Changing Food Habits During Pandemic," "Impact of Stress on Blood Glucose Levels," "Changing Status of Employment & Insurance," and "Risk of COVID Complications."

Conclusions: Topics of discussion gauged from the Reddit forums provide a holistic perspective of the impact of the pandemic on people living with T2D, which were found to be comparable to the findings of the literature review. The study was limited by only having 1 reviewer for the literature review, but biases were mitigated by consulting authors when there were uncertainties. Qualitative analysis of Reddit forms can supplement traditional qualitative studies of the behaviors of people living with T2D.

Introduction

Background

Type 2 diabetes (T2D) is characterized by the body's resistance or insufficient production of insulin. Research suggests that the risks of further complications for people living with T2D can be mitigated through proper self-management [1]. Treatment protocol for proper management of T2D includes glycemic control, weight management, adequate nutrition, regular physical activity, reducing sedentary behaviors, and taking prescribed medications [2].

COVID-19 and Managing T2D

With the emergence of the COVID-19 pandemic, beginning in March 2020, social distancing measures included business closures, remote school and work measures, prohibition of large crowds, limited socialization outside the household, and increased reliance on digital health care delivery. As a result of these changes and fear of the unknown, stress and anxiety were resulting manifestations [3]. People living with diabetes are already at increased risk for serious complications from COVID-19 due to already being immunocompromised and because the virus may thrive in an environment of high blood glucose [4]. A scoping review conducted in 2023 by Li et al [5] revealed that diabetes prevalence increased among those with severe COVID-19, accounting for 16.8% of deaths. Therefore, it was vital that those living with T2D took extra precautions to avoid the virus. However, proper management of T2D requires healthy lifestyle behaviors, which were likely impacted by the lifestyle changes that occurred during lockdowns, in addition to the exacerbated risk of attaining severe COVID-19 symptoms.

Study Objective and Rationale

Considering that proper management of T2D requires healthy behaviors and that the implications of the COVID-19 pandemic were disruptive in people's daily lives worldwide, this study aimed to consolidate the literature of studies that examined the health behaviors and attitudes of people living T2D during the first year of the COVID-19 pandemic and to compare the themes gauged from the scoping review to topics of discussion on Reddit forums among people living with T2D during the same period. Social media is a form of patient-generated health data where users can discuss with their peers how they manage T2D through sharing diet, food, symptoms, research, and recipes while obtaining peer support [6]. It also presents a public data source to gauge sentiment and topics of discussion during the initial lockdown period. Our objective was to examine if data from social media, in this case Reddit, provided insights that were similar to findings from the literature review.

Methods

Scoping Review

A scoping review was conducted following the framework of Arksey and O'Malley [7] using the following steps: (1) identifying the research question, (2) identifying relevant studies, (3) study selection, (4) charting the data, and (5) summarizing and reporting the results [8].

Search Strategy

Searches were conducted in 3 databases (PubMed, Scopus, and CINAHL) from January 2020 to May 2021 (Textbox 1). Using the keywords identified, relevant studies were identified using the inclusion and exclusion criteria from title and abstract to full-text screening. For studies included in the data charting phase, reference lists were scanned for any additional relevant studies. However, these searches did not produce any additional results.

Textbox 1. Search terms for the scoping review.

Diabetes AND (*manag** OR *behave** OR *mental* OR *stress* OR *anxiety* OR *depression*) AND (*COVID* OR *coronavirus* OR *pandemic*)

Study Selection

Following the Arksey and O'Malley [7] framework, papers were reviewed in 3 iterations. In the first iteration, abstracts were scanned and selected using the eligibility criteria below. In the second iteration, the full text was scanned using the same eligibility criteria to select papers. Finally, in the third iteration, data were extracted and charted, and studies were excluded if they did not meet the eligibility criteria. Eligibility was determined based on the criteria below and for a paper to be included, all inclusion criteria needed to be met, and not have met any exclusion criteria. Only 1 reviewer (MSN) performed the initial study screening and assessment, but uncertainties about inclusion criteria were addressed to the other authors and

solved through discussion to make the final decision for study eligibility.

The inclusion criteria are (1) the population of focus must include people living with T2D, (2) the findings of the study are patient-centered, and (3) the objectives of the study are to gauge changes in health behaviors, disease management, or mental health outcomes during the COVID-19 pandemic.

The exclusion criteria are (1) people living with other noncommunicable diseases, not as a comorbidity with T2D (an exception to this criterion was made if the population consisted of people with type 1 diabetes or gestational diabetes), (2) the study examines COVID-19 as a comorbidity to T2D, (3) clinical treatments or delivery of care for COVID-19 among people living with T2D, (4) genetic expressions of COVID-19 among people living with T2D, (5) case studies, commentary, review papers, or gray literature (ie, letters to editor, editorials, blogs, and newspapers), or (6) studies not published in English.

Charting and Extracting Data

To guide data extraction, parameters were created that included the country of study, the time in which the study was conducted, the study sample size, and the main findings. Findings were directly extracted and quoted from the paper and the remaining data parameters were interpreted through analysis from examining the paper. Given the limitations of the study, only 1 reviewer (MSN) was able to conduct the extraction, but clarity was taken from other authors when there were areas of uncertainty.

Synthesis of Data

The extracted results from the study were examined and were given numerical codes for thematic analysis. Thematic analysis was conducted by the primary reviewer (MSN) and other authors were consulted in the case of uncertainty or discrepancies. Themes were categorized to summarize the studies by their main findings to answer the research question.

Examination of Reddit Data

Data Collection

For this study, 3 communities on Reddit were examined: r/type2diabetes, r/diabetes_t2, and r/diabetes [9-11]. From the r/diabetes [11] community, only posts that were tagged with the "flair" and "type 2 diabetes" were examined. The former 2 communities are exclusively for people living with T2D, while the latter was only examined if it was tagged as T2D. While there is no way to guarantee that patients living with type 1 diabetes were excluded from this data set, it was reasonable to assume that the discussions in our data set only pertained to T2D, given that they were posted or tagged in communities for people living with T2D.

Reddit was the chosen data source because there were readily available open-source application programming interfaces (APIs) to harness the data through Python scripts. Additionally, because Reddit communities are divided by different interest groups, such as diabetes, it ensured that the data source mostly consisted of the population of interest. Finally, Reddit's terms and conditions did not forbid the use of data for research purposes and was chosen for that reason [12].

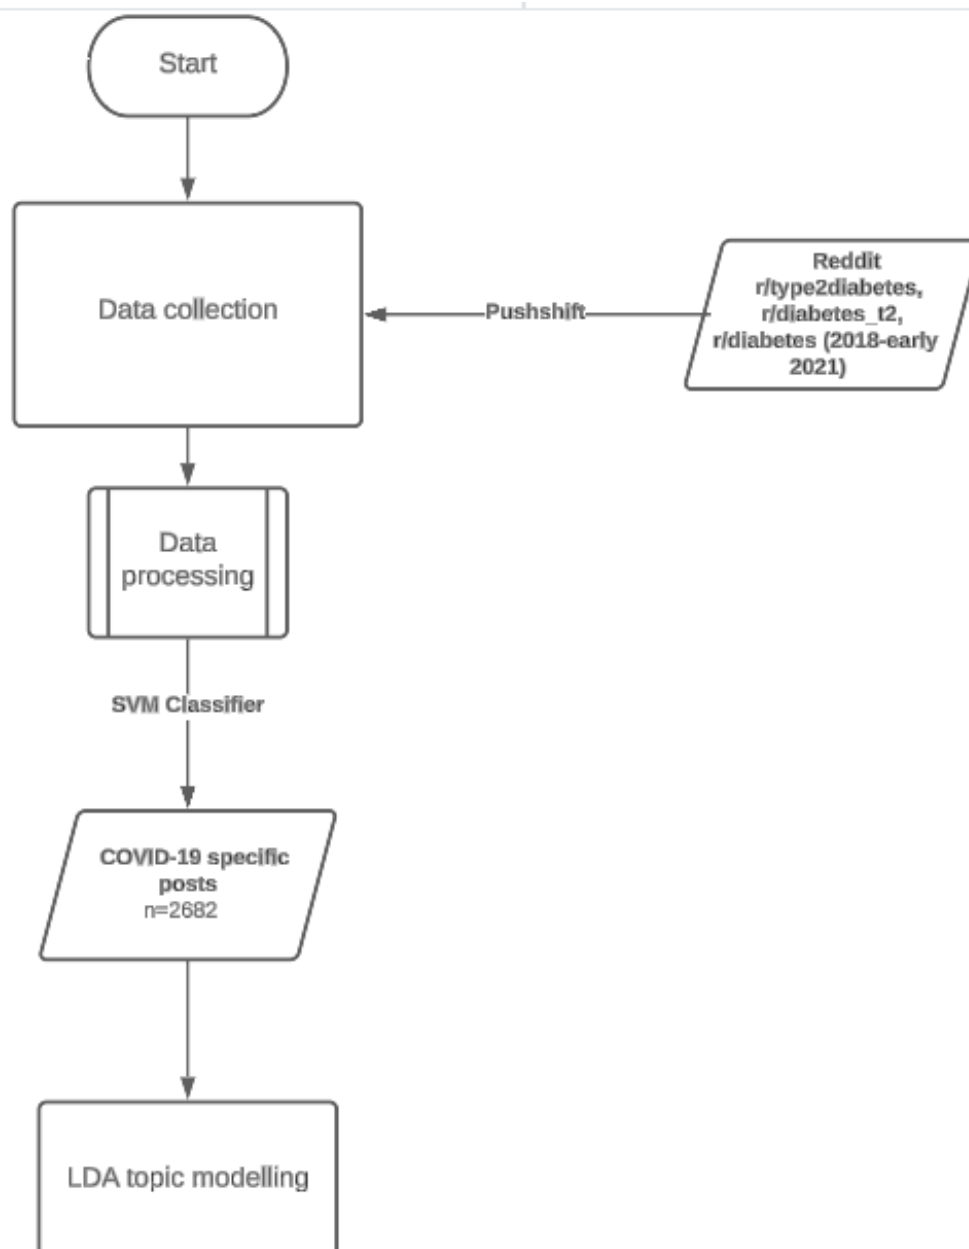
Classification of Posts

A year's worth of data were examined, a total of 48,988 posts from March 2020 to March 2021. Within the data set, terms related to the COVID-19 pandemic were manually searched for using search features on Excel (Microsoft Corp) by MSN. These terms included *COVID*, *coronavirus*, *pandemic*, *social distancing*, *lockdown*, *quarantine*, *toilet paper*, *unemploy*, *unemployed*, *work from home*, *working from home*, *telehealth*, *vaccine*, *sanitizer*, and *mask*.

Posts that contained those terms in the text body were manually evaluated for context and labeled as "covid" or "noncovid." In total, 9803 posts were manually classified by MSN and verified by NJ, with 2065 labeled as "covid" and 7738 labeled as "noncovid" and subsequently classified with the support vector machines. An additional 818 posts that were published in the context of the COVID-19 pandemic were identified, bringing the total number of pandemic-specific posts to 2883. The remainder of unlabeled posts published in the identified pandemic period were labeled as "noncovid."

Data Analysis

The latent Dirichlet allocation (LDA) topic modeling algorithm [13,14] with the MALLET (Machine Learning for Language Toolkit) package [15] was used to obtain topics of discussion by obtaining clusters of words belonging to a single topic (Figure 1). This unsupervised algorithm was chosen as there was no precedent of topics that were being detected, and thus, there were no data to train a supervised algorithm. After classifying the posts, the entire data set was reprocessed, with 2682 being specific to the COVID-19 pandemic, and topic modeling was performed. A value of k, the number of topics, was determined by evaluating the coherence scores outputted by the model for each value of k and by manually evaluating the distinction between topics for various k values.

Figure 1. Collecting and processing of Reddit data. LDA: latent Dirichlet allocation; SVM: support vector machine.


Sentiment Analysis

Sentiment analysis (SA) with the VADER (Valence Aware Dictionary for Sentiment Reasoning) [16] algorithm was performed to understand the subjective emotions, or sentiment, associated with each post. Valence scores of sentiment are calculated on both polarity (if the text is negative or positive) and intensity (how positive or negative a text is), with a normalized compound score, returned between –1 and +1. Thresholds for classifying a text as per VADER are as follows [16]: positive: compound score ≥+0.05; neutral: compound score between –0.05 and +0.05; and negative: compound score ≤–0.05.

Ethical Considerations

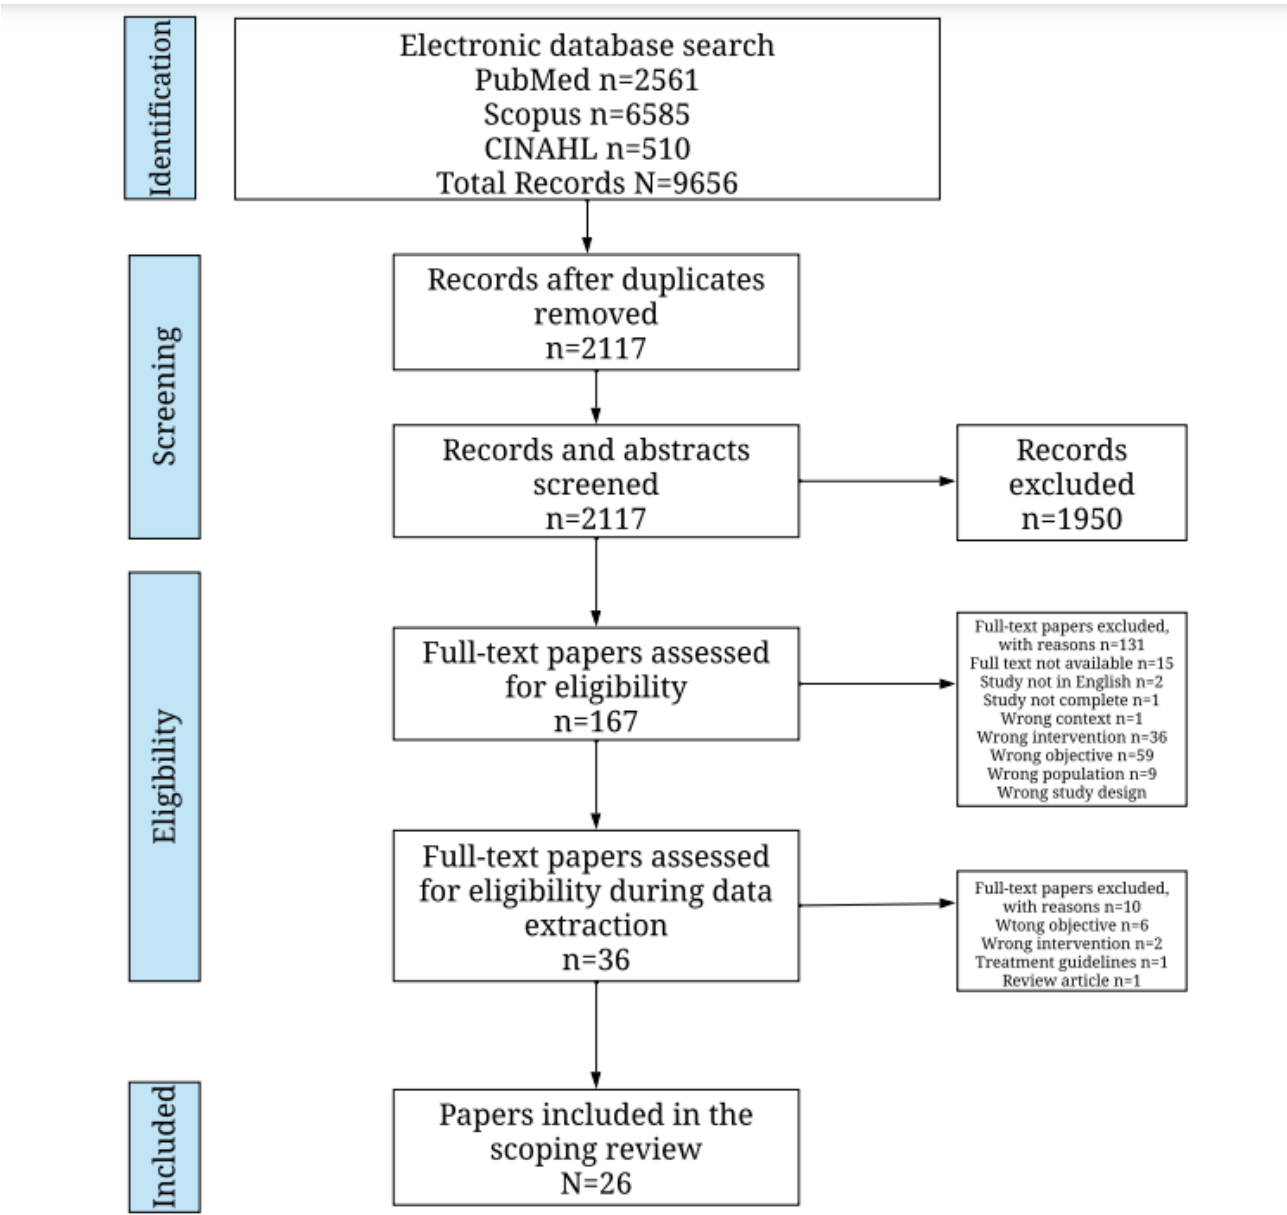
As per the University of Toronto's research ethics guides exemptions in section 1, ethical approval was not obtained for this study because it was assumed that Reddit is a public data source and it is assumed that there is no reasonable expectation of privacy [17]. Moreover, there was no direct interaction between the researcher and the participants, and hence, the researchers did not believe that ethical approval was necessary, as per section 2 [17]. The data used for our qualitative analysis was scraped directly from Reddit and it was assumed to be a public data source. As users do not need a form of authentication to view Reddit forums, it was assumed that the users who posted to them did so with the knowledge that they would be displayed publicly. Data were obtained through a data dump from the Pushshift API, and more than 100 published research studies have already harnessed Reddit data with Pushshift [18]. We do not believe that using this API was a violation of Reddit's API terms of use [19]. However, in a systematic analysis of 727 manuscripts that used Reddit as a data source, only 15% mentioned any form of ethical review [20]. We do acknowledge that there is debate on the ethics of using Reddit data for academic research purposes but nowhere on Reddit's terms and

conditions prohibit the use of data for research purposes [12]. Hence, as of the time of research, by omission of information about using data for research purposes, it was assumed that it was within Reddit's terms and conditions. While the username of the post authors was obtained, they were assumed to be pseudonyms of the user and not their actual names. However, we do acknowledge that some users may have integrated their real names into their usernames, but in this study, the usernames were not analyzed to confirm so. Reddit also does not provide identifiable characteristics of individual users, such as their name, gender, or geographical location. However, we do acknowledge that some users may put identifiable information within their text. For this study, this identifiable information was not harnessed or analyzed.

Results

Findings From Scoping Review

A total of 9656 papers were identified from the 3 databases. Of these 9656 papers, 7539 (78.1%) papers were duplicates and were subsequently removed. The abstracts of 2117 papers were screened and the full texts of 167 (7.9%) of those papers were scanned to evaluate if they met the inclusion criteria. Of those papers, 36 (1.7%) papers were included for data extraction. Finally, after close examination from data extraction, of the 36 papers, 26 (72.2%) papers were included as part of this scoping review as they met the inclusion criteria. Figure 2 summarizes the process.

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram from the scoping review.


Study Characteristics

A total of 26 studies published as of May 2021 were included in this review. With respect to data collection, of the 26 studies,

21 (80%) studies used surveys or questionnaires, 3 (11%) studies used interviews, 2 (8%) studies analyzed blood glucose readings, and 1 (4%) study used hospital consultations. The studies took place between February and September 2020 and included a

sample size of 13,673 people living with diabetes. The geographical representation includes 7 (26%) studies from India, 3 (11%) studies from Japan, 2 (8%) studies from China, 2 (8%) studies from Denmark, 2 (8%) studies from Brazil, 2 (8%) studies from the Netherlands, 1 (4%) study from Turkey, 1 (4%) study from Spain, 1 (4%) study from Germany, 1 (4%) study from Arab Gulf, 1 (4%) study from Mexico, 1 (4%) study from Singapore, 1 (4%) study from Pakistan, and 1 (4%) study from the United Kingdom.

Findings From Thematic Analysis

The main themes found from the literature review include poor glycemic control, increased consumption of unhealthy foods,

reduction in physical activity, and inability to access medical appointments. A detailed summary of all included papers is included in Multimedia Appendix 1.

Findings From Analysis of Reddit Data

The LDA topic modeling algorithm was performed on 2883 posts published between February 28, 2020, and February 28, 2021.

Findings From LDA Topic Modeling

Table 1 summarizes the topics and associated words for COVID-19–related posts.

Table 1. Topics and associated words for COVID-19–related posts.

Topic number	Topic name	Words
Topic 1	Coping With Poor Mental Health	feel, day, week, work, weight, lose, walk, bit, symptom, bad, lot, gym, night, happen, end, great, covid, felt, ill, diagnosis
Topic 2	Accessing Doctor & Medications and Controlling Blood Glucose	doctor, test, ac, year, insulin, month, metformin, diagnose, low, glucose, diet, week, med, exercise, change, level, stop, reading, check, medication
Topic 3	Changing Food Habits During Pandemic	eat, food, carbs, lot, meal, low, carb, diet, hard, hour, thing, water, keto, fast, cut, easy, glucose, add, stuff, rice
Topic 4	Impact of Stress on Blood Glucose Levels	blood, glucose, high, time, stress, number, long, exercise, bg, body, problem, morning, normal, control, sleep, make, level, effect, change, kind
Topic 5	Changing Status of Employment & Insurance	work, home, hospital, today, time, year, talk, give, advice, wait, insurance, visit, guess, state, order, meter, live, strip, situation, friend
Topic 6	Risk of COVID Complications	covid, type, health, care, risk, sick, control, issue, virus, disease, diabetic, question, pandemic, mask, hand, case, infection, wear, patient, home

Findings From Sentiment Analysis

Impact of Stress on Blood Glucose Levels and Coping With Poor Mental Health had average compound scores that fell in the threshold of being classified as neutral (odds ratio [OR] 0.0252, 95% CI –0.0344 to 0.0849 and OR 0.0492, 95% CI –0.0121 to 0.1105, respectively). Risk of COVID Complications, Accessing Doctor & Medications and Controlling Blood Glucose, and Changing Status of Employment & Insurance were ranked next from lowest to highest with average compound scores of OR 0.0876 (95% CI 0.0322-0.1430), OR 0.1457 (95% CI 0.0879-0.2035), and OR 0.1748 (95% CI 0.1263-0.2232), respectively, and finally, Changing Food Habits During Pandemic had the highest average compound score of 0.2544 (95% CI 0.1965-0.3123).

Discussion

Principal Results

Our analysis revealed that people living with T2D were negatively impacted by the pandemic mentally and were negatively impacted by how they managed their chronic disease. Our literature review found that people living with T2D were negatively impacted by the pandemic by having poorer glycemic control, poorer lifestyle behaviors, their inability to access medical appointments, and increased stress and anxiety. Our analysis of Reddit data found similar themes, with additional emphasis on the economic impacts of the pandemic among people living with T2D.

Our literature review found that the COVID-19 pandemic impacted people's lives through poorer glycemic control, increased consumption of unhealthy foods, decreases in physical activity, inability to access medical appointments, and increased stress and anxiety toward the impact of the lockdown and fear of being exposed to the coronavirus. Topic modeling from data on 3 Reddit forums for people living with T2D found the following topics: Coping With Poor Mental Health, Accessing Doctor & Medications and Controlling Blood Glucose, Changing Food Habits During Pandemic, Impact of Stress on Blood Glucose Levels, Changing Status of Employment & Insurance, and Risk of COVID Complications. The additional finding of employment as a topic of discussion on Reddit forums suggests that digital discussion presents a holistic perspective of diabetes management that considers the person's life as a whole when managing their disease.

Furthermore, the majority of the 26 studies included in our literature review mostly relied on surveys and interviews to obtain their data. Surveys and interviews are often time-consuming processes. However, analyzing data from forums such as Reddit, using machine learning algorithms such as topic modeling and SA, can be a quicker method to obtain a broad range of themes and sentiments from a large volume of participants when performing qualitative research. We do not suggest that qualitative analysis from digital forums could replace traditional qualitative research, but can rather supplement it as our study demonstrates that the results from

XSL•FO

RenderX

our analysis are comparable to results from traditional qualitative studies of people living with T2D.

Glycemic Control

As glycemic control is a major component of the self-management of T2D, it was expected that this would be a major theme found both in our literature review and in our analysis of Reddit data. While psychological stress is subjective among individuals, few studies have demonstrated that psychological stressors have been linked to hyperglycemia [21-23]. Considering that the major theme of our findings suggested that the pandemic was a stressor for people living with T2D, it was hypothesized that this stress would have an impact on glycemic control. From our Reddit analysis, the topic Impact of Stress on Blood Glucose Levels had the lowest sentiment score of OR 0.0252 (95% CI –0.0344 to 0.0849), suggesting that there was increased anxiety toward managing blood glucose levels.

Our literature review further reiterated that people living with T2D experienced increased blood glucose or increased hemoglobin A_{1c} (HbA_{1c}) levels during the pandemic [24-28]. While 1 study did correlate higher HbA_{1c} with increased levels of stress during the pandemic [29], our literature review also attributed poorer glycemic control as a result of reduced blood glucose monitoring and reduced medical visits being reasons for this [24,30-35]. This sentiment was also reflected in our analysis of Reddit data. The topic Accessing Doctor & Medications and Controlling Blood Glucose considered that reduced access to medication and health care providers impacts blood glucose levels, and while reduced health care visits were a factor in reduced glycemic control, the Reddit analysis additionally considered that losing employment was also a stressor for people living with T2D and also resulted in lost insurance benefits that reduced doctor visits and medication access.

Lifestyle Management

As T2D is managed by lifestyle behaviors, they were nonetheless a significant theme of discussion found in both our literature review and our analysis of T2D Reddit communities. Our literature review revealed that lifestyle behaviors among people living with T2D were impacted by increased consumption of unhealthy foods and reduced physical activity [24-27,30,33,36-38]. As a result of these behavior changes, participants reported changes in body weight [27,37].

These findings were supported by our analysis of Reddit as Changing Food Habits During Pandemic was a topic of discussion. Interestingly, this topic was associated with the highest average sentiment (OR 0.2544, 95% CI 0.1965-0.3123). While the literature suggests that dietary changes were attributed to stress during the pandemic [33], the positive sentiment score of the Reddit posts may be an indication that increased unhealthy food consumption may have been a coping mechanism associated with positive emotions through the stressful time and that there was a sense of camaraderie and bonding among peers through this coping mechanism.

Considering physical activity, in the topic Coping With Poor Mental Health, the terms "gym" and "walk" were included. This

may suggest that stress was related to gym closures in the initial months of the pandemic and people relying on walking as a means of physical activity. The literature review supports that gym closures and having fewer opportunities to walk due to teleworking and closures of businesses are attributed to reducing physical activity [25,27]. Moreover, the literature review attributes changes in exercise behaviors as a result of pandemic-related stress [38], and hence, it was fitting that the topic modeling algorithm pooled terms related to mental health with terms related to physical activity.

Access to Diabetes Care

During the COVID-19 pandemic, accessing care was perceived as a significant barrier to managing T2D as more clinical visits were done through telehealth as a means to protect patients and health care providers from exposure to the coronavirus. However, not all people living with T2D had access to telehealth care, particularly those living in rural communities [25]. Moreover, health care providers were called to aid in treating patients infected with COVID-19 [25], resulting in people living with T2D being unable to see their regular health care provider or being treated by health care providers who were not experienced in managing T2D [39]. Our literature review revealed that people living with T2D had difficulty managing their blood glucose levels and felt depression as a result of missed medical appointments.

Among our analysis of Reddit data, Access to Doctor & Controlling Blood Glucose was identified as a topic of discussion among people living with T2D, with an average sentiment score (OR) of 0.1457 (95% CI 0.0879-0.2035). Further examination of Reddit data revealed that while barriers to accessing health care providers existed, another barrier was presented through the fear of acquiring COVID-19 infection and avoiding hospitalization in potentially dangerous situations. The fear of acquiring COVID-19 infection was also reflected in our literature review in a general sense. Further research in the years ahead would need to examine the impact of the lessening of in-person health care visits among people living with T2D.

Mental Health

With the COVID-19 pandemic being disruptive to personal lives worldwide, many people experienced elevated stress and anxiety. The mental health impact of this pandemic is expected to be long-term due to the extreme measures that were necessary to prevent the spread of the virus and the resulting economic implications [40]. Our literature review revealed that people living with T2D were no exception to the stressors of the pandemic which included social isolation [28,29,41] and financial stress [28,29]. However, stressors that were specific to people living with T2D included missing medical appointments [42], being unable to access medications and supplies to manage diabetes [42,43], and managing their disease [29]. Additionally, people living with T2D were anxious about being exposed to COVID-19 as they felt that they were more vulnerable to serious complications or death [26,31,41-44].

Comparing these findings from our literature review to our analysis of Reddit data found Coping With Poor Mental Health,

Impact of Stress on Blood Glucose Levels, and Risk of COVID Complications as topics of discussion. Overall, these topics were associated with lower sentiment scores (OR 0.0492, 95% CI –0.0121 to 0.1105; OR 0.0252, 95% CI –0.0344 to 0.0849; and OR 0.0876, 95% CI 0.0322 to 0.1430; respectively). Specifically, within the Reddit analysis, users acknowledge that increased stress during the pandemic impacted their glycemic control but users also felt that they would be helpless if they experienced diabetes-related complications as hospitalization would put them at risk of acquiring a COVID-19 infection. Moreover, as supported in the literature review, people living with T2D were generally afraid of being exposed to the virus with their increased risk state. While our study demonstrated that people living with T2D were using peer support as a means to cope with the stressors of the pandemic, it also demonstrates that users were negatively impacted by the psychological stressors of the pandemic.

Impact to Employment

Efforts to curb the virus resulted in many employers worldwide requiring their employees to work from home [45], which resulted in changes in work-life balance and mental health issues with the inability to interact with others outside the household [46,47]. Moreover, as businesses shut down during the pandemic to curb the spread of the virus, the pandemic resulted in the loss of employment for many workers. The unemployment rate reached 14.1% in the United States in April 2020, the highest since data collection began in 1948 [48]. Additionally, only 60.2% of the labor force participated in April 2020, the lowest participation observed since the 1970s [48]. Unemployment already poses the issue of loss of income and standard of living and decreased sense of self-purpose [49], potentially impacting health behaviors due to increased stress. However, many people unemployed were also impacted by changes to their health insurance because of their job loss [50,51].

While Kishimoto et al [25] suggested that teleworking resulted in reduced physical activity among people living with T2D, there was little discussion about the financial and employment implications of the pandemic among people living with T2D. However, Changing Status of Employment & Insurance was a topic of discussion among Reddit users on T2D forums. From the Reddit discussions, it could be inferred that a loss of insurance posed a barrier for people living with T2D to get medication and blood glucose meters and strips, affecting

glycemic control. Clinicians must consider how one's employment status affects people living with T2D, especially when they are additionally posed with a barrier to accessing clinical care, and outline treatment options in these situations.

Comparison to Prior Work

This study builds upon previous studies that have harnessed data from weblogs and social media websites to understand diabetes behaviors and the sentiment associated with the texts. People living with T2D use social media and digital forums to discuss their condition and related information among their peers [52]. These themes of discussion include diet, food, symptoms, research, recipes, and news [52-55]. This study uncovered similar themes of discussion through analysis of Reddit forums, with the added context of the COVID-19 pandemic, given that this study was conducted in 2021, as the pandemic was ravaging globally. However, no other study at the time compared the findings of social media analysis to the findings from traditional qualitative studies. Our study suggests that social media can be a supplemental data source when performing clinical qualitative analysis.

Comparison of Literature Review to Reddit Analysis

Our literature review summarized 26 studies conducted on 13,673 people living with diabetes to understand how the pandemic impacted and how they managed their diseases. Our analysis of Reddit data used support vector machines to classify Reddit posts written from 2020 to early 2021, published in the context of the pandemic from 1263 distinct authors. Most of the data obtained by researchers of the studies included in the literature review were through surveys and interviews, while the data obtained in the Reddit analysis used APIs to scrape data that were posted by Reddit users and analyzed using LDA topic modeling and VADER SA. As displayed in Textbox 2, the topics gauged from both studies were comparable to one another, with the Reddit analysis gauging an additional topic of Changing Status of Employment & Insurance. This additional finding suggests that discussions on Reddit offer insight from a holistic perspective that considers aspects of a person's life in the context of their disease, beyond treating symptoms. Moreover, analyses from Reddit forums can be less time-consuming than conducting long surveys or interviews and can collect data from a larger volume of users than from a single study.

Textbox 2. Comparison of topics found in the literature review to topics found in the Reddit discussion.

Literature review topics

- Increased Consumption of Unhealthy Foods
- Decreased Physical Activity
- Inability to Access Medical Appointments
- Anxiety Toward Lockdown
- Fear of COVID Exposure

Reddit topics

- Changing Food Habits During Pandemic
- Impact of Stress on Blood Glucose Levels
- Accessing Doctor & Medications and Controlling Blood Glucose
- Coping With Poor Mental Health
- Risk of COVID Complications
- Changing Status of Employment & Insurance

Limitations

Due to the staffing limitations and reliability of remote work during the pandemic, only 1 reviewer, MSN, was able to conduct the study search and study data extraction. However, any uncertainties were addressed to DS and JAC to mitigate any risk of bias.

Topic modeling and SA were performed on the Reddit posts but the posts were not thoroughly examined for context, and hence, the authors cannot comment on the quality of the discussions posted on the forum. We cannot confirm that the users who published the posts were all people living with T2D. We only examined the 3 Reddit communities mentioned in the study and no other subreddits about the coronavirus or mental health. Furthermore, we had no information about the demographics of the users of the diabetes forums of Reddit and assumed that the demographics were similar to the demographics of all Reddit users. Under this assumption, there could be a sampling bias in our Reddit data as Reddit users are mostly male and fall into the age demographic of 18-49 years [56,57]. Geographically, the United States has the largest number of Reddit users, while other users mostly reside in English-speaking, higher-income countries [58].

Conclusions

The findings from the literature review included topics of glycemic control, lifestyle management, access to diabetes care, and the impact on mental health among people living with T2D. However, an examination of Reddit data revealed an additional theme of employment being impacted during the pandemic, affecting diabetes lifestyle behaviors. Moreover, Reddit presented a large sample size of participants. Therefore, social media presents an opportunity to holistically observe the behaviors of those managing chronic diseases.

Data Availability

The data sets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

This study was conducted by MSN. MSN received guidance on the methodology from NJ and PPM. DS served as the clinical advisor for this study. All authors contributed to conceptualization. Data curation was conducted by MSN, with assistance from NJ. The methodology was designed by PPM. Formal analysis was conducted by MSN, with assistance from NJ and PPM. The investigation was conducted by MSN. Validation and verification were provided by DS. Funding support, project administration, and supervision were provided by JAC. This paper was originally written and edited by MSN. All listed authors approved the final version of this paper.

Abstract

Background: Recently, it has been reported that older adults with type 2 diabetes mellitus (T2DM) have lower skeletal muscle mass than healthy individuals. Although skeletal muscle mass in older adults with diabetes is occasionally reported, similar reports on young to middle-aged adults are limited.

Objective: This study aims to assess the prevalence of skeletal muscle loss in young to middle-aged adults with diabetes, examine the relationship between skeletal muscle loss and physical function in these patients, and examine whether there are differences in these characteristics between men and women.

Methods: This cross-sectional, observational study included patients younger than 65 years with T2DM who were admitted to our hospital between 2014 and 2022 for educational admission for glycemic control and requested rehabilitation by the Department of Metabolic Medicine. The control group consisted of patients who received rehabilitation during their hospitalization at our hospital and did not have diabetes. The main parameters included skeletal muscle mass, muscle strength, physical function, and activities of daily living.

Results: The prevalence of skeletal muscle mass loss in this study was 18.2% (10/55) in men and 7.7% (4/52) in women. The skeletal muscle mass index (SMI) was 7.7 (SD 0.8) and 8.4 (SD 0.5) for men in the T2DM and control groups, respectively, and 7.0 (SD 0.9) and 6.8 (SD 0.7) for women in the T2DM and control groups, respectively. Therefore, compared with the nondiabetes group, a significant difference was observed in men but not in women (men: $P<.001$, women: $P=.35$). Nonetheless, the diabetes group exhibited significantly lower physical functions, such as a walking speed of 1.3 (SD 0.2) m/s and 1.2 (SD 0.43) m/s for men and women in the T2DM group and 1.6 (SD 0.2) m/s and 1.5 (SD 0.1) m/s for men and women in the control group, respectively (men: $P<.001$, women: $P<.001$). One-leg standing time was measured as 30.7 (SD 26.9) seconds and 29.4 (SD 25.5) seconds for men and women in the T2DM group, compared with 100.5 (SD 30.6) seconds and 82.5 (SD 39.8) seconds for men and women in the control group, respectively, with the T2DM group's times being significantly lower (men: $P<.001$, women: $P<.001$). Univariate logistic regression analysis showed that SMI was significantly associated with age, BMI, and peripheral neuropathy (all $P\leq.002$). Multiple logistic regression analysis showed that BMI exhibited the strongest association (odds ratio 1.15, 95% CI 1.07-1.23; $P<.001$), and peripheral neuropathy was also significantly associated with SMI ($P=.009$).

Conclusions: Patients with diabetes, even those who are not older adults, face an elevated rate of skeletal muscle mass loss, muscle weakness, and a decline in physical function; moreover, they are susceptible to dynapenia and presarcopenia. Therefore, early intervention focusing on muscle evaluation and exercise is crucial.

Introduction

The global diabetes population is estimated to be 536.6 million, with ~1 (10.5%) in 10 adults having diabetes, according to new estimates published by the International Diabetes Federation [1]. This number is expected to increase to 643 million (11.3%) by 2030 and 783 million (12.2%) by 2045. Furthermore, diabetes is expected to cause 6.7 million deaths in 2021 and is the leading cause of US $966 billion in health care costs during this year [1]. Notably, more than 90% of people with diabetes worldwide have type 2 diabetes mellitus (T2DM) [1], which is characterized by insulin resistance, inflammation, hyperglycemic product accumulation, and increased oxidative stress [2,3]. In particular, insulin resistance causes insulin deficiency, which increases blood glucose levels and leads to overall skeletal muscle weakness [4,5]. Moreover, older adult patients with T2DM have recently been reported to have lesser skeletal muscle mass than healthy controls [6-8]. Besides, skeletal muscle plays an important role in blood glucose metabolism, and reduced skeletal muscle mass has recently been suggested to be a negative predictor of diabetes-related complications [6,7,9]. Specifically, previous studies have reported an association between poor glycemic control [10], renal function [5], and osteoporosis [6]. Additionally, low skeletal muscle mass has been found to be associated with all-cause mortality in patients with T2DM [11]. Therefore, it is important to appropriately treat patients with T2DM, particularly those with reduced skeletal muscle mass. Characterization of patients at a high risk of skeletal muscle mass loss will enable early and aggressive exercise therapy and instruction, which may positively impact life expectancy and related complications [12]. Nevertheless, most previous studies reporting on diabetes and skeletal muscle loss have been conducted in older adult patients with T2DM [7,13-16], few reports have focused on skeletal muscle mass in young to middle-aged adults with T2DM, and skeletal muscle mass loss and related factors have not been clarified. Therefore, the main purpose of this study was to clarify the existence of persons with low skeletal muscle mass in young to middle-aged adult with T2DM, examine the relationship between low skeletal muscle mass and physical function, and examine whether there are differences in these characteristics between men and women. Clarification of these issues could establish the need for early intervention and lead to preventive effects.

Methods

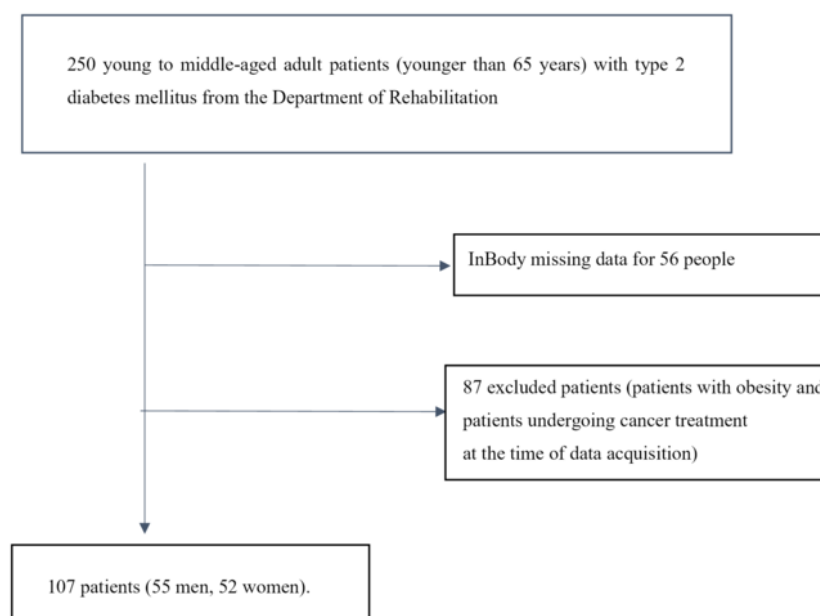
Study Design

This study was a single-center, cross-sectional, observational study.

Setting and Participants

The participants were 107 young to middle-aged adults with T2DM younger than 65 years who were admitted to the Department of Metabolic Medicine, Kumamoto University Hospital, for educational purposes and who requested rehabilitation by the Department of Metabolic Medicine. The study period was from April 2014 to March 2022, and patients were selected retrospectively based on their medical records. The exclusion criteria were patients with preexisting or primary diseases that could affect the skeletal muscle mass index (SMI) by bioelectrical impedance analysis, including patients (1) undergoing cancer treatment, (2) with neurological diseases, (3) with edema, and (4) with internal metal stents or pacemakers implanted in their bodies. The control group consisted of patients who received rehabilitation during their hospitalization at our hospital and did not have diabetes; they were selected at comparable eligible ages, and those who met the above exclusion criteria were excluded. Data for all patients were taken from the first measurement taken after admission.

Of the 250 patients with T2DM who requested rehabilitation by the Department of Metabolic Medicine during the period mentioned above, patients younger than 65 years were included and selected based on the inclusion criteria described above. A total of 56 patients were excluded due to missing data from the muscle mass measurement device, and an additional 87 patients were excluded because they were undergoing cancer treatment, or because of the presence of metals in their bodies, such as pins and screws. Finally, data from 55 men and 52 women were analyzed (Figure 1).

Figure 1. Selection of young to middle-aged adult patients with diabetes.


Variables

This study defines diabetes as exposure and outcome as skeletal muscle mass, which was the main skeletal muscle mass measured using the InBody 720 and InBody S10 (InBody Japan Inc) as the multifrequency bioelectrical impedance analysis method. InBody measurements were performed in the same limb position, using the same procedure, and were performed by a person skilled in operating the equipment. Skeletal muscle mass loss was defined as SMI <7.0 kg/m^2 in men and <5.7kg/m^2 in women based on Asian Working Group on Sarcopenia (AWGS) criteria [17]. The assessment items were age, sex, BMI, SMI, physical function (grip strength, comfortable walking speed, and one-leg standing time with eyes opened), medical history, insulin therapy, blood data, pulse wave velocity (PWV), and diabetes-related complications (retinopathy, renal impairment, or neuropathy).

Measurement

Data on age, sex, BMI, and nutritional status were collected from medical records. BMI was calculated as weight (kg) divided by the square of height (m). Serum albumin and total cholesterol levels were extracted from the blood data as indicators of nutritional status, and estimated glomerular filtration rate levels were extracted from medical records to assess renal function. Blood samples were collected after overnight fasting at admission.

Physical function was assessed based on grip strength, walking speed, and one-leg standing time. Grip strength was measured twice (once on each side), and the best value was used. The 10-m walking speed was measured using a stopwatch, and the test ended when the leading foot stepped on or crossed the 10-m starting line. The test was performed at normal walking speed, measured twice, and the better value was used. One-leg standing time was measured as the time that one leg was raised about 5 cm from the floor, and the better value of the 2 measurements, both left and right, was used. The cutoff values for grip strength

and walking speed were also based on those proposed by AWGS as follows: grip strength <26 kg for men and <18 kg for women, and walking speed 0.8 m/s for men and women [17]. In the one-leg standing time, the standard value was 30 seconds or more based on previous studies [18].

To assess glycemic control status, data on hemoglobin A_{1c} (HbA$_{1c}$; glycated hemoglobin), history of diabetes mellitus, and treatment with insulin or oral medications were extracted. History of diabetes was defined as the period from the diagnosis of diabetes mellitus. Furthermore, an ophthalmologist diagnosed diabetic retinopathy as simple retinopathy, preproliferative retinopathy, or proliferative retinopathy. Diabetic nephropathy was graded in severity based on urinary protein or albumin levels and estimated glomerular filtration rate levels and staged from stage I to stage V. Patients were identified at admission. Diabetic peripheral neuropathy was defined as the presence of diabetes mellitus as an essential condition and peripheral neuropathy other than diabetic neuropathy could be ruled out or loss of bilateral Achilles tendon reflexes was defined as having diabetic peripheral neuropathy. Moreover, arteriosclerosis is a complication of diabetes-related vascular diseases, and PWV was extracted to evaluate it. PWV, a test to determine the degree of arterial stiffness, measures the speed at which the heartbeat is transmitted through the arteries to the hands and feet, with higher readings indicating stiffer blood vessels and more advanced arterial stiffness [19].

Statistical Analysis

All statistical analyses were performed using EZR (Saitama Medical Center, Jichi Medical University), which is a graphical user interface for R (The R Foundation for Statistical Computing). More precisely, it is a modified version of R commander designed to add statistical functions frequently used in biostatistics. The Kolmogorov-Smirnov test was used to assess the normality of the distribution of variables in each group. To test for differences between the groups with and without diabetes, normally distributed data were analyzed using

the 2-tailed *t* test, whereas nonnormally distributed data were analyzed using the Mann-Whitney *U* test. Univariate logistic regression analysis was performed to determine the variables associated with SMI. In the multivariate analysis, we set age as a confounding variable and BMI as a mediator. Based on the univariate analysis, clinical findings that were statistically significantly associated with SMI were set as exposures, and the final model was constructed while accounting for multicollinearity. Missing data were excluded at the time of collection and are not included in the statistics. Statistical significance (*P* value) and odds ratios with 95% CI were calculated. In addition, sensitivity analysis was conducted by changing explanatory variables in the multivariate analysis. All results were considered statistically significant at *P*<.05.

Ethical Considerations

This study was approved by the Ethics Committee of the Graduate School of Life Sciences Research at Kumamoto University (ethics 2366) and complied with the ethical regulations of the Declaration of Helsinki (as revised in Fortaleza, Brazil, October 2013). All survey items and images used in this study were those used in routine medical practice and were conducted so that individuals could not be identified.

As for informed consent, the physician in charge of the medical care concerned conducted the research in accordance with the "Declaration of Helsinki" and the "Ethical Guidelines for Medical Research Involving Human Subjects" based on a separately specified consent document prior to conducting the research. Participation in the study was conducted on an opt-out basis, with a request for cooperation in the clinical research described on the hospital's website. The open document was published on the website of the Department of Rehabilitation Medicine. The opportunity to refuse participation was guaranteed by stating that if the patient did not wish to cooperate in the research, he or she would be contacted and would not be disadvantaged in any way, with no impact on his or her medical treatment, even if he or she refused to participate in the study. For secondary analyses that use existing data with primary consent, the initial consent covers the secondary analysis without additional consent.

Results

The characteristics of the T2DM and control groups are shown, stratified by sex (Table 1). The control group comprised 32 (20 men and 12 women) patients without diabetes younger than 65 years who were excluded based on the same criteria. The mean ages were 53.2 (SD 10.2) years and 53.2 (SD 10.1) years among the T2DM group and the control group, respectively. Furthermore, the mean age of the women was 49.5 (SD 10.3) years in T2DM group and 46.8 (SD 12.5) years in the control group, with no significant difference between the groups for either sex (all *P*>.05). Moreover, the SMI was 7.7 (SD 0.8) for the men in the T2DM group, 8.4 (SD 0.5) for men in the control group, 7.0 (SD 0.9) for the women in the T2DM group, and 6.8 (SD 0.7) for women in the control group. Additionally, the BMI was significantly higher in the T2DM group than in the control group for both sexes (*P*=.01 for men, *P*=.001 for women), whereas the SMI was significantly lower in the T2DM group among men but not women (*P*<.001 for men, *P*=.35 for women). Serum albumin levels, an indicator of nutritional status, were significantly lower in the T2DM group than in the control group for both men and women (both *P*<.001). Total cholesterol levels were significantly lower in the T2DM group than in the control group (*P*<.001 for men, *P*=.02 for women). In the T2DM group, the average history of diabetes was 12.2 (SD 10.0) years and 9.6 (SD 7.3) years for men and women, respectively, and the number of men and women with and without insulin use and the severity of each diabetic complication is shown, as well as the value of PWV as an assessment of arterial stiffness (Table 1). The prevalence of skeletal muscle mass loss in this study was 18.2% (10/55) in men and 7.7% (4/52) in women. There were no participants with decreased SMI in the control group.

Table 1. Clinical characteristics of the study sample.

[a]T2DM: type 2 diabetes mellitus.

[b]HbA$_{1c}$: hemoglobin A$_{1c}$.

[c]Not applicable.

Next, a comparison of physical function assessments between groups is presented, stratified by sex (Table 2). The grip strength was 34.2 (SD 9.8) kg and 22.2 (SD 8.5) kg for men and women in the T2DM group, respectively. Conversely, in the control group, the grip strength for men and women was recorded as 42.0 (SD 8.5) kg and 25.2 (SD 4.6) kg, respectively. Similarly, walking speed was observed to be 1.3 (SD 0.2) m/s and 1.2 (SD 0.43) m/s for men and women in the T2DM group, respectively. In the control group, the values for men and women were 1.6 (SD 0.2) m/s and 1.5 (SD 0.1) m/s, respectively. Furthermore, the time taken to stand on one leg was measured as 30.7 (SD 26.9) seconds and 29.4 (SD 25.5) seconds for men and women in the T2DM group, respectively. In contrast, the control group registered times of 100.5 (SD 30.6) seconds and 82.5 (SD 39.8) seconds for men and women, respectively. Importantly, for both

men and women, the BMI was significantly higher in the T2DM group than in the control group (men: *P*=.01, women: *P*=.001), and walking speed and one-leg standing time were significantly lower (all *P*<.001). However, muscle mass and strength were significantly lower for men in the T2DM group than those in the control group (both *P*<.001) but a similar trend was not observed among women in the T2DM group versus the control group (*P*=.35 and *P*=.24, respectively). The diagnostic criteria for sarcopenia by AWGS are a decrease in skeletal muscle mass accompanied by a decrease in muscle strength (decreased grip strength) or physical function (decreased walking speed). The prevalence of sarcopenia in this study based on this criterion was 9.1%(5/55) in men and 3.8%(2/52) in women in the T2DM group.

Table 2. Characteristics of physical function in the T2DMa and control groups.

Characteristics	Men			Women		
	T2DM (n=55), mean (SD)	Control (n=20), mean (SD)	P value	T2DM (n=52), mean (SD)	Control (n=12), mean (SD)	P value
Age (years)	53.2 (10.2)	53.2 (10.1)	.96	49.5 (10.3)	46.8 (12.5)	.57
Grip strength (kg)	34.2 (9.8)	42.0 (8.5)	<.001	22.2 (8.5)	25.2 (4.6)	.24
Gait speed (m/s)	1.3 (0.2)	1.6 (0.2)	<.001	1.2 (0.43)	1.5 (0.1)	<.001

[a]T2DM: type 2 diabetes mellitus.

To examine differences in characteristics between men and women, factors correlated with skeletal muscle mass were examined separately for men and women (Table 3). In men, there was a negative correlation with age, history of disease, diabetic neuropathy, diabetic retinopathy, insulin use, and PWV, and a positive correlation with BMI. In women, on the other hand, age and diabetic peripheral neuropathy were negatively correlated with age and diabetic neuropathy, and positively correlated with BMI, indicating differences in correlating factors between the sexes.

Table 3. Correlation between skeletal muscle mass index and each factor by gender.

The relationship between skeletal muscle mass loss (SMI loss) and physical function in the entire T2DM group was analyzed. Univariate logistic regression analysis showed that the SMI was significantly associated with age, BMI, and peripheral neuropathy (all $P \leq .002$). In the multiple logistic regression analysis, BMI exhibited the strongest association (odds ratio 1.15, 95% CI 1.07-1.23; $P<.001$). Peripheral neuropathy was also significantly associated with SMI ($P=.009$; Table 4).

Table 4. Logistic regression analysis of factors related to the presence of muscle mass loss.

Discussion

Principal Findings

This study is one of the few to focus on skeletal muscle mass loss in young to middle-aged adult patients with diabetes. The results showed that a certain percentage of middle-aged patients with diabetes also had decreased skeletal muscle mass, resulting in decreased muscle strength and physical ability compared with healthy individuals. Furthermore, middle-aged men with diabetes had higher rates of skeletal muscle mass loss, muscle weakness, and loss of physical ability than women with diabetes.

According to the AWGS 2019, sarcopenia is defined as a loss of skeletal muscle mass and a loss of muscle strength or physical capacity, while severe sarcopenia is defined as a loss of skeletal muscle mass plus a loss of both muscle strength and physical capacity; moreover, severe sarcopenia is defined as a loss of both muscle strength and physical performance in addition to a loss of skeletal muscle mass. The results of this study suggest that middle-aged patients with diabetes, especially men, have a higher risk for loss of muscle mass and decline in both muscle strength and physical function than those without diabetes. To elucidate the relationship between diabetes and sarcopenia, skeletal muscle mass plays a substantial role in peripheral blood glucose uptake and use, and its reduction in sarcopenia results in compromised glucose tolerance due to diminished peripheral blood glucose uptake. Similarly, reduced physical activity stemming from loss of muscle mass also contributes to impaired glucose tolerance, exacerbating diabetes and leading to difficulty in controlling T2DM. Thus, T2DM promotes the development of sarcopenia, which contributes to the onset and worsening of diabetes, coupled with diabetic complications, leading to a vicious cycle of decreased physical activity, a secondary decrease in skeletal muscle mass, and worsening diabetes [20].

Comparison With Prior Work

Previous studies have reported that older adult patients with diabetes are more prone to age-related loss of skeletal muscle mass than healthy individuals and that sarcopenia occurs several years earlier in patients with diabetes than in healthy individuals [21]. Furthermore, studies in mice have shown that hyperglycemia, a central disease of diabetes, promotes muscle atrophy via the WWP1/KLF15 pathway and that in mice lacking KLF15, specifically in the skeletal muscle, hyperglycemia-induced muscle atrophy is suppressed [4]. Moreover, it has been reported that terminal glycation products, a major cause of diabetic vascular complications, accumulate with chronic hyperglycemia and aging in various tissues; additionally, their accumulation contributes to a decline in muscle mass and strength, possibly leading to sarcopenia and dynapenia in T2DM [22]. Similar to previous studies on older adult patients with diabetes, this study found that skeletal muscle mass and strength loss occur earlier in young to middle-aged adult patients with diabetes, especially in men, than in healthy individuals. In addition to age, male sex, low BMI, elevated HbA$_{1c}$, diabetic nephropathy, and low serum albumin concentration have been reported as risk factors associated with low muscle strength in patients with diabetes [6]. In contrast, other studies have reported that diabetic polyneuropathy contributes to lower limb muscle weakness in older patients with T2DM [19]. In this study, logistic regression analysis showed that BMI and peripheral neuropathy were associated with skeletal muscle mass loss in middle-aged adult patients with T2DM, similar to the results in older adult patients with T2DM [23]; however, there was no association with HbA$_{1c}$ or diabetic complications. Furthermore, Korean older adults with T2DM had a prevalence of skeletal muscle loss of 57.6% in men and 7.1% in women. The association between T2DM and skeletal muscle loss appeared more prominent in men, with the risk of muscle loss being approximately 2 to 4 times higher in

older adults with T2DM than in healthy controls [24]. In this study, the prevalence of skeletal muscle loss in young to middle-aged individuals with T2DM was 18.2% in men and 7.7% in women, suggesting that even in younger populations, T2DM is associated with an increased risk of skeletal muscle mass loss, particularly in men.

This study showed no differences in skeletal muscle mass or muscle strength between middle-aged adult women with T2DM and healthy controls. This outcome was anticipated owing to the younger average age and elevated BMI of the women participants in this study. Moreover, the limited number of control participants used for comparison is also believed to have influenced this result. Nonetheless, despite preserving skeletal muscle mass and strength, the participants notably underperformed, compared with healthy controls, in terms of physical performance and balance function. This indicates that the quality of skeletal muscle may have been compromised. Therefore, the prospect of dynapenia occurring in women was anticipated. Although many previous studies have compared sarcopenia-related factors, such as skeletal muscle mass, muscle strength, and walking speed, few have examined balance function, which makes this study significant. Furthermore, we found that the same functional decline in both men and women differed between those with and without loss of skeletal muscle mass and strength.

Limitations

This study had some limitations. First, owing to the nature of the study, the number of participants was inadequate, especially in the female control group. This was due to the fact that this was a single-center, backward-looking study, which limited the selection of participants. Moreover, because this was a retrospective study, there were many missing data points, which made it difficult to select the participants.

Finally, this study aimed to elucidate the presence of skeletal muscle mass and muscle weakness in young and middle-aged patients with diabetes. The study also sought to identify associated factors that will be applied in clinical education and exercise therapy for patients with diabetes. Importantly, this information should be considered from an early stage for the purpose of preventive rehabilitation. Therefore, this study shows that young to middle-aged adult patients with diabetes exhibit reduced skeletal muscle mass, muscle weakness, sarcopenia, and loss of physical performance, proving the importance of exercise therapy and the need for strength training. We believe this information can be applied to patient education in future clinical practice. Moreover, as a future prospect, we would like to develop this study further to examine sex differences and develop better teaching and more effective strength training methods.

Conclusions

In conclusion, young to middle-aged adult patients with diabetes, especially men, have lower skeletal muscle mass than those without diabetes and may experience further decline in physical function. Therefore, early and detailed assessment of muscle mass and strength as well as physical function will be necessary even in young and middle-aged individuals.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Abstract

Background: Research on personality types among doctors reveals its impact on medical specialty choices, suggesting that considering personality in career planning may enhance work satisfaction and reduce burnout risks.

Objective: This study, encompassing 2104 medical students, explores how personality types, traits, and gender relate to specialty preferences.

Methods: Participants of this study were medical students from various universities in Poland. The study surveyed 2104 participants. Each participant completed a general questionnaire and a NERIS Type Explorer personality test, based on the Myers-Briggs Type Indicator inventory and the "Big Five" personality traits concept. The questionnaire was distributed on social media groups for medical students from all Polish universities. An exploratory statistical analysis was performed to find relationships. For each tested relationship a Fisher exact test was conducted and the significance level was $P<.05$. Each test resulted in a P value and odds ratio (OR) with a CI. To ensure we included undecided students and obtained meaningful data, we allowed participants to select up to three medical specialties from the 77 available in Poland at the time of the study.

Results: The findings unveil significant relationships between gender, personality types, traits, and specialty preferences. Women tended to favor Neonatology (OR 9.15, 95% CI 3.02-45.46), while men leaned toward Orthopedics and traumatology of the locomotor system (OR 7.53, 95% CI 4.87-11.94). Extroverted, Intuitive, Feeling, Prospecting, and Turbulent students showed a heightened interest in Psychiatry (OR 2.23, 95% CI 1.64-3.01), whereas Introverted, Observant, Feeling, Judging, and Turbulent types favored Family Medicine (OR 2.98, 95% CI 2.08-4.24) and Pediatrics (OR 2.13, 95% CI 1.51-2.99).

Conclusions: In conclusion, this research establishes a link between personality and medical specialty selection. Taking into account the significant role of personality traits, it should be considered to integrate them into the process of selecting a medical career or designing a medical curriculum. This approach may allow for the customization of programs to match students' traits, thereby cultivating improved clinical communication skills, fostering interprofessional collaboration and ultimately enhancing treatment outcomes and professional fulfillment among physicians. The main limitation of this study is that it was conducted on medical students, who lack the full knowledge of the work as a specific specialist. A study surveying medical doctors with longer internships across different wards could be conducted to check for any variabilities. Moreover, there are other significant factors that influence one's medical specialty choice. Certainly, this area could be further explored.

Introduction

Personality traits affect many significant life choices including career path. It was proven that a good match between the personality traits of an individual and those of the work environment has a positive effect on job satisfaction [1]. For instance, people with low levels of neuroticism will be more satisfied in occupations where there is a lower mean level of neuroticism, such as careers in science or technology, skilled, and managerial occupations [1]. The same is true for openness—the greater the fit between a worker's personality and the average personality of the occupation, the bigger job satisfaction [1].

The above study's results strongly correspond with two major theories of career choice. The first theory is the attraction-selection-attrition (ASA) model presented by Schneider [2]. The ASA model claims that people are attracted to, and selected by, specific environments according to their individual predispositions [2]. This selection effect creates environments that are consistent with people with specific attributes, which leads to significant person-environment fit. Moreover, employees who do not fit sometimes leave, and people who remain in the occupation will be similar to each other, and therefore, create a more homogenous group than those who were attracted to the work environment in the beginning [2].

The second model is Holland's Vocational Theory [3]. It states that people select themselves into an occupation environment that matches their vocational interests, which further leads to greater contentment and better performance. Holland's theory declares that most people fit into one of 6 personality types: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional. The 6 vocational types characterize both occupational interests and individual differences in interests. Holland asserts that people of the same personality type when working together, create an environment that is best suited to them and their working style. The conclusion is that working among people with similar personality types brings more satisfaction and success at work [3].

The above results suggest that considering these career choice theories, choosing a medical specialty according to one's personality type might lead to greater job satisfaction.

Existing research has demonstrated the applicability of vocational theories to the medical field. A study by Petrides and McManus [4] discovered strong similarities between Holland's general career typology and the structure of medical careers, implying that the two frameworks are homologous. The research involved 3 large cohorts of medical students to generate maps of medical career paths. Medical specialties typical of Holland's 6 RIASEC categories were Surgery (Realistic), Hospital Medicine (Investigative), Psychiatry (Artistic), Public

Health (Social), Administrative Medicine (Enterprising), and Laboratory Medicine (Conventional) [4]. This homology between medical careers and RIASEC may mean that the map can be used as the basis for understanding career choice, and for providing career counseling [4].

Moreover, in their research, Borges et al [5] tested the hypothesis that medical specialties classified as technique-oriented or patient-oriented would be distinguished by the RIASEC code, with technique-oriented specialists resembling Investigative-Realistic types and patient-oriented specialists resembling Investigative-Social types. RIASEC code was consistent across both specialty groups, specifically Investigative-Social. The findings indicated that many medical students could be suited to a range of different specialties, suggesting that Holland's model could help them assess how well their personalities align with various specialties and practice settings [5].

Apart from enhancing job satisfaction, improving the doctor-patient relationship is undoubtedly an important matter. One study showed that only around 11% of the medical personnel and 15% of the general population believe that the current doctor-patient relationship is harmonious [6]. It has been shown that doctors' personalities differ significantly from their potential patients [7]. A small study of 313 medical graduates from the United Kingdom found that, compared to the general adult population, doctors had a preference for Introversion over Extraversion, Intuitive Perception over Sensing Perception, Thinking Judgment over Feeling Judgment, and a Judging orientation over a Prospecting orientation [7]. It has been shown that training can help alleviate the challenges posed by personality differences, leading to better interaction outcomes [8]. A recent study suggests that communication training, based on students' personality traits and aimed toward improving the doctor-patient relationship should be implemented in medical studies curriculum [9].

Furthermore, existing research confirmed that empathy is related to personality and that it can be improved and taught [10,11]. Medical empathy is defined as primarily the cognitive ability to understand patients' experiences, concerns, and perspectives, and to communicate this understanding with the intent to help [12,13]. Different personality factors can be integrated into medical education to enhance empathy, with pedagogical objectives focused on empathy development [10]. Individualized intervention strategies based on personality traits should be comprehensive, considering the complexity of empathy [10,11]. Moreover, personality preference research has contributed to a better understanding of teaching styles and clinical performance test achievements [14,15]. These results highlight the importance of exploring the personality traits of medical students and doctors in order to develop effective training programs aimed at enhancing empathy. Such programs could also serve as a

foundation for research on how this training impacts the doctor-patient relationship.

Beyond improving empathy and the doctor-patient relationship, it is also crucial to prioritize physicians' mental health. In Poland, burnout affects as many as 67% of physicians [16]. The literature demonstrates that certain personality types, especially Realistic types, are more prone to burnout than, for example, Social or Artistic personality [17]. Regarding medical specialties, burnout prevalence is notably higher in surgical specialties compared to clinical specializations [18]. Students who are aware of their personality traits might make more informed decisions when selecting between these fields.

Up to now, no research has been done on Polish medical students that would so extensively investigate the influence of personality type on the choice of a medical career. This paper is notable because it surveyed a large number of students questioned (around 6% of all medical students in Poland [19]) and considered various factors including gender, academic year, personality type, and personality traits. Furthermore, it facilitates the comparison of the data with existing research on the subject. The authors analyzed the link between demographic factors and personality traits exhibited by medical students and their choice of specialties. Such a thorough examination allows for better comprehension of choices regarding medical specialties made by Polish students. This may benefit in raising awareness about burnout prevention and job satisfaction.

This study aimed to determine whether personality type affects Polish medical students' career choices.

Methods

Study Design

This cross-sectional study was conducted in March 2020. Each participant answered a questionnaire that included both the NERIS Type Explorer, as well as other questions regarding demographics and the chosen medical specialty. The questionnaire was distributed on social media groups for medical students from all Polish universities and it was available for 1 week from March 16, 2020, to March 23, 2020. It was completely anonymous and all participants took part in the digital survey out of their own free will, using their own personal devices, such as smartphones or PCs. The only inclusion criterion was being a medical student. Participants, who admitted they were not medical students were omitted in the analysis. Not to exclude undecided students from our study and to receive as meaningful data as possible, we asked for the choice of up to three medical specialties from 77 available in Poland at the moment of the study.

The data collected in the questionnaires were analyzed using NERIS Type Explorer to obtain each participant's personality type. We analyzed each respondent's personality type and the intensity of a specific personality trait, measured on a scale from –100 to +100, as seen in the Multimedia Appendix 1. Surveys were collected using a web-based tool Typeform (Typeform S.L.) [20].

Statistical Analysis

An exploratory statistical analysis, descriptives, crosstables, and logistic regression were performed to find associations between the personality type, personality traits, chosen specialty, and demographic data. The study was designed to obtain pilot data from Polish students. For each tested association a Fisher exact test was conducted since this test is fairly resilient to variations in sample characteristics. However, in this case, these characteristics are not well controlled. The significance level was $P<.05$. Each test resulted in a P value and odds ratio (OR) with a CI. For a test to be conducted, the following inclusion criteria had to be met: for each subgroup in the contingency table, there had to be at least one person in the subgroup and the number of expected frequencies for each subgroup had to be at least 5. Scatter plots were used to visualize data. The required sample size to achieve statistically significant effects at an α significance level of 5%, assuming a beta sensitivity of 80% in the Fisher exact test for an effect size with an OR in the range of (0.75-1.5), considering Bonferroni correction for multiple comparisons across a family of related hypotheses, and assuming a response accuracy rate of >95%, was 2108.

To account for the multiple comparisons problem, we applied the Bonferroni correction for the cutoff point of the significance level. A primary limitation in multiple comparisons is that as the number of dimensions compared increases (which is considerable in this study), the mathematical probability of obtaining statistically significant results also increases. This probability is present here, necessitating a more cautious interpretation of the findings. To estimate the family wise error rate, the associations were divided into a few families (personality type vs specialty, personality type vs gender etc). The cutoff value for recognizing a P value as significant, which ranged from 0.003 to 0.02 depending on the number of tests conducted, was determined by dividing the significance level (5%) by the number of tests within a family.

All the computations were performed using R software (version 4.1.2; R Core Team, R Foundation for Statistical Computing). The packages used were stats, dplyr, and ggplot2.

Instrument for Data Collection

Myers-Briggs Type Indicator (MBTI) is a personality inventory created by Isabel Briggs Myers and Katherine Briggs and based on the theory described by Carl Gustav Jung [21-23]. It identifies 4 personality types and later divides each of them into 4 more subtypes, distinguishing overall 16 personality types. The name of the type consists of 4 letters, describing certain personality traits: E or I (for Extraversion or Introversion, understood as the preference for the outer or inner world), S or N (for Sensing or Intuition, understood as the preference for relying on the basic information or interpreting and adding meaning), T or F (for Thinking or Feeling, understood as the preference for logical thinking or seeing special circumstances), and J or P (for Judging or Prospecting, understood as the preference for making strong decisions or being open to new options). The MTBI instrument has been validated, used in various studies over the past 40 years, and described as reliable and accurate [21-23].

NERIS Type Explorer is an instrument used by the creators of the website 16personalities [24]. It is based on the MBTI inventory, as well as on the "Big Five" personality traits concept [24]. In addition to using 16 types identical to the Myers-Briggs test, it allows to add another aspect to the classic 4-letter personality type of the MTBI inventory, using either -A or -T (for Assertive or Turbulent, understood as how confident people are in their decisions and abilities). In consequence, it consists of 32 separate subtypes all of which are presented in Multimedia Appendix 2.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and was approved by the ethics committee of the Medical University of Warsaw (AKBE/62/2023, March 06, 2023). Participation in the questionnaire was voluntary and data acquired from it were completely anonymous.

Results

Characteristics of the Study Group

In 2020 there were approximately 37,000 medical students studying at 22 different Polish medical universities [19]. Our questionnaire was filled out by 2104 medical students from Poland.

Among 2104 students who filled in our questionnaire, the majority (n=1645, 78%) of people were female, while only 454 (22%) were male. Five students chose the "other" option in the gender-related question. A total of 1830 (86%) surveyed students declared heterosexual orientation, 141 (6%) students as bisexual, 84 (4%) students as homosexual, 16 (0.4%) students as asexual, and 33 (1.6%) students chose the option "other or refuse to answer."

The mean age of our surveyed population was 23 (SD 2.150) years, with the age range from 18 to 40 years.

In Poland, medical studies last 6 years and clinical rotations start during the third year. Students participating in our survey represented all 6 years of studies, however, at the moment of the survey, most students were in their third or fourth year. Consequently, around 3/4 of our surveyed population had started classes in the hospital, encountered patients, and by this time could already have an opinion on the type of clinical work they enjoy or value the most.

In total, 99.6% of the students questioned in our study came from public-funded Polish universities.

Most Common Personality Types

We examined what were the most common personality types in our study population. Using the division into 16personalities, the most common types were: ESFJ (Extroverted, Observant, Feeling, Judging; n=280, 13.3%), ISFJ (Introverted, Observant, Feeling, Judging; n=258, 12.3%), ENFJ (Extroverted, Intuitive, Feeling, Judging; n=233, 11.1%), ENFP (Extroverted, Intuitive, Feeling, Prospecting; n=210, 9.9%), and INFJ (Introverted, Intuitive, Feeling, Judging; n=204, 9.7%). These 5 most popular personality types were true for more than half of our study group. After differentiation into Assertive and Turbulent subtypes, within 32 possible variants, 5 most popular were: ISFJ-T (Introverted, Observant, Feeling, Judging, Turbulent; n=187, 8.9%), INFJ-T (Introverted, Intuitive, Feeling, Judging, Turbulent; n=160, 7.6%), ESFJ-A (Extroverted, Observant, Feeling, Judging, Assertive; n=144, 6.8%), ENFJ-T (Extroverted, Intuitive, Feeling, Judging, Turbulent; n=143, 6.8%), and ENFP-T (Extroverted, Intuitive, Feeling, Prospecting, Turbulent; n=136, 6.5%). It should be noted that there was a vast disproportion between the prevalence of the most and least common types and subtypes, as we discovered only 31 (1.5%) cases of the ISTP (Introverted, Observant, Thinking, Prospecting) type and only 9 (0.4%) of the ISFP-A (Introverted, Observant, Feeling, Prospecting, Assertive) subtype. Table 1 shows the number and percentage of participants presenting specific personality traits.

Table 1. Number and percentage of participants presenting Extroverted or Introverted (E/I), Intuitive or Observant (I/O), Thinking or Feeling (T/F), and Judging or Prospecting (J/P) traits in our study group.

Trait	Value (N=2104), n (%)
E/I	
Extroverted[a]	1142 (54.3)
Introverted	962 (45.7)
N/S	
Intuitive[a]	1112 (52.8)
Observant	992 (47.2)
T/F	
Thinking	638 (30.3)
Feeling[a]	1466 (69.7)
J/P	
Judging[a]	1403 (66.7)
Prospecting	701 (33.3)

[a]The trait with a higher prevalence in each pair.

Interestingly, personality type that combined all of the above predominating features (ENFJ) was only the third most common type in our population. It shows how the prevalence of certain traits is not always reflected in the prevalence of one of 16 personality types that present all of these individual traits at once.

Most Common Specialties

Among 77 medical specialties available in Poland, the ones that were chosen the most often in our survey were Pediatrics (n=393, 18.68%), Psychiatry (n=325, 15.45%), Family Medicine (n=294, 13.97%), Anesthesiology and Intensive Care (n=284, 13.50%), Endocrinology (n=282, 13.40%), Internal Medicine (n=264, 12.55%), Cardiology (n=254, 12.07%), Obstetrics and Gynecology (n=237, 11.26%), Dermatology and Venereology (n=216, 10.27%), and Radiology and Imaging Diagnostics (n=200, 9.51%).

Gender Differences

Men more often belonged to the Thinking group (OR 3.18, 95% CI 2.55-3.98), while women were more dominant in the Turbulent group (OR 2.85, 95% CI 2.3-3.55). Moreover, men more frequently were INTJ-A (Introverted, Intuitive, Thinking, Judging, Assertive; OR 7.16, 95% CI 3.45-15.52) and ISTJ-A (Introverted, Observant, Thinking, Judging, Assertive; OR 3.87, 95% CI 2.1-7.14). They were also more abundant in ESTP (Extroverted, Observant, Thinking, Prospecting; OR 4.22, 95%

CI 2.12-8.44), INTP (Introverted, Intuitive, Thinking, Prospecting; OR 3.83, 95% CI 2.24-6.54), and INTJ (Introverted, Intuitive, Thinking, Judging; OR 2.7, 95% CI 1.7-4.23) groups regardless of A/T feature. The women group was characterized by greater presence of ISFJ-T (Introverted, Observant, Feeling, Judging, Turbulent; OR 2.95, 95% CI 1.74-5.34) and ENFP-T (Extroverted, Intuitive, Feeling, Prospecting, Turbulent; OR 2.28, 95% CI 1.53-3.5) personality types. The strongest association between gender and preference of medical specialty was observed in Neonatology, which was chosen over 9 more times by women (OR 9.15, 95% CI 3.02-45.46), and Orthopedics and traumatology of locomotor system—chosen 7 times more by men (OR 7.53, 95% CI 4.87-11.94). Moreover, women were more commonly interested in Obstetrics and Gynecology (OR 4.2, 95% CI 2.5-7.56), Pediatrics (OR 2.82, 95% CI 1.99-4.08), and Dermatology and Venereology (OR 2.78, 95% CI 1.75-4.65). Men were more inclined to choose Urology (OR 5.4, 95% CI 3.11-9.48), Cardiology (OR 2.08, 95% CI 1.55-2.97), and Anesthesiology and Intensive Care (OR 1.96, 95% CI 1.48-2.59). Generally, women were more drawn to choose pediatric specialties (OR 3.33, 95% CI 2.47-4.51). On the other hand, men preferred specialties related to surgeries (OR 2.76, 95% CI 2.2-3.48). Table 2 shows the number and percentage of participants reporting interest in specialties depending on gender.

The association between medical specialty choice and gender, presented as ORs with 95% CIs, is shown in Figure 1.

Table 2. Number and percentage of participants reporting interest in specialties depending on gender.

Specialty	Women, n (%)	Men, n (%)
Neonatology	96 (5.84)	3 (0.66)
Orthopedics and traumatology of locomotor system	35 (2.13)	65 (7.71)
Obstetrics and gynecology	218 (13.25)	17 (3.74)
Pediatrics	355 (21.58)	38 (8.37)
Dermatology and venereology	196 (11.91)	20 (4.41)
Urology	23 (1.4)	35 (7.71)
Cardiology	170 (10.33)	83 (18.28)
Anesthesiology and intensive care	194 (11.79)	90 (19.82)

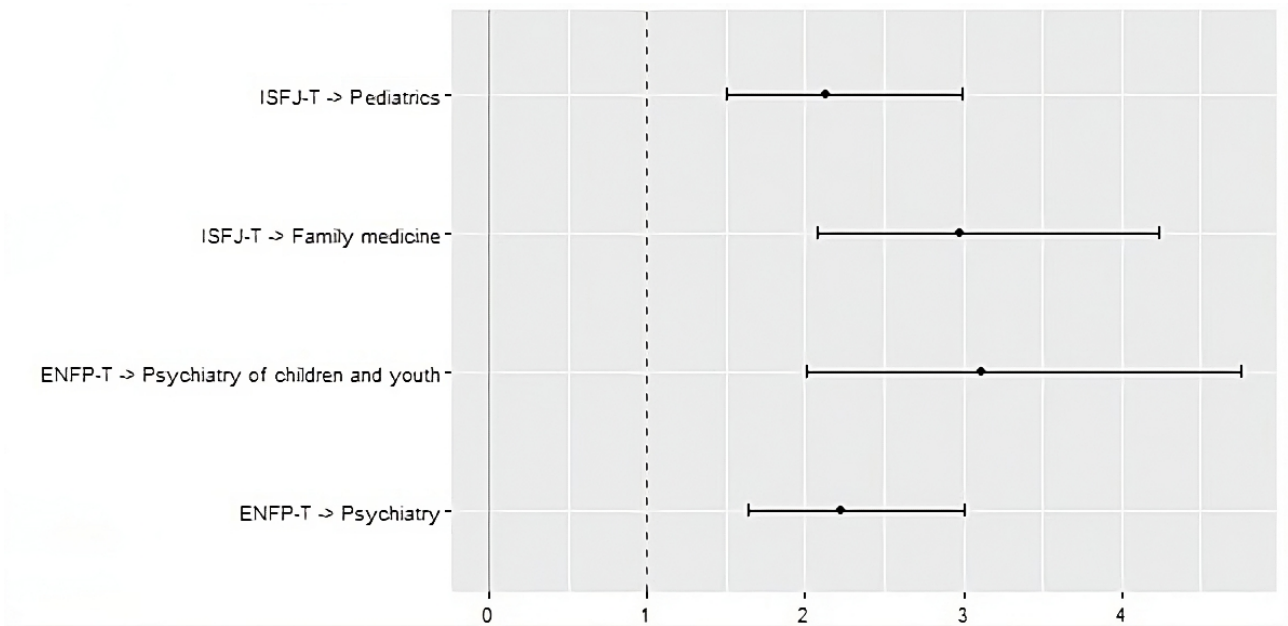
Figure 1. The association between medical specialty choice and gender, presented as odds ratios with 95% CIs.
Personality Traits

Family Medicine was chosen almost two times more often by Introvert (OR 1.96, 95% CI 1.52-2.53), Observant (OR 1.98, 95% CI 1.54-2.56), or Judging (OR 1.68, 95% CI 1.27-2.24). Being Intuitive (OR 2.22, 95% CI 1.73-2.86) and Prospective (OR 1.79, 95% CI 1.41-2.26) are associated with interest in Psychiatry. Moreover, Prospective students were also keen on the Psychiatry of Children and Youth (OR 2.16, 95% CI 1.48-3.17). Thinking trait was more common in the group of students choosing Neurosurgery (OR 4.14, 95% CI 2.37-7.34), Forensic Medicine (OR 2.7, 95% CI 1.69-4.31), Plastic Surgery (OR 2.33, 95% CI 1.57-3.45), and General Surgery (OR 2.02, 95% CI 1.46-2.79) while Feeling was more popular in Pediatrics (OR 2.09, 95% CI 1.58-2.8). Overall, Thinking went with specialties involving surgeries (OR 1.69, 95% CI 1.39-2.06). Feeling was associated with pediatric specialties (OR 1.84, 95% CI 1.46-2.32). Respondents with Assertive trait were more commonly picking surgical specialties (OR 1.64, 95% CI 1.37-1.97), especially Orthopedics and traumatology of locomotor system (OR 2.64, 95% CI 1.71-4.08) and General Surgery (OR 1.87, 95% CI 1.36-2.57). In contrast, the Turbulent trait favored specialties of Internal Medicine (OR 1.42, 95% CI 1.17-1.71). Additionally, Turbulent also favored Pediatrics (OR 1.62, 95% CI 1.27-2.08) and Endocrinology (OR 1.78, 95% CI 1.33-2.41). The association between the chosen medical specialty and personality trait presented as ORs with 95% CIs, is shown in Figure 2.

Figure 2. The association between the chosen medical specialty and personality trait, presented as odds ratios with 95% CIs.

Personality Type

Respondents with ENFP-T personality type seemed to be interested in Psychiatry (OR 2.23, 95% CI 1.64-3.01) and Psychiatry of Children and Youth (OR 3.11, 95% CI 2-4.75). Moreover, ESTJ-A were often choosing specialties related to surgeries (OR 2.61, 95% CI 1.57-4.5). ISFJ-T personality type was negatively associated with interest in surgical specialties (OR 0.32, 95% CI 0.18-0.53), but positively with Family Medicine (OR 2.98, 95% CI 2.08-4.24) and Pediatrics (OR 2.13, 95% CI 1.51-2.99). INTJ-A very rarely chose pediatric specialties, choosing them over 16 times less than the rest of the respondents (OR 0.06, 95% CI 0.002-0.385). The association between chosen medical specialty and personality type presented as ORs with 95% CIs, is shown in Figure 3.

Figure 3. The association between the chosen medical specialty and personality type, presented as odds ratios with 95% CIs.


Specialties, Which Associate Each Other

Students who chose Anesthesiology and Intensive Care often chose Emergency Medicine (OR 4.51, 95% CI 2.6-7.71). General Surgery was often picked together with Oncological Surgery (OR 9.26, 95% CI 5.22-16.23) and Pediatric Surgery (OR 4, 95% CI 2.23-6.92). Internal Medicine was associated with Gastroenterology (OR 3.28, 95% CI 1.98-5.29). Endocrinology was commonly cochosen with Gynecological Endocrinology with reproductiveness (OR 3.82, 95% CI 2.13-6.7), which was also common among students, who picked Obstetrics and Gynecology (OR 5.61, 95% CI 3.22-9.91). Just like Pediatrics and Neonatology (OR 4.46, 95% CI 2.93-6.78), Pediatrics and Pediatric Gastroenterology together were a common founding (OR 12.76, 95% CI 5.14-35.99). Specialties, that were very common among students interested in Psychiatry, were Psychiatry of Children and Youth (OR 8.15, 95% CI 5.51-12.11) and Sexology (OR 5.08, 95% CI 2.54-10.15).

Figure 4 illustrates the ten most frequently selected medical specialties based on the year of study.

Figure 4. Ten frequently selected medical specialties based on the year of study.

Discussion

Principal Findings

In this research, we aimed to find relationships between personality types defined by NERIS Type Explorer and future specialty preferences among the Polish medical school population. The analysis showed that Extraverted, Intuitive, Feeling, and Prospecting (ENFP) personality, as well as Intuitive and Prospecting assets in general, are more common in students interested in Psychiatry. Moreover, the Thinking trait and ESTJ-A (Extraverted, Observant, Thinking, Judging, Assertive) personality type related positively with the choice of specialties that involved surgeries. Students who were classified as Introverted, Observant, and Judging or had ISFJ-T personality were more likely to choose Family Medicine.

Our findings are consistent with those of previous research conducted on American medical students [25]. A longitudinal study that collected data from both students and graduates showed a statistically significant relationship between the Extroversion-Introversion (E-I) and Thinking-Feeling (T-F) axes and the choice between primary and nonprimary specialties [25]. According to the authors, Extraverted and Thinking types were more inclined toward surgical professions whereas Introverted and Feeling types are more likely to favor primary care [25]. Another research sought for the relationships between the MBTI type assigned in the first year of school and the actual specialty choice in the postgraduate year [26]. Three associations were found statistically significant. The interviewees who were

classified as Sensing, Feeling, and Judging type tended to choose Family Medicine. Sensing, Thinking, and Judging types were also prone to follow a career path in Obstetrics-Gynecology. Last but not least, Psychiatry was preferred by Intuitive, Feeling, and Prospecting types [26]. As far as particular MBTI personality types are concerned, our findings are consistent with data adapted from Freeman [27] and McCaulley [28], which indicates that Feeling and Intuitive types tend to prefer Psychiatry, while Sensing, Thinking, and Judging (STJ) types are more inclined toward Surgery.

Similar studies were performed in veterinary medicine students, but their results differ significantly. In the study describing students of the Veterinary Faculty in Slovenia, more students presented Introverted, Sensing, Thinking, and Judging traits, and the most common type was ISTJ [29]. These findings are very different than in this study's results, as in our population, most medical students had Extroverted, Intuitive, Feeling, and Judging traits and ISTJ type was only the eighth most common personality type. The authors of the discussed veterinary students study suggested that veterinarians are often more caring, have high levels of compassion, and choose their careers because of their social responsibilities awareness [29]. By contrast, one might wonder if traits more common in medical students could be more associated with the need for contact with other people (Extroversion) and compassion for patients experiencing suffering (Feeling). Certainly, this topic needs further research.

Another veterinary student's research regarding MBTI types was performed in Canada and showed predominant traits to be

Extraversion, Sensing, Thinking, and Judging [30]. Two of the most prevalent MBTI types in the overall sample were ESTJ and ISTJ, respectively, the seventh and eighth most common types in our group [30]. This study is particularly interesting because it compared factors such as MBTI types, gender, and career preferences in a similar way as this work. Some findings are parallel to our results: for example, the odds of preferring Thinking rather than Feeling were approximately three times greater for male veterinary students compared to female students, which is consistent with our OR of 3.18 for men belonging to the Thinking group. In this Canadian work, the only statistically significant association between gender and desired specialty was surgery with an OR of 1.48 [30]. The authors found differences in the preferred career path and personality traits, that is, students were more likely to select equine practice for their final-year stream if they exhibited the Prospecting trait versus Judging [30]. Furthermore, students from the Thinking group were more likely to consider herd health management, reproduction, or pursuing a career in the government [30]. It was suggested that these fields, with the logical and impersonal preference of Thinking, are more appealing to such persons [30]. The above results show that veterinary school students had different personality traits and types than our group of medical students and that there are important influences of gender and personality on the choice of the future career path in veterinary students, as well as in medical students.

What is more, previous studies have shown that certain personality traits appear more often in physicians of some medical specialties. For instance, physicians working in Emergency.

Medicine was more likely to be extroverted [31]. It has also been proven that surgical specializations are much more often chosen by people with a personality preference for Thinking rather than Feeling [25]. What is interesting is the matter of why certain personality traits relate to specific specialty preferences.

The website 16 personalities offers users a detailed explanation of various personality traits and types, which can be determined through the personality test [24]. For example, Extroverts are described as being interested in engaging with their environment and feeding off the responses of the people and events around them, which may help them manage stress in specialties requiring frequent interpersonal interactions or unpredictable situations [32]. This corresponds with our findings, where Psychiatry—characterized by extensive interpersonal interaction—or Surgery, which can involve unexpected procedures, were more commonly chosen by Extroverted individuals. Introverts, by contrast, are characterized by a preference for solitary environments where they can regulate their surroundings and engage in focused "alone time," potentially leading to deeper insights [32]. This indicates that Introverts may experience lower stress in stable environments with fewer new interactions. Our finding that Introverted types more often choose specialties like Family Medicine or Pediatrics, where patients are typically familiar to the physician, aligns with this observation.

The idea behind our study is concern about preventing burnout among the population of medical doctors by finding the best fit between one's personality type and a medical specialty. In the *ICD-11* (*International Statistical Classification of Diseases and Related Health Problems, 11th Revision*), burnout is classified as an occupational phenomenon, characterized by 3 dimensions: "feelings of energy depletion or exhaustion; increased mental distance from one's job, or feelings of negativism or cynicism related to one's job; and reduced professional efficacy" [33]. The concept of making occupational choices based on personality traits has been present in psychological discourse for decades, resulting in many inspiring works. One of them is Holland's Theory of Career Choice (RIASEC), which links one's key skills and interest areas to certain occupations and subjects [3]. This approach, which Kristof-Brown calls person-vocation fit, seems to be a suitable theoretical framework in terms of matching MBTI personality types with particular medical specialties [34].

To establish a connection between personality traits, as well as problem-solving approaches, and the RIASEC code, Ackerman's [35] and Ackerman and Heggestad's [36] work provide valuable insights. Ackerman [35] and Ackerman and Heggestad [36] demonstrated that measures of intellectual ability predominantly relate to interests in Realistic, Investigative, and Artistic careers. Individuals with higher verbal abilities tend to prefer Artistic and Investigative careers, while those with stronger spatial and mathematical abilities are more inclined toward Realistic and Investigative careers [35,36]. In terms of personality measures, Ackerman found relationships with the SEC components of the RIASEC code, using the Big Five personality typology for description [35,36]. Specifically, Extraversion is primarily correlated with an interest in Social and Enterprising careers, whereas Conscientiousness is linked to an interest in Conventional and Enterprising careers. Openness to Experience is somewhat a mixture of intellectual ability and personality and correlated positively to Artistic, Investigative, and Realistic careers, and negatively with Conventional careers [35,36]. Similar results were obtained by Larson et al [37], who conducted a meta-analysis, revealing significant correlations between Holland's 6 vocational interest dimensions and the Big Five personality traits. For instance, they found strong correlations such as Artistic with Openness, Enterprising with Extraversion, Social with both Extraversion and Agreeableness, and Investigative with Openness [37].

By applying Holland's Theory of Career Choice to our results, and following the approach of Petrides and McManus, we can align each element of the RIASEC code with a corresponding medical specialty [4]. Surgery is considered the best representation of the Realistic type, characterized by those who "enjoy activities requiring physical strength, aggressive action, motor coordination, and skill" [3,4]. Its heavy reliance on manual and technical skills at the operating table makes Surgery particularly fitting. In this study, individuals interested in Surgery predominantly exhibited Thinking and Assertive traits. According to 16personalities, those with the Thinking trait rely on objective information, testing alternatives against logic and reason to determine the most effective or realistic decision [38]. Assertive individuals are characterized as self-assured,

even-tempered, and stress-resistant [39]. These descriptions may match Ackerman's findings that intellectual ability and a logic-based approach to problem-solving correlate with Realistic careers [35,36].

Holland defines the "Investigative Type" as someone who prefers systematic and creative investigation of physical, biological, and cultural phenomena [3]. Petrides and McManus [4] identify doctors in Internal Medicine as Investigative types, given the necessity of a comprehensive, investigative approach, particularly in hospital settings. Our research found that the Turbulent trait is strongly associated with this specialty. 16personalities describes Turbulent individuals as success-driven, perfectionistic, and eager to improve, often addressing minor issues before they escalate [39]. This trait might align with the Investigative type's inclination for in-depth analysis.

"Artistic Type" is defined by Holland as individuals with aesthetic interests who prefer indirect interactions and express themselves through artistic means [3]. Petrides and McManus [4] identified Psychiatry and General Practice (Family Medicine in our research) as fitting this description [4]. However, we chose to separate these specialties, associating Family Medicine with the Artistic Type and Psychiatry with the Social Type. This decision was based on the lack of significant associations between the Public Health specialty (representing the Social Type in Petrides and McManus) and personality in our research. Additionally, in the Petrides and McManus research, Psychiatry in the general population sample was still more concerned with People, which fits well with the reduction of Holland's hexagon to the two dimensions of Things-People and Ideas-Data [3,4]. In our research, Family Medicine associates with the ISFJ-T personality, known for being sensitive, caring, analytical, and detail-oriented, with strong people skills despite their reserved nature [40]. This aligns with Ackerman's depiction of Artistic careers, where people noted for their strong verbal and social abilities are most fitting [35,36].

Holland's "Social Type" refers to individuals who prefer activities involving influencing others to inform, train, develop, cure, or enlighten [3]. As mentioned above, we identified Psychiatry as the most fitting specialty for this type, with our results showing an association between Psychiatry and the ENFP-T personality, known for being extraverted, outgoing, and seeking deep emotional connections [41]. These findings match with Ackerman's research, which links extraversion to Social careers [35,36].

Holland describes the "Enterprising Type" as someone who has "a preference for actives that entail the manipulation of others to attain organization goals or economic gain...these behavioral tendencies lead in turn to an acquisition of leadership, interpersonal, and persuasive competencies" [3]. Petrides and McManus [4] suggest that Administrative Medicine is most suited to this type, though our research identified no equivalent specialty. Previous research shows the relationship between interest in Enterprising careers with Extraversion and Conscientiousness [35,36]. In the NERIS Type Explorer, the trait analogous to Conscientiousness is Judging, characterized by a strong work ethic and prioritization of duties [42]. Our

results indicated that surgical specialties were associated with both Extraversion and Judging traits, aligning them closely with Holland's Enterprising type [3].

Holland defines the "Conventional Type" as individuals who prefer systematic manipulation of data to achieve organizational goals. Petrides and McManus [4] have linked this type with Laboratory Medicine; however, our research found no significant association between Laboratory Medicine and personality traits or types. Interest in Conventional careers correlated with Conscientiousness, which, as mentioned above, may be represented by the Judging trait. Our findings revealed that the Judging trait was associated with Family Medicine and was also present in the ESTJ-A personality type, which is associated with surgical specialties, and the ISFJ-T personality type, linked to Family Medicine and Pediatrics. Thus, there is no clear link between Holland's Conventional Type and specific medical specialty in our findings.

Although some skills, qualities, and requirements are to be found in a number of medical disciplines, some of these traits are exclusive to a certain specialty. For instance, the authors of a study conducted at Chang Gung Memorial Hospital observed that emergency physicians demonstrated less preference for Sensing trait than other attending physicians [43]. It was suggested that the Intuitive trait of the emergency physicians is a result of the circumstances of the work in the emergency department, where pattern recognition is crucial to diagnose conditions presenting ambiguous symptoms in a short time. A notable finding from the study is that while both junior doctors and attending physicians displayed similar personality types depending on their medical specialty, attending physicians exhibited more pronounced Sensing, Thinking, and Judging traits. The study's authors suggest that clinical experience and an evidence-based approach contribute to this tendency [43]. However, according to the ASA model, organizational culture is shaped by three factors [2]: (1) individuals are attracted to organizations where members share similar personalities, values, interests, and attributes; (2) organizations tend to select individuals who possess knowledge, skills, and abilities similar to those of existing members; and (3) those who do not fit well are more likely to leave.

This raises the question: does the similarity among attending physicians result from the work environment—where individuals who are dissatisfied or unable to adapt leave—or from the environment imposing specific personality traits on people? Or maybe it is the interpersonal influence, where colleagues develop specific traits from each other? Or perhaps the combination of both? Subsequently, research that defines if having more distinct MBTI personality traits is related to job satisfaction would also be beneficial to early burnout prevalence.

Some personality traits are also crucial for satisfaction from the working conditions. Given the fact that our survey was distributed during the early weeks of the pandemic of SARS-CoV-2 when most Polish universities switched to a web-based–classes-only policy, it might have influenced the moods of certain students due to their preferences for the intensity of social life. Our group had a slight predominance of Extroverts. It was proven that university students with this trait

tended to dislike web-based classes as they preferred meeting people and consulting with their lecturers face-to-face. They also had trouble focusing during such classes. In contrast, Introverts preferred staying at home and communicating by writing [44]. Perhaps such preference influences the perception of subjects that were taught digitally versus the ones that were taught in person. It would seem interesting to examine this topic in the future to assess whether the fact that different subjects were taught digitally or not at the university during the pandemic influenced the choice of medical specialty by Extroverted and Introverted medical students after their studies.

Our findings correspond with studies on populations from different cultural and socioeconomic backgrounds within contrasting health care systems. This suggests that a model similar to the Holland Occupational Themes, tailored to medical fields as proposed by Petrides and McManus [4], could be used to develop programs that help match students' traits with the most suitable specialties. These programs could also be used to enhance students' self-awareness, helping them to identify and develop their strengths while addressing weaknesses as they prepare for a career in their chosen medical specialty. Such programs should be considered as guidance rather than strict recommendations for student's career choices, given that numerous factors could influence job satisfaction and performance. A recent study of medical students identified key influences on the decision to pursue a career in Orthopedics, including familial and peer pressure, perceptions of job prestige, gender considerations, parental involvement, elective rotations, opportunities for research and teaching, and aspirations for leadership roles [45]. Consistent with our findings, the study also identified an association between the choice of Orthopedics and male gender [45]. Another study on medical students and interns in Saudi Arabia found that factors influencing the choice of a medical specialty were interests in the procedures and techniques specific to the specialty, dissertation research experience, high-quality teaching within the program, connections with friends, relatives, or others in the health care field, and positive experiences with physician role models [46]. Additionally, work-life balance was found to be a significant consideration for students when selecting a specialty [47].

Nevertheless, exploring students' personalities could also be used in cultivating and enhancing behaviors desirable in physicians, such as empathy. All of the above with the aim to improve treatment outcomes and professional satisfaction among physicians. Such initiatives could serve as a foundation for longitudinal research to examine whether this training impacts the doctor-patient relationship and burnout rates. Extensive sociopsychological research on the medical doctor population would be needed. Undoubtedly, this area is yet to be covered.

This study is noteworthy due to the extensive size of the respondent group surveyed while considering various factors such as gender, academic year, personality type, and personality traits. Additionally, it facilitates the comparison of the data with prior research in the field.

Limitations

There are several limitations inherent in this study.

First, the major limitation that could be addressed in future research is that it was conducted on medical students, who, inevitably, do not possess the full picture of the work as a specialist in a specific area. Therefore, their declared choice of future specialty is based on a general impression that was formed during a relatively short time spent in particular wards.

Second, as Kristof Brown indicates, apart from the person-vocation fit, there are other significant factors that influence one's job satisfaction, that is, person-job, person-organization, person-group, and person-supervisor fit [34]. Hence, even if a model linking personality type with medical discipline is created, the true impact on the individual level cannot be concluded.

Third, although some distinctive traits seem to be unique for particular specialties regardless of country, many aspects of work as a medical doctor are inseparably intertwined with cultural and socioeconomic conditions found in particular communities. What is more, these conditions change over time.

Furthermore, it is contentious if accepting environmental determinism is beneficial to an organization. Creating a homogenous group, as Schneider [2] indicates, may decrease the capability to adapt to the changing demands and requirements of society.

Conclusions

To conclude, the findings of this study showed that there is a link between one's personality and their choice of medical specialty. In general, women exhibited a greater preference for pediatric specialties, while men tended to favor surgical specialties. Introverted, Observant, and Judging individuals showed a notable inclination toward Family Medicine, while Intuitive and Prospective traits were associated with an interest in Psychiatry, particularly in Child and Youth Psychiatry. Additionally, the Thinking trait was prevalent among students opting for surgical specialties such as Neurosurgery, Forensic Medicine, Plastic Surgery, and General Surgery, whereas the Feeling trait was more common among those choosing pediatric specialties. Taking into consideration students' personality traits, the medical curriculum should be designed to match clinical communication skills, interprofessional collaboration, and teamwork for the best outcomes of treatment, as well as physicians' professional fulfillment.

design, execution, and interpretation of the data. Generative artificial intelligence was not used during the preparation of the manuscript.

Data Availability

The datasets generated during and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

MT conceptualized the manuscript and coordinated the writing process. MT, JJ, KM, TK, JG, and NW reviewed, edited, and wrote the final version of the manuscript. JM and JG conducted statistical analyses. JM prepared the Figures 1-3. MT prepared Figure 4. KM prepared Table 1. JJ prepared Table 2. MT, JJ, and KM prepared and distributed the survey. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1

16Personalities report – an analysis of each respondent's personality type and the intensity of specific personality traits.

Abstract

Background: Adherence to evidence-based practice is indispensable in health care. Recently, the utility of generative artificial intelligence (AI) models in health care has been evaluated extensively. However, the lack of consensus guidelines on the design and reporting of findings of these studies poses a challenge for the interpretation and synthesis of evidence.

Objective: This study aimed to develop a preliminary checklist to standardize the reporting of generative AI-based studies in health care education and practice.

Methods: A literature review was conducted in Scopus, PubMed, and Google Scholar. Published records with "ChatGPT," "Bing," or "Bard" in the title were retrieved. Careful examination of the methodologies employed in the included records was conducted to identify the common pertinent themes and the possible gaps in reporting. A panel discussion was held to establish a unified and thorough checklist for the reporting of AI studies in health care. The finalized checklist was used to evaluate the included records by 2 independent raters. Cohen κ was used as the method to evaluate the interrater reliability.

Results: The final data set that formed the basis for pertinent theme identification and analysis comprised a total of 34 records. The finalized checklist included 9 pertinent themes collectively referred to as METRICS (Model, Evaluation, Timing, Range/Randomization, Individual factors, Count, and Specificity of prompts and language). Their details are as follows: (1) Model used and its exact settings; (2) Evaluation approach for the generated content; (3) Timing of testing the model; (4) Transparency of the data source; (5) Range of tested topics; (6) Randomization of selecting the queries; (7) Individual factors in selecting the queries and interrater reliability; (8) Count of queries executed to test the model; and (9) Specificity of the prompts and language used. The overall mean METRICS score was 3.0 (SD 0.58). The tested METRICS score was acceptable, with the range of Cohen κ of 0.558 to 0.962 (*P*<.001 for the 9 tested items). With classification per item, the highest average METRICS score was recorded for the "Model" item, followed by the "Specificity" item, while the lowest scores were recorded for the "Randomization" item (classified as suboptimal) and "Individual factors" item (classified as satisfactory).

Conclusions: The METRICS checklist can facilitate the design of studies guiding researchers toward best practices in reporting results. The findings highlight the need for standardized reporting algorithms for generative AI-based studies in health care, considering the variability observed in methodologies and reporting. The proposed METRICS checklist could be a preliminary

helpful base to establish a universally accepted approach to standardize the design and reporting of generative AI-based studies in health care, which is a swiftly evolving research topic.

Introduction

The integration of generative artificial intelligence (AI) models into health care education and practice holds promising perspectives with numerous possibilities for continuous improvement [1-5]. Examples of generative AI-based conversational models characterized by ease of use and perceived usefulness include ChatGPT by OpenAI, Bing by Microsoft, and Bard by Google [6-8].

The vast potential of generative AI-based models in health care can be illustrated as follows. First, generative AI-based models can facilitate streamlining of the clinical workflow, with subsequent improvement in efficiency manifested in reduced time for care delivery and reduced costs [1,9-11]. Second, generative AI-based models can enhance personalized medicine with a huge potential to achieve refined prediction of disease risks and outcomes [1,12,13]. Third, generative AI-based models can be implemented to improve health literacy among lay individuals through the provision of easily accessible and understandable health information [1,14,15].

Despite the aforementioned advantages of generative AI-based models in health care, several valid concerns were raised, which should be considered carefully owing to their serious consequences [1,4,16]. For example, the lack of clarity on how generative AI-based models are trained raises ethical concerns [17,18]. Additionally, these models have an inherent bias in the generated content based on the modality of training used for their development and updates [17,18]. Importantly, the generation of inaccurate or misleading content, which might appear scientifically plausible to nonexperts (referred to as "hallucinations"), could have profound negative impacts in health care settings [1,19-21]. Furthermore, the integration of generative AI-based models in health care could raise complex medicolegal and accountability questions, compounded by the issues of data privacy and cybersecurity risks [1,4,22,23].

Similarly, the use of generative AI-based models can cause a paradigm shift in information acquisition, particularly in health care education [1,24-26]. However, careful consideration of the best policies and practices to incorporate AI-based models in health care education is needed [27]. This issue involves the urgent need to address the issues of inaccuracies, possible academic dishonesty, decline in critical thinking development, and deterioration of practical training skills [1].

Recently, a remarkable number of studies investigated the applicability and disadvantages of prominent generative AI-based conversational models, such as ChatGPT, Microsoft Bing, and Google Bard, in various health care and educational settings [1,2,4,28-34]. However, synthesizing evidence from such studies can be challenging owing to several reasons.

Variations in methodologies implemented in various studies as well as in the reporting standards is a major limitation. This issue could hinder the efforts aiming to compare and contrast the results of generative AI-based studies in health care, contributing to the complexity in this domain. This variability arises from several factors, including different settings of the tested models, prompt variability, varying approaches used to evaluate the generated content of generative AI-based models, varying range of tested topics, and possible bias in selecting the tested subjects. Additionally, variability can be related to the different number and varying expertise of individual raters of content quality, as well as the variable number of queries executed, among other factors [35-37].

Therefore, it is important to initiate and develop an approach that can aid in establishing standardized reporting practices for studies aiming to evaluate the content of generative AI-based models, particularly in health care. This standardization can be crucial to facilitate the design of generative AI-based studies in health care, ensuring rigor and achieving precise comparison and credible synthesis of findings across different studies. Thus, we aimed to propose a preliminary framework (checklist) to establish proper guidelines for the design and reporting of findings of generative AI-based studies that address health care–related topics.

Methods

Study Design

The study was based on a literature review to highlight the key methodological aspects in studies that investigated 3 generative AI-based models (ChatGPT, Bing, and Bard) in health care education and practice. The literature review was conducted to identify relevant literature indexed in databases up to November 11, 2023 [38]. The databases used for this literature search were Scopus, PubMed/MEDLINE, and Google Scholar.

Ethical Considerations

This study did not involve human subjects, and thus, the requirement of ethical permission was waived.

Literature Search to Identify Relevant Records

The Scopus string query was as follows: (TITLE-ABS-KEY("artificial intelligence" OR "AI") AND TITLE-ABS-KEY ("healthcare" OR "health care") AND TITLE-ABS-KEY ("education" OR "practice")) AND PUBYEAR > 2022 AND DOCTYPE (ar OR re) AND (LIMIT-TO (PUBSTAGE , "final")) AND (LIMIT-TO (SRCTYPE , "j")) AND (LIMIT-TO (LANGUAGE , "English")). The Scopus search yielded a total of 843 documents.

The PubMed advanced search tool was used as follows: ("artificial intelligence"[Title/Abstract] OR "AI"[Title/Abstract]) AND ("healthcare"[Title/Abstract] OR "health care"[Title/Abstract]) AND ("education"[Title/Abstract] OR "practice"[Title/Abstract]) AND ("2022/12/01"[Date - Publication] : "2023/11/11"[Date - Publication]). The PubMed search yielded a total of 564 records.

In Google Scholar and using the Publish or Perish software (version 8), in the title words and in the years 2022-2023, the search was as follows: "artificial intelligence" OR "AI" AND "healthcare" OR "health care" AND "education" OR "practice," with a maximum of 999 records retrieved [39].

Criteria for Record Inclusion

The records from the 3 databases were merged using EndNote 20.2.1 software. This was followed by removal of duplicate records and removal of preprints by using the following function: ANY FIELD preprint OR ANY FIELD rxiv OR ANY FIELD SSRN OR ANY FIELD Researchgate OR ANY FIELD researchsquare OR ANY FIELD. The retrieved records were eligible for the final screening step given the following inclusion criteria: (1) Original article; (2) English record; (3) Published (peer reviewed); and (4) Assessment in health care practice or health care education. Finally, the imported references were subjected to the search function in EndNote as follows: Title contains ChatGPT OR Title contains Bing OR Title contains Bard. The selection of the included records was performed by the first author (Malik Sallam).

Development of the Initial Checklist Items

Initial development of the proposed checklist began with the assessment of the methodology and results sections of the included records, a majority of which were regarded as cross-sectional descriptive studies. Then, we referred to 2 commonly used reporting and quality guidelines to proactively explore pertinent themes for the proposed checklist based on the nature of the included records: (1) STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) Statement: guidelines for reporting observational studies (checklist: cross-sectional studies) and (2) CASP (Critical Appraisal Skills Programme) Checklist (CASP qualitative studies checklist) [40,41]. This facilitated the allocation of ethical considerations, including transparency, methodological rigor, and issues related to bias, in the proposed checklist. Then, the 3 authors conducted an independent content review process to identify all the possible essential themes and best practices in generative AI-based health care studies among the included records. Finally, the authors had a collaborative discussion to refine the selected themes and classify these themes into specific components relevant to the study objectives. Special attention was given to aspects of method and result reporting that were perceived to impact the quality and reproducibility of the records, as identified by the 3 authors.

Establishing the Final Checklist Criteria

Careful examination of the included records resulted in the compilation of 3 independent lists of "pertinent themes," which are herein defined as being critical or recurring in the reporting of results of generative AI-based studies. A thorough discussion among the authors followed to reach a consensus on the pertinent themes. Recurring themes were defined as those found in the methods of at least three separate records. Critical aspects were defined as those that would impact the conclusions of the included records as agreed by the 3 authors.

The final pertinent themes were selected based on their author-perceived significance in the quality and reproducibility of the findings. A final list of 9 themes was agreed upon by the authors as follows: (1) the "Model" of the generative AI-based tool or tools used in the included record and the explicit mention of the exact settings employed for each tool; (2) the "Evaluation" approach to assess the quality of the content generated by the generative AI-based model in terms of objectivity to reach unbiased findings and subjectivity; (3) the exact "Timing" of generative AI-based model testing and its duration; (4) the "Transparency" of data sources used to generate queries for the generative AI-based model testing, including the permission to use copyrighted content; (5) the "Range" of topics tested (single topic, multiple related topics, or various unrelated topics, as well as the breadth of intertopic and intratopic queries tested); (6) the degree of "Randomization" of topics selected to be tested to consider the potential bias; (7) the "Individual" subjective role in evaluating the content and the possibility of interrater reliability concordance or discordance; (8) the number ("Count") of queries executed on each generative AI model entailing the sample size of queries tested; and (9) the "Specificity" of prompts used on each generative AI-based model, including the exact phrasing of each prompt and the presence of feedback and learning loops, and the "Specificity" of the language or languages used in testing, besides any other cultural issues. Thus, the final checklist was termed METRICS (Model, Evaluation, Timing, Range/Randomization, Individual factors, Count, and Specificity of prompts and language).

Scoring the METRICS Items and Classification of the METRICS Score

Testing of the included records was performed by 2 independent raters (Malik Sallam and Mohammed Sallam) independently, with each METRICS item scored using a 5-point Likert scale as follows: 5=excellent, 4=very good, 3=good, 2=satisfactory, and 1=suboptimal. For the items that were deemed "not applicable" (eg, individual factors for studies that employed objective methods for evaluation), no score was given. The scores for the 2 raters were then averaged. The average METRICS score was calculated as the sum of average scores for each applicable item divided by 10 minus the number of items deemed not applicable.

The subjective assessment of the 2 raters was performed based on predefined criteria as a general guide. For example, if the exact dates of model queries were mentioned, the "Timing" item was scored as excellent. The count of queries was agreed to be categorized as excellent if it was more than 500, while a single case or no mention of the count was considered suboptimal. For the prompt attributes, scores were assigned based on the availability of exact prompts, explicit mention of the language used, and details of prompting. Thus, prompts and language specificity were appraised positively if the study clearly and explicitly made the exact prompts available and if

there was an explicit mention of the language employed in the prompts. The evaluation method was agreed to be rated higher for objective assessments with full details and lower for subjective assessments. The explicit mention of the method of interrater reliability testing was agreed to be scored higher for the "Individual" item. Transparency was assessed based on the comprehensiveness of the data source, and the presence of full database disclosure and permission to use the data was agreed to be given an excellent score. Randomization was agreed to be scored the lowest for the absence of details and the highest for explicit detailed descriptions.

Finally, we decided to highlight the records that scored the highest for each METRICS item. The decision to take this approach was based on an attempt to refrain from providing examples for the other quality categories to avoid premature conclusions regarding the quality of the included studies owing to the preliminary pilot nature of the METRICS tool.

Statistical and Data Analysis

The average METRICS scores were classified into distinct categories of equal weights as follows: excellent (score

4.21-5.00), very good (3.41-4.20), good (2.61-3.40), satisfactory (1.81-2.60), and suboptimal (1.00-1.80).

The Cohen κ measure was used to assess the interrater reliability by 2 independent raters. The Cohen κ measure was categorized as follows: <0.20, poor agreement; 0.21-0.40, fair agreement; 0.41-0.60, good agreement; 0.61-0.80, very good agreement; and 0.81-1.00, excellent agreement.

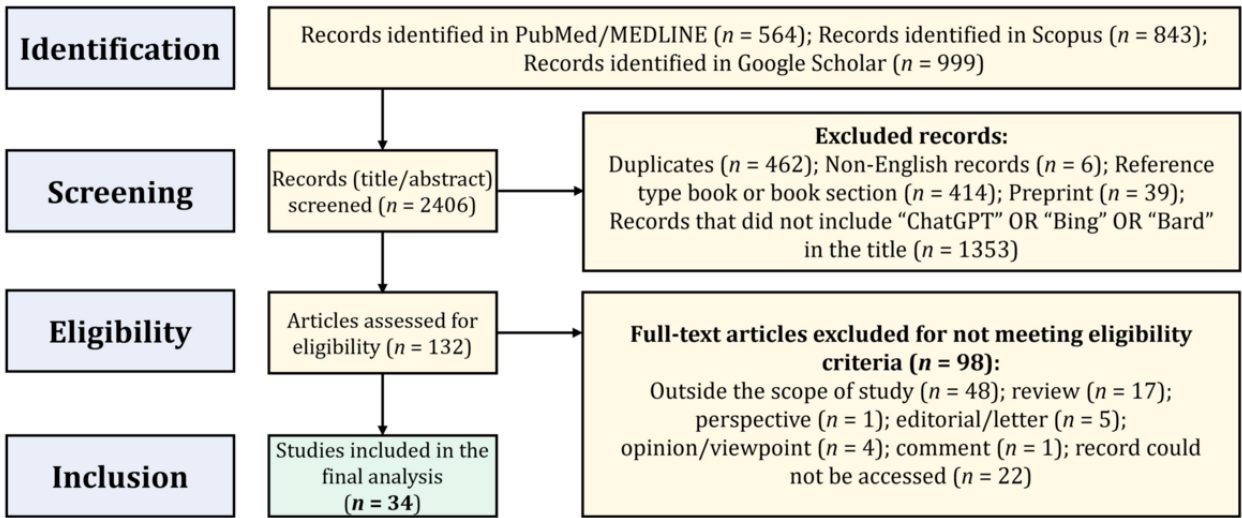
For statistical analysis, we used IBM SPSS Statistics for Windows, Version 26.0 (IBM Corp). A P value $<.05$ was considered significant.

Results

Description of the Included Studies

A total of 34 studies were included in the final analysis that aimed to establish the METRICS criteria (Figure 1).

The most common source of records was Cureus, with 9 of the 34 records (27%), followed by BMJ Neurology Open, with 2 of the 34 records (6%). The remaining 23 records were published in 23 different journals.

Figure 1. The approach for selecting articles.


Evaluation of the Included Records Based on MED-METRICS Items

The METRICS checklist was divided into the following 3 parts: "Model" attributes, "Evaluation" approach, and features of "Data" (MED-METRICS).

The complete details of the model attributes of the included studies are presented in Table 1.

ChatGPT was tested in all the records included (34/34, 100%), followed by Google Bard (5/34, 15%) and Bing Chat (5/34, 15%). The exact dates of generative AI-based model queries were explicitly mentioned in 13 of the 34 records (38%). The count of cases or questions that were tested in the studies ranged from a single case to 2576 questions. The majority of studies (23/34, 68%) tested the AI models based on queries in the English language.

The complete details of the evaluation approach of the content generated by the AI-based models in the included studies are presented in Table 2.

Objective evaluation of the content generated by the generative AI-based model was noted in 15 of the 34 records (44%).

The complete details of the features of data used to generate queries for testing on the generative AI-based models, including the range of topics and randomization, are presented in Table 3.

Explicit mention of the randomization process was only noted in 4 of the 34 included studies (9%). Of the 34 records, 6 (18%) involved broad multidisciplinary medical exam questions (18%). Moreover, 2 studies (6%) explicitly mentioned the permission to use the data for the studies.

Table 1. Details of the model attributes of the included studies.

Authors	Model	Timing	Count	Specificity of the prompts and language
Al-Ashwal et al [42]	ChatGPT-3.5, ChatGPT-4, Bing, and Bard with unclear settings	One month, May 2023	255 drug-drug pairs	The exact prompts were provided in English.
Alfertshofer et al [43]	ChatGPT with unclear settings	Not provided	1800 questions	The exact prompt was used for each question. The questions were taken from United States, United Kingdom, Italian, French, Spanish, and Indian exams. A new session was used for each question.
Ali et al [44]	ChatGPT Feb 9 free version with unclear settings	Not provided	50 items	Information was provided fully in the supplementary file of the article in English.
Aljindan et al [45]	ChatGPT-4 with unclear settings	Not provided	220 questions	Initial prompting that involved role playing as a medical professional. The language was English.
Altamimi et al [46]	ChatGPT-3.5	Single day not otherwise specified	9 questions	The exact prompts were provided in English.
Baglivo et al [47]	Bing, ChatGPT, Chatsonic, Bard, and YouChat with full details of the mode and large language model, including plugins	Exact dates were provided for each model (April 12, 13, and 14, 2023, and July 13, 2023)	15 questions	Italian was used.
Biswas et al [48]	ChatGPT-3.5 with unclear settings	Exact date provided (March 16, 2023)	11 questions	The exact prompts were provided in English, with a new session for each question.
Chen et al [49]	ChatGPT-4 with unclear settings	Not provided	560 questions	The exact prompts were provided in English.
Deiana et al [50]	ChatGPT-3.5 and ChatGPT-4 with unclear settings	Not provided	11 questions	The exact prompts were not explicitly provided. English was used. A new session was used for each question. Up to three iterations were allowed for incorrect responses.
Fuchs et al [51]	ChatGPT-3 and ChatGPT-4 with unclear settings	Exact dates provided (February 19, 2023, and March 25, 2023)	60 questions	Dental medicine questions were translated from German to English, while the other questions were already present in English. Exact prompts were provided in English with prompting in 2 groups for the same questions: one group was primed with instructions, while the other was not primed. A total of 20 trials were conducted per group, and chat history was cleared after each trial.
Ghosh & Bir [52]	ChatGPT (version March 14, 2023) with unclear settings	March 14 and 16, 2023	200 questions	The exact prompts and language were not explicitly provided. The first response was taken as final, and the option of "regenerate response" was not used.
Giannos [53]	ChatGPT-3 and ChatGPT-4 with unclear settings	Not provided	69 questions	Not explicitly provided.
Gobira et al [54]	ChatGPT-4 with unclear settings	Not provided	125 questions	Portuguese was used.
Grewal et al [55]	ChatGPT-4 with unclear settings	The first week of May 2023	Not clear	The exact prompts were provided in English. One follow-up prompt was used for enhancement of some prompts.
Guerra et al [56]	ChatGPT-4 with unclear settings	Not provided	591 questions	The exact prompts were provided, while the language was not explicitly provided.
Hamed et al [57]	ChatGPT-4 with unclear settings	Not provided	Not clear	The exact prompts and language were not explicitly provided. Different prompts were tried to identify the most suitable.
Hoch et al [58]	ChatGPT (May 3rd version) with unclear settings	May 5 and 7, 2023	2576 questions	The exact prompts were provided, while the language was not explicitly provided.

XSL•FO

RenderX

Authors	Model	Timing	Count	Specificity of the prompts and language
Juhi et al [59]	ChatGPT with unclear settings	February 20, 2023, to March 5, 2023	40 drug-drug pairs	The exact prompts were provided in English.
Kuang et al [60]	ChatGPT with unclear settings	Not provided	Not clear	The exact prompts were not explicitly provided. English was used.
Kumari et al [61]	ChatGPT-3.5, Bard, and Bing with unclear settings	July 30, 2023	50 questions	The exact prompts were not explicitly provided. English was used.
Kung et al [62]	ChatGPT-3.5 and ChatGPT-4 with unclear settings	July 2023	215 questions	Not clear
Lai et al [63]	ChatGPT-4 (May 24; Version 3.5) with unclear settings	Not provided	200 questions	The exact prompts and language were not explicitly provided. Three attempts to answer the complete set of questions over 3 weeks (once per week), with a new session for each question.
Lyu et al [64]	ChatGPT with unclear settings	Mid-February 2023	Not clear	The exact prompts were provided in English.
Moise et al [65]	ChatGPT-3.5 with unclear settings	Not provided	23 questions	The exact prompts were provided in English, with a new session for each question.
Oca et al [66]	ChatGPT, Bing, and Bard with unclear settings	April 11, 2023	20 queries for each model	The exact prompts were provided in English.
Oztermeli & Oztermeli [67]	ChatGPT-3.5 with unclear settings	Not provided	1177 questions	The exact prompts were not explicitly provided. Turkish was used, with a new session for each question.
Pugliese et al [68]	ChatGPT with unclear settings	March 25, 2023	15 questions	The exact prompts were provided in English, with a new session for each question.
Sallam et al [69]	ChatGPT (default model) with unclear settings	February 25, 2023	Not provided	The exact prompts were provided in English.
Seth et al [70]	ChatGPT-3.5, Bard, and Bing AI	Not provided	6 questions	The exact prompts were provided in English.
Suthar et al [71]	ChatGPT-4 with unclear settings	Not provided	140 cases	The exact prompts were not explicitly provided. English was used.
Walker et al [72]	ChatGPT-4 with unclear settings	Not provided	5 cases	The exact prompts were not explicitly provided. English was used, with a new session for each question.
Wang et al [73]	ChatGPT-3.5 and ChatGPT-4 with unclear settings	February 14, 2023, for ChatGPT-3.5 and May 14-16, 2023, for ChatGPT-4	300 questions	The exact prompts were provided. Chinese and English were used. The prompts were enhanced though role play.
Wang et al [74]	ChatGPT-3.5 with unclear settings	March 5-10, 2023	Not clear	Chinese (Mandarin) and English were used. Examples of prompts were provided.
Zhou et al [75]	ChatGPT-3.5 with unclear settings	April 24-25, 2023	Single case and multiple poll questions	The exact prompts were provided in English.

Table 2. Classification based on the evaluation approach of the content generated by the artificial intelligence–based models.

Authors	Evaluation of performance	Individual role and interrater reliability
Al-Ashwal et al [42]	Objective via 2 different clinical reference tools	Not applicable
Alfertshofer et al [43]	Objective based on the key answers, with the questions screened independently by 4 investigators	Not applicable
Ali et al [44]	Objective for multiple-choice questions and true or false questions, and subjective for short-answer and assay questions	Assessment by 2 assessors independently with intraclass correlation coefficient for agreement
Aljindan et al [45]	Objective based on key answers and historical performance metrics	Not applicable
Altamimi et al [46]	Subjective	Not clear; Assessment for accuracy, informativeness, and accessibility by clinical toxicologists and emergency medicine physicians
Baglivo et al [47]	Objective based on key answers and comparison with 5th year medical students' performance	Not applicable
Biswas et al [48]	Subjective by a 5-member team of optometry teaching and expert staff with over 100 years of clinical and academic experience between them; Independent evaluation on a 5-point Likert scale ranging from very poor to very good	The median scores across raters for each response were studied; The score represented rater consensus, while the score variance represented disagreements between the raters
Chen et al [49]	Objective based on key answers	Not applicable
Deiana et al [50]	Subjective based on qualitative assessment of correctness, clarity, and exhaustiveness; Each response rated using a 4-point Likert scale scored from strongly disagree to strongly agree	Independent assessment by 2 raters with experience in vaccination and health communication topics
Fuchs et al [51]	Objective based on key answers	Not applicable
Ghosh & Bir [52]	Objective based on key answers; Subjectivity by raters' assessment	Scoring by 2 assessors on a scale of 0 to 5, with 0 being incorrect and 5 being fully correct, based on a preselected answer key
Giannos [53]	Objective based on key answers	Not applicable
Gobira et al [54]	Objective based on key answers, with an element of subjectivity through classifying the responses as adequate, inadequate, or indeterminate	Two raters independently scored the accuracy; After individual evaluations, the raters performed a third assessment to reach a consensus on the questions with differing results
Grewal et al [55]	Not clear	Not clear
Guerra et al [56]	Subjective through comparison with the results of a previous study on the average performance of users, and a cohort of medical students and neurosurgery residents	Not applicable
Hamed et al [57]	Subjective	Not clear
Hoch et al [58]	Objective based on key answers	Not applicable
Juhi et al [59]	Subjective and the use of Stockley's Drug Interactions Pocket Companion 2015 as a reference key	Two raters reached a consensus for categorizing the output
Kuang et al [60]	Subjective	Not clear
Kumari et al [61]	Subjective; Content validity checked by 2 experts of curriculum design	Three independent raters scored content based on their correctness, with an accuracy score ranging from 1 to 5
Kung et al [62]	Objective based on key answers	Not applicable
Lai et al [63]	Objective based on key answers	Not applicable
Lyu et al [64]	Subjective	Two experienced radiologists (with 21 and 8 years of experience) evaluated the quality of the ChatGPT responses
Moise et al [65]	Subjective through comparison with the latest American Academy of Otolaryngology–Head and Neck Surgery Foundation Clinical Practice Guideline: Tympanostomy Tubes in Children (Update)	Two independent raters evaluated the output; The interrater reliability was assessed using the Cohen κ test; To confirm consensus, responses were reviewed by the senior author
Oca et al [66]	Not clear	Not clear

Authors	Evaluation of performance	Individual role and interrater reliability
Oztermeli & Oztermeli [67]	Objective based on key answers	Not applicable
Pugliese et al [68]	Subjective using the Likert scale for accuracy, completeness, and comprehensiveness	Multirater: 10 key opinion leaders in nonalcoholic fatty liver disease and 1 nonphysician with expertise in patient advocacy in liver disease independently rating the AI[a] content
Sallam et al [69]	Subjective based on correctness, clarity, and conciseness	Fleiss multirater κ
Seth et al [70]	Subjective through comparison with the current health care guidelines for rhinoplasty, and evaluation by a panel of plastic surgeons through a Likert scale to assess the readability and complexity of the text and the education level required for understanding, and the modified DISCERN[b] score	Not clear
Suthar et al [71]	Subjective by 3 fellowship-trained neuroradiologists, using a 5-point Likert scale, with 1 indicating "highly improbable" and 5 indicating "highly probable"	Not applicable
Walker et al [72]	Modified EQIP[c] Tool with comparison with UK National Institute for Health and Care Excellence guidelines for gallstone disease, pancreatitis, liver cirrhosis, or portal hypertension, and the European Association for Study of the Liver guidelines	All answers were assessed by 2 authors independently, and in case of a contradictory result, resolution was achieved by consensus; The process was repeated 3 times per EQIP item; Wrong or out of context answers, known as "AI hallucinations," were recorded
Wang et al [73]	Subjective	Unclear
Wang et al [74]	Objective based on key answers	Not applicable
Zhou et al [75]	Subjective	Unclear

[a]AI: artificial intelligence.

[b]DISCERN is an instrument for judging the quality of written consumer health information on treatment choices.

[c]EQIP: Ensuring Quality Information for Patients.

Table 3. Classification of the included studies based on the features of data used to generate queries for testing on the generative artificial intelligence–based models.

Authors	Transparency	Range	Randomization
Al-Ashwal et al [42]	Full description using 2 tools for assessment: Micromedex, a subscription-based drug-drug interaction screening tool, and Drugs.com, a free database	Narrow; Drug-drug interaction prediction	Nonrandom; Purposeful selection of the drugs by a clinical pharmacist; 5 drugs paired with the top 51 prescribed drugs
Alfertshofer et al [43]	Full description using the question bank AMBOSS, with official permission for the use of the AMBOSS USMLE step 2CK practice question bank for research purposes granted by AMBOSS	Broad	Randomly extracted
Ali et al [44]	Developed by the researchers and reviewed by a panel of experienced academics for accuracy, clarity of language, relevance, and agreement on correct answers; Evaluation of face validity, accuracy, and suitability for undergraduate dental students	Narrow intersubject (dentistry); Broad intrasubject in restorative dentistry, periodontics, fixed prosthodontics, removable prosthodontics, endodontics, pedodontics, orthodontics, preventive dentistry, oral surgery, and oral medicine	Not clear
Aljindan et al [45]	Saudi Medical Licensing Exam questions extracted from the subscription CanadaQBank website	Broad in medicine, with 30% of the questions from medicine, 25% from obstetrics and gynecology, 25% from pediatrics, and the remaining 20% from surgery	Randomized through 4 researchers to ensure comprehensive coverage of questions and eliminate potential bias in question selection
Altamimi et al [46]	Snakebite management information guidelines derived from the World Health Organization, Centers for Disease Control and Prevention, and the clinical literature	Narrow	Not clear
Baglivo et al [47]	The Italian National Medical Residency test	Narrow; Vaccination-related questions from the Italian National Medical Residency Test	Not clear
Biswas et al [48]	Constructed based on the frequently asked questions on the myopia webpage of the Association of British Dispensing Opticians and the College of Optometrists	Narrow involving 9 categories: 1 each for disease summary, cause, symptom, onset, prevention, complication, natural history of untreated myopia, and prognosis, and 3 involving treatments	Not clear
Chen et al [49]	BoardVitals, which is an online question bank accredited by the Accreditation Council for Continuing Medical Education	Neurology-based; Broad intrasubject: basic neuroscience; behavioral, cognitive, psychiatry; cerebrovascular; child neurology; congenital; cranial nerves; critical care; demyelinating disorders; epilepsy and seizures; ethics; genetic; headache; imaging or diagnostic studies; movement disorders; neuro-ophthalmology; neuro-otology; neuroinfectious disease; neurologic complications of systemic disease; neuromuscular; neurotoxicology, nutrition, metabolic; oncology; pain; pharmacology; pregnancy; sleep; and trauma	Not clear
Deiana et al [50]	Questions concerning vaccine myths and misconceptions by the World Health Organization	Narrow on vaccine myths and misconceptions	Not clear
Fuchs et al [51]	Digital platform self-assessment questions tailored for dental and medical students at the University of Bern's Institute for Medical Education	Broad with multiple-choice questions designed for dental students preparing for the Swiss Federal Licensing Examination in Dental Medicine, and allergists and immunologists preparing for the European Examination in Allergy and Clinical Immunology	Not clear
Ghosh & Bir [52]	Department question bank, which is a compilation of first and second semester questions from various medical universities across India	Biochemistry	Random without details of randomization
Giannos [53]	Specialty Certificate Examination Neurology Web Questions bank	Neurology and neuroscience	Not clear

Authors	Transparency	Range	Randomization
Gobira et al [54]	National Brazilian Examination for Revalidation of Medical Diplomas issued by Foreign Higher Education Institutions (Revalida)	Preventive medicine, gynecology and obstetrics, surgery, internal medicine, and pediatrics	Not clear
Grewal et al [55]	Not clear	Radiology	Not clear
Guerra et al [56]	Questions released by the Congress of Neurological Surgeons in the self-assessment neurosurgery exam	Neurosurgery across 7 subspecialties: tumor, cerebrovascular, trauma, spine, functional, pediatrics, and pain or nerve	Not clear
Hamed et al [57]	Guidelines adapted from Diabetes Canada Clinical Practice Guidelines Expert Committee, the Royal Australian College of General Practitioners, Australian Diabetes Society position statement, and the Joint British Diabetes Societies	Management of diabetic ketoacidosis	Not clear
Hoch et al [58]	Question database of an online learning platform funded by the German Society of Oto-Rhino-Laryngology, Head and Neck Surgery	Otolaryngology with a range of 15 distinct otolaryngology subspecialties, including allergology, audiology, ear, nose and throat, tumors, face and neck, inner ear and skull base, larynx, middle ear, oral cavity and pharynx, nose and sinuses, phoniatrics, salivary glands, sleep medicine, vestibular system, and legal aspects	Not clear
Juhi et al [59]	A list of drug-drug interactions from previously published research	Narrow on drug-drug interaction	Not clear
Kuang et al [60]	Not clear	Neurosurgery	Not clear
Kumari et al [61]	Designed by experts in hematology-related cases	Hematology with the following intrasubject aspects: case solving, laboratory calculations, disease interpretations, and other relevant aspects of hematology	Not clear
Kung et al [62]	Orthopedic In-Training Examination	Orthopedics	Not clear
Lai et al [63]	The United Kingdom Medical Licensing Assessment, which is a newly derived national undergraduate medical exit examination	Broad in medicine with the following aspects: acute and emergency, cancer, cardiovascular, child health, clinical hematology, ear, nose and throat, endocrine and metabolic, gastrointestinal including liver, general practice and primary health care, genetics and genomics, infection, medical ethics and law, medicine of older adults, mental health, musculoskeletal, neuroscience obstetrics and gynecology, ophthalmology, palliative and end of life care, perioperative medicine and anesthesia, renal and urology, respiratory, sexual health, social and population health, and surgery	Not clear
Lyu et al [64]	Chest computed tomography and brain magnetic resonance imaging screening reports collected from the Atrium Health Wake Forest Baptist clinical database	Radiology	Not clear
Moise et al [65]	Statements published in the latest American Academy of Otolaryngology–Head and Neck Surgery Foundation Clinical Practice Guideline: Tympanostomy Tubes in Children (Update)	Narrow involving otolaryngology	Not clear
Oca et al [66]	Not clear	Narrow involving only queries on accurate recommendation of close ophthalmologists	Not clear

Authors	Transparency	Range	Randomization
Oztermeli & Oztermeli [67]	Turkish medical specialty exam, prepared by the Student Selection and Placement Center	Broad: basic sciences including anatomy, physiology-histology-embryology, biochemistry, microbiology, pathology, and pharmacology; clinical including internal medicine, pediatrics, general surgery, obstetrics and gynecology, neurology, neurosurgery, psychiatry, public health, dermatology, radiology, nuclear medicine, otolaryngology, ophthalmology, orthopedics, physical medicine and rehabilitation, urology, pediatric surgery, cardiovascular surgery, thoracic surgery, plastic surgery, anesthesiology and reanimation, and emergency medicine	Not clear
Pugliese et al [68]	Expert selection of 15 questions commonly asked by patients with nonalcoholic fatty liver disease	Narrow involving nonalcoholic fatty liver disease aspects	Not clear
Sallam et al [69]	Panel discussion of experts in health care education	Broad on health care education, medical, dental, pharmacy, and public health	Not clear
Seth et al [70]	Devised by 3 fellows of the Royal Australasian College of Surgeons, with experience in performing rhinoplasty and expertise in facial reconstructive surgery	Narrow involving technical aspects of rhinoplasty	Not clear
Suthar et al [71]	Quizzes from the Case of the Month feature of the American Journal of Neuroradiology	Narrow involving radiology	Not clear
Walker et al [72]	Devised based on the Global Burden of Disease tool	Narrow involving benign and malignant hepatopancreaticobiliary-related conditions	Not clear
Wang et al [73]	Medical Exam Help. A total of 10 inpatient and 10 outpatient medical records to form a collection of Chinese medical records after desensitization	Clinical medicine, basic medicine, medical humanities, and relevant laws	Not clear
Wang et al [74]	The Taiwanese Senior Professional and Technical Examinations for Pharmacists downloaded from the Ministry of Examination website	Broad involving pharmacology and pharmaceutical chemistry, pharmaceutical analysis and pharmacognosy (including Chinese medicine), pharmaceutics and biopharmaceutics, dispensing pharmacy and clinical pharmacy, therapeutics, pharmacy administration, and pharmacy law	Not clear
Zhou et al [75]	A single clinical case from OrthoBullets, a global clinical collaboration platform for orthopedic surgeons; Written permission to use their clinical case report	Very narrow involving a single orthopedic case	Not clear

Examples of Optimal Reporting of Each Criterion Within the METRICS Checklist

The records with the highest scores for each METRICS item, as determined by the average subjective interrater assessments, are shown in Table 4.

XSL•FO
RenderX

Table 4. Included records that had the highest METRICS score per item.

Item	Issues considered in each item	Excellent or very good reporting examples
#1 Model	What is the model of the generative AI[a] tool used for generating content, and what are the exact settings for each tool?	Baglivo et al [47]: Bing, ChatGPT, Chatsonic, Bard, and YouChat, with full details of the mode and large language model, including plugins
#2 Evaluation	What is the exact approach used to evaluate the content generated by the generative AI-based model and is it an objective or subjective evaluation?	Al-Ashwal et al [42]: Objective via 2 different clinical reference tools; Alfertshofer et al [43]: Objective based on key answers, with the questions screened independently by 4 investigators; Ali et al [44]: Objective for multiple-choice questions and true or false questions, and subjective for short-answer and assay questions; Aljindan et al [45]: Objective based on key answers and historical performance metrics; and Baglivo et al [47]: Objective based on key answers and comparison with 5th year medical students' performance
#3a Timing	When is the generative AI model tested exactly and what are the duration and timing of testing?	Baglivo et al [47]; Biswas et al [48]; Fuchs et al [51]; Ghosh & Bir [52]; Hoch et al [58]; Juhi et al [59]; Kumari et al [61]; Kung et al [62]; Oca et al [66]; Pugliese et al [68]; Sallam et al [69]; Wang et al [73]; and Zhou et al [75]
#3b Transparency	How transparent are the data sources used to generate queries for the generative AI-based model?	Alfertshofer et al [43]
#4a Range	What is the range of topics tested and are they intersubject or intrasubject with variability in different subjects?	Ali et al [44]; Chen et al [49]; Hoch et al [58]; and Wang et al [73]
#4b Randomization	Was the process of selecting the topics to be tested on the generative AI-based model randomized?	Alfertshofer et al [43] and Aljindan et al [45]
#5 Individual	Is there any individual subjective involvement in generative AI content evaluation? If so, did the authors describe the details in full?	Ali et al [44] and Moise et al [65]
#6 Count	What is the count of queries executed (sample size)?	Alfertshofer et al [43]; Chen et al [49]; Guerra et al [56]; Hoch et al [58]; and Oztermeli & Oztermeli [67]
#7 Specificity of the prompt or language	How specific are the exact prompts used? Were those exact prompts provided fully? Did the authors consider the feedback and learning loops? How specific are the language and cultural issues considered in the generative AI model?	Alfertshofer et al [43]; Biswas et al [48]; Fuchs et al [51]; Grewal et al [55]; Wang et al [73]; Moise et al [65]; and Pugliese et al [68]

[a]AI: artificial intelligence.

Interrater Assessment of the Included Records Based on METRICS Scores

The overall mean METRICS score was 3.0 (SD 0.58). For each item, the κ interrater reliability ranged from 0.558 to 0.962 ($P<.001$ for the 9 tested items), indicating good to excellent agreement (Table 5).

With classification per item, the highest average METRICS score was recorded for the "Model" item, followed by the "Specificity" item, while the lowest scores were recorded for the "Randomization" item (classified as suboptimal) and "Individual factors" item (classified as satisfactory) (Table 5).

Table 5. Interrater reliability per METRICS item.

METRICS[a] item	Score		Quality	Cohen κ	Asymptotic standard error	Approximate T	P value
	Mean[b] (SD)	Range					
Model	3.72 (0.58)	2.5-5.0	Very good	0.820	0.090	6.044	<.001
Timing	2.90 (1.93)	1.0-5.0	Good	0.853	0.076	6.565	<.001
Count	3.04 (1.32)	1.0-5.0	Good	0.962	0.037	10.675	<.001
Specificity of prompts and language	3.44 (1.25)	1.0-5.0	Very good	0.765	0.086	8.083	<.001
Evaluation	3.31 (1.16)	1.0-5.0	Good	0.885	0.063	9.668	<.001
Individual factors	2.50 (1.42)	1.0-5.0	Satisfactory	0.865	0.087	6.860	<.001

[a]METRICS: Model, Evaluation, Timing, Range/Randomization, Individual factors, Count, and Specificity of prompts and language.

[b]The mean scores represent the results of evaluating the included studies averaged for the 2 rater scores.

Discussion

Principal Findings

The interpretation and synthesis of credible scientific evidence based on studies evaluating commonly used generative AI-based conversational models (eg, ChatGPT, Bing, and Bard) can be challenging. This is related to the discernible variability in the methods used for the evaluation of such models, as well as the varying styles of reporting. Such variability is fathomable considering the emerging nature of this research field with less than a year of reporting at the time of writing. Therefore, a standardized framework to guide the design of such studies and to delineate the best reporting practices can be beneficial, since rigorous methodology and clear reporting of findings are key attributes of science to reach reliable conclusions with real-world implications.

In this study, a preliminary checklist referred to as "METRICS" was formulated, which can help researchers aspiring to test the performance of generative AI-based models in various aspects of health care education and practice. It is crucial to explicitly state that the proposed METRICS checklist in this study cannot be claimed to be comprehensive or flawless. Nevertheless, this checklist could provide a solid base for future studies and much needed efforts aiming to standardize the reporting of AI-based studies in health care.

The principal finding of this study was the establishment of 9 key themes that are recommended to be considered in the design, testing, and reporting of generative AI-based models in research, particularly in the health care domain. These features included the model of the generative AI tool, evaluation approach, timing of testing and transparency, range of topics tested and randomization of queries, individual factors in the design and assessment, count of queries, and specific prompts and languages used. The relevance of these themes in the design

and reporting of generative AI-based model content testing can be illustrated as follows.

First, the variability in generative AI model types used to conduct queries and the variability in settings pose significant challenges for cross-study comparisons. The significant impact of generative AI models on the resultant output is related to the distinct architectures and capabilities of various generative AI models, with expected variability in the performance and quality of the content generated by generative AI [76]. Additionally, various options to configure the models further affect the content generated by generative AI. Consequently, it is important to consider these variations when evaluating research using different generative AI models [77-81]. These issues can be illustrated clearly in the records included in this study that conducted contemporary analysis of at least two models. For example, Al-Ashwal et al [42] showed that Bing had the highest accuracy and specificity for predicting drug-drug interaction, outperforming Bard, ChatGPT-3.5, and ChatGPT-4. Moreover, Baglivo et al [47] showed not only intermodel variability but also intramodel variability in performance in the domain of public health. Additionally, in the context of providing information on rhinoplasty, Seth et al [70] showed that this intermodel variability in performance was the most comprehensible with the content of Bard, followed by ChatGPT and Bing.

Second, the continuous updating of generative AI models introduces significant temporal variability, which would influence the comparability of studies conducted at different times. The updates of generative AI models enhance their capabilities and performance [82]. Consequently, this temporal variability can lead to inconsistencies in synthesizing evidence, as the same model may demonstrate different outputs over time. Therefore, when analyzing or comparing studies involving AI models, it is crucial to consider the specific version and state of the model at the time of each study to accurately interpret and compare results. In this context, it is important to conduct

future longitudinal studies to discern the exact effect of changes in performance of commonly used generative AI models over time.

Third, the count of queries in the evaluation of generative AI models was identified among the pertinent themes of assessment. This appears understandable since studies employing a larger number of queries can provide a more comprehensive evaluation of the tested model. An extensive number of queries can reveal minor weaknesses, despite the difficulty to establish what constitutes an "extensive" number of queries of the minimum number of queries needed to reveal the real performance of a generative AI model in a particular topic. In this study, the number of queries varied from a single case to more than 2500 questions, showing the need for standardization and establishing a clear guide on the number of queries deemed suitable [58,75].

Fourth, a key theme identified in this study was the nature and language of the prompts used to conduct the studies. This involved the imperative of explicitly stating the used prompts and the language in which they were framed. The exact prompting approach and the presence of cultural and linguistic biases appear to be critical factors that can influence the quality of content generated by generative AI-based models [83]. Slight differences in wording or context in the prompt used to generate the generative AI content can lead to recognizable differences in the content generated [36,84,85]. Additionally, feedback mechanisms and learning loops that allow generative AI-based models to learn from interactions can change the model performance for the same query, which might not be consistently accounted for in all studies. These minor variations in prompts across different studies can also complicate the synthesis of evidence, highlighting the need for standardizing such an aspect. Additionally, as highlighted above, generative AI-based models may exhibit biases based on their training data, affecting performance across various cultural or linguistic contexts [86-88]. Thus, studies conducted in different regions or involving various languages might yield varying results. In this study, we found that a majority of the included records tested generative AI-based models using the English language, highlighting the need for more studies on other languages to reveal the possible variability in performance based on language. Comparative studies involving multiple languages can reveal such inconsistencies, for example, the study by Wang et al [74]. In the aforementioned study assessing ChatGPT performance in the Taiwanese pharmacist licensing exam, the performance in the English test was better than that in the Chinese test across all tested subjects [74]. Another comprehensive study by Alfertshofer et al [43] that assessed the performance of ChatGPT on 6 different national medical licensing exams highlighted the variability in performance per country and language. Based on the previous points, more studies that encompass diverse language and cultural perspectives are essential to assess and address possible cultural and language biases in generative AI-based models. Additionally, the design of generative AI-based models trained on a more diverse set of languages and cultural contexts is important to ensure that the training data sets are representative of different linguistic groups, which is of paramount importance in health care. Furthermore, cross-cultural validation studies appear valuable for understanding the performance of generative AI-based models in various language and cultural settings. These approaches could enhance the broad applicability of generative AI-based models in health care to ensure the fair distribution of the benefits of generative AI technologies.

Fifth, an important theme highlighted in this study was the approach of evaluating the content generated by generative AI-based models. Variable methods of assessment can introduce a discernible methodological variability. Specifically, the use of objective assessment ensures consistency in assessment. On the other hand, subjective assessment, even by experts, can vary despite the professional judgment and deep understanding provided by such an expert opinion [89].

Similarly, the number and expertise of evaluators or raters involved in constructing and evaluating the generative AI-based studies were identified as a pertinent theme in this study [90,91]. Variations in rater numbers across studies can lead to inconsistencies in synthesized evidence [68,69,92]. Additionally, the method used to establish agreement (eg, kappa statistics and consensus meetings) might differ in various studies, affecting the comparability of results.

Finally, data-pertinent issues were identified as key themes in this study. These involved the need for full transparency regarding the sources of data used to create the queries (eg, question banks, credible national and international guidelines, clinical reports, etc) [93,94]. Additionally, ethical considerations, such as consent to use copyrighted material and consent or anonymization of the clinical data, should be carefully stated in the evaluation studies of AI-based models. An important aspect that appeared suboptimal in the majority of included records was randomization to reduce or eliminate potential bias in query selection. Thus, this important issue should be addressed in future studies to allow unbiased evaluation of the content of generative AI-based models. Another important aspect is the need to carefully select the topics to be tested, which can belong to a broad domain (eg, medical examination) or a narrow domain (eg, a particular specialty) [95-97]. A comprehensive description of topics is essential to reveal subtle differences in generative AI performance across various domains. Biased query coverage per topic may result in unreliable conclusions regarding generative AI model performance.

The value of the METRICS checklist in guiding researchers toward more rigorous design and transparent reporting of health care studies assessing the performance of generative AI-based models can be highlighted as follows. Two studies exemplified the practical utility of the METRICS checklist (presented in its preprint form) across different research scenarios (health care education and health care practice) [98]. The first study conducted a detailed assessment of ChatGPT-3.5 performance in medical microbiology multiple choice questions compared with dental students [99]. By applying the METRICS checklist retrospectively, the study quality was delineated, including the identification of potential limitations, such as the absence of randomization, thus offering a more critical evaluation of the research design [99].

The second study investigating the performance of both ChatGPT-3.5 and ChatGPT-4 in the context of diagnostic microbiology case scenarios was conceived based on the METRICS checklist [100]. The prospective incorporation of the METRICS checklist was particularly instrumental in refining the study design and the reporting of results [100].

Thus, the aforementioned studies emphasize the effectiveness of the METRICS checklist as a tool to standardize research practice in a rapidly growing research field. The real-world application of the METRICS checklist has been valuable in identifying potential research limitations and in enhancing the overall structure and clarity of the reporting of results. These studies also demonstrate the value of the METRICS checklist for guiding researchers toward more rigorous design and transparent reporting of generative AI-based studies in health care [99,100].

Limitations

It is crucial to explicitly mention the need for careful interpretation of the findings based on the following limitations. First, the initial search process involved the broad term "artificial intelligence" and was conducted by a single author, which may have inadvertently resulted in missing relevant references. The record selection process was further limited by the screening of record titles for only 3 generative AI models (ChatGPT, Bing, and Bard) using the EndNote search function. Additionally, the reliance on including published English records, indexed in Scopus, PubMed, or Google Scholar, could raise concerns about potential selection bias and the exclusion of relevant studies. However, it is important to consider this limitation in light of the context of our study, which represents a preliminary report that needs to be validated by future comprehensive and exhaustive studies. Second, it is important to acknowledge that a few pertinent themes could have been overlooked despite our attempt to achieve a thorough analysis, given the limited number of authors. Therefore, future follow-up studies can benefit from inclusion of authors with diverse backgrounds, including different health care disciplines, computer scientists, researchers in the field of human-AI interaction, and AI developers. Additionally, the subjective nature of the pertinent theme selection can be considered as another important caveat in this study. This shortcoming extended to involve the raters' subjective assessments in assigning different METRICS scores. Moreover, the equal weight given to each item of the checklist in the METRICS score might not be a suitable approach, given the possibility of varying importance of each component. Thus, future comprehensive studies should focus on the relative importance of each METRICS component and its possible impact on the reporting of generative AI model performance. Third, the focus on a few specific generative AI-based conversational models (ie, ChatGPT, Bing, and Bard) can potentially overlook the nuanced aspects of other generative AI

models. Nevertheless, our approach was justified by the popularity and widespread use of these particular generative AI-based models. However, it is important for future studies to expand the scope to include models, such as Llama or Claude, which could provide a more comprehensive evaluation of the utility of the METRICS checklist. Lastly, we fully and unequivocally acknowledge that the METRICS checklist is preliminary and needs further verification to ensure its valid applicability.

Future Perspectives

The METRICS checklist proposed in this study could be a helpful step toward establishing useful guidelines to design and report the findings of generative AI-based studies. The integration of generative AI models in health care education and practice necessitates a collaborative approach involving health care professionals, researchers, and AI developers. Synthesis of evidence with critical appraisal of the quality of each element in the METRICS checklist is recommended for continuous enhancement of AI output, which would result in successful implementation of AI models in health care while avoiding possible concerns. Regular multidisciplinary efforts and iterative revisions are recommended to ensure that the METRICS checklist properly reflects its original intended purpose of improving the quality of study design and result reporting in this swiftly evolving research field. Future studies would benefit from expanding the scope of literature review and data inclusion, with the incorporation of a wider range of databases, languages, and AI models. This is crucial for reaching the ultimate aim of standardization of the design and reporting of generative AI-based studies.

Conclusions

The newly devised "METRICS" checklist may represent a key initial step to motivate the standardization of reporting of generative AI-based studies in health care education and practice. Additionally, the establishment of this algorithm can motivate collaborative efforts to develop universally accepted reporting guidelines for the design and reporting of results of generative AI-based studies. In turn, this can enhance the comparability and reliability of evidence synthesis from these studies. The METRICS checklist, as presented by the findings of this study, can help to elucidate the strengths and limitations of the content generated by generative AI-based models, guiding their future development and application. The standardization offered by the METRICS checklist can be important to ensure the reporting of reliable and replicable results. Subsequently, this can result in the exploitation of the promising potential of generative AI-based models in health care while avoiding its possible concerns. The METRICS checklist could mark the significant progress in the evolving research field. Nevertheless, there is room for refinement through revisions and updates to verify its validity.

Abstract

Background: Radiogenomics is an emerging technology that integrates genomics and medical image–based radiomics, which is considered a promising approach toward achieving precision medicine.

Objective: The aim of this study was to quantitatively analyze the research status, dynamic trends, and evolutionary trajectory in the radiogenomics field using bibliometric methods.

Methods: The relevant literature published up to 2023 was retrieved from the Web of Science Core Collection. Excel was used to analyze the annual publication trend. VOSviewer was used for constructing the keywords co-occurrence network and the collaboration networks among countries and institutions. CiteSpace was used for citation keywords burst analysis and visualizing the references timeline.

Results: A total of 3237 papers were included and exported in plain-text format. The annual number of publications showed an increasing annual trend. China and the United States have published the most papers in this field, with the highest number of citations in the United States and the highest average number per item in the Netherlands. Keywords burst analysis revealed that several keywords, including "big data," "magnetic resonance spectroscopy," "renal cell carcinoma," "stage," and "temozolomide," experienced a citation burst in recent years. The timeline views demonstrated that the references can be categorized into 8 clusters: lower-grade glioma, lung cancer histology, lung adenocarcinoma, breast cancer, radiation-induced lung injury, epidermal growth factor receptor mutation, late radiotherapy toxicity, and artificial intelligence.

Conclusions: The field of radiogenomics is attracting increasing attention from researchers worldwide, with the United States and the Netherlands being the most influential countries. Exploration of artificial intelligence methods based on big data to predict the response of tumors to various treatment methods represents a hot spot research topic in this field at present.

Introduction

Radiogenomics is an emerging technology that combines radiomics and genomics, with the ultimate goal of improving prognosis and outcomes [1]. Radiogenomics can be used to investigate the relationship between imaging features and gene mutations and expression patterns [2-4]. Unlike traditional gene sequencing methods, which are associated with inherent drawbacks such as invasive and high-cost procedures, radigenomics provides a noninvasive, convenient, and cost-effective method by using quantitative imaging parameters extracted from the entire lesions [5,6]. Many scholars have demonstrated that radiogenomics may predict the pathologic

type, prognosis, and outcome of cancers, including lung cancer and liver cancer, based on pretreatment multimodal imaging (computed tomography [CT] or magnetic resonance imaging [MRI]) [7-10]. This technology has also been proposed as a useful biomarker for nontumor diseases, such as in the diagnosis, classification, and prognostic assessment of coronary heart disease [11].

Radiogenomics is an important potential tool for precision medicine. Some review articles summarized the routine process of radiogenomics and its various applications in the management of disease [12,13]. However, these reviews generally focused on presenting the research directions rather than analyzing the dynamic changes in the field, only highlighting the process and application status of radiogenomics. Bibliometrics can be used to quantitatively analyze the countries, institutions, authors, keywords, and other information related to the entire body of literature in a specific field. This approach can also help to visually display the dynamic progress in the field through network mapping [14]. Therefore, the aim of this study was to summarize the research status and dynamic changes of research hot spots in radiogenomics over time using bibliometric methods, thus providing a comprehensive understanding of the emerging trends in this field.

Methods

Bibliometric Data Acquisition

The published literature on radiogenomics was retrieved from the Web of Science Core Collection (WoSCC), which is the most widely used database in bibliometric analysis, on March 1, 2024 [15]. The initial search phase showed that the first relevant article in this field was published in 2005; hence, we restricted the publication time period to 2005-2023 [16]. The search string was as follows: "(TS=(Radiogenomics) OR TS=(Radiomics AND genomics) OR TS=((Radiomics) AND (gene* OR DNA OR RNA OR expression OR mutation OR molecular subtype))) AND FPY=(2005-2023)."

The literature retrieval and refining processes were carried out by one author (YW), while the other authors supervised the whole process. A total of 3669 documents were retrieved. The refine function of the WoSCC website was used to screen the language and document type of the retrieved documents sequentially. The exclusion criteria were as follows: (1) document type is not a research or review article (eg, proceeding paper, meeting abstract, or editorial) and (2) articles written in languages other than English (eg, Japanese or Chinese). There were 420 papers excluded due to an inappropriate document type and 12 papers excluded due to language; thus, 3237 papers remained for analysis, which were exported in plain-text format. The information on corresponding countries, institutions, authors, and journals obtained from the WoSCC were recorded.

The original data of the retrieved articles are provided in Multimedia Appendix 1.

Data Analysis and Visualization

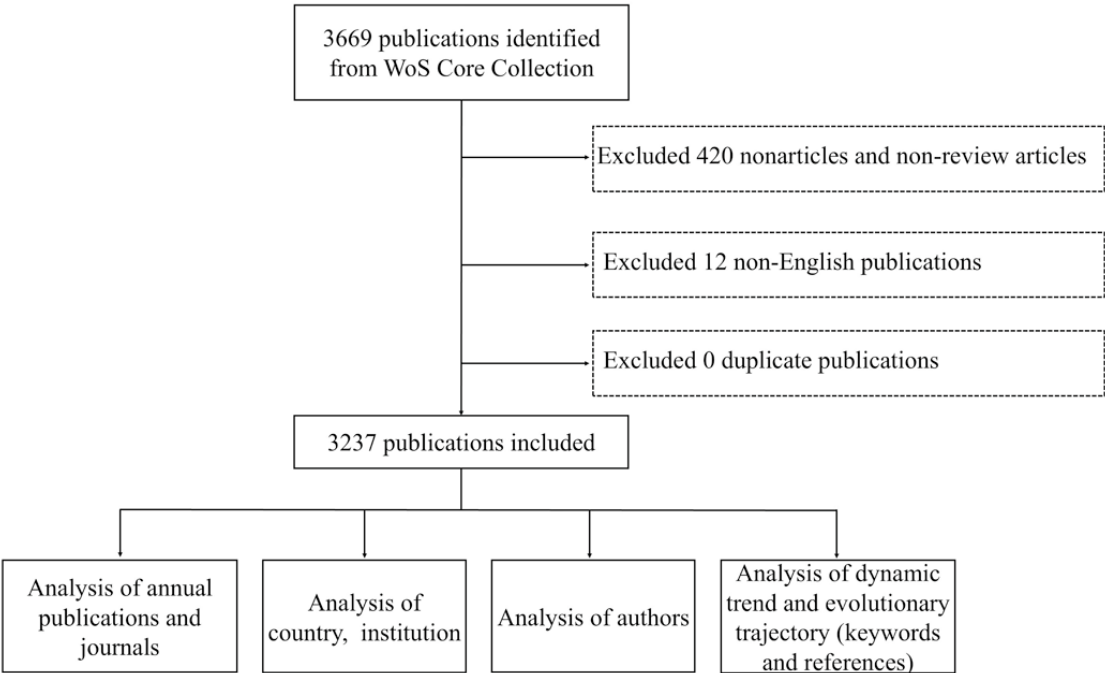
After detecting duplicate documents using CiteSpace (version 6.3.R1), Excel 2016, CiteSpace, and VOSviewer (version 1.6.19.0) were used to perform the bibliometrics analysis. Excel was used to analyze the annual publications, whereas VOSviewer was used to generate visualization networks of keywords co-occurrence and of collaboration among countries and institutions. The networks were constructed with keywords, countries, and institutions as nodes, respectively. The thickness of the line connecting nodes indicates the strength of the association. The betweenness centrality (BC) parameter was used to assess the importance of each node in the network; a higher BC value signifies greater importance in the network [17].

CiteSpace was used to determine the citation burst of keywords and to map the timeline of references by keywords. Burst detection can detect the citation burst of a specific keyword (or document) within a certain field, at least within a short period of time during a given time frame [18]. Keywords with a burst of occurrences are indicators of hot spot research topics in a field. According to the instructions of CiteSpace [19], the timeline of reference clusters is an analysis based on references for the exported literature. CiteSpace can extract noun phrases from the titles, keyword lists, or abstracts of articles that cited the particular cluster. The automatically selected labels will be displayed and the clusters are numbered in descending order of the cluster size, starting from the largest as cluster 0, the second largest as cluster 1, and so on. In this way, the network characterizes the development of the field over time, showing the most important footprints of the related research activities.

Certain data, including the number of publications, impact factor, h-index, and average per item of journals, countries, and authors, were retrieved from the WoSCC website. The h-index and average per item were used in the country, institution, and author analyses. The h-index was introduced by Hirsch [20] in 2005 and is commonly used as a scientific contribution metric corresponding to the number of times a paper is cited. The average per item is calculated by dividing the total number of citations by the number of publications, resulting in the average number of citations per publication.

Synonym Substitution of Keywords

The keywords with the same meaning were merged by synonym substitution. For example, terms such as "computed tomography," "computed tomography (ct)," "computed-tomography," "ct," and "ct images" were uniformly labeled as "CT." The full list of keyword synonyms is provided in Multimedia Appendix 2. Figure 1 shows a workflow of the analytical procedures.

**Figure 1.** Workflow of the analytical procedures. WoS: Web of Science.


Results

Annual Publications Trend

A total of 3237 papers were included for the final analysis. No duplicate article was found. The results indicated a clear upward trend in research on radiogenomics since 2013 (Figure 2).

Figure 2. Global trend of publications on radiogenomics from 2005 to 2023.

Journals

Table 1 presents the top 15 journals with the highest number of publications on radiogenomics. *Frontiers in Oncology, Cancers, and European Radiology* were the top three journals publishing in this field with 284, 196, and 135 papers, respectively.

Table 1. Top 15 journals publishing in the field of radiogenomics.

Rank	Journal	Articles, n	IF[a] (2022)
1	Frontiers in Oncology	284	4.7003
2	Cancers	196	5.5999
3	European Radiology	135	5.9003

[a]IF: impact factor.

Countries and Institutions

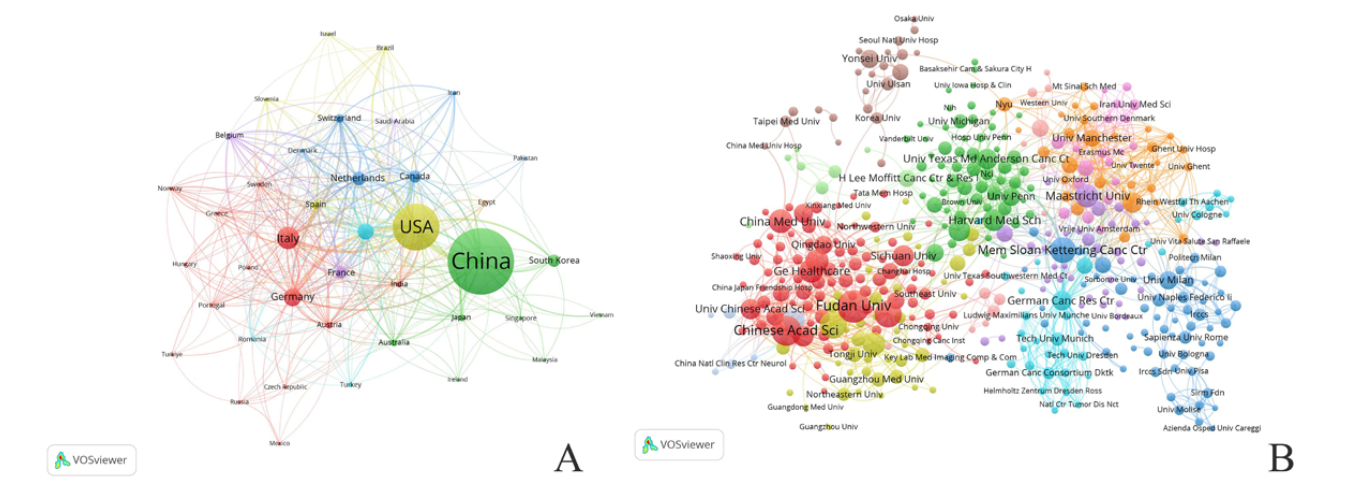
A total of 71 countries have published articles related to radiogenomics. Table 2 highlights the top 10 countries in terms of the number of publications. China ranks first with 1470 articles, followed by the United States with 891 articles and Italy with 326 articles. The United States obtained the highest citation count and the second highest average citation per item. Only three countries, the Netherlands (99.86), the United States (52.11), and Canada (51.46), have average citations per item above 50, with the average citation count for the Netherlands standing high above those of the other countries. Six countries, including the United States, England, Italy, Canada, China, and the Netherlands, had high BC values (≥0.1).

Table 2. Top 10 productive countries with the most publications in the field of radiogenomics.

Rank	Total link strength	BC[a]	Country	Publications, n	H-index	Times cited	Average per item
1	329	0.11	China	1470	68	25,319	17.22
2	820	0.36	United States	891	87	46,426	52.11
3	311	0.13	Italy	326	41	7327	22.48
4	353	0.06	Germany	233	39	7966	34.19
5	418	0.19	England	209	37	6185	29.59
6	328	0.1	Netherlands	161	37	16,077	99.86
7	54	0.01	South Korea	142	31	4296	30.25
8	248	0.12	Canada	140	36	7204	51.46
9	223	0.08	France	128	32	4099	32.02
10	181	0.01	Switzerland	88	23	1893	21.51

[a]BC: betweenness centrality.

Among the total 71 countries/regions that have contributed to radiogenomics research, 40 have published 5 or more documents. Figure 3A presents the visualization of the countries network. A total of 3523 institutions have contributed to radiogenomics research and 432 institutions published 5 or more documents. Figure 3B presents the visualization of the institutions network. These results show that there is relatively more cooperation between developed countries and their institutions.

Figure 3. Countries (A) and institutions (B) collaboration networks in the field of radiogenomics. The size of the nodes corresponds to the number of published documents and the line width between nodes indicates the strength of coauthorship. Thicker lines indicate a higher frequency of cooperation.


Authors

A total of 17,727 authors have contributed to radiogenomics. Table 3 presents the top 10 productive authors and the most cited authors in this field. The authors with the most publications are Philippe Lambin (33 papers), Catharine M West (32 papers), and Robyn Gillies (32 papers). Three of the top 10 productive authors, including Philippe Lambin (the Netherlands), Robyn Gillies (Australia), and Hugo Aerts (United States), also ranked in the top 3 for citations.

Table 3. Top 10 most productive and highly cited authors on radiogenomics.

Rank	Publications					Citations		
	Author	Articles, n	Country	H-index	Average per item	Author	Citations, n	Country
1	Philippe Lambin	33	Netherlands	21	358.06	Philippe Lambin	1573	Netherlands
2	Catharine M West	32	England	17	44.78	Robyn Gillies	1109	Australia

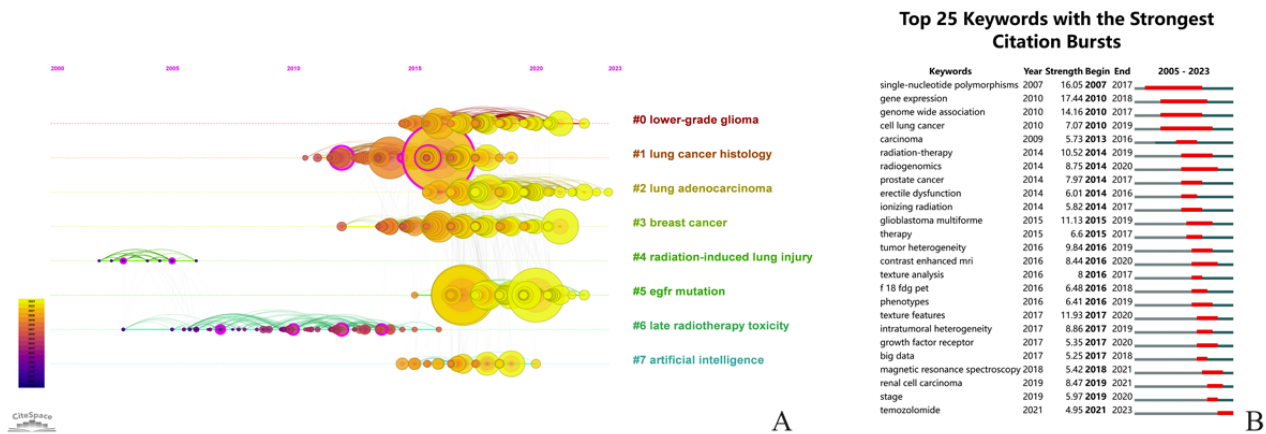
[a]CT: computed tomography.

[b]MRI: magnetic resonance imaging.

[c]F-18 FDG PET: fludeoxyglucose F18 positron emission tomography.

Keywords Burst and References Cluster

The top 25 keywords with the strongest citation bursts are depicted in Figure 5A. The top 3 keywords with the strongest citation bursts were "gene expression" (17.44), "single nucleotide polymorphism" (16.05), and "genome-wide association" (14.16). The keywords "big data," "magnetic resonance spectroscopy," "renal cell carcinoma," "stage," and "temozolomide" experienced a citation burst in recent years. Figure 5B illustrates the reference clusters along horizontal timelines. CiteSpace generated 8 clusters: cluster 0 for lower-grade glioma, cluster 1 for lung cancer histology, cluster 2 for lung adenocarcinoma, cluster 3 for breast cancer, cluster 4 for radiation-induced lung injury, cluster 5 for epidermal growth factor receptor (EGFR) mutation, cluster 6 for late radiotherapy toxicity, and cluster 7 for artificial intelligence.

Figure 5. Timeline view of reference clustering analysis on radiogenomics (A) and top 25 keywords with the strongest citation bursts (B).


Based on this comprehensive analysis, the time frame from 2005 to 2023 can be artificially segmented into distinct phases based on the evolution of hot topics in the field. The first phase is approximately from 2005 to 2010, represented by the keywords "radiation-induced lung injury," "late radiotherapy toxicity," and "single nucleotide polymorphism." The second phase spans from approximately 2011 to 2017, represented by the keywords "lung cancer histology," "breast cancer," "tumor heterogeneity," "contrast enhanced MRI," and "F-18 FDG PET" (fludeoxyglucose F18 positron emission tomography). The third phase is after 2018, represented by the keywords "phenotypes," "big data," "magnetic resonance spectroscopy," "renal cell carcinoma," "stage," "EGFR mutation," "temozolomide," and "artificial intelligence."

Discussion

Principal Findings

The concept of precision medicine has propelled increased attention toward radiogenomics, a fusion of genomics and radiomics, to achieve personalized treatment, owing to its potential as a noninvasive tool to predict treatment responses. This study analyzed 3237 relevant documents in the field of radiogenomics published between 2005 and 2023 from the WoSCC. The increasing number of annual publications, especially the extremely high growth rate after 2017, indicates how interest in radiogenomics research in the clinical field has been increasing from year to year.

Current Status of Publications for Countries and Authors

China currently has the highest number of publications in radiogenomics, although the total citation count is lower than that for the United States, with the average citation number per item lower than that of the other top 10 countries. The Netherlands, the United States, and Canada obtained the highest averages per item. It can be concluded that the United States and the Netherlands have performed reasonably well both in terms of the number and quality of published documents, demonstrating their strong influence in the field. Philippe Lambin of the Netherlands ranked first in both number of publications and number of citations, indicating his major contributions to this field.

Dynamic Publication Trend and Evolutionary Trajectory

The time frame of publications in this relatively new field can be artificially segmented into three phases according to the evolution of hot topics. In the first phase (2005 to 2010), radiogenomics primarily focused on the genetic variation associated with the response to radiation therapy in the field of radiation oncology [12]. Radiation therapy plays a crucial role in tumor treatment, accounting for 50% of all tumor therapies performed worldwide [21]. However, individuals with similar tumors often exhibit significant differences in radiosensitivity, and many patients experience various types of adverse reactions, including radiation-induced lung injury and late radiotherapy toxicity, after radiation therapy [22,23]. To develop precise and personalized treatments that achieve the best efficacy with minimal adverse reactions, researchers have been searching for biomarkers that can predict treatment outcomes. Through analysis of the complete genome using techniques such as genome-wide association analysis, particularly focusing on single-nucleotide polymorphism markers, researchers have identified numerous genomic variation sites associated with the response to radiotherapy [24,25].

In the second phase (2011 to 2017), the concept of radiogenomics expanded. Studies incorporating medical imaging features and biological parameters beyond genomics were also included in radiogenomics studies [26]. It is believed that the features from medical images such as MRI, CT, and PET-CT of lesions are closely related to tumor heterogeneity. Therefore, researchers have extracted the features (including semantic features and texture analysis features) of the tumors and adopted radiomics for a differentiation diagnosis, such as histological subtype identification. Doshi et al [27] found that MRI-based first-order texture metrics can help discriminate between type 1 and type 2 papillary renal cell carcinoma.

From the late second phase onward (ie, 2017 to 2023), the purpose of radiogenomics is not only limited to the prediction of radiotherapy side effects or differential diagnosis but also to analyzing the relationship between gene expression and imaging data. For example, through the analysis of quantitative features of enhanced MRI, Yeh et al [28] found that partial features were correlated with the expression levels of molecules in the Janus kinase-signal transducer and activator of transcription and

vascular endothelial growth factor signaling pathways in breast cancer [28].

The distinction between the second and third phases is unclear, with some of the hot topics beginning during the second phase and continuing beyond 2018. In the third phase, the scope of radiogenomics has gradually expanded and become more comprehensive. From the view of raw data, apart from conventional images, some functional imaging techniques such as magnetic resonance spectroscopy have started to be used for radigenomics analysis [29]. Moreover, with the use of a picture archiving and communication system, the storage and re-extraction of medical data are more convenient, which promotes the progress of big data research and improves the credibility of radiogenomics. From the research purposes perspective, more and more therapeutic methods (eg, neoadjuvant therapy, chemoarterial chemoembolization, transcatheter arterial chemoembolization) have been developed and applied in clinical practice. Researchers are beginning to explore the use of radiogenomics to identify patients who may not be sensitive to certain therapies, thereby reducing unnecessary treatment to avoid side effects [30]. From the view of research methods, the studies in the second phase tended to screen for the quantitative features (which were manually extracted in most cases) associated with gene expression status. At present, many studies use machine learning algorithms that are sometimes combined with deep learning algorithms, which can automatically segment lesions to achieve higher predictive performance [27].

Limitations

Our study has several limitations. First, only research articles and review articles published in English from the WoSCC were included in this analysis, potentially introducing language, publication type, and database biases. Second, this study focused on an in-depth analysis of the dynamic trend and evolutionary trajectory in radiogenomics based on the keywords and references. There are other analyses that could have been considered to better understand the evolution of radiogenomics as a subject, such as more comparative analyses of various factors (ie, authors, countries, keywords, and journals). Third, our results showed that radiogenomics is currently applied mostly in cancer research. Bibliometrics may overlook other topics that are not current research hot spots in the field. For example, keywords related to nononcologic diseases such as mental illness are not included in the tables and figures.

Conclusion

In conclusion, radiogenomics has attracted substantial attention in recent years. The United States and the Netherlands are the leading countries publishing research in this field, obtaining the highest total citations and average per item, respectively. Before 2010, radiogenomics was mainly used to explore the genetic factors associated with radiotherapy-induced toxicity. Subsequently, the field has evolved to encompass the combination of radiomics and genomics, enabling the prediction of cancer histology, gene mutations, and gene expression status based on the tumor heterogeneity information obtained from medical imaging. More and more researchers tend to be exploring the feasibility of radiogenomics to predict the response of tumors to various treatments such as neoadjuvant chemotherapy. The application of artificial intelligence methods based on big data is emerging as a hot spot research topic in this field at present.

Authors' Contributions

MW performed the formal analysis, validation, investigation, visualization, and data curation. YP and YW contributed to methodology, software, formal analysis, validation, visualization, study supervision, and resources. DL was responsible for study conceptualization, validation, formal analysis, supervision, project administration, and data curation. All authors contributed to the writing and review of the manuscript.

Conflicts of Interest

Abstract

Background: The World Health Organization recommends a daily sodium intake of less than 2000 mg for adults; however, the Mexican population, like many others globally, consumes more sodium than this recommended amount. Excessive sodium intake is often accompanied by inadequate potassium intake. The association between knowledge, attitudes, and behaviors (KAB) and actual sodium intake has yielded mixed results across various populations. In Mexico, however, salt/sodium-related KAB and its relationship with sodium and potassium intake have not been evaluated.

Objective: This study primarily aims to describe salt/sodium-related KAB in a Mexican population and, secondarily, to explore the association between KAB and 24-hour urinary sodium and potassium excretion.

Methods: We conducted a cross-sectional study in an adult population from Mexico City and the surrounding metropolitan area. Self-reported KAB related to salt/sodium intake was assessed using a survey developed by the Pan American Health Organization. Anthropometric measurements were taken, and 24-hour urinary sodium and potassium excretion levels were determined. Descriptive statistics were stratified by sex and presented as means (SD) or median (25th-75th percentiles) for continuous variables, and as absolute and relative frequencies for categorical variables. The associations between KAB and sodium and potassium excretion were assessed using analysis of covariance, adjusting for age, sex, BMI, and daily energy intake as covariates, with the Šidák correction applied for multiple comparisons.

Results: Overall, 232 participants were recruited (women, n=184, 79.3%). The mean urinary sodium and potassium excretion were estimated to be 2582.5 and 1493.5 mg/day, respectively. A higher proportion of men did not know the amount of sodium they consumed compared with women (12/48, 25%, vs 15/184, 8.2%, P=.01). More women reported knowing that there is a recommended amount for daily sodium intake than men (46/184, 25%, vs 10/48, 20.8%, P=.02). Additionally, more than half of men (30/48, 62.5%) reported never or rarely reading food labels, compared with women (96/184, 52.1%, P=.04). Better salt/sodium-related KAB was associated with higher adjusted mean sodium and potassium excretion. For example, mean sodium excretion was 3011.5 (95% CI 2640.1-3382.9) mg/day among participants who reported knowing the difference between salt and sodium, compared with 2592.8 (95% CI 2417.2-2768.3) mg/day in those who reported not knowing this difference (P=.049).

XSL•FO
RenderX

Similarly, potassium excretion was 1864.9 (95% CI 1669.6-2060.3) mg/day for those who knew the difference, compared with 1512.5 (95% CI 1420.1-1604.8) mg/day for those who did not (P=.002). Additionally, higher urinary sodium excretion was observed among participants who reported consuming too much sodium (3216.0 mg/day, 95% CI 2867.1-3565.0 mg/day) compared with those who claimed to eat just the right amount (2584.3 mg/day, 95% CI 2384.9-2783.7 mg/day, P=.01).

Conclusions: Salt/sodium-related KAB was poor in this study sample. Moreover, KAB had a greater impact on potassium excretion than on sodium excretion, highlighting the need for more strategies to improve KAB related to salt/sodium intake. Additionally, it is important to consider other strategies aimed at modifying the sodium content of foods.

Introduction

Cardiovascular diseases (CVDs) are the leading cause of death worldwide, with hypertension being one of the primary contributors, affecting over 20% of the Mexican adult population [1]. Excessive sodium intake is recognized as a major diet-related risk factor for hypertension; thus, reducing dietary sodium has been identified as a cornerstone in medical nutritional therapy for managing hypertension and other CVDs [2]. The World Health Organization (WHO) recommends a daily sodium intake of up to 2000 mg [3]. However, the adult Mexican population has been reported to consume 1.5 times this amount, averaging between 3100 and 3500 mg per day [1,2,4]. Notably, high sodium intake is often accompanied by low potassium intake [1,2,4], which is considered an indicator of poor diet quality [5]. Additionally, the combination of high sodium and low potassium intake is linked to an increased cardiovascular risk in a dose-response relationship [6].

Several policies and campaigns have been implemented to support sodium reduction at the population level, including labeling products high in sodium for easier identification and removing table salt from restaurant tables. Preventable risk models indicate that reducing salt/sodium consumption could prevent a significant number of deaths from CVDs [7].

By contrast, patients' beliefs and perceived knowledge are strong predictors of their attitudes (ie, actions) and may, therefore, directly impact adherence to medical nutrition therapy [8,9]. Knowledge is defined as the understanding of a subject or topic, including the cognitive ability to retain such information [10]. Attitudes refer to the emotional, motivational, perceptual, and cognitive beliefs that positively or negatively influence a person's behavior. They affect future behavior independently of an individual's knowledge, helping to explain, at least in part, why a person adopts one behavior over others [10]. Finally, behaviors are defined as a set of responses of an individual or organism to external stimuli or internal motivation [11].

Although people may be aware of the health implications of high salt or sodium intake, their knowledge, attitudes, and behaviors (KAB) on this issue can still be lacking, as shown in a systematic review of 24 studies across 12 high-income countries [12]. Moreover, studies on the association between KAB and actual sodium intake have yielded mixed results in diverse populations; some studies report no association between salt- or sodium-related KAB and sodium excretion, while others have found certain associations [13-20]. Additionally, the relationship between KAB and potassium intake has received less attention [15]. In Mexico, salt- and sodium-related KAB and its association with sodium and potassium intake have not yet been studied.

Given this context, we aimed to describe self-reported KAB related to salt and sodium consumption in a sample of volunteers from Mexico City and the metropolitan area. Additionally, we explored the association between salt- and sodium-related KAB and 24-hour urinary sodium and potassium excretion as a surrogate for actual intake.

Methods

Study Design

This is a secondary analysis of data from a cross-sectional study designed to test the criterion validity of an online tool [21] for estimating sodium intake in the adult population. The validation results are currently under review for publication elsewhere.

Study Population and Setting

The original study included men and women over 18 years of age who were apparently healthy. Exclusion criteria were individuals over 65 years; those with a previous diagnosis of CVD, kidney disease, or liver disease; and those who were menstruating, pregnant, or had urinary tract infections at the time of 24-hour urine collection. A convenience sample of participants meeting the eligibility criteria was recruited from various workplaces in Mexico City and the metropolitan area from June 2022 to January 2023. Participants were invited to join through printed advertisements on bulletin boards and a word-of-mouth strategy. Once eligibility was confirmed, they received both verbal and written instructions to collect a 24-hour urine sample and maintain a 3-day food record, which they were to bring on the day of their study visit. All assessments took place at designated areas within each work center.

For this secondary analysis, participants who provided a complete 24-hour urine sample and completed the salt/sodium-related KAB survey were included.

Ethical Considerations

This study posed no risk to participants, and their data were handled with privacy and confidentiality. Participants' data were deidentified for analysis, with only the principal investigator having access to the identified data. The study was

approved by the Research and Ethics Board of the Instituto Nacional de Ciencias Médicas y Nutrición, under registration number 3314. All participants were fully informed about the study, and written informed consent was obtained. No compensation was offered to participants for their involvement in this study, other than the provision of the results from the body composition assessment conducted as part of the original study, as well as the results of the urinary analysis.

Assessments

Anthropometrics

Weight and height were measured with the participant fasting, without shoes, and wearing a hospital gown, following the guidelines established by the International Society for the Advancement of Kinanthropometry (ISAK) [22]. Weight was measured using a Seca 769 mechanical column scale with a capacity of 200 kg and a precision of 0.05 kg. Height was measured with a Seca 220 stadiometer with a precision of 1 mm. BMI was calculated and reported as kg/m^2.

24-Hour Urinary Sodium and Potassium

Participants were given both oral and written instructions to collect a 24-hour urine sample the day before the study visit. They were instructed to discard the first-morning void and collect all urine over the following 24 hours, including the first void of the next morning, using a preservative-free container. Participants were also instructed to store the collected urine in a cool place during the collection period. Twenty-four-hour urinary excretion of sodium, potassium, and creatinine was determined.

Urinary samples were considered complete if they met the creatinine excretion rate criteria: 15-25 mg/kg/24 hours for men and 10-20 mg/kg/24 hours for women [23]. Additionally, urine samples with a volume of less than 500 ml per 2 hours were considered incomplete.

Energy Intake

Participants were instructed to complete a 3-day food record, including 1 weekend day. On the day of the study visit, a member of the research team verified the completeness and clarity of the food record with the participant. Dietary information was collected by trained personnel using a nutrient analysis software program (ESHA Food Processor SQL version 10.11; ESHA Research). The mean energy intake from the 3 days was used for analysis.

Knowledge, Attitudes, and Behaviors

A self-administered questionnaire developed by a subgroup of the Pan American Health Organization (PAHO) expert group, tasked with examining excessive dietary salt as a health risk in the Americas, was used. This tool was designed to assess salt-related knowledge (eg, the difference between sodium and salt), attitudes (eg, concern about reducing salt consumption), and behavior (eg, frequency of adding salt to food during cooking and at the table), self-reported presence of chronic diseases, and labeling preferences. The questionnaire was field-tested in Latin America and Canada. The questions included in this tool were developed based on the experience and expertise of the expert group members, as well as questions used in other surveys [24].

Participants received guidance from research team members to clarify any unclear questions as needed to complete the questionnaire.

Questions regarding labeling preferences (eg, whether participants would like food labeling indicating high/medium/low levels of salt or sodium) were not included in the analysis, as they were beyond the scope of this study.

Other Data

Information on age, sex, and highest level of education was also collected.

Statistical Analysis

Descriptive statistics were stratified by sex and reported as mean (SD) or median (25th-75th percentiles) for continuous variables, based on their distribution as determined by the Kolmogorov-Smirnov test. Categorical variables were presented as absolute frequencies and proportions. Comparisons of KAB related to health and salt/sodium consumption categories between sex groups were made using the chi-square test. In addition, one-way fixed-effects analyses of covariance were used to compare the adjusted means of 24-hour urinary sodium and potassium excretion across the KAB related to salt/sodium consumption categories (groups) for each KAB item. Separate models were constructed for 24-hour urinary sodium and potassium excretion. In these models, urinary sodium and potassium excretion were treated as the dependent variables, with each relevant item of salt/sodium-related KAB tested separately as the independent variable (factor) with multiple categories (groups). Factors known to be associated with sodium and potassium intake (age, sex, BMI, and daily energy intake [DEI]) [2,4] were included as covariates in all models. The general linear model used to compare 24-hour urinary sodium and potassium excretion among salt/sodium-related KAB groups, adjusting for the effect of covariates, can be expressed as follows [25,26]:

$$24\text{-hour UNa}_{ij} = \mu + \alpha_i + \beta_1 \text{age}_{ij} + \beta_2 \text{sex}_{ij} + \beta_3 \text{BMI}_{ij} + \beta_4 \text{DEI}_{ij} + e_{ij}$$

$$24\text{-hour UK}_{ij} = \mu + \alpha_i + \beta_1 \text{age}_{ij} + \beta_2 \text{sex}_{ij} + \beta_3 \text{BMI}_{ij} + \beta_4 \text{DEI}_{ij} + e_{ij}$$

where 24-h UNa$_{ij}$ is the 24-hour urinary sodium excretion of the jth participant in the ith salt/sodium-related KAB group, 24-h UK$_{ij}$ is the 24-hour urinary potassium excretion of the jth participant in the ith salt/sodium-related KAB group, μ is a grand mean, a$_i$ is the ith group effect, β$_1$ is the slope coefficient of age, β$_2$ is the slope coefficient of sex, β$_3$ is the slope coefficient of BMI, β$_4$ is the slope coefficient of DEI, and e_{ij} is the residual.

95% CIs were constructed for the adjusted means, and the Šidák correction was applied for multiple comparisons. All statistical analyses were performed using SPSS version 20 for Windows (IBM Corp.). A P value of $<.05$ was considered statistically significant.

Results

Study Sample Descriptive Characteristics

Overall, 365 participants were recruited. Of these, 232 completed the salt/sodium-related KAB questionnaire and provided a valid 24-hour urinary sodium sample; these participants were included in this subanalysis. Study sample characteristics by sex are shown in Table 1. The majority of the study sample were women (184/232, 79.3%), with a median age of 39.0 (25th-75th percentiles 27.3-49.0) years and a BMI of 25.8 (25th-75th percentiles 22.9-29.2) kg/m^2 for the overall population. In terms of education, most participants had completed an education level higher than secondary (101/232, 43.5%). The median energy intake was estimated to be 2704.7 (25th-75th percentiles 2128.0-3271.1) kcal/day. Estimates of urinary sodium, potassium, and creatinine are also shown in Table 1.

Table 1. Study sample characteristics by sex[a].

Characteristics	Overall (n=232)	Women (n=184)	Men (n=48)
Age (years)	39.0 (27.3-49.0)	41 (29-50)	36.9 (12.5)
Weight (kg)	63.7 (55.5-71.8)	62.7 (12.3)	70.8 (62.4-80.4)
Height (cm)	156.0 (150-162.8)	154.0 (6.8)	167.1 (8.2)
BMI (kg/m^2)	25.8 (22.9-29.2)	26.4 (5.0)	25.6 (23.6-27.4)
Education level			
None	6 (2.6)	6 (3.3)	0 (0)
Primary	29 (12.5)	25 (13.6)	4 (8.3)
Secondary	93 (40.1)	72 (39.1)	21 (43.8)
Higher	101 (43.5)	79 (42.9)	22 (45.8)
No answer	3 (1.3)	2 (1.1)	1 (2.1)
Energy intake (kcal/day)	2704.7 (2128.0-3271.1)	2726.6 (2141.5-3254.4)	2778.2 (981.8)
Diuresis (ml/24 hours)	1225.0 (900.0-1700.0)	1200 (900-1587.5)	1400.0 (1000.0-2000.0)
Sodium (mg/24 hours)	2582.5 (1701.6-3347.2)	2570.4 (1222.3)	2845.1 (2231.4-3631.1)
Potassium (mg/24 hours)	1493.5 (1096.3-1934.7)	1431.9 (1071.0-1894.5)	1873.2 (736.4)
Sodium-to-potassium ratio (mg/mg/24 hours)	1.7 (1.3-2.3)	1.7 (1.3-2.3)	1.6 (1.3-2.1)
Creatinine (mg/24 hours)	87.1 (61.4-119.7)	81.0 (56.6-111.11)	108.8 (86.2-163.2)

[a]Numerical data are presented as mean (SD) or median (25th-75th percentiles), according to their distribution. Categorical data are presented as n (%).

Regarding the self-reported presence of chronic diseases included in the survey, 43 of the 232 (18.5%) participants reported having high blood pressure. Other pathologies associated with excessive salt consumption were also surveyed and are reported, stratified by sex, in Table 2.

Table 2. Self-reported history of chronic diseases by sex.

Disease	Overall (n=232)	Women (n=184)	Men (n=48)
High blood pressure, n (%)	43 (18.5)	40 (21.7)	3 (6.3)
Heart attack, n (%)	7 (3.0)	6 (3.3)	1 (2.1)
Stroke, n (%)	1 (0.4)	1 (0.5)	0 (0)
Kidney stones, n (%)	14 (6.0)	10 (5.4)	4 (8.3)
Asthma, n (%)	10 (4.3)	10 (5.4)	0 (0)
Osteoporosis, n (%)	2 (0.9)	2 (1.1)	0 (0)
Stomach cancer, n (%)	1 (0.4)	1 (0.5)	0 (0)

Attitudes, Knowledge, and Behaviors

As shown in Table 3, more than half of the participants reported trying to eat a healthy diet and consistently feeling pressure to do so. Nearly the entire sample (229/232, 98.7%) acknowledged that excessive salt is associated with health problems, although only two-thirds believed they were capable of distinguishing between products low or high in salt. Furthermore, less than half of the sample indicated that there was sufficient information on salt content in food packages. Notably, only 93 of the 232 (40.1%) participants reported overall good health, with a trend toward a lower proportion of women compared with men

(71/184, 38.6%, vs 22/48, 45.8%, *P*=.07). The number of participants who reported trying to minimize the amount of salt they consumed was 174 (75%) in the overall population (N=232), and this tendency was higher among women than men (143/184, 77.7%, vs 31/48, 64.6%, *P*=.08). However, no significant differences were found between men and women in any of the questions (*P*≥.05; Table 3).

Table 3. The proportion of participants who agreed with the statement on self-reported attitudes, knowledge, and behavior related to health, diet, and salt intake in the study sample.

Statement	Overall (n=232)	Women (n=184)	Men (n=48)	*P* value[a]
I try to eat a healthy diet, n (%)	153 (65.9)	120 (65.2)	33 (68.8)	.71
A diet high in salt can cause serious health problems, n (%)	229 (98.7)	182 (98.9)	47 (97.9)	.52
I try to minimize the amount of fat I consume, n (%)	187 (80.6)	149 (81.0)	38 (79.2)	.68
My health is generally good, n (%)	93 (40.1)	71 (38.6)	22 (45.8)	.07
There is too much pressure to eat healthy these days, n (%)	134 (57.8)	109 (59.2)	25 (52.1)	.76
I try to minimize the amount of salt I consume, n (%)	174 (75.0)	143 (77.7)	31 (64.6)	.08
I generally know if foods contain a lot or little salt, n (%)	148 (63.8)	122 (66.3)	26 (54.2)	.12
There is sufficient nutritional information on food packaging, n (%)	106 (45.7)	84 (45.7)	22 (45.8)	.34

[a]For differences between sex groups by chi-square test.

Additionally, 150 of the 232 (64.7%) participants reported always adding salt when preparing food at home, while more than 90% considered limiting the amount of salt or sodium in their diet to be very or somewhat important (210/232, 90.5%). Around 60% believed they consumed the right amount of salt (139/232, 59.9%), yet less than a quarter knew there was a recommended daily amount of sodium consumption; 186 of 232 (80.2%) participants did not know the difference between salt and sodium, and over half reported rarely or never reading nutrition labels on food packages. Comparison between sex groups revealed a higher proportion of men who did not know the amount of sodium they consumed compared with women (12/48, 25%, vs 15/184, 8.2%, *P*=.01), while more women reported knowing that there was a recommended daily sodium intake than men (46/184, 25%, vs 10/48, 20.8%, *P*=.02). Notably, there was a difference in the frequency of reading nutrition labels on food packages between sex groups, with more than half of men (30/48, 62.5%) reporting that they never or rarely read food labels, compared with women (96/184, 52.1%, *P*=.04; Table 4).

Table 4. Answers to questions about knowledge, attitudes, and behaviors regarding sodium intake.

Question	Overall (n=232)	Women (n=184)	Men (n=48)	P value[a]
How many times do you add salt to food at the table?, n (%)				.12

Salt/Sodium-Related Attitudes, Knowledge, and Behaviors and 24-Hour Urinary Sodium and Potassium Excretion

A comparison of the adjusted means (95% CI) for 24-hour urinary sodium and potassium excretion across categories of salt/sodium-related KAB is shown in Table 5. A higher mean 24-hour urinary sodium excretion was observed among participants who reported consuming too much sodium, compared with those who believed they consumed the right amount. It was also higher among participants who knew that there was a recommended daily sodium intake and who understood the difference between salt and sodium, compared with those who did not. Additionally, participants who frequently paid attention to the text on food packaging had a higher mean urinary sodium excretion than those who rarely did so. Although the overall comparison for the frequency of reading nutrition labels showed a significant difference among frequency categories (P=.02), pairwise comparisons did not reveal any significant differences ($P≥$.05 for all pairwise comparisons).

Regarding urinary potassium excretion, participants who tried to eat a healthy diet had a higher mean potassium excretion compared with those who were unsure if they were trying to eat a healthy diet. Additionally, although a significant difference in potassium excretion was observed in the overall comparison among categories of the amount of salt participants thought they consumed (P=.02), pairwise comparisons did not reveal any significant differences ($P≥$.05 for all pairwise comparisons). Higher potassium excretion was also observed among participants who knew there was a recommended daily sodium intake and those who claimed to know the difference between salt and sodium, compared with those who did not. In terms of reading food labels, participants who reported often paying attention to the text on food packaging had greater potassium excretion compared with those who rarely did so. Similarly, individuals who always read nutrition food labels had higher potassium excretion compared with those who sometimes, rarely, or never read food labels (Table 5).

Table 5. Comparison of urinary sodium and potassium excretion adjusted means (95% CI) among groups within the items of knowledge, attitudes, and behaviors regarding sodium intake.

Question	24-h urinary sodium excretion (mg/day), adjusted means (95% CI)	24-h urinary potassium excretion (mg/day), adjusted means (95% CI)
I try to eat a healthy diet

Discussion

Principal Findings and Comparison With Prior Work

Based on the data collected and analyzed in this study, several important findings can be reported regarding consumers' attitudes, knowledge, and behavior concerning salt intake, and their association with urinary sodium and potassium excretion.

According to the self-reported KAB related to health, diet, and salt consumption, among the total participants (N=232), only 56 (24.1%) knew there was a recommended daily intake for salt/sodium, 44 (19%) understood the difference between salt and sodium, and only 12 (5.2%) always paid attention to the text on food packaging or read nutrition labels. Importantly, a high proportion of participants reported trying to maintain a healthy diet (153/232, 65.9%) and reduce the amount of fats (187/232, 80.6%) or salt (174/232, 75%) they consumed. However, these responses did not align with their perception of health, as only 93 (40.1%) considered their health to be generally good. It is likely that participants were making these dietary changes in an effort to improve their health, which they perceived as poor.

In our study, we observed a trend where a smaller proportion of women (71/184, 38.6%) compared with men (22/48, 45.8%) reported having good health. Additionally, self-reported history of comorbidities related to excessive sodium intake revealed that 40 of 184 (21.7%) women and 3 of 48 (6.3%) men had high blood pressure. This lower perception of good health and higher frequency of self-reported high blood pressure among women is consistent with the observed trend of a higher proportion of women trying to minimize their salt consumption. Overall, studies that disaggregate KAB by sex have reported better KAB related to salt/sodium consumption in women than in men. In this study, we found that more women (46/184, 25.0%) reported knowing that there was a recommended daily sodium/salt intake compared with men (10/48, 20.8%). Additionally, more men (30/48, 62.5%) reported never or rarely reading food labels compared with women (96/184, 52.2%).

In the overall study sample, the median 24-hour urinary sodium excretion was 2582.5 mg/day, which exceeds the WHO daily intake recommendation of 2000 mg/day [3], but is lower than previous reports in the Mexican population, where it ranged from 3100 to 3500 mg/day [1,2,4]. This discrepancy may be attributed to the fact that nearly 80% (n=184) of the participants in this study were women, and sodium intake has been shown to be, on average, lower in women than in men [2,4], as also confirmed in this study; 32 out of 232 (13.8%) reported always or often adding salt to food at the table; however, a higher proportion (189/232, 81.5%) of participants reported always or often adding salt during food preparation. In Mexico, the consumption of processed and ultra-processed foods contributes to 39% of total sodium intake in adults and 50% in school-age children [27]. Nevertheless, salt added during cooking remains an important source of sodium in the diet [27]. In fact, it has been reported that street food (*antojitos* in Spanish) and homemade-style meals (*comida corrida* in Spanish), which are unpackaged and unlabeled prepared foods, contain high levels of sodium, with many providing more than 25% of the daily sodium intake recommended by the WHO [28]. Thus, the use of table salt in food preparation remains a significant challenge in Mexico, as it does in other countries such as Brazil, China, Costa Rica, Guatemala, India, Japan, Mozambique, and Romania, where a large proportion of overall daily sodium intake comes from the discretionary use of salt [29].

In terms of potassium intake, the median urinary excretion was 1493.5 mg/day in the overall study sample, which is considerably lower than the WHO's recommended intake of 3510 mg/day for adults to prevent chronic disease and improve health [30]. Low urinary potassium excretion was also reported in 2 studies of the Mexican population, with values ranging from 1909 to 1981 mg/day [2,4], while another report indicated a higher mean potassium intake (3401 mg/day) in this population, as determined by a 24-hour food recall [27]. Importantly, potassium intake, whether determined by urinary excretion or dietary analysis, has been found to be an indicator of diet quality [5,31] and is inversely associated with BMI, diastolic blood pressure, and heart rate [31]. Additionally, the combination of higher sodium and lower potassium intakes, as observed in this and other studies [2,4,27], is associated with an increased cardiovascular risk [6]. Therefore, dietary strategies aimed at modifying both sodium and potassium intakes are necessary for the Mexican population.

Diverse studies have reported no association between salt/sodium-related KAB [13,17,18,20] and sodium excretion, while others have found some level of association [14,15,19]. To explore the relationship between salt/sodium-related KAB and sodium and potassium intake, we compared the adjusted means of 24-hour urinary sodium and potassium excretion across categories of salt/sodium-related KAB. Interestingly, the mean sodium excretion was similar among participants, regardless of whether they were trying to eat a healthy diet. However, potassium excretion was higher among participants who reported trying to eat a healthy diet compared with those who were unsure, after adjusting for sex, age, BMI, and calorie intake. Similarly, participants who often paid attention to the text on packaging had higher levels of both sodium and potassium excretion compared with those who rarely did so. Potassium excretion was also higher in participants who always read nutrition food labels compared with those who did so less frequently, although this behavior was not associated with sodium excretion in the multiple comparisons. These results suggest that attempts to follow a healthy diet may impact the quality of the diet by likely incorporating more food sources of potassium, such as fruits, vegetables, and legumes, but not necessarily modifying the selection of foods based on their sodium content. Another possibility is that to reduce sodium intake, people may increase the consumption of low-sodium processed foods that contain hidden potassium in the form of additives, such as sodium-reduced meat and poultry products and industrialized bakery items [32,33]. Further research is needed to clarify these findings.

Knowing that there is a recommended amount of daily salt/sodium consumption or understanding the differences between salt and sodium was not associated with lower sodium intake either; in fact, participants who reported knowing this exhibited higher sodium and potassium excretion than those who did not. These results are relevant as they support the findings of a study in a Chinese population, where self-reported salt/sodium-related KAB had a smaller effect on sodium but a greater effect on potassium excretion [15].

The results of this study provide evidence for the need to continue improving KAB related to salt/sodium consumption at the population level. The implementation of education and communication campaigns is one of the strategies endorsed by the WHO to raise awareness about the health risks and dietary sources of salt, aiming to induce behavioral changes [34]. In Mexico, the "Less Salt, More Health" campaign was implemented in 2013 by the Ministry of Health. This communication strategy aimed to increase knowledge and educate the population about the benefits of reducing salt consumption. However, the impact of its implementation was not assessed [1]. In fact, this is the first study to report KAB related to salt/sodium intake in a Mexican population.

Worldwide, other strategies beyond communication campaigns that have shown the greatest impact on dietary sodium reduction at the population level include mandatory food reformulation, food labeling, and taxes [35]. In 2020, Mexico implemented a

mandatory front-of-pack warning labeling system [36]. The reformulation of processed and ultra-processed foods that contain large amounts of sodium should be one of the next steps in Mexico's sodium reduction strategy. While some work has been done in this area, further progress is needed in line with the WHO regional sodium benchmarks [1].

Finally, even though better salt/sodium-related KAB was not associated with lower sodium excretion, participants had some awareness of their actual sodium intake level. Specifically, those who reported consuming the right amount of dietary sodium had lower sodium excretion compared with those who believed they consumed too much salt. Nonetheless, participants who reported an adequate intake (the right amount) still had sodium consumption levels above the recommended 2000 mg/day. This underscores the ongoing need to improve salt/sodium-related KAB and further reduce sodium intake, as previously discussed.

Limitations

This study has several limitations. First, its cross-sectional design prevents the establishment of causal relationships between salt/sodium-related KAB and urinary sodium and potassium excretion. Second, the study was conducted with a sample from Mexico City and its surrounding area, limiting the generalizability of the results to the national population. Third, nearly 80% (n=184) of the study sample were women; however, data were stratified by sex, and the adjusted urinary sodium and potassium means accounted for sex as a covariate. Fourth, the available data do not distinguish between potassium naturally

occurring in foods and that added as an additive in processed foods. Further studies are needed to explore the sources of dietary potassium in the Mexican population and its impact on health-related outcomes. Finally, no sample size calculation was conducted; instead, all available data from participants meeting the eligibility criteria for this secondary analysis were analyzed. Longitudinal and properly powered studies exploring this association are warranted. The main strength of this study lies in the use of an objective method to assess sodium and potassium intake, namely, the measurement of their excretion levels in 24-hour urine.

Conclusions

Results of this study indicate that self-reported KAB related to salt/sodium intake is poor in this study sample. Therefore, new initiatives are needed to improve KAB in order to promote better food choices, which, in turn, could help reduce sodium intake. In this context, educating individuals about the sodium content of unpackaged prepared foods is particularly relevant. In addition, salt/sodium-related KAB had a greater impact on potassium excretion than on sodium excretion, highlighting the need for more strategies to improve KAB related to salt/sodium intake. It also emphasizes the importance of considering other approaches to modify the sodium content of foods, such as the reformulation of processed and ultra-processed foods. Finally, monitoring KAB related to salt/sodium consumption, along with actual sodium intake, in larger populations is essential, especially when new strategies to reduce sodium intake are implemented.

Abstract

Background: Health care workers (HCWs) played a key role in preventing and controlling COVID-19. Higher infection risks and intensive work led to occupational burnout for many HCWs, which may affect their lifestyle behaviors and weight.

Objective: This study aimed to assess HCWs' self-rated health status, overweight and obesity rates, lifestyle behaviors, and psychoemotional changes from 2019 to 2022 across China and to analyze the factors associated with changes from underweight or normal weight in 2019 to overweight or obese in 2022.

Methods: In this retrospective study, 100 health care institutions were randomly selected from 5 provinces or regions in China. All HCWs who worked in the institutions for at ≥3 years were invited to complete the electronic questionnaire and participate in the online survey from August 1, 2022, to August 31, 2022. Collected data included changes in lifestyle behaviors (dietary habits, physical activity, sleep quality, smoking, alcohol consumption), psychoemotional conditions (persistent stress or recurrent anxiety or depressed mood), health status, and chronic disease control from December 2019 to August 2022. Height and weight in 2019 and 2022 were retrieved from annual physical examination records. Overweight and obesity were defined as $24.0 \text{ kg/m}^2 \leq BMI < 28.0 \text{ kg/m}^2$ (overweight) and $BMI \geq 28.0 \text{ kg/m}^2$ (obesity). Chi square tests and ANOVAs were used to assess the associations between groups. Logistic regression models were used to analyze the factors associated with HCWs becoming overweight or obese from 2019 to 2022.

Results: The questionnaire was submitted by 23,234 HCWs. Of the underweight or normal weight HCWs in 2019, 12.67% (1486/23,234) became overweight or obese in 2022; this change was associated with the following factors: 34-43 years old (OR 0.843, 95% CI 0.740-0.960), 44-53 years old (OR 0.738, 95% CI 0.635-0.960), and 54-63 years old (OR 0.503, 95% CI 0.368-0.685; reference: 24-33 years old), reduction in or never or rarely engaging in physical activity (OR 1.201, 95% CI 1.055-1.368; reference: increase in physical activity; *P*=.006), increased appetite (OR 2.043, 95% CI 1.788-2.034; reference: reduction or no change in appetite; *P*<.001). From 2019 to 2022, 51.29% (11,917/23,234) of the respondents experienced increased persistent stress or

recurrent anxiety or depressed mood; 44.38% (10,311/23,234) stayed up late more often. Increased persistent stress or recurrent anxiety or depressed mood was associated with physical activity (OR 0.421, 95% CI 0.398-0.447; *P*<.001) and appetite (OR 1.601, 95% CI 1.483-1.728; *P*<.001).

Conclusions: The pandemic was associated with overweight and obesity for HCWs due to changes in lifestyle behaviors, especially reduced physical activity and increased appetite related to increased persistent stress or recurrent anxiety or depressed mood caused by excessive workload. An integrated approach is needed to address overweight and obesity and lifestyle changes among HCWs by releasing negative psychoemotional conditions through workload reduction in future stressful events.

Introduction

Health care workers (HCWs) have played a key role in the COVID-19 pandemic control since the end of 2019. The high risk of infection [1], long-term isolation, and intensive work not only caused burnout for many HCWs but also substantially affected their mental health [2], daily routine [3,4], physical activity, diet, and other lifestyle behaviors [5] and has put them at high risk for obesity [6-9]. A literature review in 2020 showed that HCWs gained weight and changed their lifestyles to varying degrees during the pandemic [10]. A study in the United States on lifestyle behaviors and weight changes among frontline HCWs since the COVID-19 outbreak [11] showed that dietary patterns of HCWs during the pandemic (January 2021) were negatively impacted, with an increase in snack, fast food, take-away food, and alcohol consumption and an average weight increase of 2.99 pounds compared with prepandemic levels (March 2021). Jin et al [12] found that 39.7% were less physically active and 36% had less sleep in a survey of 589 Chinese HCWs. A study by Zhang et al [13] surveyed the Chinese frontline medical staff who supported Hubei Province during the initial stage of the pandemic and found that most had an unbalanced diet and 26.2% gained weight. A survey of Brazilian doctors by Gomes et al [6] found that 60% had less physical activity, 39.9% consumed more alcohol, and 32.9% gained weight.

Being overweight or obese and lifestyle behavior changes increase the risk of various chronic diseases, such as hypertension, type 2 diabetes mellitus, coronary heart disease, stroke, certain cancers, and osteoporosis [14-20]. Being overweight or obese can directly affect daily activities or even lead to mental and emotional disorders [21], impairing work performance [22], increasing the absenteeism rate due to illness and frequent overtime [23-25], and increasing occupational injuries, and can endanger the sustainable development of health care institutions [26].

Basically, overweight and obesity result from consuming more calories than expended [27]; hence, any factor that can increase food calorie intake and reduce exercise expenditure may lead to overweight and obesity. Studies indicated that occupational factors such as working hours, work intensity, work stress, and shifts are associated with overweight or obesity in HCWs [28-31]. Shift nurses are more likely to consume excessive food, have more coffee and snacks, and participate in less exercise

during night shifts [32-34], which further increases the likelihood of overweight or obesity. Negative psychoemotional conditions (eg, chronic stress, anxiety, and depression) can have a substantial impact on a person's diet and physical activity [35-37]. According to a survey by the American Psychological Association, 39% of adults cope with stress by overeating and eating unhealthy foods [35]. A longitudinal study of nearly 1400 women in Australia showed an association between higher stress and less physical activity and more frequent consumption of fast food [36]. This is due to the fact that constant stress can activate the hypothalamic-pituitary-adrenal axis in humans, promote cortisol secretion, affect sleep, and increase the intake of "self-rewarding foods" (high in fat and sugar), thereby increasing the incidence of obesity, especially in the abdomen [37].

HCWs are considered to experience a heavier workload and mental stress than their counterparts in many other industries due to their longer working hours, less personal time, and higher burnout rates, possibly making them more susceptible to the risk of overweight or obesity [38]. Over the past 3 years, the extra burden from the COVID-19 pandemic has been substantial for HCWs. A systematic review and meta-analysis of anxiety-related symptoms among HCWs affected by the pandemic reported that 42% showed characteristics of anxiety, 40% experienced acute stress, 37% experienced burnout, and 32% had posttraumatic stress disorder [39].

There have been many studies on the impact of the pandemic on weight changes and lifestyle behaviors in the general population [11,40-42]; however, few focused exclusively on HCWs nationwide in China. Weight, lifestyle behavior, and psychoemotional changes and the relationship between them among the Chinese HCWs remain unknown.

The aim of this study was to assess HCWs' self-rated health status, overweight and obesity rates, lifestyle behaviors, and psychoemotional changes from 2019 to 2022 across China as well as to analyze the factors associated with weight changes resulting in them moving from underweight or normal weight in 2019 to overweight or obese in 2022.

Methods

Study Design

This study was based on a retrospective anonymous web survey [43] using a structured self-administered questionnaire and was conducted in accordance with the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) [44]. The respondents were randomly sampled, and relevant data were collected via recall, including sociodemographic characteristics, health status, and height and weight in 2019 and 2022, as well as changes in lifestyle behaviors and psychoemotional states from 2019 to 2022.

Study Population, Sampling Strategy, and Eligibility Criteria

A multistaged, clustered, random sampling method was used. First, 5 provincial administrative regions (Beijing City, Shandong Province, Henan Province, Gansu Province, and Xinjiang Uygur Autonomous Region) were selected at random from 32 provinces, autonomous regions, and municipalities of China. Second, 20 health care institutions were sampled from each of the 5 provincial administrative regions considering interprovincial differences and intraprovincial homogeneity of the institutions. Third, HCWs from the selected institutions who met the inclusion and exclusion criteria were included. A total of 100 medical institutions were sampled. The survey was conducted from August 1, 2022, to August 31, 2022.

The inclusion criteria were as follows: (1) age ≥24 years, (2) working in the health care institutions for at least 3 years from 2019 to 2022, (3) possessing and using a smartphone with the WeChat app, and (4) providing informed consent and voluntarily participating in the survey.

Sample Size Estimation

The sample size of this study was estimated by using the formula for staged clustered random sampling:

where *p*=6.5% (estimated obesity rate among HCWs) [45], *d* is the absolute error and was calculated as 10% (error tolerance)×6.5%, *u*=1.96, *deff* is the design efficiency with a value of 2.0, and sampling was stratified into urban and rural areas (×2). Considering nonresponse, an additional 10% of the calculated sample size was added, leading to a required sample size of 24,314 HCWs.

Survey Tools

The survey questionnaire was developed purposely by the study group to collect data. First, we pooled the items based on a literature review and expert interviews. Second, a nominal group discussion with 10 senior experts in lifestyle was organized, and only the items (questions) with face validity above 0.8 were included [46,47]. Third, we invited 10 HCWs to conduct a pretest using the initial questionnaire to validate all the items. The weak items were removed or revised. The final questionnaire was comprised of the following modules: informed consent, answering guide, sociodemographic information, general health status (self-rated, presently and in 2019), height

(m) and weight (kg) in 2019 and 2022 (based on their annual physical examination record), and changes in lifestyle behaviors (dietary habits, physical activity, sleep quality, smoking, alcohol consumption, and persistent stress or recurrent anxiety or depressed mood) from 2019 to 2022.

Sociodemographic information included gender, age, education, and working and living locations (urban or rural). General health status was self-rated, and presence of chronic diseases (eg, diagnosed hypertension, cardiovascular and cerebrovascular diseases, cancer, diabetes, chronic obstructive pulmonary disease, osteoporosis [48,49]) was compared with that in 2019. Dietary habits included consumption of take-out food (generally regarded as ultraprocessed), vegetables and fruits, fried food, snacks or desserts, and sugar-sweetened beverages as well as breakfast frequency. Data about sleep quality (staying up late [not falling asleep after 12 AM due to specific affairs, voluntarily or involuntarily [50]] and sleep duration) were also collected. Overweight or obese was based on BMI (BMI=weight [kg]/height [m]^2); underweight was defined as BMI<18.5 kg/m^2, normal weight was defined as 18.5 kg/m^2≤BMI<24.0 kg/m^2, overweight was defined as 24.0 kg/m^2≤BMI<28.0 kg/m^2, and obese was defined as BMI≥28.0 kg/m^2 [51].

To measure psychoemotional states, we defined persistent stress with the following question: "Have frequently experienced feelings of being under too much mental or emotional pressure made one angry/irritated/moody/frustrated, worried, or unable to sleep for at least 6 months?" We defined recurrent anxiety with the following statement: "has experienced recurrent feelings of being nervous or restless or a sense of impending danger, panic, or doom with increased heart rate/sweating/ accelerated breathing/trembling for at least 6 months." We defined recurrent anxiety or depressed mood with the following statement: "has experienced persistent feelings of sadness, tearfulness, emptiness or hopelessness, and loss of interest or pleasure in most or all normal activities, such as sex, hobbies or sports, with angry outbursts, irritability or frustration, even over small matters for at least 6 months."

Each item (question) was rated on a 5-point Likert scale [52] using the responses "great increase/great improvement," "increase/improvement," "no change," "reduction/deterioration," "great reduction/great deterioration," or "never or rarely" or "no diagnosed such disease." Except for height and weight, which are continuous variables, all other variables in this study are categorical. In order to increase the statistical power, we merged 3 psychoemotional states into 1 variable of "persistent stress and/or recurrent anxiety/depressed mood" for analysis, and an increase in any of the 3 conditions were considered to increase persistent stress or recurrent anxiety or depressed mood.

The Cronbach α of the final questionnaire was 0.82, with 3 factors explaining 63.55% of the total variance based on exploratory factorial analysis [53].

Data Collection

The Wenjuanxing Web Survey System (an online questionnaire research platform in Chinese) [54] was used to generate a QR code for the electronic questionnaire. The investigators contacted

the liaison of the selected health care institutions and sent the QR code to all the HCWs at the institution. The respondents were required to scan or press the QR code through WeChat to fill out the electronic questionnaire and submit it to the Wenjuanxing backstage after completion. Their WeChat ID was used to ensure that each respondent could only submit the questionnaire once.

Participants' responses were anonymous and confidential. The anonymity and confidentiality policy was declared at the beginning of the electronic questionnaire. The respondents were also informed that data would be used for research purposes only. Participants completed the questionnaire when directly connected to the Wenjuanxing platform. In total, 25,000 questionnaires were sent out, and 24,344 questionnaires were returned, with a recovery rate of 97.38%. Each submitted questionnaire was reviewed, and questionnaires with incomplete or missing items, incorrect information, and obvious logical errors were regarded as invalid (1110/24,344, 4.56%); 23,234 questionnaires entered the final analysis.

Statistical Analysis

Statistical analysis was performed using SPSS 25.0 (IBM Corp) software. The sociodemographic characteristics were analyzed using descriptive statistics, and the quantitative data are represented by mean (SD). Chi square tests were used to assess the association between categorical variables and trends within a categorical variable. ANOVAs were performed to compare continuous variables among 2 or more groups. Multivariate binary logistic regression was used to test the independent variables (changes in sociodemographic characteristics, lifestyle behaviors, and psychoemotional states) related to the BMI changes, and a multivariate binary logistic regression model was constructed taking the identified statistically significant lifestyle behaviors as dependent variables and "persistent stress and/or recurrent anxiety/depressed mood" as the independent variable. $P<.05$ was considered statistically significant for all analyses.

Ethical Considerations

This study was conducted in compliance with the Declaration of Helsinki and was reviewed and approved by the ethics committee of Fuwai Hospital, Chinese Academy of Medical Sciences (number 2021-1559). Informed consent was obtained from participants in accordance with ethical guidelines. This study abided by the principles of scientific research ethics, clearly stated the purpose of this survey in the preface of the electronic questionnaire, and strictly protected the privacy of all respondents. All respondents were required to be honest in their responses. Participants were able to stop answering and leave the questionnaire at any stage before the end of the process, with no answers being saved. Respondents' answers were saved just by clicking on the "submit" button. Upon completing the survey, participants acknowledged their voluntary consent to participate in this anonymous study. Every participant could obtain daily necessities as rewards upon submission, such as napkins, towels, soap, and hand sanitizer.

Results

Sociodemographic Characteristics of the Respondents

Of the 23,234 HCWs, 31.8% (7388/23,234) were male, and 68.2% (15,846/23,234) were female. The average age was 39.85 (SD 9.41; range 24-80) years, and more than 60% (14,804/23,234, 63.72%) were in the following age groups: 34-43 years and 44-53 years. In total, 73.78% (17,143/23,234) of the respondents had an education at the college or university level, and 61.44% (14,276/23,234) worked and lived in urban areas. See Table 1.

Table 1. Sociodemographic characteristics of the respondents (N=23,234).

Sociodemographic characteristics	Results, n (%)
Gender	
Male	7388 (31.8)
Female	15,846 (68.2)
Age (years)[a]	
24-33	6768 (29.13)
34-43	7895 (33.98)
44-53	6909 (29.74)
54-63	1405 (6.05)
≥64	222 (0.96)
Education level	
Junior high school or less	247 (1.06)
Senior high school or secondary specialized school	5138 (22.11)
College or undergraduate degree	17,143 (73.78)
Master's degree or higher	706 (3.04)
Working and living location	
Urban	14,276 (61.44)
Rural	8958 (38.56)

[a]35 missing responses.

Health Status of the Respondents

From 2019 to 2022, 31.19% (7247/23,234) of the respondents reported that their health condition deteriorated; meanwhile, 18.76% (4359/23,234) reported that it improved, and 50.05% (11,628/23,234) reported no change. In total, 22.45% (5215/23,234) had chronic diseases, of which 66.17% (3451/5215) reported their disease was better controlled and 33.83% (1764/5215) reported their disease was less controlled.

BMI Changes From 2019 to 2022

In 2019, the mean BMI of the participants was 23.63 (SD 3.48) kg/m^2; 32.26% (6651/20,619) were overweight, and 10.84% (2236/20,619) were obese. In 2022, the mean BMI was 23.85 (SD 3.42) kg/m^2; 34.26% (7403/21,608) were overweight, and 11.22% (2424/21,608) were obese. The difference in mean BMI between 2019 and 2022 was statistically significant ($P<.001$). Nevertheless, the proportion of those who were overweight or obese increased by 2% ($P<.001$) and 0.38% ($P<.001$), respectively (Table 2).

The mean BMIs of males in 2019 and 2022 were 25.39 (SD 3.43) kg/m^2 and 25.50 (SD 3.33) kg/m^2, respectively, and both were higher than those of females (mean 22.78, SD 3.17 kg/m^2 in 2019 and mean 23.06, SD 3.18 kg/m^2 in 2022). The male overweight and obesity rates in 2019 and 2022 were 66.01% (4445/6734) and 67.73% (4717/6964), respectively, and both were higher than those of women (4442/13,885, 31.99% in 2019 and 5110/14,644, 34.89% in 2022). The proportions of overweight or obesity in those aged ≥64 years (126/197, 63.95% in 2019 and 126/204, 61.76% in 2022) and with a junior high school education or less (125/211, 59.24% in 2019 and 134/222, 60.36% in 2022) were higher than those of the other age groups and education groups, respectively. The overweight and obesity rates for those working and living in rural areas (4214/8108, 52.56% in 2019 and 4549/8355, 54.45% in 2022) were higher than those working and living in urban areas (Table 2).

From 2019 to 2022, 12.67% (1486/11,732) of underweight or normal weight respondents became overweight or obese, and the rates were higher for men (425/2289, 18.57%) and those in rural areas (536/3804, 14.09%) than for women (1061/9443,

11.24%) and those in urban areas (950/7928, 11.98%), respectively. In total, 10.51% (934/8887) of overweight or obese respondents became underweight or normal weight; the rates were higher for women (638/4442, 14.36%) and those in urban areas (570/4673, 12.2%) than for men (296/4445, 6.65%) and those in rural areas (364/4214, 8.64%), respectively. Additionally, a statistically significantly higher proportion of overweight or obese respondents aged 24-33 years (213/1334, 15.97%) became underweight or normal weight than the other age groups. With an increase in education level, the proportion who moved from overweight or obese to underweight or normal weight increased. All of these differences were statistically significant (Table 3).

Table 3. Proportion of participants who changed BMI from 2019 to 2022 (N=23,234).

Lifestyle Behavior and Psychoemotional Changes for Chinese HCWs From 2019 to 2022

The proportions of respondents with a great increase or increase in physical activity, vegetable and fruit consumption, breakfast frequency, staying up late, and persistent stress or recurrent anxiety or depressed mood were statistically significantly higher than those of respondents with a reduction or great reduction in these factors. Of the respondents, 51.29% (11,917/23,234) reported a great increase or increase in persistent stress or recurrent anxiety or depressed mood. The top 3 lifestyle behaviors with a "great increase/increase" were staying up late (10,311/23,234, 44.38%), physical activity (9729/23,234, 41.87%), and vegetable and fruit consumption (9268/23,234, 39.89%). The proportions of respondents with a great increase or increase in their consumption of take-out food, fried food, snacks or desserts, and sugar-sweetened beverages; cigarette smoking; alcohol consumption; and sleep duration were significantly lower than those with a reduction or great reduction. The top 3 lifestyle behaviors that were reduced or greatly reduced were sleep duration (10,648/23,234, 45.83%), fried food consumption (8328/23,234, 35.84%), and sugar-sweetened beverage consumption (7781/23,234, 33.49%). All of these differences were statistically significant (Figure 1).

Figure 1. Lifestyle and psychoemotional changes of respondents from 2019 to 2022.
Univariate Analyses of Lifestyle Behavior and Psychoemotional Changes Associated With HCWs Becoming Overweight or Obese From 2019 to 2022

Among the respondents, those who regularly exercised (539/8656, 6.23%) and consumed vegetables and fruit (546/8207, 6.65%) were less likely to have a change in BMI from underweight or normal weight to overweight or obese. Fewer respondents became overweight or obese from underweight or normal weight in those with a reduction or great reduction in their consumption of take-out food (369/3954, 9.33%), fried food (178/1623, 10.97%), snacks or desserts (221/2081, 10.62%), and sugar-sweetened beverages (192/1866, 10.29%); appetite (428/3427, 12.49%); alcohol consumption (84/882, 9.52%); persistent stress or recurrent anxiety or depression (819/10,584, 7.74%); and staying up late (740/9115, 8.12%) than the opposite. All of these were statistically significant (Table 4).

Table 4. Univariate analyses of lifestyle behavior and psychoemotional changes associated with health care workers becoming overweight or obese from 2019 to 2022.

Multinomial Binary Logistic Regression Analyses of Factors Associated With HCWs Becoming Overweight or Obese From 2019 to 2022

Logistic regression analyses showed that the following were significant factors for BMI changes from underweight or normal weight in 2019 to overweight or obese in 2022: being 34-43 years (OR 0.843, 95% CI 0.740-0.960), 44-53 years (OR 0.738, 95% CI 0.635-0.960), and 54-63 years (OR 0.503, 95% CI 0.368-0.685) old; reduced physical activity (OR 1.201, 95% CI 1.055-1.368); and increased appetite (OR 2.043, 95% CI 1.788-2.034; Table 5).

Associations Between Persistent Stress or Recurrent Anxiety or Depressed Mood and Physical Exercise and Appetite

The results of the logistic regression analysis are shown in Table 6. Note that the sociodemographic characteristics were included as independent variables.

Table 6. Associations between persistent stress and/or recurrent anxiety/depressed mood (reference: reduction/no change/never or rarely) and physical activity and appetite.

Variables	Odds ratio (95% CI)	P value
Increased physical activity[a]	0.421 (0.398-0.447)	<.001
Increased appetite[b]	1.601 (1.483-1.728)	<.001

[a]Physical activity was the dependent variable.

[b]Appetite was the dependent variable.

Discussion

This study investigated the self-rated health status, overweight and obesity rates, and lifestyle behavior changes of HCWs from 2019 to 2022 across China and analyzed the factors associated with weight changes from underweight or normal weight in 2019 to overweight or obese in 2022.

Principal Findings

This study found that more HCWs reported a deteriorated health status than an improved status from 2019 to 2022. More than one-fifth reported having chronic diseases, which is significantly lower than that of a cross-China survey (34.29%) [55], and more of the chronic diseases improved rather than worsened, which is consistent with earlier findings in China [56].

The results demonstrated that, in 2019 and 2022, the overweight and obesity rates of HCWs were 43.1% and 45.48%, respectively, which is close to the survey in some Chinese cities among HCWs (44.98%) [57] but lower than that of the general population across China during the same period (49.6%) [58]. From 2019 to 2022, although the overweight and obesity rates among HCWs only increased by 2.38%, with an average annual growth rate that was slightly lower than that across China during the same period [58], the proportion of those changing from underweight or normal weight to overweight or obese was much higher than that of those changing from overweight or obese to underweight or normal weight.

This study showed that, from 2019 to 2022, the lifestyle behaviors of Chinese HCWs generally improved, and more had increased physical activity, vegetable and fruit consumption, and breakfast frequency as well as reduced consumption of take-out food, fried food, snacks or desserts, and sugary beverages as well as cigarette smoking.

Wang et al [59] conducted a study among doctors and nurses in north China in the same period and found that the top 5 predictors of a BMI change were an unbalanced diet, poor sleep quality, work-family conflict, lack of exercise, and soft drink consumption. This study's univariate analyses revealed that increased physical activity and vegetable and fruit consumption could reduce the likelihood of going from underweight or normal weight to overweight or obese, while increasing the frequency of staying up late and consumption of take-out food, fried food, snacks or desserts, sugary beverages, and alcohol as well as appetite could increase the likelihood. These findings showed

that lifestyle behavior changes are closely related to weight changes [60]. Multinomial binary logistic regression analyses demonstrated that increased appetite and reduced physical activity were significant risk factors for HCWs becoming overweight or obese from underweight or normal weight, suggesting that healthy dietary patterns and promotion of physical activity should be highlighted for the prevention of overweight or obesity among HCWs [61]. This study found that younger HCWs (24-33 years old) were more likely to become overweight or obese from underweight or normal weight than other age groups, which might be related to their increased involvement in frontline work in the pandemic [62].

An excessive workload can have a significant impact on lifestyle behaviors, resulting in becoming overweight or obese [63]. Studies have shown that the level of physical activity by HCWs was greatly reduced due to participating in pandemic prevention and control [64]. Liu et al [65] found that the risk of shift workers being overweight or obese increased by 25% and 17%, respectively. A study in China found that 48.5% of nurses developed sleep disorders during the COVID-19 pandemic due to overwork [66]. Mu et al [67] found that, during the pandemic, doctors slept significantly less. This survey found that, since the outbreak of COVID-19 in 2019, nearly 44.38% of HCWs stayed up late more or much more often and nearly 45.83% had a reduction or great reduction in sleep duration. Additionally, the relationship between sleep disorders and being overweight or obese has been confirmed by a substantial body of studies [68]. In this study, although univariate analysis found that an increased frequency of staying up late was statistically significantly associated with becoming overweight or obese, the increase was not a significant predictor in the logistic regression analysis. This discrepancy may stem from the fact that we only collected and analyzed changes in sleep duration (great increase/increase) without investigating and analyzing the actual sleep duration.

Increased stress and fear due to intensive work and a high risk of infection can have significant psychological and emotional effects [69-71]. A recent retrospective study revealed that, due to the impact of the COVID-19 pandemic, 40% of medical staff suffered from anxiety disorders and 37% suffered from depression disorders [72]. This survey discovered that persistent stress or recurrent anxiety or depressed mood among Chinese HCWs increased significantly, higher than the Chinese national average [73]. Psychological problems such as anxiety,

XSL·FO

RenderX

depression, and stress can affect physical activity [74] and diet-related behaviors [75-77] and thus affect weight gain. Depression and obesity are reciprocal risk factors [78], and stress can lead to sleep disturbances [79], resulting in reduced physical activity and metabolic disorders [80]. This study demonstrated that increased persistent stress or recurrent anxiety or depressed mood were significantly associated with reduced physical activity and increased appetite. Therefore, providing psychological support for HCWs during the pandemic could not only benefit their mental health but could also reduce the possibility of becoming overweight or obese.

As far as the results of this study are concerned, an integrated approach is needed to address the problem of becoming overweight or obese and lifestyle changes among HCWs. At the national level, the right to rest and physical and mental health promotion should be ensured under a legal framework [81,82], especially in the event of a pandemic. At the institutional level, a system of rotational rest for HCWs should be established while ensuring institutional continuity. Second, regular psychological counselling and support services should be provided to ensure that stress and emotions are addressed in a timely manner [83,84]. Third, routine healthy lifestyle guidance (eg, by health coaches) and the modification of unhealthy dietary patterns and physical inactivity should be provided systematically and specifically [85]. Fourth, for those who are overweight or obese, lifestyle medicine intervention services should be given based on the principle of informed voluntary participation [86].

Notably, the impact of the COVID-19 epidemic on HCWs' weight and lifestyle behaviors might be temporary. For instance, Oliver et al [11] found that, compared with before March 2020 (before the COVID-19 outbreak), in January 2021, nearly 70% of American HCWs experienced an increase in snacking, 60% consumed more fast food or take-out food, and 50% consumed more alcohol; however, by January 2022, the dietary habits of American HCWs returned to prepandemic patterns. More research is needed on the persistence of the impact of the pandemic on overweight and obesity rates and lifestyle behaviors of HCWs.

Comparison With Prior Work

This study used a retrospective methodology to explore the weight gain status of Chinese HCWs during the pandemic period from December 2019 to August 2022, along with their psychoemotional and lifestyle exposures. To our knowledge, this is the first nationwide, large-scale study in China focusing on weight gain and influencing factors of HCWs during the pandemic. Compared with previous studies, its advantages are mainly manifested in 4 ways. First, this study adopted a 3-year retrospective cohort study design, making the conclusion on the correlation between the influencing factors and weight changes more reliable than previous studies using cross-sectional methods [13,32-34,66]. Second, although previous studies only analyzed the association between lifestyle behaviors and weight gain for HCWs during the pandemic [6,11], this study took lifestyle behaviors as both the independent variables of weight

gain and the dependent variables of persistent stress or recurrent anxiety or depressed mood to conduct a correlational study, uncovering the significant effects of psychoemotional changes on lifestyle behaviors. Third, this study highlights the fundamental contributions of persistent stress or recurrent anxiety or depressed mood caused by high-risk and high-intensity work to weight gain rather than lifestyle behaviors [6,11,13], which were the mediating factors. Fourth, this study suggests that intervention and policy should focus on effectively alleviating intensive work-related stress to reduce the risk of weight gain for HCWs instead of only on lifestyle behavior interventions [6,13] during the pandemic.

Limitations

This study had the following limitations. First, the data in this study were collected through online self-reporting; their accuracy largely depended on the respondents' ability to understand and willingness to answer questions. They may have underestimated or exaggerated the truth. However, because the respondents are medical and health personnel with professional backgrounds, the information collected is accurate to a certain extent. Second, this study did not divide the respondents into frontline personnel and nonfrontline personnel for a comparative analysis; hence, the conclusions should be cautiously accepted. Third, recall bias might not be excluded due to the retrospective nature of the study. However, the sample size of this study is large enough to compensate for these limitations to a certain extent, and the conclusions of this study still have validity.

Future Directions

This study provides a new perspective for understanding the impact of psychological stress on HCW weight gain during the pandemic period. Further research might be needed to distinguish the pattern of the effect of psychological stress on lifestyle behaviors and weight gain among the different nature of pandemic-related work (ie, frontline and nonfrontline) and occupational categories (such as doctors, nurses, and disease prevention and control personnel). Additionally, a nested case control study [87] design can be adopted to more effectively distinguish the intensity of the impact of psychological stress on different lifestyle behaviors and weight gain. Finally, it could be of great significance to conduct research on the effectiveness of different psychological support strategies for improving the lifestyles of HCWs during an epidemic.

Conclusions

In summary, the pandemic had an impact on Chinese HCWs becoming overweight or obese due to lifestyle behavior changes, especially reduced physical activity and increased appetite related to increased persistent stress or recurrent anxiety or depressed mood caused by an excessive workload. An integrated approach is needed to address overweight and obesity rates and lifestyle changes among HCWs, by releasing negative psychoemotional states through workload reduction in future stressful life events.

Data Availability

The data sets used or analyzed in this study are available from the corresponding author on reasonable request.

Authors' Contributions

XT (healthtian@163.com) and SG (1963149992@qq.com) have contributed equally to this work and should be considered co-corresponding authors.

XF, XT, XG, SG, YC, and XH designed the research. XF, XT, XG, SG, YC, XH, TS, JW, ZW, JH, XZ, and SW collected the data. XG, XT, SG, YC, and XH analyzed the data. XG wrote the original draft. Correction of: https://www.i-jmr.org/2024/1/e43585

In "Influence of Environmental Factors and Genome Diversity on Cumulative COVID-19 Cases in the Highland Region of China: Comparative Correlational Study" (Interact J Med Res 2024;13:e43585) the authors noted one error.

In the originally published manuscript, author Zhuoga Deji was noted as having contributed to the manuscript as the first author.

This has been corrected to note that both authors Zhuoga Deji and Yuantao Tong contributed equally to the manuscript, and they should be regarded as joint first authors.

The correction will appear in the online version of the paper on the JMIR Publications Interactive Journal of Medical Research publication website on April 10, 2024, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Abstract

Background: Metabolically associated fatty liver disease (MAFLD) insidiously affects people's health, and many models have been proposed for the evaluation of liver fibrosis. However, there is still a lack of noninvasive and sensitive models to screen MAFLD in high-risk populations.

Objective: The purpose of this study was to explore a new method for early screening of the public and establish a home-based tool for regular self-assessment and monitoring of MAFLD.

Methods: In this cross-sectional study, there were 1758 eligible participants in the training set and 200 eligible participants in the testing set. Routine blood, blood biochemistry, and FibroScan tests were performed, and body composition was analyzed using a body composition instrument. Additionally, we recorded multiple factors including disease-related risk factors, the Forns index score, the hepatic steatosis index (HSI), the triglyceride glucose index, total body water (TBW), body fat mass (BFM), visceral fat area, waist-height ratio (WHtR), and basal metabolic rate. Binary logistic regression analysis was performed to explore the potential anthropometric indicators that have a predictive ability to screen for MAFLD. A new model, named the MAFLD Screening Index (MFSI), was established using binary logistic regression analysis, and BFM, WHtR, and TBW were included. A simple rating table, named the MAFLD Rating Table (MRT), was also established using these indicators.

Results: The performance of the HSI (area under the curve [AUC]=0.873, specificity=76.8%, sensitivity=81.4%), WHtR (AUC=0.866, specificity=79.8%, sensitivity=80.8%), and BFM (AUC=0.842, specificity=76.9%, sensitivity=76.2%) in discriminating between the MAFLD group and non-fatty liver group was evaluated ($P<.001$). The AUC of the combined model including WHtR, HSI, and BFM values was 0.900 (specificity=81.8%, sensitivity=85.6%; $P<.001$). The MFSI was established based on better performance at screening MAFLD patients in the training set (AUC=0.896, specificity=83.8%, sensitivity=82.1%) and was confirmed in the testing set (AUC=0.917, specificity=89.8%, sensitivity=84.4%; $P<.001$).

Conclusions: The novel MFSI model was built using WHtR, BFM, and TBW to screen for early MAFLD. These body parameters can be easily obtained using a body fat scale at home, and the mobile device software can record specific values and perform calculations. MFSI had better performance than other models for early MAFLD screening. The new model showed strong power and stability and shows promise in the area of MAFLD detection and self-assessment. The MRT was a practical tool to assess disease alterations in real time.

Introduction

Nonalcoholic fatty liver disease (NAFLD) is regarded as an important cause of liver disease, affecting more than 25% of the general population worldwide; more than 50% of patients with NAFLD also have dysmetabolism [1,2]. In 2020, experts redefined NAFLD as metabolically associated fatty liver disease (MAFLD), and much emphasis was placed on the presence of metabolic-related diseases or dysfunction [3-5]. Researchers have found that MAFLD is a multisystem disease, and liver steatosis is associated with type 2 diabetes, chronic kidney disease, cardiovascular disease, and other diseases that interact and form a vicious cycle [6-14]. China has the highest incidence of NAFLD or MAFLD morbidity in Asia [3,15,16]. Therefore, much attention should be given to MAFLD by enhancing awareness of MAFLD and optimizing its management.

To date, guidelines have suggested that liver biopsy could serve as the gold standard to diagnose histological liver damage, but noninvasive, quantitative assessment of liver fibrosis may also have prognostic implications. Ratziu et al [17] collected liver biopsy samples from 51 patients and found that 41% of the patients were at different stages of liver fibrosis or had nonalcoholic steatohepatitis. The uneven distribution of histological lesions inevitably led to sampling error when performing biopsy. Abdominal imaging, such as B-ultrasound imaging and the controlled attenuation parameter (CAP) technique, can be used to diagnosis liver disease; the former is less sensitive to mild steatosis, while the latter can detect steatosis of more than 5% and is one of the most common noninvasive methods for quantifying hepatic steatosis and fibrosis clinically [18,19]. The European Association for the Study of the Liver, European Association for the Study of Diabetes, and European Association for the Study of Obesity updated the clinical practice guidelines that propose that the nonalcoholic fatty liver disease fibrosis score (NFS) and fibrosis-4 (FIB-4) index can be used as prognostic markers for the progression of liver disease [20]. The NFS has higher specificity in the older adult population (individuals aged >65 years old) [21,22]. The predictive performance of the NFS, FIB-4 index, and aspartate aminotransferase-to-platelet ratio index (APRI) has been consistent in relation to rates of liver-related disease and mortality but is less valuable for the prediction of liver fibrosis [23]. One study found that the combination of the NFS, FIB-4 index, and liver stiffness measurement greatly improved the diagnostic accuracy, and the performance was similar to that of liver biopsy [24]. A cross-sectional study found that the triglyceride glucose (TyG) index was positively correlated with the likelihood and severity of NAFLD. The TyG index is generally considered a biomarker of steatosis, while its causal role in the judgement of fibrosis progression remains unclear [25,26]. In addition, the hepatic steatosis index (HSI) is more accurate in discriminating between MAFLD and nonfatty liver disease (non-FLD) than ultrasound. The predictive ability of the CAP for steatosis is superior to that of the HSI, and the HSI is more effective at discriminating patients with moderate-to-severe disease [18,27].

Studies have shown that numerous anthropometric indicators, such as BMI, waist-height ratio (WHtR), waist-hip ratio, and body adiposity index, are applicable for the quantification of visceral steatosis [28-32]. Body fat scales, a new popular domestic tool for health analysis, can be used to analyze basic parameters of body conditions such as the basal metabolic rate (BMR), body water distribution, and fat distribution. Reputable experts in the field have conducted extensive long-term studies on NAFLD and MAFLD, yet few noninvasive scoring models that accurately reflect disease activity or progression have been identified [33,34].

Therefore, there is an urgent need to identify more accurate predictive indicators and develop new screening methods for early MAFLD screening. The aim of this study was to construct a noninvasive prediction system for MAFLD, explore this new system for early screening in public, and establish a home-based tool for regular self-assessment and monitoring of MAFLD.

Methods

Study Population

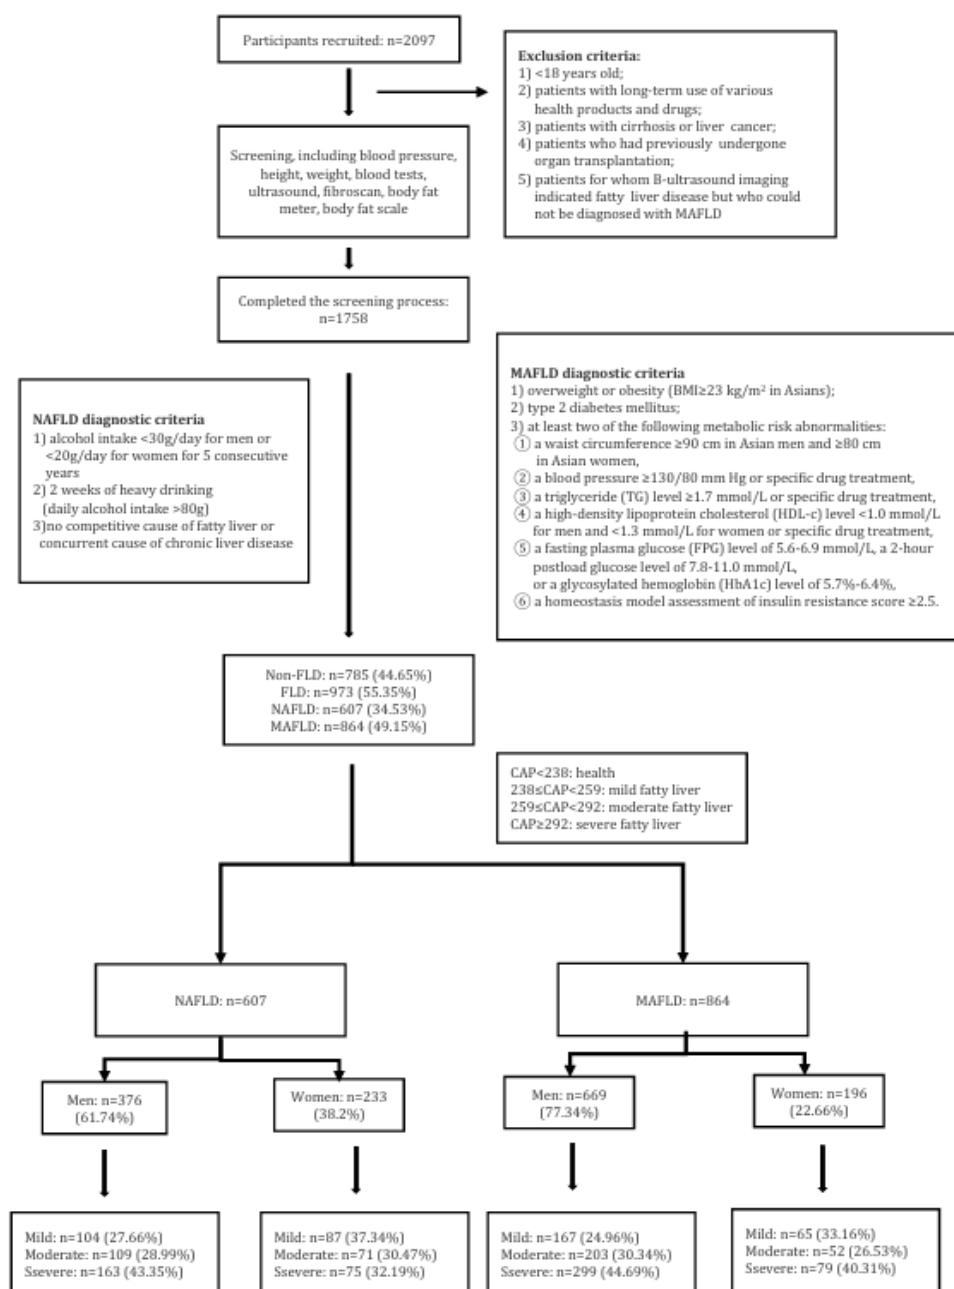
The participants came from Hangzhou, Shaoxing, and Quzhou from March 2021 to November 2021, and a total of 2097 participants were enrolled (Figure 1). All participants signed the informed consent form and completed the examination as required. There were 1758 eligible participants in the training set who truthfully and completely answered the questionnaire, which contained items regarding height, weight, drinking history, past medical history, and other basic information.

To validate the results of the training set, there were 200 eligible participants grouped into the testing set.

All participants were diagnosed using the liver stiffness measurement and classified according to the CAP. CA*P* values <238 was considered to indicate a healthy liver, ≥238 and <259 was considered to indicate mildly fatty liver, ≥259 and <292 was considered to indicate moderately fatty liver, and ≥292 was considered to indicate severely fatty liver [35,36].

XSL•FO

RenderX

Figure 1. Flowchart of the inclusion process for the participants in the training set and the proportion of mild, moderate, and severe fatty liver disease in the nonalcoholic fatty liver disease (NAFLD) group and metabolically associated fatty liver disease (MAFLD) group. CAP: controlled attenuation parameter; FLD: fatty liver disease.


Exclusion Criteria

Patients who met one or more of the following criteria could not participate in this study: (1) <18 years old; (2) long-term use of various health products and drugs; (3) presence of cirrhosis or liver cancer; (4) previous organ transplantation; and (5) patients for whom B-ultrasound imaging indicated FLD but who could not be diagnosed with MAFLD.

Diagnostic Criteria

The researchers in this study entered and organized the data, and the following diagnostic criteria were used to distinguish MAFLD patients [3]: (1) overweight or obese (BMI ≥23 kg/m^2 in Asians), (2) presence of type 2 diabetes mellitus, and (3) at least 2 of the following metabolic risk abnormalities: waist

circumference ≥90 cm in Asian men and ≥80 cm in Asian women; blood pressure ≥130/80 mm Hg or specific drug treatment; triglyceride (TG) level ≥1.7 mmol/L or specific drug treatment; high-density lipoprotein cholesterol (HDL-c) level <1.0 mmol/L for men and <1.3 mmol/L for women or specific drug treatment; fasting plasma glucose (FPG) level of 5.6 mmol/L to 6.9 mmol/L, 2-hour postload glucose level of 7.8 mmol/L to 11.0 mmol/L, or glycosylated hemoglobin level of 5.7% to 6.4%; and homeostasis model assessment of insulin resistance score ≥2.5.

Data Collection and Model Selection

All items were completed under the guidance of the researchers. The participants underwent fasting blood tests. Waist circumference and hip circumference were measured with the

participants wearing thin clothes. Body composition analysis was performed with bare feet. The patients were in a supine position during the FibroScan exam, and the right upper limb was held high and flat close to the ear. The probe was moved a small distance from the anchor point so that the most suitable detection point could be determined.

We collected basic information, including sex, age, height, weight, BMI, waist circumference, hip circumference, blood pressure, heart rate, and alcohol consumption history. The following laboratory results were included: alanine aminotransferase (ALT), aspartate aminotransferase (AST), glutamyl transpeptidase (GGT), alkaline phosphatase, hemoglobin, total cholesterol (TC), TG, HDL-c, low-density lipoprotein cholesterol (LDL-c), uric acid, and FPG levels, as well as white blood cell, red blood cell, and platelet (PLT) counts.

A body composition analyzer (InBody770, Biospace) was used to measure body composition and determine total body water (TBW), intracellular water, skeletal muscle mass, protein, and body fat mass (BFM). A body fat scale (3 Pro, Huawei) was used to determine the BMR, fat%, and visceral fat area (VFA).

The models or formulas involved in this study, including BMI, FIB-4 index, Forns index score, APRI, glutamyl transpeptidase-to-platelet ratio index (GPR), HSI, and TyG index, were developed using the following standard equations:

$$BMI=weight/height^2$$

$$FIB\text{-}4=age \times AST/(PLT \times \sqrt{ALT})$$

$$Forns\ index\ score=7.811-3.131 \times In\ PLT(109/L)+0.781 \times In\ GGT+3.467 \times In\ age-0.014 \times TC$$

$$APRI=(AST/upper\ limit\ of\ normal)/PLT \times 100$$

$$glutamyl\ transpeptidase\text{-}to\text{-}platelet\ ratio\ index=(GGT/upper\ limit\ of\ normal)/PLT \times 100$$

$$HSI=8 \times (ALT/AST)+BMI\ (female+2,\ diabetes+2)$$

$$TyG=ln\ (TG \times FPG/2)$$

Statistical Analysis Methods

Participants were divided into the non-FLD group, which was the healthy group; MAFLD group; and NAFLD group.

All data obtained in this study were analyzed using SPSS version 26.0 (IBM Corp). The continuous variables were tested for normality and homogeneity of variance. A *t* test was performed for measurement data that followed a normal distribution, and the results are expressed as the mean (SD). Nonnormally distributed data were analyzed using nonparametric tests, and the results are represented by quartiles. The chi-square test or Fisher precision probability test was used for quantitative data such as sex. ANOVA was followed by post hoc analysis tests

to compare numerical data among the 3 groups (MAFLD, NAFLD, and non-FLD). A *P*<.01 indicated that the difference was statistically significant.

Binary logistic regression analysis was performed to explore the potential anthropometric indicators with predictive ability to screen for MAFLD. A receiver operating characteristic (ROC) curve was drawn based on the selected indicators, and the area under the ROC curve (AUC) was calculated correspondingly. The indicator with the highest AUC was considered the most valuable indicator. The maximum Youden index (using the formula sensitivity + specificity - 1) was used to define the optimal cutoff value. Potential confounding variables were added into the logistic regression equation step by step, including age; blood pressure; and FPG, TC, TG, HDL-c, and LDL-c levels. Calibration Model I (age, blood pressure, and FPG level were added to the logistic regression equation) and Model II (age; blood pressure; and FPG, TC, TG, HDL-c, and LDL-c levels were added to the logistic regression equation) were established, and the predictive ability was evaluated before and after calibration. All significant indicators were included for the combination of diagnostic tests, and ROC curves were drawn. A new prediction model, the MAFLD Screening Index (MFSI), was constructed using logistic regression analysis, and the model was validated with the testing set. All tests were 2-tailed, and *P*<.01 was considered statistically significant.

Ethical Considerations

Every participant signed a written informed consent form and participated in the study anonymously. We ensured it was not possible to identify individual participants in any images used in manuscripts or other materials.

Every participant was given an allowance of ¥300 (US $0.14) upon completion of the research project. The study protocol was approved by the Ethics Committee of Shulan Hangzhou Hospital (approval number KY2021001).

The study did not involve additional invasive procedures, and there were no associated adverse reactions.

Results

Comparing Numerical Data Among the 3 Groups (MAFLD, NAFLD, and Non-FLD)

Using ANOVA to compare the basic information and anthropometric indicators among the 3 groups, the results showed that all parameters were significantly different among the MAFLD, NAFLD, and non-FLD groups. After the post hoc analysis, PLT count (*P*=.10) was not significantly different between the MAFLD and non-FLD groups, and white blood cell count (*P*=.26), TC (*P*=.35), LDL-c (*P*=.11), VFA (*P*=.07), and Fat% (*P*=.38) were not significantly different between the MAFLD and NAFLD groups (Table 1).

Predictive Performance of Different Anthropometric Indicators

The variables in the previous section with a *P*<.01 were further included in the logistic regression analysis. The ROC curves and optimal cutoff points for the selected indicators are shown in Table 2 and Figure 2. The AUCs of the WHtR, the Forns index, the HSI, the TyG index, TBW, BFM, and BMR were 0.866, 0.684, 0.873, 0.835, 0.760, 0.842, and 0.778, respectively (*P*<.001; Table 2).

**Table 2.** Cutoff points and areas under the curve (AUCs) were used to demonstrate the screening ability of the different anthropometric indicators for metabolically associated fatty liver disease (n=1649).

Anthropometric indicators	AUC (95% CI)	P value	Cutoff point	Specificity (%)	Sensitivity (%)

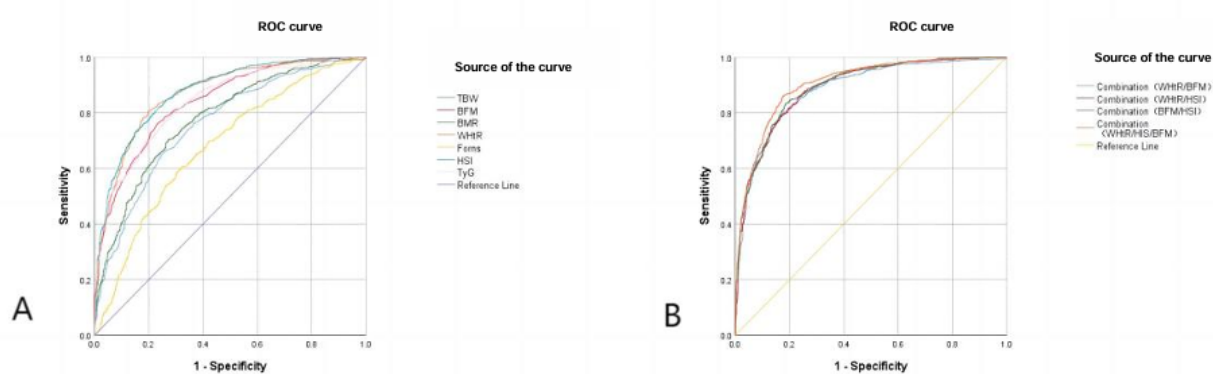
Figure 2. Receiver operating characteristic (ROC) curves for the screening ability of different anthropometric indicators for metabolically associated fatty liver disease (MAFLD): (A) screening ability of the waist-height ratio (WHtR), Frons index, hepatic steatosis index (HSI), triglyceride glucose (TyG) index, total body water (TBW), body fat mass (BFM), basal metabolic rate (BMR) and (B) screening ability of combinations of WHtR, HSI, and BFM. Diagonal segments were produced by ties.


According to the ROC curve and AUC (Figure 2), HSI had the strongest predictive performance for MAFLD in the training set, and the performance ranking was as follows: HSI, WHtR, BFM, TyG index, TBW, and Forns index. The confounding factors were further corrected for in the logistic regression analysis (Model I: age, blood pressure, and FPG level were added to the logistic regression equation; Model II: age; blood pressure; and FPG, TC, TG, HDL-c, and LDL-c levels were added to the logistic regression equation). After correction for confounding factors, the odds ratio (OR) of the Forns index in Model I was 1.043 (95% CI 0.851-1.277), and that in Model II was 1.050 (95% CI 0.854-1.293; Table 3). The results showed

that the performance of the Forns index for MAFLD screening was unstable and the performance of other anthropometric indicators was not easily influenced by confounders.

The HSI and WHtR showed better predictive performance than the other indicators. The sensitivity of the HSI was higher than that of the other anthropometric indicators (sensitivity=81.4%), and the specificity of the WHtR was higher than that of the other anthropometric indicators (specificity=79.8%). The combination of WHtR, HSI, and BFM increased the predictive ability for MAFLD, and the AUC was 0.900 (specificity=81.8%, sensitivity=85.6%; P<.001; Table 2).

Table 3. Confounders were corrected in the binary logistic regression analysis to compare changes in screening power for different anthropometric indicators (n=1649).

Anthropometric indicators	Nonadjusted model		Model I		Model II	
	OR[a] (95% CI)	*P* value	OR (95% CI)	*P* value	OR (95% CI)	*P* value
TBW[b] (kg)	1.079 (1.051-1.109)	<.001	1.086 (1.055-1.118)	<.001	1.075 (1.042-1.108)	<.001

Development of a New MAFLD Screening Model

The HSI, WHtR, and BFM displayed strong power in screening for MAFLD. The HSI was calculated based on BMI, ALT levels, and AST levels and was not suitable for early screening for MAFLD. The purpose of establishing a new model was to reduce the need for invasive procedures and reduce the frequency of medical visits, as well as to screen for MAFLD in high-risk populations. The predictive ability of TBW was stable after correcting for confounders (Model I: 95% CI 1.055-1.118; Model II: 95% CI 1.042-1.108; Table 3). Therefore, TBW was included in the new model. Logistic regression analysis was used to establish the MAFLD early screening model, which was named the MFSI. The formula was as follows: MFSI=−13.968+0.120×TBW+0.254×BFM+10.793×WHtR (Figure 3). The AUC of the MFSI was 0.896 (specificity: 83.8%, sensitivity: 82.1%; *P*<.001; Table 4). Collectively, the performance of the MFSI and the WHtR/HSI/BFM combination models was similar.

Performance of the MFSI in the Testing Set

There were a further 200 participants enrolled in the testing set, including 51 non-FLD patients and 149 MAFLD patients. To evaluate the predictive ability of the MFSI for screening for MAFLD in a high-risk population, the MFSI was used with the testing set, and ROC curves were drawn based on the MFSI; BFM; WHtR; HSI; TBW; and the combined model with WHtR,

HSI, and BFM (Figure 4). The AUC (testing set) of the MFSI was 0.917, the specificity was 89.8%, and the sensitivity was 84.4%. The AUC (testing set) of the combined model with WHtR, HSI, and BFM was 0.920, the specificity was 89.8%, and the sensitivity was 81.6% (Table 5). The performance of the MFSI was similar to that of the combined model with WHtR, HSI, and BFM in the testing set.

Figure 4. Receiver operating characteristic (ROC) curves for the screening ability of different anthropometric indicators and metabolically associated fatty liver disease screening index (MFSI) in the testing set. Diagonal segments were produced by ties. BFM: body fat mass; HSI: hepatic steatosis index; TBW: total body water; WHtR: waist-height ratio.

Table 5. Areas under the curve (AUCs) were used to compare the ability of the different anthropometric indicators and the metabolically associated fatty liver disease (MAFLD) screening index (MFSI) to screen for MAFLD in the testing set (n=200).

MAFLD Rating Table for Prediction of MAFLD

The scoring system based on the MFSI and the application program was more practical for patient self-assessment. The

MAFLD Rating Table (MRT) also included TBW, BFM, and WHtR. An MRT score ranging from 0 to 2 indicated a healthy individual, and a score ≥3 indicated MAFLD (Table 6). The

AUC of the MRT for MAFLD prediction was 0.876 ($P<.001$; Figure 5).

Figure 5. Receiver operating characteristic (ROC) curves of the correlation between the metabolically associated fatty liver disease (MAFLD) Rating Table (MRT) and MAFLD. Diagonal segments were produced by ties.
Discussion

WHtR, BFM, and TBW were predictors of MAFLD. The AUC of the WHtR was 0.866 (specificity=79.8%, sensitivity=80.8%), the AUC of BFM was 0.842 (specificity=76.9%, sensitivity=76.2%), and the AUC of TBW was 0.760 (specificity=75.3%, sensitivity=65.3%). The novel MFSI model, derived through logistic regression analysis, included the WHtR, BFM, and TBW. Notably, the MFSI demonstrated independence from laboratory findings. Upon validation, the MFSI exhibited stability while offering advantages in terms of sensitivity and specificity for MAFLD screening (training set: AUC=0.896, specificity=83.8%, sensitivity=82.1%; testing set: AUC=0.917, specificity=89.8%, sensitivity=84.4%).

Researchers found that the measurement of visceral fat can predict the occurrence of chronic diseases, such as diabetes, hyperuricemia, and metabolic syndrome [37,38]. NAFLD and MAFLD affect more than 25% of the global population and are considered different stages of the disease course. Because of long-term subtle inflammation and unobvious clinical manifestations, some patients gradually develop liver fibrosis and cirrhosis [1]. It is important to raise awareness within the population and optimize the management of this disease.

In recent decades, researchers have considered that the APRI, FIB-4 index, BMI, HSI, and TyG index have high accuracy for the diagnosis of liver fibrosis. Nonfibrosis scores were higher in patients with MAFLD than in those with NAFLD [11,39-42]. Similar conclusions were drawn in this work. To distinguish patients with MAFLD in our study population, we compared traditional indicators and body composition between the MAFLD and non-FLD groups and found there was a significant difference between the 2 groups. Although traditional indicators had efficient performance for the prediction of liver fibrosis, it was doubtful that these indicators were robust for the screening of MAFLD before being confirmed by histological liver examination. Previously published work mainly focused on the predictive ability of indicators for the detection of liver fibrosis,

while much work omitted the performance of these indicators for the early screening of MAFLD.

Lee et al [27] suggested a new indicator named the HSI, and they found that NAFLD cannot be diagnosed when the HSI was <30.0, with a sensitivity of 92.5% (95% CI 91.4-93.5) The HSI showed similar performance for MAFLD diagnosis in this study. Italian researchers proposed another new indicator, the fatty liver index (FLI), which is calculated based on waist circumference, BMI, TG levels, and GGT levels. When the FLI is <30, a diagnosis of FLD can be ruled out, and when the FLI is ≥60, patients can be diagnosed with FLD. Waist circumference and BMI are the most robust predictors for the screening of FLD [43]. In contrast to the HSI, the FLI was established by incorporating waist circumference. However, BMI and waist circumference are totally different for people with varied dietary habits, and the study did not take this into account. Zheng et al [44] found that the WHtR had great performance for MAFLD screening, with a sensitivity of 96% and specificity of 64%. In our study, the WHtR showed a sensitivity of 80.8% and specificity of 79.8% for MAFLD screening.

TG and FPG levels are considered 2 pivotal inducers of metabolic syndrome. TGs are produced excessively in the process of fat accumulation, and insulin resistance accelerates hepatic steatosis. The TyG index can be used as a simple alternative marker for the detection of insulin resistance in the diagnostic test combining TG and FPG levels. The prevalence and severity of MAFLD are positively correlated with the TyG index [25,45-47]. The AUC of the TyG index for predicting MAFLD was 0.835 (95% CI 4.560-9.427), which might be valuable for clinical practice.

A meta-analysis revealed that the visceral adiposity index was an independent predictor of MAFLD, which could be used to predict potential morbidity [48]. However, the predictive ability of the visceral adiposity index has not been verified. Wang et al [49] found that nonobese MAFLD patients had higher BFM and VFA values than the healthy population, and most of them had abnormal lipid metabolism. In addition, BFM and VFA were valuable for distinguishing MAFLD patients from nonobese people [49,50]. This conclusion was also confirmed in this study (BFM for the prediction of MAFLD: AUC=0.842, sensitivity=76.2%, specificity=76.9%).

This study aimed to establish a home-based model for early screening of MAFLD to promote disease self-assessment and management. Compared with previously published models that rely heavily on laboratory indicators, our model combined body composition and the WHtR to screen for MAFLD, and the body parameters that were used to build the screening model can be easily obtained using a body fat scale at home. The mobile device software can record specific values and perform calculations.

There were 2 significant advantages of our model: (1) The need for an invasive examination and medical expenditures were reduced; (2) early screening models can provide early warning signs of disease, prompting people to modify diet and exercise or seek medical treatment if necessary; (3) patient-physician interactions were enhanced.

There were also some limitations of our work. First, this study was limited by geographical factors, and regional bias existed. Second, due to ethical considerations, the results in this study cannot be confirmed by histological liver examination. Third, in some villages we went to for recruitment, we were unable to obtain a radiological diagnosis due to manpower, transportation, and other constraints. In addition, it was difficult to follow participants who underwent physical examination in different areas, and reexamination data could not be compared with previous data.

Although our study found that the new MFSI model and MRT were valuable for MAFLD prediction, disease diagnosis still requires experienced clinicians, and those with the disease or at high risk should seek timely medical attention.

Abstract

Background: Previous research and safety advocacy groups have proposed various behaviors for older adults to actively engage in medication safety. However, little is known about how older adults perceive the importance and reasonableness of these behaviors in ambulatory settings.

Objective: This study aimed to assess older adults' perceptions of the importance and reasonableness of 8 medication safety behaviors in ambulatory settings and compare their responses with those of younger adults.

Methods: We conducted a survey of 1222 adults in the United States using crowdsourcing to evaluate patient behaviors that may enhance medication safety in community settings. A total of 8 safety behaviors were identified based on the literature, such as bringing medications to office visits, confirming medications at home, managing medication refills, using patient portals, organizing medications, checking medications, getting help, and knowing medications. Respondents were asked about their perception of the importance and reasonableness of these behaviors on a 5-point Likert rating scale in the context of collaboration with primary care providers. We assessed the relative ranking of behaviors in terms of importance and reasonableness and examined the association between these dimensions across age groups using statistical tests.

Results: Of 1222 adult participants, 125 (10.2%) were aged 65 years or older. Most participants were White, college-educated, and had chronic conditions. Older adults rated all 8 behaviors significantly higher in both importance and reasonableness than did younger adults (*P*<.001 for combined behaviors). Confirming medications ranked highest in importance (mean score=3.78) for both age groups while knowing medications ranked highest in reasonableness (mean score=3.68). Using patient portals was ranked lowest in importance (mean score=3.53) and reasonableness (mean score=3.49). There was a significant correlation between the perceived importance and reasonableness of the identified behaviors, with coefficients ranging from 0.436 to 0.543 (all *P*<.001).

Conclusions: Older adults perceived the identified safety behaviors as more important and reasonable than younger adults. However, both age groups considered a behavior highly recommended by professionals as the least important and reasonable. Patient engagement strategies, common and specific to age groups, should be considered to improve medication safety in ambulatory settings.

Introduction

Engagement of older adult patients has been recognized as key to health outcomes including safety [1]. While specific skills and attitudes related to patient engagement have been identified and measured [2,3], there is a lack of clarity regarding the specific roles and responsibilities expected of patients in community settings, where patients and families are responsible for the medication use process. Health care organizations often set implicit expectations regarding the roles and responsibilities of patients and their families in collaborative activities such as planning, implementation, and discourse about their health [4].

The purpose of our study was to use a crowdsourcing approach to investigate individuals' perceptions of the importance and reasonableness of medication safety behaviors across various age groups. We chose patient portal use as a reference for patient engagement behaviors due to extensive efforts by health care organizations and regulators to encourage this behavior. A survey conducted in 2020 showed that more than half of individuals nationwide were offered access to patient portals, with nearly 40% accessing their records [5]. Patients' perspectives on the importance and reasonableness of using portals are important to understand in order to devise interventions to encourage the behavior, such as patients' interest, willingness, and ability [6-8], especially among older adults [9].

Health care professionals are encouraged to guide patients and their families to actively participate in their care by adopting safety behaviors, although little is known about older adults' perspectives on these behaviors and roles within the collaborative process to improve patient engagement in medication safety. By understanding the perspectives of laypeople, we can identify the gaps in engaging patients and family members in medication safety improvements and design interventions that can better meet their needs. Furthermore, understanding the relation between importance and reasonableness in perceiving medication safety behaviors is crucial for health care professionals to tailor their interventions and communication strategies effectively, particularly for older adults, to promote safer medication practices.

The aim of this study is to assess how older adults perceive the importance and reasonableness of 8 medication safety behaviors in ambulatory settings and to compare their responses with those of younger adults.

Methods

Study Design

This cross-sectional study was conducted using a role-playing survey to assess the importance and reasonableness of medication safety behaviors.

Setting

The study was conducted using Amazon Mechanical Turk (MTurk), a crowdsourcing platform, from October to December 2022. Participants completed the survey online. This approach allowed us to efficiently gather data from a large group of participants [10].

Participants

Our study limited participants to US adults (≥18 years old) who had established a strong reputation on MTurk, defined as completed 100+ tasks with at least 95% approval ratings [11]. This choice leverages the acknowledged representativeness of US MTurk samples for diverse psychological dimensions [12] while ensuring engaged and reliable participation, as users with good reputations are generally more motivated and provide accurate data [13]. We used the Software Platform for Human Interaction Experiments (SoPHIE; SoPHIELabs) to administer the surveys. Participants were screened for eligibility through SoPHIE and were required to read and sign a consent form before participating. Qualified participants were given an online consent form, where they expressed their voluntary agreement to participate by clicking on the "Continue" button on their computer screen.

Assessments

Participants were asked to envision themselves as older adults, retired individuals living alone with multiple health conditions (detailed instructions in Figure S1 in Multimedia Appendix 1). To identify safety behaviors in managing medication use in ambulatory settings, we reviewed literature and recommendations from safety organizations to represent professionals' views on what patients should do to contribute to medication safety. For example, 1 study targeted behaviors associated with an office visit for patient engagement, including writing out a list of medications or bringing medications to visit [14]. In our survey, we defined the "importance" of a behavior as the extent to which all patients and families should adopt it for medication safety. "Reasonableness" was judged based on the assumption that following a treatment regimen makes sense if it leads to better health outcomes [15].

Study Survey

This study used a carefully developed survey instrument. Initial pilot studies, with 14 closed-ended questions, assessed medication safety behaviors. Based on feedback from

participants and experts, the survey was refined and consolidated for clarity and focus, resulting in a final 8-item instrument (Table 1). Throughout pilot testing, we iteratively evaluated the content validity of the questions against existing literature and organizational recommendations in medication safety. While patient involvement in developing the criteria and indicators was not direct, they were informed by a comprehensive review of relevant literature, safety advocacy group recommendations, and expert consensus in the field. Safe self-administration of medication heavily relies on patients' knowledge about their treatments [16], their purpose, proper usage instructions, identifying and reporting adverse effects, obtaining refills, and effectively communicating any issues related to their prescribed medications with their health care provider. While the 8 behaviors specified in this study are not exhaustive, they encompass these crucial components and are presented for ease of understanding and application.

Table 1. Targeted patient behaviors in medication safety used in the survey.

Medication safety behaviors	Examples provided to participants	Justifications and references
Bring medications		
Patients are expected to bring all medications and all relevant health-related documents to their health care provider office visits.	Collect all medicine bottles, including those over the counter such as Tylenol and vitamins, and bring them with you to the health care provider's office. Make sure to also bring documents such as medication lists and blood sugar and blood pressure logs (if asked to keep one).	• The FDA[a] recommends keeping a list of all medications (prescribed and over the counter) and bringing it to all doctors' appointments [17]. • Although often encouraged by primary care providers [18,19]. • Only about 20%-40% of the patients bring in their medications or medication list. • Medication reviews lack standardization which can result in increased mortality, morbidity, and poor patient outcomes [20,21].
Confirm medications		
Patients will verify any changes in their medications after each provider's visit.	You have been taking 20 mg of Simvastatin every day for cholesterol for a long time. In the last visit, your cholesterol level has decreased. Your provider reduced the medication dose to 10 mg. You make this change on your personal medication list.	• FDA recommends to verify the medication list at least once a year or any time there is a change [17]. • Medication discrepancies are very common among patients with chronic conditions, especially those who require frequent hospitalizations or see numerous providers [22,23].
Refill system		
Patients will establish a refill system.	Your provider advised you to call the pharmacy when you are about to run out of refills, and not their office. The pharmacy will contact the provider's office for refill prescriptions. Using two 7-day pill boxes allows you to know 2 weeks in advance when a medicine will run out.	• Current recommendations are to address all refill needs during the provider's visit and send all prescriptions ideally to one pharmacy only in order to prevent gaps in medication therapies in chronic care due to disruptions and lapses in obtaining refills timely. Innovative systems use technological advances; however, older patients and individuals who speak English as a second language are less likely to use technology to refill medications [24-28].
Use portals		
Using patient health care portals.	Your provider's office sent you a link for creating an account to access the patient portal website. After you sign up, you can use the portal to communicate with your provider and access your health information.	• Patient portals were intended to improve the communication between the health care team and patients. They allow patients to be actively involved in their care, access their medical records, verify for accuracy, report concerns, and seek medical advice or medication refill [6,8,29-31].
Organize medications		
Using pill dispensers and other organizer tools.	Pill boxes are effective tools to remind you when and what medicines to take. You may also set reminders on your phone. To-go boxes are convenient to carry in your bag or purse when you are out, running errands. Charts, calendars, and electronic pill boxes are other ways of organizing medications.	• The importance of having a system to organize medications was extensively studied. A list of memory tips and reminder systems (such as daily pillbox, calendar, or chart) to help organize scheduled prescriptions are available on various online resources [32-35].
Check medications		
Verifying medications for duplicates and expired medications.	The mail-order pharmacy sends you your refills automatically, so they always arrive before you run out of it. You know how to check the medicines against your list, as the color of the pills and names of medications (eg, generic vs brand name) may change from time to time, and you do not want to take duplicate medicines. You also dispose of expired medicines, so you do not accidentally take them.	• The FDA and NIH[b] recommend that patients check all medications for expiration dates. Ingesting expired medications may pose significant health hazards [17,36].
Medication awareness		

Medication safety behaviors	Examples provided to participants	Justifications and references
Accessing resources pertaining to medication-related issues.	You went to the pharmacy to pick up a prescription, but they did not have it. To clarify the situation, you call your provider's office to inquire if you are still supposed to take the medication and verify the correct pharmacy on file. In another situation, you may need to call the pharmacist or the provider to find out what you need to do if you accidentally doubled your heart medicine.	• The World Health Organization recommends that patients learn to identify and report any issues or side effects pertaining to taking medication [17,36].
Know medications		
Have basic knowledge about medications.	When you look at your medicine bottle, you are able to locate the medicine name, dose, when and how to take this medicine, how many refills are left, expiration date, and telephone number to call if you have questions about this medicine. For instance, you are prescribed to take a round white pill twice a day for high blood pressure. You wrote the name ("metoprolol") on the medication list. You know to take 1 pill in the morning and 1 pill in the evening. You also know that you should take the pill with food. Symptoms to watch for are lightheadedness or very slow heartbeats.	• Patients are advised to read carefully all information provided with the medications such as package inserts and pharmacy instructions. As many as an estimated 87% of patients do not read these instructions. Health illiteracy continues to be a challenge. Patients who are younger and have a higher formal education are more likely to have an adequate knowledge of medications [35,37-39].

[a]FDA: US Food and Drug Administration.

[b]NIH: National Institutes of Health.

Data Sources

Participants were asked to rate their perceptions of these behaviors in terms of importance and reasonableness on a 5-point Likert scale, with response categories of 1 (strongly disagree), 2 (disagree), 3 (neither agree nor disagree), 4 (agree), and 5 (strongly agree). After completing the survey, participants were asked to provide their demographic information (age, sex, race, ethnicity, education, and income) and number of chronic medical conditions.

Study Size

The study size was determined by targeting a minimum of 1000 participants to ensure sufficient power to detect differences between age groups. This target was based on previous studies in the field that used similar methodologies and sample sizes to achieve robust statistical power and generalizability of findings [40,41]. We received 1222 completed surveys, achieving a completion rate of 94.5%, of the total 1293 attempts.

Data Analysis

Statistical analyses were performed using Stata software (version 17; StataCorp). Differences in importance and reasonableness between 2 age groups (younger than 65 years and 65 years or older) were assessed by the Wilcoxon rank-sum tests. The associations between importance and reasonableness were assessed by the Pearson correlation coefficient. Disagreement was assessed by differences in ratings of reasonableness and importance scores for the same behavior by the same participant, with serious disagreement defined as a difference of 3 or more points. For ordered logistic regression models, the outcome variables were the perceived importance and reasonableness of the 8 medication safety behaviors, while the independent variables included age group, sex, ethnicity, education, income, and the number of chronic medical conditions. Each model used only 1 independent variable at a time to assess its individual impact on the outcome. Subgroup analyses with ordered logistic regression based on sex, ethnicity, education, income, and chronic medical conditions were conducted to understand how various factors influenced age-related perceptions of the 8 health behaviors.

Ethical Considerations

Human Participant Ethics Review Approvals or Exemptions

This study was approved by the institutional review board (IRB) at the University of Texas at Arlington (protocol 2022-0581). The research involved human participants and adhered to appropriate ethical review and approvals as per institutional guidelines.

Informed Consent

Participants were given an online consent form, detailing the study's purpose, procedures, potential risks, and benefits. They expressed their voluntary agreement to participate by clicking on the "Continue" button on their computer screen. Participants were informed of their ability to opt out of the study at any time without any consequences.

Privacy and Confidentiality

All data collected were anonymized to protect the privacy and confidentiality of participants. No personally identifiable information was collected. Data were stored securely on password-protected servers, and only the research team had access to the anonymized data set.

Compensation Details

Participants were compensated for their time and effort. Each participant received US $0.25 for completing the survey, which is a standard compensation rate for similar studies conducted on MTurk. This compensation was designed to be fair and transparent, ensuring that participants were adequately reimbursed for their contribution to the research.

Results

We received 1222 completed surveys (completion rate of 94.5%) from a total of 1293 attempts in December 2022. Participants took an average of 3 minutes to complete the survey. The majority of the participants were younger than 65 years, White, held a bachelor's degree, reported an income range of US $40,000-80,000, and had 1 or more chronic conditions (Table 2). Detailed comparisons on sex, race, education, income, and number of chronic conditions are reported in the Multimedia Appendix 1.

Across age groups, "confirming medications" was rated as the most important behavior while "knowing medications" was rated as the most reasonable behavior (Figure 1). In contrast, the behavior of using portals received the lowest scores for both importance and reasonableness. The perceived importance and reasonableness of each behavior were positively correlated ($P<.001$; correlations in Table S1 in Multimedia Appendix 1). Serious disagreements between importance and reasonableness for the 8 behaviors were between 6% and 7.3% among the

participants (Table S2 in Multimedia Appendix 1). In addition, older adult participants reported higher importance and lower reasonableness ratings across the 8 identified behaviors (Multimedia Appendix 2).

Among older adult participants, the behavior of confirming medication was scored highest in importance, whereas the younger age participants scored the behavior of bringing medications as highest in importance (Multimedia Appendix 3). Furthermore, among the older adult participants, the behaviors of getting help ($P=.007$) and knowing medications ($P=.03$) were rated as the second and third most important, respectively, and were found to be significantly higher than those rated by younger adult participants.

The behavior of using portals scored lowest in both reasonableness and importance for both age groups. In addition, there was no significant difference in the scoring of this behavior between the 2 age groups. Out of the total, 3 of the remaining behaviors were scored significantly higher by older adult participants than younger adult participants (Multimedia Appendix 3).

Across different age groups, we observed a general negative association between the perceived importance and reasonableness of these behaviors with male, Hispanic or Latino ethnicity, and education levels. Conversely, higher income was associated with a positive perception of importance. In addition, chronic medical conditions were linked to a negative perception of reasonableness. A detailed breakdown of these findings by individual behavior is shown in the Multimedia Appendix 1.

Table 2. Demographics of study participants (n=1222).

Characteristic	<65 years	≥65 years	Proportion test across age groups, *P* value

Figure 1. Perceptions of behaviors in terms of importance and reasonableness (n=1222). Range scale was used.
Discussion

Our study found that older adults perceive a higher importance and reasonableness of medication safety behaviors compared with younger adults. Specifically, confirming medications and knowing medications were rated as the most important and reasonable behaviors across age groups while using patient portals was perceived as the least important and reasonable.

Previous research and safety advocacy organizations have suggested behaviors that patients can adopt to improve medication safety in ambulatory settings. Figure 1 provides an overview of participants' perceptions of each behavior in terms of importance and reasonableness. Despite advocacy from policy makers and professional organizations for patient portal usage [6,42], the results show that it is perceived as the least reasonable and important behavior across age groups. This could be due to a perceived disconnection between portals and medication-related safety, although our study did not directly explore this link. It is important to note that the survey question about patient portal usage did not explicitly link its use to performing other medication safety behaviors, which may have influenced participants' perceptions. Nonetheless, the discrepancy highlights the importance of understanding patients' perspectives in shaping policy and clinical practices.

Conversely, the behaviors of confirming medications and knowing medications received the highest scores in terms of both importance and reasonableness. These findings emphasize the significance of these behaviors in patient engagement and medication safety efforts. Health care providers should recognize the value placed by patients on these aspects of medication management and incorporate discussions and interventions related to these behaviors into clinical practice.

Our analysis also revealed a strong correlation between reasonableness and importance for all behaviors among participants. This suggests that intervention strategies may consider targeting efforts to explain the importance and values of these behaviors. This aligns with a cost-benefit thinking approach, where something is considered reasonable when its benefits (ie, importance) are perceived as higher than the efforts required [43]. By emphasizing the benefits of engaging in medication safety practices, health care providers can encourage patients to adopt these behaviors more effectively.

Our results suggested that older adults may be more cognizant of and experienced with health issues, making them more willing to expend effort to carry out the identified behaviors. Further research is needed to understand the reasons behind this observed difference in scores between the 2 age groups.

Our study has several limitations. While role-playing experiments are widely used in marketing science and health care [10,44], the online platform used in the study, MTurk, may introduce biases in the sample population [45]. Consequently, the perspectives of our participants may not fully represent the broader demographic, particularly older adults, in terms of sex, race, education level, and chronic conditions. Furthermore, the underrepresentation of participants older than 65 years (10% vs 17% in the US population) could limit the generalizability of our findings. However, we mitigated this by analyzing participants older than 65 years separately from those younger than 65 years, allowing us to explore differences in perceptions of medication safety behaviors between these distinct age groups.

In addition, it is important to recognize the complexity inherent in assessing perceptions of importance, particularly across diverse demographic groups. While our study aimed to capture patient perspectives on medication safety behaviors, the construct of importance is multifaceted and may be influenced by individual experiences, beliefs, and priorities. This highlights the potential for bias in responses when using a single age frame,

particularly for younger participants who might underestimate the capabilities and perspectives of older adults.

Furthermore, the survey question about patient portal usage did not explicitly link its use to performing other medication safety behaviors, which may have influenced participants' perceptions. The lack of context regarding the comprehensive use of patient portals could have impacted the ratings given by participants, thus presenting a limitation in accurately assessing the perceived importance and reasonableness of using patient portals.

Future research should consider using alternative sampling methods, such as stratified sampling or oversampling of underrepresented groups, to ensure greater representativeness in the sample. Conducting similar studies with a purposive sampling strategy could provide a more comprehensive understanding of patient perceptions of medication safety behaviors across diverse demographic groups, including older adults with multiple chronic conditions. Given the study's limited scope, qualitative components were not integrated into the survey. Subsequent studies should encompass qualitative interviews with a spectrum of individuals, both laypersons and professionals. Furthermore, careful consideration should be given to the age-related framing of survey questions. Using age-specific framing tailored to different groups, such as presenting scenarios relevant to their age experiences, could minimize bias and provide more accurate insights into participant perceptions and behaviors across various age ranges, ultimately leading to findings with greater validity and generalizability.

Conclusion

Our study found that older adults perceive higher importance of a set of safety medication behaviors and see these behaviors as more reasonable to perform than younger adults. Using portals is generally perceived lower in importance and reasonableness by patients in ambulatory settings when compared with other medication safety behaviors, such as bringing medications to clinic visits. Future studies should explore additional factors influencing patient engagement in medication safety behaviors including social determinants of health. Longitudinal studies are needed to understand how improvement efforts can take advantage of patient perspectives on medication safety to design interventions to encourage the adoption of specific behaviors.

Data Availability

All data generated or analyzed during this study are included in this published paper and its supplementary information files.

Conflicts of Interest

As per the University of Texas at Arlington policy, the following statement is included. K-YC has a potential research conflict of interest due to a financial interest with companies Hewlett-Packard Enterprise, Boostr, and DecisionNext. A management plan has been created to preserve objectivity in research in accordance with the University of Texas at Arlington policy. All other authors had neither competing financial interests nor other potential conflicts of interest.

Abstract

Background: Home medication management has been insufficiently studied, including the factors that impact the development and effectiveness of adherence strategies under both routine and anomalous circumstances. Older adults are a particularly important population to study due to the greater likelihood of taking medication in combination with the desire to "age in place."

Objective: This interview study aims to understand how older adults develop medication management strategies, identify when and why such strategies succeed or fail, learn more about how older adults think about their medication, and explore interventions that increase medication adherence.

Methods: This study used a qualitative, semistructured interview design to elicit older adults' experiences with home medication management. Overall, 22 participants aged ≥50 years taking 1 to 3 prescription medications were recruited and interviewed. Interview responses were recorded, and thematic, qualitative analysis was performed by reviewing recordings and identifying recurring patterns and themes. Responses were systematically coded, which not only facilitated the identification of these themes but also allowed us to quantify the prevalence of behaviors and perceptions, providing a robust understanding of medication management and medication adherence.

Results: Participants reported developing home medication management strategies on their own, with none of the participants receiving guidance from health care providers and 59% (13/22) of the participants using trial and error. The strategies developed by study participants were all unique and generally encompassed prescription medication and vitamins or supplements, with no demarcation between what was prescribed or recommended by a physician and what they selected independently. Participants thought about their medications by their chemical name (10/22, 45%), by the appearance of the pill (8/22, 36%), by the medication's purpose (2/22, 9%), or by the medication's generic name (2/22, 9%). Pill cases (17/22, 77%) were more popular than prescription bottles (5/22, 23%) for storage of daily medication. Most participants (19/22, 86%) stored their pill cases or prescription bottles in visible locations in the home, and those using pill cases varied in their refill routines. Participants used ≥2 routines or objects as triggers to take their medication. Nonadherence was associated with a disruption to their routine. Finally, only 14% (3/22) of the participants used a time-based reminder or alarm, and none of the participants used a medication adherence device or app.

Conclusions: Participants in our study varied considerably in their home medication management strategies and developed unique routines to remember to take their medication as well as to refill their pill cases. To reduce trial and error in establishing a strategy, there are opportunities for physicians and pharmacists to provide adherence guidance to older adults. To minimize the impact of disruptions on adherence, there are opportunities to develop more durable strategies and to design aids to medication adherence that leverage established daily routines.

KEYWORDS

Introduction

Background

Medication adherence—defined as taking medication as agreed with one's prescriber—is a crucial part of aging well. Studies have shown that ≥50% of US adults do not take their prescriptions as directed and that medication nonadherence is responsible for as many as 33% to 69% of hospital admissions and 125,000 deaths annually [1-3]. The World Health Organization emphasizes the importance of medication adherence, stating that "[i]ncreasing the effectiveness of adherence interventions may have a far greater impact on the health of the population than any improvement in specific medical treatment" [4].

There is a rising rate of medication nonadherence across all ages, sex, and race groups in the United States [5]. The greatest concern, however, is for older adults. According to population estimates by the United Nations World Population Prospects report, 1 in every 4 persons will be aged ≥65 years by 2050 in Europe and Northern America [6]. This represents a doubling in the older adult population—approximately 9% in 2019 to an estimated 16% in 2050. Aging populations require consistent medication adherence for health maintenance; approximately 67% of US adults aged 45 to 64 years take at least 1 prescription drug, and this figure rises to 88.5% for those aged ≥65 years [7].

Older adults are underrepresented in research on medication adherence and may face some unique barriers compared to the average population [8,9]. There is a consistently strong preference to "age in place" by older populations, preferring to remain within communities instead of institutional care [10]. However, home settings are associated with medication nonadherence [8,11]. Identifying barriers to medication adherence related to home medication management, specifically related to unintentional nonadherence, may lead to successful strategies to aid older adults who wish to age in place [12]. Forgetting to take medication is one of the most common contributors to unintentional medication nonadherence and is particularly relevant for older adults desiring to live independently [12].

Many interventions have been designed to aid in individual medication adherence, generally specific to a disease or treatment. Innovation in general prescription packaging, distribution, and education has been limited. Some innovations in container, labeling, and package design include blister packs, PillPack, and a variety of adherence devices ranging from digital pill containers to dispensing devices [13-16]. Studies have shown limitations to many of these innovations, particularly in their design and usability. These innovations have also had limited commercial success. Overall, no substantial impact on adherence has resulted from the use of simple adherence devices [17,18]. More than 700 medication adherence apps exist, but users often report technical difficulties such as schedule inflexibility because many do not take, or need to take, their medication at an exact time, as well as notification fatigue from daily timed reminders to take their medication [19,20]. Therefore, innovation in containers, packaging, devices, and apps represents potential targets for improvement of adherence [21-24].

Another way to improve medication adherence is counseling patients on home medication management practices [25]. Health care providers can play an efficacious role in encouraging behaviors to support adherence, especially ones tailored to patients' medication regimens and needs [20,26]. External influences such as reduced time for medical appointments and the increased use of mail delivery of prescriptions, necessitating fewer pharmacy visits, reduce opportunities for medication adherence guidance from physicians or pharmacists, respectively.

Medication adherence often relies on the development of a behavior that is repeated in response to triggers and fits into a routine [27]. Triggers are actions that are taken or objects that are encountered that can help patients remember to take their medication. Habit formation is a main determinant of behavior change but can take trial and error to be established, especially when no guidance is provided by a health care provider or suggested from past caregiving experience [28]. Selection of triggers and formation of habits specific to medication management are understudied, especially regarding the factors that may impact the development and sustainability of strategies within the context of both routine and anomalous circumstances.

Objectives

This study aimed to identify home medication management practices used by community-dwelling older adults with simple medication regimens. Specifically, this qualitative study aimed to (1) understand how older adults develop medication management strategies, (2) identify strategies that lead to adherence and when and why such strategies succeed or fail, (3) learn more about how older adults think about their medication, and (4) explore interventions that increase medication adherence.

Methods

Approach

On the basis of the results of a survey [29], we planned an interview study to learn in depth about the medication management experiences of older adults in their homes. Our goal was to better understand how older adults fit medication taking into their daily lives. Hence, our interest was in patients with simple regimens involving 1 to 3 medications because, with more, medication management is a more all-consuming daily task.

We developed an interview guide and semistructured interview process to elicit responses from older adults on their experiences with home medication management, including selection of medication storage location and development of medication-taking routines, to characterize which factors positively influence medication adherence when managing a relatively small number of medications. Many interview questions were based on survey results, which showed what respondents did but did not reveal why or how they made their decisions [29]. Therefore, the interview questions were designed to elicit a richer narrative of how and why home medication

management decisions are made and patients' perceptions about what worked and what did not. The protocol was piloted on Zoom (Zoom Video Communications, Qumu Corporation) with 1 individual in the study demographic to test timing, flow, and wording, and no changes were made. The interview guide is included in Multimedia Appendix 1.

The interview questions were developed to elicit information about how older adults manage their medications in their homes as part of the daily routine and under anomalous circumstances such as travel. Interview questions asked participants to recount their medication routines and were designed to cover the 3 components of adherence—initiation, implementation, and discontinuation—to fully address the stages of adherence [30].

For the initiation phase, participants were asked who prescribed their medications, whether this was during in-person or virtual visits, and if they visited a pharmacy or used mail delivery. Participants were questioned about the extent of their health care provider's counseling or advice on home medication management, including how and where to store prescriptions and how to remember to take them. For the implementation phase, patients were asked about their daily home medication management practices, including how they administer, store, and identify their prescription medications. They were questioned about any vitamins or supplements they take. They were asked about any stigma they experienced about taking medication or about visitors to their home seeing their medication. In addition, participants were questioned about their strategies for ascertaining adherence, including alarms, apps, devices, and assistance from others, and their interest in the use of a medication adherence device that used sensors to alert them only when they forgot to take their medication. This device was described as using the same principle as a seat belt, chiming only when you both forgot to latch it and turn on the ignition in a car. The device was described as using one sensor on the participant's prescription bottle or pill case and another sensor on a coffee pot, toothbrush, or another object related to the participant's daily routine. Finally, in the discontinuation phase, participants were questioned about nonadherence. Demographic questions were asked at the end.

Participants

Participants included older adults recruited in July 2022 through the Osher Lifelong Learning Institute (OLLI) at Tufts University [31]. Participants were recruited through postings in the weekly email newsletter sent to approximately 2000 OLLI members who subscribed. Inclusion criteria were participants aged ≥50 years, taking 1 to 3 prescription medications for chronic conditions (as opposed to taking on a short-term or an as-needed basis), proficient in English, and with no cognitive impairment.

A total of 22 people responded to the recruitment materials using a link in the OLLI newsletter. All the 22 respondents consented to the web form, responded to the email to schedule a time for an interview, and participated in the study. Ages ranged from 56 to 87 (mean 70.5, SD 6.3) years, and 82% (18/22) of the participants identified as female and 18% (4/22) as male. All participants were White, and all had a bachelor's degree or higher educational status. All were community

dwelling, living in a house or apartment alone or with a partner, and all lived in an urban or suburban setting in Greater Boston.

Despite the constraints imposed by a small sample size, data saturation was largely achieved. This was evident by recurring patterns and themes emerging in the responses and the ability to draw meaningful conclusions from our sample.

Semistructured qualitative interviews were conducted with 22 participants during August 2022. The study was conducted during the COVID-19 pandemic, and owing to physical distancing protocols, all interviews were conducted via Zoom teleconferencing software. The duration of each interview was 30 to 45 minutes. Consent to participate was obtained at recruitment, and consent to record the interview was obtained at the start of each interview.

Interview Team

The interviews were conducted by 1 researcher (LG), who had many years of prior experience conducting interviews. Emails were sent to arrange an interview time, and at the start of each interview, participants were told that the purpose of the interview was for a research project on medication adherence and were asked to consent to recording the session. No bias, assumptions, or interests in the topic were reported about the interviewer. Another researcher (MR) attended all sessions but did not conduct any interviews. Both researchers (LG and MR) took informal notes during the sessions. Recorded sessions were transcribed verbatim.

Ethical Considerations

Study protocols were approved by the Tufts University Health Sciences Institutional Review Board (STUDY00002865). All participants consented to participate in the interviews and were told the purpose of the research in the consent form. All participants were asked at the start of the interview if they would consent to recording the interviews, that they would be only identified by a participant number and their names or any identifying information would not be used, that all recordings would be securely stored and erased at the culmination of the research, and that they could skip any question they did not wish to answer. The recordings and all data were identified only by a participant number and were thus deidentified. All participants were compensated with a US $50 Amazon gift card, which was sent to their email address as a way of showing our appreciation for their time. This amount was deemed appropriate for 30 to 45 minutes without being coercive.

Analysis

The transcript analysis aimed to explore and understand the experiences of the participants; therefore, thematic analysis was chosen as the analytic strategy. Thematic analysis is a qualitative descriptive approach that is used to identify, analyze, and report patterns within data and is useful for analyzing narratives [32]. Thematic analysis was performed by 2 researchers reviewing and coding recordings and transcripts. A subset of interview questions, deemed most relevant to uncovering home medication management practices, were coded as part of this analysis.

To initiate the analysis, the researchers reviewed the interview responses to identify prominent themes and noteworthy topics

emerging from the data. After identifying potential areas of interest, a structured list of questions and topics was developed to serve as a preliminary coding framework for the analysis. The researchers independently reviewed the recordings and interview notes to apply the initial coding framework. They engaged in regular meetings to compare their findings and discuss any discrepancies. This collaborative approach ensured consistency and reliability in theme identification. It also allowed for the iterative refinement of the coding scheme through both deductive and inductive methods, as themes were allowed to evolve naturally from the data, while the initial framework provided a guide to maintain focus on the study's aims.

Coding the responses facilitated the identification of significant themes and allowed the research team to quantify the prevalence of behaviors and perceptions, providing a robust understanding of medication management and medication adherence.

Results

Sample Description

Five themes were identified relevant to home medication management strategies. These themes corresponded to the stages of medication adherence: initiation, implementation, and discontinuation.

Theme 1: Participants' Experiences of Obtaining Medications

The first set of interview questions asked participants how their medications were prescribed and obtained. The purpose of these questions was to start the interview with straightforward questions that were simple to answer yet relevant to this research. An additional objective was to ask participants if they received counseling or advice from a physician or pharmacist regarding home management of medication, including where to store them or how to remember to take them.

In response to being asked about who prescribed their medications, how they obtained them, and if any counseling or advice was provided, all the participants obtained prescriptions from their primary care physician or specialist, yet none received guidance from a health care provider about how to devise an effective medication management strategy. More than half of the participants (13/22, 59%) used trial and error to develop a strategy, which included trying different locations in the home or trying a pill case after seeing one in a local pharmacy. Five participants devised a strategy based on experience assisting someone else manage their medication. One participant who devised a strategy based on prior experience stated the following:

> I have managed medications in the past for my mother and aunt, both of whom are deceased, but they had pill cases [which are] pretty common. It seems [like] it's a good organizational tool. I didn't think a whole lot about it [and] went out and got a pill case when I first started having prescriptions. [Participant 13]

The remaining 4 participants devised their medication management strategy using suggestions from a friend or family member.

Approximately half of the participants (10/22, 45%) received prescriptions by mail delivery only, 14% (3/22) of the participants used a combination of mail and pharmacy pickup, and the remaining 41% (9/22) used pharmacy pickup only. All but 1 participant (21/22, 95%) received a 90-day supply of their prescription medication.

Theme 2: Participants' Experiences of Taking Medications at Home

All participants (22/22, 100%) responded to the question, "Can you walk us through your daily schedule for taking your medications, specifically when you take your medications and where you store them?" All participants provided a description of their home management practices, which constituted unique routines. All participants reported on what they used for medication storage and where containers were placed, refill strategies for pill cases, and how they remembered to take their medication.

For medication storage, only 23% (5/22) of the participants kept their medication in the prescription bottles it was received in. Most of the participants (17/22, 77%) used pill cases to store their medication. Of these, there was considerable variance in the type of pill case used, including the number of compartments. Of the 17 participants, 7 (41%) used 1 weekly pill case with 7 compartments. For participants with morning and evening medication, 6% (1/17) used a 14-compartment pill case, while 29% (5/17) used 2 separate pill cases each week. Two participants 12% (2/17) used 2 pill cases each to be able to refill them together for a 2-week medication supply, 1 of them citing the inconvenience of refilling pill cases and the desire to do so as infrequently as possible. Referring to their pill case, one participant describes the following:

> It's kind of a pain to fill so I kind of put it off...but if it's obviously empty [or if] there's maybe one slot to go, I'll say awesome, let's just fill it...I've got some time. [Participant 5]

One participant 6% (1/17) had a separate pill case for each of their medications, and another participant 6% (1/17) used a pill case that stored a 4-day supply of medication.

Most US pill cases are designed with "Sunday" on the left-hand side; hence, we expected participants to have a weekend refill routine; instead, there was variance in when pill cases were refilled and how participants remembered to refill them. Overall, 41% (7/17) of the participants relied on the visual cue of an empty pill case to refill it; however, this method did not typically lead to them refilling their case on the same day every week. One participant stated the following:

> When I get to the point where something is empty, and I say, oh, time to refill. It should be every seven days, but sometimes I might forget. Or I don't know why. But it doesn't always work out to be every seven days. But anyway, whenever they're empty, then they need to be refilled. [Participant 7]

Furthermore, 59% (10/17) of the participants consistently refilled on a specific day of the week. One described the routine for refilling as follows:

> Sunday morning, it's a routine. After breakfast, I drag [my medication] out. I have two different sets [of pill cases]. So I always have one in reserve in the closet with the bottles of the pills. I can easily take [the medication] on Sunday. I don't have to wait till I fill them in order to take pills [since] I already have a set ready. Usually after breakfast or when I have a chance during the day on Sunday, I'll go ahead and fill the one that I've just emptied in the previous week and put it in the closet. [Participant 17]

Participants using prescription bottles used 1 storage location for their currently used bottle; those who received a 90-day supply in multiple bottles used a secondary location for excess. Participants using pill cases used 2 storage locations: a primary storage location for the pill case itself and a secondary storage location for the prescription bottles used to refill the pill case. The primary storage locations used for prescription bottles and pill cases were visible locations in their home for 86% (19/22) of the participants. The kitchen table was the most common primary storage location (10/22, 45%), and the bathroom counter was the second most common primary storage location (4/22, 18%). For the 17 participants using pill cases, 14 (82%) used a secondary storage location that was hidden from sight. The most common secondary storage location was the kitchen cabinet (7/22, 32%), followed by the bathroom cabinet (5/22, 23%).

Independent of the storage container used, most of the study participants (20/22, 91%) took their medication during a time range tied to a routine, such as eating a morning meal, while only a small number (2/22, 9%) reported taking medication at an exact time every day. One participant reported taking her evening medication as follows:

> Sometime after dinner and before going to sleep. It's probably a two-, three-, or four-hour range there. [Participant 11]

Only a few participants (3/22, 14%) used a digital time-based reminder or alarm to manage their medication. One participant set an Alexa device to give her an oral reminder to take her pill at 10 AM every day, 1 participant used a smartphone reminder, and 1 participant used an alarm. None of the participants used medication adherence devices or apps for reminders.

All participants (22/22, 100%) relied on at least 2 triggers to remind them to take their medication. No 2 medication-taking routines were identical among participants. Action triggers included eating a meal (10/22, 45%), getting ready for bed (5/22, 23%), and brushing teeth (4/22, 18%); object triggers included a visible pill case (17/22, 77%) and a water glass (4/22, 18%). Because most participants stored their medication in a visible area, they could see their medication container as they engaged in a routine; for example, of the 10 participants who took their medication during a meal, 8 (80%) stored their prescription bottle or pill case on a kitchen table or counter. Storing their medication in a visible area served as a second trigger, backing up the routine-based trigger. One participant recounted the following:

> I have what I call my staging area, which is an area between my kitchen and my dining room. [My medication] stays in the [staging area] and since I take that medication right after dinner it's right there. As I'm clearing the table, after I put the dishes in the sink, I just go and I take the medication right after dinner, and it's visibly right there. [Participant 6]

Some triggers were tactile, not just visible. One participant used the spatial orientation of her pill bottles to manage medication adherence, reporting the following:

> I came up with a scheme, where I keep the medicines on one side of my microwave, or my toaster oven. When I take it, I put it on the other side. [Participant 4]

While all participants relied on at least 2 triggers to remind them to take their medication, more than half (15/22, 68%) of the participants relied on ≥3 triggers. One participant who relied on 3 triggers, taking medication with a meal, using a pill case, and placing it on the dining table, missed the first trigger but saw their pill case, which acted as a fallback reminder.

Theme 3: Factors Contributing to Nonadherence

From the participants' descriptions of their medication management, the use of ≥2 triggers served as "a safety net" most of the time, providing multiple reminders to take medication. Yet even multiple triggers failed at times. The most reported reason for medication nonadherence among participants was an unplanned or unexpected change of routine (13/22, 59%), such as missing breakfast, waking up later in the day, or being distracted by a phone call. Such events typically led to the absence of, or overlooking, a specific trigger. For example, a participant who relied on eating breakfast as a cue reported forgetting to take her medication if she skipped breakfast:

> If I have to go somewhere, first thing in the morning, that's a typical time when I forget. Because sometimes I don't even have time for breakfast or for one reason or another didn't get around to it. Then the next day, it's Monday, but I'm looking at the Sunday [compartment of the pill] case saying, "Oh, I guess I forgot to take it yesterday." [Participant 7]

Another participant acknowledged difficulties when her usual routine was interrupted or altered, reporting the following:

> I just got distracted. I was on the phone with a friend. [Forgetting medication is] more apt to happen if I'm with my mom or somewhere other than in my own home because I'm out of the routine, even though I have the pill with me. [Participant 17]

The second most reported reason for nonadherence was travel. The 8 participants who reported nonadherence during travel explained it by citing a change in schedule, not being able to store their medication in the same place, or not having the same triggers in their usual routine available. One participant recalled the following:

> I have occasionally forgotten. Frankly, it's when I'm on vacation; even though I have them in the [weekly pill case], my routine is different on vacation. It [the

pill case is] not in my kitchen on vacation. I'm away someplace. [Participant 19]

Another participant reported forgetting to pack his medication:

There was one time, I remember, when I left my pills home. So there were like three days where I was not taking the pills. [Participant 18]

Stigma was not reported as a contributor to nonadherence. No participants reported experiencing stigma about taking medication or about visitors to their home seeing medication. When asked about stigma, respondents spoke about how common it was for older adults they knew to be on medication, which, to them, eliminated the experience of stigma or embarrassment.

Theme 4: Perception of Medication

Participants were asked about how they thought about their medication, for example, prescription name, pill purpose, or pill appearance. In response to this question, approximately half of the participants (10/22, 45%) thought about their medication by the chemical name, with the next most popular response being by the appearance of the pill (8/22, 36%). A smaller number (2/22, 9%) thought about the medication's purpose or the medication's generic name. One participant described medications as follows:

I can't name the one that I have been taking the longest, which is upstairs in the bathroom. [The medication for] underactive thyroid I just remember by the name Levoxyl. And I've always remembered it. The one downstairs I just recently started and it's a statin. I still don't know what the name of it is. But it's just for cholesterol. [Participant 14]

Another participant described medications as follows:

I know all of them by their generic names. And when they're new, I think about what they're meant to do. But over time, I recognize them by their shape and color. On a day to day basis, I probably look for the shapes. And it really is off-putting when the pharmacy either changes the generic or I change my insurance plan and deal with the pharmacy benefits manager who happens to have a different generic. [Participant 20]

Furthermore, of the 19 participants who took vitamins or supplements in addition to their prescription medication, 18 (95%) treated their medications the same, not distinguishing between what was prescribed by a physician, recommended by a physician, or something they were taking independent of their physician. These 18 participants stored their vitamins and supplements in the same pill case as prescription medication, and they integrated them into their medication routine, rather than distinguishing between their prescription medications and their vitamins and supplements.

Theme 5: Interest in Adherence Device

The final question to participants was about their interest in the use of a medication adherence device that used sensors to alert them only when they forgot to take their medication. Of the 22 participants, 17 (77%) were interested in using this device; 12

(71%) participants expressed interest in using the device immediately, whereas 5 (29%) were open to using the device if their medication routine got more complicated or they experienced any cognitive decline. Of those 5 participants, 1 (20%) talked about the need to use a device in the future, saying the following:

At this point now, I wouldn't [be interested in a device], because I just don't need it. But certainly, if I was struggling to remember to take them or if I had, like some people I know, this very, very complex regimen. So, I would be open to it at some point, but not now. [Participant 9]

Out of the 5 participants who were not interested in the device, 3 (60%) explained that they saw no need to change or add to their current routine, while 2 (40%) rejected the idea due to the potential of notification fatigue or an unwillingness to use technology for medication adherence.

Discussion

Principal Findings

The purpose of this qualitative study was to explore the experiences of older adults managing their medication in their homes. In conducting this study, our most significant finding was the complexity and uniqueness of what participants did to manage simple medication regimens. Another significant finding was the extent to which trial and error or prior experience were used to develop strategies without guidance from health care professionals.

Medication management strategies need to encompass how people think about their medication and not the artificial demarcation of prescription medication only. Study participants who took vitamins and supplements thought about their medication as prescriptions, vitamins or supplements recommended by physicians, and vitamins or supplements recommended by a friend or another source.

Another finding was the variability in the use of pill cases, including the number and type of pill cases used and the frequency and timing to refill them. Related to this was the complexity of medication storage location selection for both primary storage, for example, a storage location accessed daily for medication, and secondary storage, for example, storage used for extra medication supply. Overall, the sheer variability in home medication management strategies was surprising and unexpected, especially for participants with relatively simple medication regimens.

Additional results from each theme are discussed in the subsequent sections.

Theme 1: Participants' Experiences of Obtaining Medications

All study participants expressed that they received no guidance from a physician or pharmacist on any aspect of home medication management, including how to establish a routine to be adherent. Of the 22 participants, 13 (59%) designed their own medication management regimens. A small number relied on prior experience helping someone else manage their

medication or through the advice of a friend or family member. This lack of guidance from health care providers presents a missed opportunity to increase medication adherence from a trusted professional [30]. A survey conducted by Gualtieri et al [29] found that 96% of middle-aged and older adult respondents were receptive to receiving guidance from a physician or pharmacist regarding their medication management. This guidance could occur as part of prescribing or a medication review by a physician or by a pharmacist during prescription pickup.

With more than half of participants receiving prescriptions by mail only (10/22, 45%) or a combination of mail and pharmacy pickup (3/22, 14%) and approximately all receiving a 90-day supply of their prescription medication, fewer pharmacy visits are required as part of obtaining prescriptions. While this may decrease the likelihood of running out of medication, it also serves to decrease the need to enter a pharmacy location and therefore may reduce the extent to which an older adult establishes a relationship with or asks questions of a pharmacist. Less time in a pharmacy may limit opportunities to explore adherence-related tools, such as pill cases, which are often displayed next to or near pharmacies in retail stores. Less explored consequences of the rise in mail delivery may be theft or degradation of medicine by extreme temperatures, rain, or humidity.

Theme 2: Participants' Experiences of Taking Medications at Home

Participants described a wide range of routines for taking their medication. Each routine was unique with varying degrees of complexity. Most integrated multiple tactile and visual triggers into their daily routines to prompt them to take their medication each day. These adherence regimens may be so varied due to a lack of physician or pharmacist guidance or established norms for home medication management. Additional diversity was found in the unique locations where participants stored their medication and the timing with which they refilled it.

When participants described their experiences of home medication management, they included how they stored their pills. Pill cases were the most popular medication adherence device used at home. A possible reason for the high prevalence of weekly pill cases is that they provide direct feedback on whether someone took their medication using visual cues. Whether the slot in the pill case is empty or full is a straightforward indicator, unlike a prescription bottle, where users have no way of knowing if they took a pill that day unless they count pills. Weekly pill cases are also the most commonly seen medication adherence tool at pharmacies, though as evidenced by the interviews, the style and how they are used can vary greatly. This theory aligns with other literature, which demonstrates that pill boxes can effectively aid medication adherence. Another study on medication adherence found that some patients favored using pill boxes for managing their medications because they provided a visual reminder that they had taken their doses [33].

The most common primary storage location for medication was the kitchen, which was associated with using food preparation or consumption as a trigger for medication taking. This may be because mealtimes are a stable component of a daily routine. Another possible factor explaining the popularity of a kitchen storage location is that the participants enter the kitchen to complete specific tasks, as opposed to using it for long periods. This prescription bottle or pill case may act as a visual cue in the kitchen.

Theme 3: Factors Contributing to Nonadherence

Participants, in describing their medication management strategies, referred to the use of multiple triggers that served as reminders to take their medication. Because triggers sometimes fail, they may depend on their specific context. An object or action without its usual context might be less effective as a reminder.

When asked to recount the last time they were nonadherent, participants described a disruption leading to a change in routine in their home or being in a different location due to travel. Because the recounted occurrences are events that are not under the control of the participant, developing a robust medication management strategy should ideally accommodate these anomalies. During a change in routine, a trigger that is usually relied upon may be absent. More robust routines with multiple triggers may endure disruptions better, or more durable triggers that are not disrupted by unexpected events are needed. More planning may also be needed to accommodate disruptions and unplanned events. Adherence devices may provide reminders to reduce nonadherence under anomalous circumstances.

Our study pinpointed factors contributing to nonadherence that are consistent with those identified in an interview study by Mickelson and Holden [34]. Their findings highlighted that disruptions in daily routines or travel could result in lapses in medication adherence. In addition, they observed a variety of tools and technologies being used to manage medications, including pill boxes. Uniquely, their study also revealed that stigma played a role in nonadherence; participants were hesitant to be seen as sick, leading them to skip medications in social settings, a finding that contrasts with our study [34]. Our participants noted that medication use among older adults is so common that it does not carry any stigma for them.

Theme 4: Perception of Medication

How participants referred to their medication varied considerably, with most referring to their medication using the chemical name, followed by appearance. The use of chemical names could be due to education because all participants had obtained a bachelor's degree or higher. Another factor influencing how people refer to their medication could be the number of medications that they take; it may be harder to keep track of chemical names as the number of medications increases, especially with the complexity of chemical names.

The second most common mode of reference participants used was appearance. When pills are similar in appearance, concerns about medical error arise. It is worth investigating the correlation between how people think of their medication and medication adherence and if discussion with a physician or pharmacist should emphasize the medication name, appearance, and purpose to aid in accurate identification by patients, especially for tasks such as filling a pill case. The primary concern for medical error

may be when a patient who relies on appearance for prescription identification receives a new generic or a dosing change and the new pill is a different shape, size, or color.

Most participants thought of their medication as prescription medication, vitamins, and supplements, without categorizing differently what they were prescribed, recommended by a physician, or took of their own volition. Adherence is more critical for prescription medications, but strategies to guide patients should ideally address how they think about their medication regimen and, for pill case users, how they select, use, and refill pill cases.

Theme 5: Interest in Adherence Device

Only 1 participant currently relied on a general, as opposed to adherence, technology to assist with medication; this participant relied on a daily reminder from Alexa. None of the study participants currently used adherence devices or apps to generate reminders. More than two-thirds of the participants (17/22, 77%) expressed interest in using a device to assist with adherence only when needed, in contrast to devices with timed reminders. Only 2 individuals expressed a lack of interest in this technology. In addition, most study participants lived alone without others to remind them to take their medication, providing an opportunity where an adherence device might be beneficial as a backup. A lack of experience, positive or negative, with medication adherence device or app use did not seemingly deter participants from expressing interest in a device that integrated naturally into their routine.

Strengths and Limitations

The strength of participant recruitment through the OLLI at Tufts University was that our recruitment goal of ≥20 participants was met quickly. However, the disadvantage was that our sample was not representative of the US Census for adults aged >50 years. The narrowness of our study population, due to our recruitment strategy, is a limitation of this study. A subsequent interview study was conducted with adults who identify as racial or ethnic minority individuals.

While our cohort consisted of participants who were more educated, and hence likely to have higher health literacy skills, they still experienced unintentional nonadherence. A higher level of education is associated with higher socioeconomic status; however, none of the strategies deployed for medication adherence by participants were costly. Furthermore, many participants were not working full time or were retired, which may influence their daily routines and their ability to travel. Because most of the participants lived alone, they were less likely to be able to rely on others to remind them.

Finally, participants were limited to those taking 1 to 3 medications and experiencing no cognitive decline. A more representative sample of older adults should include those taking more medications, including those with complicated schedules. It should also include those who are experiencing minor cognitive decline yet are living independently because this might add additional barriers to medication adherence strategy development and may increase forgetfulness.

Despite some limitations in the diversity of participants, this study has strengths in uncovering home medication strategy development and execution through the set of questions eliciting participants' experiences. Face-to-face interviews lasting 30 to 45 minutes through Zoom enabled us to gain more insight and details than we would have discovered through a survey; in fact, our prior survey work led to the design of an interview guide to gain a deeper understanding. Participants shared freely how they developed and executed a home medication management strategy, when the strategy was successful, and when and why it failed.

Future Directions

Future work will build on the results of this study as well as the completed interview studies on racial and ethnic minorities. One goal is to create educational interventions that lead to improved adherence under routine and anomalous circumstances and eliminate or reduce the trial and error process so often used. Ideally, an educational intervention would be delivered by physicians when prescribing, by pharmacists when dispensing, or by either professional when nonadherence is indicated by a patient or by refill frequency.

Related to this, and in support of patient-physician communication about adherence, another goal is to develop a scale for home medication management, much like those for medication adherence but focused on home practices. This scale could be used by physicians when prescribing medication to determine how likely a patient is to be adherent based on their current lifestyle or by pharmacists or family caregivers to provide guidance in developing an individualized medication management strategy.

Another goal is to design and test medication adherence devices that take a failsafe approach to helping older adults live independently longer. While current medication adherence devices and apps rely on time-based triggers, our study shows the reliance on routine, leading to our interest in routine-based triggers. Our study found that participants managed their medication in the context of a routine, yet their routines did not take place at an exact time but rather upon rising or in the morning. Alerts or reminders set for a specific time may be disruptive if the timing of the routine is variable. They can be even more confusing if the person has already taken their medication but still receives a reminder to do so. This may result in notification fatigue or in turning off notifications altogether. Thus, we plan to design and test a medication adherence device that reminds users to take their medication only when their current routine fails them and is robust enough to accommodate disruptions. Given the high interest from our participants when asked about this new medication adherence device, this has the potential to reduce unintentional nonadherence in older adults who are aging in place.

Given that study participants' medication management strategies treated prescribed medication the same way as vitamins and supplements, we will further explore the implications of this for adherence. Home medication management strategies, to be effective, should align with how patients think about their medication. This should include any medication, prescription, or nonprescription that patients take. Related to how people

think about medication is further pursuit of the implications of identifying medication by name, appearance, or purpose. The special concern is if there are transitions due to a change to a generic or in dosing and the ensuing challenges when refilling pill cases.

Related to this, a future study will seek to better understand the selection and use of pill cases over prescription bottles and the impact on remembering to take medication as prescribed, not taking extra doses when unsure if a dose was taken, and making refilling a case easier and more convenient. For both users of pill cases and prescription bottles, we aim to research how to support the development of more durable, disruption-proof triggers that function under routine and anomalous circumstances.

A final interest stemming from this study is the influence of home environments. We noted that participants who lived alone could develop a medication routine with substantial triggers with no limitations in terms of where they could place medication. An open question is whether this affords more flexibility to optimize the placement of a pill case or prescription bottle. Yet these same individuals lack someone in the home to remind them to take their medication, which for some provides an additional safety net. Another question is the influence of home size and the number of levels in a home in developing a strategy, in particular, how much proximity is needed between storage locations and heavily used locations in the home.

Conclusions

The findings of this study provide important insights into the challenges older adults face in managing their medication and indicate opportunities to improve medication adherence in older adults. Our study participants formulated home medication management strategies without physician or pharmacist guidance, which represents an unexplored opportunity for improving adherence strategies through patient education provided by health care professionals during discussions with patients. Another opportunity is to reduce the extent to which trial and error is used to develop and refine medication management strategies through tailored guidance. Individualized guidance should include identifying more durable, disruption-proof triggers that function under routine and anomalous circumstances, including sufficient portability to accommodate travel. This qualitative study suggests that, in addition to supporting older adults who occasionally forget to take their medication, there are opportunities to improve adherence guidance to older adults when they are receiving their first long-term prescription or during a regimen change. It also suggests pathways for designing better adherence aids that integrate with established daily routines.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

LG designed the study with assistance from MR and DW. LG conducted the interviews with assistance from MR, and both of them took notes. MR and DW conducted the thematic analysis of the interviews and independently replayed the interview recordings and used the transcripts to develop a list of preliminary codes, which were then reviewed by LG, MR, and DW and collated into potential themes until consensus was reached about the themes. MR and DW selected candidate quotes to illustrate the themes. Finally, LG, MR, and DW collated the themes into descriptive text and reviewed the chosen quotes to find exemplars for each theme. EM assisted in writing, reviewing, and editing the manuscript.

Abstract

Background: The concept of oral frailty has gained scientific and clinical relevance in recent years, and early detection can facilitate timely intervention to manage its progression. The Oral Frailty Index-8 (OFI-8) was developed to assess community-dwelling older adults at risk for oral frailty.

Objective: This study aims to investigate the psychometric validity of the OFI-8 in the Portuguese population, named the Portuguese version of the OFI-8 (OFI-8-PT), which may serve as a reference for future studies related to longevity and oral function.

Methods: This study included 2 main phases, involving patients aged 60 years or older, Portuguese speakers, and those who consented to participate in the study. First, the researchers translated and cross-culturally adapted the original questionnaire to make it suitable for native Portuguese speakers. The translated tool was then assessed for psychometric validation, which consisted of test-retest reliability, internal consistency, construct validity, and sex invariance measurement.

Results: A total of 159 older adults participated in the baseline survey, with almost equal numbers of male (n=79, 49.7%) and female participants (n=80, 50.3%). The OFI-8-PT demonstrated good reliability (Cronbach α=0.95) and construct validity (goodness-of-fit index=0.96; comparative fit index=0.85; and root mean square error of approximation=0.05, 90% CI 0.00-0.09). The study found sex invariance, indicating that the OFI-8-PT is equally valid for male and female participants, and the tested-retest reliability of the OFI-8-PT was good, indicating consistent results over time.

Conclusions: The OFI-8-PT showed psychometric validity and good reliability to be used in the Portuguese population.

Introduction

Contemporary societies are grappling with an unprecedented aging phenomenon, propelled by the evolving age distribution of the global population [1,2], largely owing to remarkable gains in life expectancy [3]. The increasing longevity—considered a testament to medical advancements, improved access to treatments, and an emphasis on preventive care including oral health maintenance [1,4,5]—presents a notable societal achievement. However, amid this transition emerges the challenge of frailty—a condition marked by heightened vulnerability attributed to age-related declines in physiological reserves [6,7]. Frailty, often exacerbated by a prolonged lifespan, poses distinct health and societal complexities [2], underscoring the multifaceted nature of aging in contemporary times.

Within this spectrum, oral frailty was introduced in 2013 in Japan and has gained increased attention in recent years [8,9]. Oral frailty is defined as a decline in oral health and functional capacity, with broader implications for overall health and quality of life [8,9]. Tanaka et al [10] developed an 8-item

questionnaire, referred to as the Oral Frailty Index-8 (OFI-8), for the purpose of surveying community-dwelling older adults who are at risk of oral frailty. Evidence suggests that early identification and intervention can slow the progression of oral frailty and may even prevent its onset [11,12]. This has led to a growing international interest in identifying the effects of aging on oral health and appropriate strategies for its prevention [11,13]. For this reason, oral frailty is currently considered one of the main determinants of oral health and dentistry policies [9].

Maintaining good oral function can then be one of the keys to increasing longevity, but the evidence is limited and has not been studied in detail [8]. Thus, additional high-quality studies are needed, and it is extremely important to increase awareness of oral frailty and provide appropriate literature related to this concept to promote healthy aging in the future [5,10].

Therefore, considering the potential impact of the OFI-8 and the need for further validation worldwide, the purpose of this research is to serve as a reference for future studies related to longevity and focused on oral function by translating and exploring the psychometric validity of OFI-8 in the Portuguese population, named the Portuguese version of the OFI-8 (OFI-8-PT).

Methods

Design, Setting, and Participants

This was a cross-sectional study that aimed to translate and validate the OFI-8-PT in a sample of patients aged 60 years older from the Egas Moniz Dental Clinic (Almada, Portugal).

To be eligible, participants needed to be aged 60 years or older; be fluent in Portuguese; and consent to participate. The recruitment was carried out between December 30, 2022, and February 17, 2023, which corresponds to a total period of approximately 7 weeks. The recruitment procedure and sampling method consisted of a consecutive convenience sample of participants eligible for participation that presented at the Egas Moniz Dental Clinic for a first dental appointment.

Sample Size Calculation

To achieve the proposed aim, we calculated a minimum sample size based on the rules of thumb from Terwee et al [14] (between 4 and 10 participants per variable), with a minimum of 10 individuals per questionnaire item. As such, considering an 8-item questionnaire with a dichotomous nature, we estimated a minimum number of 80 participants to ensure the stability of the variance-covariance matrix when performing confirmatory factor analysis (CFA).

Translation and Cross-Cultural Adaptation of the OFI-8

The original OFI-8 questionnaire measures the oral frailty using 8 dichotomous items, representing the number of natural teeth, masticatory performance, maximum tongue pressure, articulatory oral motor skill, subjective difficulties in eating tough food, and subjective swallowing difficulties.

Each question is assigned a score that is then added together to obtain the total score of the questionnaire, resulting in a numerical scale that ranges from 0 to 11 points; higher scores indicate a greater degree of oral frailty, which in turn has other implications previously described, such as physical frailty, dependence, and mortality [5]. For questions 1, 2, and 3, a response of "Yes" was allocated 2 points, while for questions 4 and 5, a response of "Yes" was allocated 1 point. In contrast, a "No" response was awarded 0 points. Conversely, for questions 6, 7, and 8, a response of "No" was given 1 point, while a response of "Yes" was not awarded any points [10].

Two independent, bilingual individuals fluent in both Portuguese and English translated the original English version of the OFI-8 into Portuguese (VM and JB) in a "double-blind" process. Because no disagreements were recorded, a final version of the questionnaire was named OFI-8-PT. After back-translation to English and comparing with the original to identify discrepancies, no ambiguous wording or cultural nuances were identified. The semantic and conceptual equivalence was attested (Table 1).

Table 1. Original version and Portuguese translation of the Oral Frailty Index-8 (OFI-8).

Item	Original (English)	Translation (Portuguese)
1	Do you have any difficulties eating tough foods compared to 6 months ago?	Em comparação com há 6 meses, sentiu dificuldades em comer alimentos duros?
2	Have you choked on your tea or soup recently?	Recentemente, engasgou-se com chá ou sopa?
3	Do you use dentures?	Usa prótese dentária?
4	Do you often have a dry mouth?	Costuma ter a boca seca?
5	Do you go out less frequently than you did last year?	Sai de casa com menos frequência do que no ano passado?
6	Can you eat hard foods like squid jerky or pickled radish?	Consegue comer alimentos duros como carne seca ou nozes?
7	How many times do you brush your teeth in a day? (2 or more times/day)	Quantas vezes escova os dentes por dia (2 ou mais vezes/dia)
8	Do you visit a dental clinic at least annually?	Visita o Médico Dentista pelo menos uma vez por ano?

Variables

The dependent variable in this study was the older adults' self-perception of their own oral health (oral frailty score), which occurs as a result of the independent variable. The way in which participants define their oral health condition is used as an indicator for the oral frailty score.

Some parameters of the participants in this study, such as age and sex, were considered independent variables of the study. These variables can be used to determine if there is any relationship with the oral frailty score of the individuals.

Statistical Analyses

The statistical analysis was conducted in the R *plyr* package (R Foundation for Statistical Computing).

Reliability

The OFI-8-PT was pilot-tested on a random sample of 10% of the total sample required for validation (and this subsample was not part of the validation stage). The eligibility criteria of this pilot test were the same as the validation. We used the Kuder-Richardson formula 20 to test the internal consistency of each item, considering its dichotomous nature [15].

Validity

Using the *lavaan* package, we performed the CFA to compute the factorial loads and model fitness. To compute the model, we used the maximum likelihood method, with the differences between models being explored through chi-square (χ^2) and likelihood ratio tests. To test the fitness of CFA, we used the χ^2/df ratio (good adjustment with values <2) [16], the root mean squared error of approximation (RMSEA; a good model adjustment considered for values between 0.05% and 0.10%; 90% CI) [17], the confirmatory fit index (CFI; a cutoff criterion of ≥0.90 indicates a good fit) [18], goodness-of-fit index (GFI; values of 0.90 or greater indicate well-fitting models) [19], and normed fit index (a cutoff criterion of 0.90) [20].

Then, to make sure that the change of the state variables indicates state variability and not trait change, such as sex, we analyzed the sex invariance of the OFI-8-PT. To do this, we estimated 4 consecutive models: (1) unconstrained model; (2) factor loading–constrained model (Model 1); (3) factor loading– and structural covariance–constrained model (Model 2); and (4) factor loading–, structural covariance–, and measurement residual–constrained model (Model 3). Then, we were able to obtain the Δ values for CFI (ΔCFI) and chi-square ($\Delta\chi^2$). We defined a cutoff point of ΔCFI<0.01 as the presence of invariance [18,21] and $\Delta\chi^2$=0.095 as invariance between the models [22,23]. In addition, we explored the relationships between the OFI-8-PT items to confirm instrument dimensionality via the Spearman rank correlation coefficient (ρ) and the effect of the previously mentioned 2 confounding variables, sex and age, through the Spearman correlation with the overall OFI-8-PT score. The level of statistical significance was set at 5% in all inferential analyses.

Ethical Considerations

The data collection was performed electronically, ensuring the confidentiality and anonymity of the participants' data through a cloud-based system [24]. The study was conducted in accordance with the regulations applicable to research and was approved by the Ethics Committee of the Egas Moniz (ID: 1140/2022). Informed consent was obtained from each participant before their inclusion in the study. Participants entered into this research voluntarily, fully aware of their right to withdraw from the study at any point without the need for justification. The informed consent process ensured that participants had a clear understanding of the study's purpose, procedures, and the voluntary nature of their involvement. Patients received compensation in the form of free diagnosis and treatment without costs.

Results

Participant Characteristics

A total of 159 participants completed the OFI-8-PT, with an average age of 73.9 (SD 9.4; range 60-99) years (mean 74.8, SD 9.7 years and mean 73.1, SD 9.0 years for female and male participants, respectively), and the group was equally composed by female and male participants (n=80, 50.3% female vs n=79, 49.7% male).

Test-Retest Reliability

To test the reliability of the OFI-8-PT, 16 participants answered the translated tool 2 times (baseline and 2 weeks after). Of these participants, 6 (38%) were female and 10 (62%) were male, with similar age intervals (female: mean 70.8, SD 4.7 years vs male: mean 71.7, SD 9.2 years). The median total score of the instrument was 3 (range 0-7).

The overall internal consistency through Kuder-Richardson formula 20 was 0.69, thus considered to be a good reliability score. Nominally, each question had excellent reliability (Multimedia Appendix 1).

The OFI-8-PT exhibited an adequate reliability (with a Cronbach α coefficient of 0.95) and an adequate psychometric feature.

Construct Validity

The CFA analysis attested the unifactorial structure of the OFI-8-PT. The first-order unifactorial model resulted in an adequate model fit (GFI=0.96; CFI=0.85; and RMSEA=0.05, 90% CI 0.00-0.09; Table 2).

XSL•FO

1	48.6	47	<.001	1.03	1.00	0.96	0.00 (0.00-0.07)	0.10	4.8	7
2	56.0	54	<.001	1.04	0.95	0.99	0.02 (0.00-0.08)	0.05	7.4	7
3	56.0	54	<.001	1.04	0.95	0.99	0.02 (0.00-0.08)	0.00	0.0	0

[a]CFI: comparative fit index.

[b]GFI: goodness-of-fit index.

[c]RMSEA: root mean square error of approximation.

[d]Not applicable.

A multigroup CFA assessed the invariance across sex groups in the OFI-8-PT (Table 1). Accordingly, there was invariance for sex groups based on the comparisons of CFI, χ^2, and df values across the unconstrained and constrained models studied.

In order to learn the agreement level of OFI-8-PT components, we analyzed the correlation between the items using Spearman rank correlation coefficient. There was a low number of significant correlations (4/28, 14% of all correlations; Table 3).

Confounding Variables

When correlating the overall OFI-8-PT score, age was significantly correlated (ρ=0.259; P<.001), whereas sex was not (ρ=–0.035; P=.66), confirming as well the absence of sex invariance.

Discussion

Principal Findings

This study demonstrated the psychometric validity of the OFI-8-PT to depict individuals at risk of oral frailty and functional disability in this Portuguese sample. In addition, we found an adequate internal consistency and reliability of this questionnaire.

The assessment of oral frailty in older adult individuals through a comprehensive scale holds great clinical significance due to its potential influence on geriatric care and the overall health outcomes of these individuals. Older adults typically face a variety of oral health challenges, such as tooth loss, periodontal disease, and dry mouth, which can significantly impact their quality of life and general well-being [25,26]. Despite the prevalence of oral health problems in the older adult population, there is a scarcity of specialized tools designed to assess oral frailty, which encompasses the functional and structural vulnerabilities of the oral cavity [27,28].

Expanding the usability of the OFI-8 to other languages could help health care professionals detect, intervene, and track oral health in older adults, potentially improving their quality of life through preventive care and tailored hygiene. Moreover, incorporating oral frailty assessment into routine geriatric assessments can facilitate comprehensive care planning and interdisciplinary collaboration among health care providers [29]. By addressing the clinical need for a validated scale to assess oral frailty in older adults, this study contributes to enhancing the holistic approach to geriatric health care and underscores the importance of oral health in promoting healthy aging.

The GFI indicated that the observed covariance matrix of the data fitted the covariance matrix implied by the model, revealing a very good fit. The CFI, however, suggested a reasonable fit with room for improvement when compared to a null model. The RMSEA also revealed a good fit with a value of 0.05. These results support the validity of the OFI-8-PT, although they cannot be directly compared with the original study by Tanaka et al [5] due to differences in methodology. Additionally, this is the first study to validate the OFI-8 in a language other than Japanese, which may contribute to future comparability with other validations and cultural adaptations.

With the introduction of the OFI-8-PT, health professionals and researchers will have a valuable tool for assessing oral frailty in older adults in Portugal. This standardized and validated questionnaire will enable early detection of oral frailty, allowing for targeted interventions and preventive strategies. With the current aging population, understanding and managing oral frailty is becoming increasingly important to promote healthy aging and improve overall well-being. By identifying individuals at risk, the OFI-8-PT can facilitate appropriate oral health services, ultimately contributing to improved oral health outcomes and quality of life.

The OFI-8-PT questionnaire offers several advantages that make it a valuable tool for assessing oral frailty in older adults in Portugal. Its standardized and validated nature ensures reliable and consistent assessment, while its ease of administration and scoring facilitates its incorporation into routine assessments. Implementation of the OFI-8-PT also allows for data collection on oral frailty in the Portuguese population, contributing to a better understanding of its prevalence and impact on health outcomes. However, it is important to acknowledge potential drawbacks, such as its primary focus on oral health aspects and its reliance on self-reporting, which may introduce bias or inaccuracy. Addressing these limitations and ensuring proper training and awareness of participants will be critical to maximizing the benefits of the OFI-8-PT questionnaire.

Strengths and Limitations

Overall, the study provides valuable insights into the psychometric validity of the OFI-8-PT questionnaire in the Portuguese population. However, there are some important limitations worth discussing that should be considered when interpreting the results.

First, the sample size used in the study was relatively small, which may limit the generalizability of the findings to a larger population. Yet, this shortcoming is limited as the OFI-8 is a 1-factor scale and we followed a previous validated strategy. Additionally, the study relied solely on self-report measures, based on self-perception of oral health, which could result in bias or social desirability effects. Furthermore, the study was conducted in a specific population from a university clinic, consisting solely of patients who visited the dental clinic, and therefore, findings may not be generalizable to the entire Portuguese population or other populations in different geographical locations. Nevertheless, these participants live in the largest metropolitan area in Portugal and may provide a considerable percentage of representation. Moreover, the presence of confounding variables, such as chronic diseases and medications, could influence the oral frailty score of individuals. Although these variables were acknowledged, the study did not extensively analyze their impact or control for their effects, and the study could not assess longitudinal effects due to its design.

Accordingly, conducting further research with larger and more diverse samples is recommended to address these limitations and strengthen the validity of the findings.

Conclusion

In conclusion, the OFI-8-PT was shown to have psychometric validity and reliability in the population under study, providing a snapshot of its oral frailty and functional disability. This consistency and ease of use may contribute to better screening and monitoring oral frailty prevalence and its impact on health outcomes. It may have an impact on future public health strategies to address oral frailty.

Abstract

Background: Long-term care hospitals have been considered an efficient response to the health care needs of an increasingly aging population. These centers are expected to contribute to better hospital bed management and more personalized care for patients needing continuous care. The evaluation of their outcomes is necessary after a sufficient period to assess their impact. Hospitals for Acute and Chronic Long-Term Extended Stay (HACLES) emerged in Spain in the late 20th century as a response to the aging population and the increase in chronic diseases.

Objective: This study aimed to analyze the profile of patients treated in a HACLES, particularly analyzing gender differences, and evaluate the cost savings associated with using these centers.

Methods: A retrospective study was conducted based on data from patients 65 years old or older admitted to a HACLES between 2022 and 2023. Gender, age, household cohabitation data, diagnosis and comorbidity, daily medication intake, and degree of dependency were obtained to describe the profile of patients who attended the HACLES. Data coded in SIA-Abucasis (version 37.00.03; Consellería Sanitat, Generalitat Valenciana; a digital medical record system used in the Valencian region) were reviewed, and descriptive statistics and comparison tests were used. The direct cost savings of HACLES admissions were calculated by comparing the daily cost of a general hospital bed with that of a HACLES bed.

Results: Data from 123 patients with a mean age of 77 years were analyzed. Most (n=81, 65.9%) had a cohabiting family member as their primary caregiver. Palliative care was the most frequent reason for admission (n=75, 61%). The mortality rate (odds ratio [OR] 61.8, 95% CI 53.2-70.5) was similar between men and women (OR 54.1, 95% CI 47.8-71.5 vs OR 59.7, 95% CI 42.2-66.0; P=.23). The cognitive assessment, using the Pfeiffer scale, improved at discharge (mean 3.2, SD 3.2 vs mean 2.5, SD 3.1; P=.003). The length of stay was significantly larger for patients who returned home compared with patients discharged to other facilities (mean 89.8, SD 58.2 versus mean 33.1, SD 43.1 days; P<.001). The direct cost savings were estimated at US $42,614,846 per 1000 admissions.

Conclusions: Patients typically treated in HACLES are older, with a high level of cognitive impairment and physical dependency, and a significant proportion are in palliative care, highlighting the importance of adapting care to the individual needs of the admitted patients. The HACLES model contributes to the sustainability of the public health system.

Introduction

In all high-income countries, long-term care hospitals have been considered an efficient response to the health care needs of an increasingly aging population that have multiple chronic conditions simultaneously [1]. However, the care model is being reviewed, and new ideas are emerging to leverage the potential of these health care resources [2].

In Spain, Hospitals for Acute and Chronic Long-Term Extended Stay (HACLES) were initially designed to free up beds in general hospitals occupied by patients with chronic conditions who did not require an acute care but needed a suitable hospital environment [3]. These hospitals continue to focus on managing complex medical needs that extend beyond short-term acute care settings, with an emphasis on long-term care and support for patients with chronic illnesses, disabilities, or conditions requiring prolonged medical treatment.

In the mid-90s, HACLES were established in the Valencian Community as a response to the need for specialized care for patients with chronic conditions and those requiring long-term care. These centers integrated medical, nursing, rehabilitation, psychological, and social support [4]. By the early 21st century, this model was consolidated with investments to make them more accessible and comfortable for prolonged stays, adapting to the profiles and needs of patients with chronic conditions, including those requiring palliative care. These centers are expected to contribute to better hospital bed management and more personalized care for patients needing continuous care.

The HACLES model, as is happening in other countries [5] and having gone through its period of implosion and consolidation, requires the development of long-term strategies that respond to the demographic and technological changes in our society. This study aims to describe the profile of patients receiving care in a HACLES, particularly analyzing gender differences, and evaluate the cost savings associated with using these centers.

Methods

Overview

A retrospective observational study was conducted based on the review of data coded in SIA-Abucasis (the digital clinical history system used in the Valencian Community) from a systematic sample of patients >65 years old admitted to the HACLES. The STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines were used to describe this study (Multimedia Appendix 1).

Patient Eligible Criteria

Data were recorded from all patients admitted over a period 2 years, between January 2022 and December 2023. A blinded registration system was used for the research team. A web-based platform was developed to ensure data quality, accessed through a personalized key, respecting data anonymization.

Sample Size

Considering the annual number of admissions (N=294), an α risk of .05, and a precision of 5%, the sample size was estimated at 168 medical records. This calculation was made using the formula for sample size in finite populations.

Sample Selection

Among the patients randomly assigned to each reviewer, a total of 30 cases were selected through simple randomization (k=3).

The reviewers included 4 nurses (all women). The reviewers were trained in the review procedure and in using a data registration tool, ensuring uniformity in the interpretation of the study protocol. A call center was available during the field study to resolve any issues related to data entry on the web platform.

Study Variables

These included binary variables such as gender; continuous variables such as age, polypharmacy (daily medication intake), average stay, and, when available, Barthel [6], Pfeiffer [7], and Gijón [8] scales scores at admission and discharge; and nominal variables such as household cohabitation data, primary diagnosis, comorbidity (based on the *International Classification of Diseases, 10th revision* [*ICD-10*]), reason for admission, degree of dependency, residence at the time of admission, destination upon discharge (home, institution, death, or others), and who the primary caregiver is.

Cost Analysis

The direct cost savings represented by admission to a HACLES were estimated by the difference between the daily cost of a bed in a general hospital, established at US $1047 [9], and the daily cost of a bed in a HACLES, estimated at US $373 [10]. Declared costs were adjusted to 2024 values considering increases in the cost of living.

Data Analysis

Data curation included eliminating outliers in the variable of hospital stay duration to avoid distorting the used statistics. Specifically, outliers in the variable of hospital stay duration were identified using the IQR method. Observations falling below the first quartile minus 1.5 times the IQR or above the third quartile plus 1.5 times the IQR were considered outliers. These were removed to prevent distortion in the statistical analyses, ensuring a more accurate reflection of the central tendency and variability.

Descriptive statistics (mean and SD) were used to summarize data and identify patterns. Comparative analyses were conducted using both parametric and nonparametric tests, depending on the data distribution. The Student t test (2-tailed) was used to compare men and women for continuous variables, while the chi-square test was used for qualitative variables such as identifying patterns in the origin and destination of patients after discharge. The Cochran-Mantel-Haenszel test was conducted to analyze gender-adjusted differences in assistance rates. Nonparametric tests such as Kruskal-Wallis and Wilcoxon tests were used when assumptions for parametric tests were not met. Statistical significance was set at $P<.05$ (2-sided) for all tests.

Ethical Considerations

The Ethics Committee of the Health Department of Alicante-Sant Joan approved the study (reference 24/044). The

XSL•FO

RenderX

Ethics Committee waived the requirement to obtain informed consent from all patients, as it was an epidemiological study that met the criteria of necessity, proportionality, and adequacy, offering comprehensive guarantees for the protection of personal data and respect for the privacy of the individuals involved, in accordance with Spanish Law 14/2007 on Biomedical Research.

Results

Data from a total of 123 patients (73.2% of the expected total of 168) were recorded. Almost half of the sample were men (61/123, 49.6%). The mean age of the sample was 77.2 (SD 13.1) years. In 81 (65.9%) cases, the primary caregiver was a cohabiting family member (Table 1).

The average duration of the hospital stay was 83.3 (SD 80.5) days. Excluding outliers, the stay for men (55.2, SD 52.6 days) and women (53.1, SD 53.4 days) was similar (P=.21). At discharge, the number of daily medications administered to patients was 7.7 (SD 4) for men and 8.2 (SD 3.8) for women (P=.33). The reason for admission to the HACLES was similar between men (36/61, 59% palliative care; 14/61, 23% rehabilitation; 5/61, 8.2% convalescence; and 6/61, 9.8% long stay) and women (39/62, 62.9% palliative care; 14/62, 22.6% rehabilitation; 5/62, 11.3% convalescence; and 6/62, 3.2% long stay; P=.52).

Table 1. Sample description.

Variable	Total (N=123)	Men (n=61, 49.6%)	Women (n=62, 50.4%)
Age (years), mean (SD)	77.2 (13.1)	79.2 (12.8)	74 (11.8)

In total, 70 patients died during their stay at the HACLES, while 54 were discharged and returned home (Table 2). The mortality rate was similar between men and women (men: 54.1%, 95% CI 47.8-71.5; women: 59.7%, 95% CI 42.2-66.0; P=.23). The degree of dependency at admission was higher in patients who

eventually died compared with those who did not (*P*=.008; Table 2).

Table 2. Factors related to mortality.

Variable	Died during admission		*P* value
	Yes (n=70)	No (n=53)	
Scale, mean (SD)			
Pfeiffer at admission	4.3 (2.3)	3.3 (3.2)	.11
Barthel at admission	27.4 (33.4)	29.2 (33.2)	.75
Degree of dependency at admission[a], n (%)			.008[b]

Palliative care	39 (55.7)	36 (67.9)	
Rehabilitation	14 (20)	14 (26.4)	
Convalescence	7 (10)	5 (9.4)	
Long-term stay	2 (2.9)	6 (11.3)	

[a]47 patients were under review and were not included.

[b]The chi-square test does not include patients under review.

The average length of stay for patients who died at the HACLES was 35.4 (SD 80.1) days for women and 48.4 (SD 44.8) days for men (*P*=.40).

A total of 57 (46.3%) of the 123 patients admitted to the HACLES had a nonfamily caregiver or were institutionalized. Among those cared for by a cohabiting family member (81/123, 65.9%), the recognized degree of administrative dependency was higher (mean 1.3, SD 1.1 vs mean 1.9, SD 0.7; *P*=.001).

At discharge, a higher number of women than men were referred to another residential institution (11/25, 44% vs 7/28, 25%), although the difference was not statistically significant (*P*=.16). Most returned to their home (men: 21/28, 75%; women: 13/25, 52%; *P*=.11; Table 3). The length of stay was significantly larger for patients who returned home compared with patients discharged to other facilities (mean 89.8, SD 56.8 vs mean 33.1, SD 36.9 days; *P*<.001).

Table 3. Origin and destination of patients treated in the HACLES (Hospitals for Acute and Chronic Long-Term Extended Stay).

Residence	At admission (N=123), n (%)	At discharge (N=123), n (%)	Men (n=61), n (%)	Women (n=62), n (%)
Home	113 (91.9)	34 (27.6)	21 (34.4)	13 (21)
Institution	2 (1.6)	18 (14.6)	7 (11.5)	11 (17.7)

Scores on the Barthel scale at discharge were 4 points higher than at admission, but this difference was not statistically significant (*P*=.46; Table 4). On the Pfeiffer scale, scores were higher at the beginning compared to discharge, with an initial score of 3.2 (SD 2.8) versus 2.5 (SD 2.8) at discharge (*P*=.03). At discharge, the Barthel score was the same for men and women (mean 36.4, SD 29.9 vs mean 30.2, SD 29.9; *P*=.45), while the Pfeiffer score for men was lower than for women (mean 1.7, SD 2.5 vs mean 3.9, SD 3.3; *P*=.01). The Gijón social-familial scale score was very similar for men and women at discharge (men: mean 7.6, SD 3.2; women: mean 8.3, SD 3.8; *P*=.27).

Table 4. Scores on the Barthel, Pfeiffer, and Gijón scales.

Scale at admission	At admission, mean (SD)	At discharge, mean (SD)	Men at discharge, mean (SD)	Women at discharge, mean (SD)
Barthel (autonomy)	29.7 (29.5)	33.5 (26.1)[a]	36.4 (29.9)	30.2 (29.9)
Pfeiffer (cognitive function)	3.2 (3.2)	2.5 (3.0)	1.7 (2.5)	3.9 (3.3)
Gijón (socio-familial support)	__[b]	8 (3.2)	7.6 (2.9)	8.3 (3.5)

[a]P=.04.

Table 5 summarizes the estimated cost savings represented by the HACLES, both for the study sample and the extrapolation per 1000 admitted patients, for both men and women, considering the average stay of this study. On average, for every 1000 patients admitted to HACLES, the total hospital stay cost is reduced by US $42,614,846 (considering 61/123, 49.6% men and 62/123, 50.4% women). If the average length of stay is not corrected by eliminating outliers (average stay of 98.6 days for male patients and 69 days for female patients calculated during the study period), the cost differential for admissions in a general hospital compared with HACLES would be US $56,877.01.

Table 5. Cost savings from admissions in HACLES (Hospitals for Acute and Chronic Long-Term Extended Stay) compared with a general hospital[a].

	Men	Women
Average stay (days), mean (SD)	98.6 (119.9)	69.0 (82.7)
Estimated savings per 1000 patients (US $ millions)	46.3	39.8

[a]Average daily savings per bed of US $6280 compared with a general hospital.

Discussion

Principal Findings

The data from this study reflect that HACLES fulfill their function by offering an alternative admission option for patients requiring diversified and varying intensity care but for a longer duration, reducing the higher per-bed costs of general hospitals. The average age of patients admitted to a HACLES is around 77 years, with no significant differences between men and women. These patients have, on average, about 5 chronic conditions. In this sample, a significant proportion were admitted to the HACLES for palliative care, although almost a quarter were admitted for rehabilitation treatment in special conditions.

The average duration of stay in these centers is about 2 months, significantly different from the average of 7.5 days in general hospitals [11]. In this study, men had a 9.6-day longer stay than women, but this difference is not statistically significant due to the wide range of days of stay (including some stays up to 591 days).

HACLES could be responsible for saving over US $650 per patient per day of hospitalization, which means that both in terms of their specialization for the described patient profile and in economic terms, their existence is justified.

Interpretation of Findings

Patients in long-term care facilities tend to be older and have a higher burden of chronic illnesses and comorbidities compared with the broader older adult population. Among the patients, 15 (15%) out of 100 had formal recognition of their level of dependency and were receiving state aid to manage their situation, with this being slightly more common among women than men. However, this does not imply that the patients admitted to HACLES had a less severe profile compared with other patients analyzed in different studies [12,13]; rather, it reflects the slow administrative process. Furthermore, it should be noted that almost 4 out of 10 patients admitted to HACLES are still awaiting evaluation of their degree of dependency due to significant delays in Spain's evaluation, registration, and subsidy assignment process, which can extend for over a year and a half.

Slightly more than half of the patients admitted died, consistent with or slightly lower than findings reported in similar studies [12]. This result contrasts with the lower mortality rates reported in studies conducted in general hospitals [14] and among patients with severe cognitive decline admitted to critical care units [15].

Most of those who died did not have recognized dependency, although a part (27/70, 38.2%) was pending resolution or under study. The reason for admission was not related to the mortality rate. Among those with formal administrative recognition of dependency, this situation does not account for differences in mortality, length of stay, or discharge destination. The mortality rate in this study was practically the same between men and women, as highlighted in other studies conducted in contexts more comparable to this one [16].

Scores on the Barthel scale indicated that both men and women generally showed severe dependency. In this sample, women presented greater cognitive deterioration than men admitted during the study period. Greater functional impairment in women, along with a similar mortality rate between men and women, have been reported in other studies [17], and our data confirm this trend. In this case, while women's social risk was moderate, men faced lower risk, which could explain their higher proportion of home returns upon discharge. However, it should be noted that the life expectancy for men (84.8 years) and women (88.3 years) in Spain [18] for this age group is significantly different.

The frequency with which women are referred to a residential institution upon discharge instead of returning home requires attention and new studies with larger samples. The trend in our data, combined with scores on autonomy, cognitive function, and social and family relationships, suggests that the difference may be due to women more frequently assuming the role of caregivers compared with men because of gender bias ingrained in our society. Other studies suggest that this is a phenomenon that extends beyond Spain [19]; thus, when planning alternative long-term care services, the different needs and preferences of men and women [19,20] should be taken into consideration.

The main reason for organizing care for this patient profile around a HACLES remains unchanged. Nearly 30 years after its implementation [21], its function is still necessary, and with the increase in chronic conditions, its capacity will likely be limited to respond to demand. The care needs required by older patients with multiple chronic conditions and limitations in their autonomy, along with the cost savings these centers have compared with general hospital admissions, corroborate the function of these centers, in line with what happens in other countries [22,23]. Furthermore, not only is the cost per bed lower but it is also important to consider, as some studies point out [24], that the number of medical tests and therapeutic interventions for this patient profile is higher when admitted to an acute care hospital. This increases risks for patients, affects their well-being, and raises the cost of care.

In the literature on long-term care hospitals and chronic patient management, the redistribution of spending across care settings has long been recognized usually as a decisive factor in cost savings [25,26]. The reinvestment of these savings should contribute to the expansion of services for older adults. Management models like the Chronic Care Model [27] have been adopted in various countries [28], including Spain [29], to provide a comprehensive approach to care. This aspect is crucial, as highlighted by the results of this study.

Practical Implications

The health care teams in HACLES and their management teams could review their action protocols, promoting integrated actions with community resources to ensure a return home that addresses the social and personal needs of the people they serve, particularly in the case of women who show a greater tendency toward institutionalization after discharge. It should not be ruled out that while women commonly assume the role of informal caregivers for their male partners, men who take on this caregiving role face more limitations due to having less experience with domestic tasks. In this context, developing new approaches to involve relatives in long-term care is a significant challenge in many countries. Engaging family members effectively can improve patient outcomes and overall well-being, but it requires innovative strategies and resources to support both the patients and their caregivers [30].

Most patients were cared for by a cohabiting relative, typically the spouse or 1 or more children. Almost a quarter might present loneliness, which is in line with data analyzing the frequency of loneliness in the general population in Spain [31], despite almost half of this group receiving help from a non-cohabiting caregiver. This data suggest that one function HACLES could assume is to address, before discharge and in collaboration with community or social welfare resources, measures to limit the impact of loneliness upon return home. This would help address a growing social problem and reduce primary care costs [32].

The study findings have further implications for health care policies. First, since these facilities meet a significant practical need, particularly for older adult patients requiring prolonged hospital care at a much lower cost than general hospitals, health care planners should consider this approach as a viable alternative due to its efficiency in both public health systems, like Spain's, and in other mixed or predominantly private systems. Second, health care planners and managers of health care structures, such as primary and community care, should work together to address the challenges of integrating care after discharge from a long-term care hospital, as has already been suggested [33]. Home care should be considered to maintain positive outcomes for as long as possible after leaving the long-term care facility, thereby preventing readmissions.

Future Research

Given the high mortality rate within a year after discharge [16], it should be analyzed in relation to the discharge destination of these patients, monitoring differences between men and women and considering the different options available to each group.

The impact of HACLES activities diminishes if adequate postdischarge care is not ensured. This requires offering integrated care [28] that addresses the needs and preferences of both men and women during this phase of their lives. Further research providing insights into the critical success factors of these interventions would facilitate more rapid implementation of effective solutions when patients are discharged from long-term care facilities.

Strengths

This study is conducted in a field where the number of studies is limited, particularly in Spain. It describes the profile of patients treated in HACLES, analyzing gender differences. It identifies potential gender bias in home care provision. It also analyzes cost differences with general hospitals.

Limitations

This study was conducted in a HACLES in one Autonomous Community in Spain. There may be long-term care centers organized to treat patients with other chronic conditions that do not fit the profile of patients treated in this center. Information records in clinical histories may sometimes be incomplete. When interpreting these data, the impact of the long stay on postadmission mortality should be considered [34].

Conclusion

In summary, HACLES contribute to the sustainability of the health care system, and the reasons for their creation remain valid. The profile of needs of the patients admitted to these centers requires an integral approach, combining clinical, rehabilitative, psychological, and social aspects, not only during admission but also to set up appropriate mechanisms and resources according to needs, to offer integrated quality care to this generally more vulnerable group.

Abstract

Background: Interdisciplinary evaluation of older adults' health care is a priority in the prevention of chronic health conditions and maintenance of daily functioning. While many studies evaluate different physical performance tests (PPTs) from a retrospective view in predicting mortality or cardiopulmonary health, it remains unclear which of the commonly used PPTs is the most effective at evaluating the current health of older adults. Additionally, the time and participant burden for each PPT must be considered when planning and implementing them for clinical or research purposes.

Objective: This cross-sectional study aimed to determine how elements of overall physical capacity, performance, and other nongait factors in older adults affect the results of 3 commonly used tests: the Short Physical Performance Battery (SPPB), 6-minute walk test (6MWT), and Incremental Shuttle Walk Test (ISWT).

Methods: A total of 53 community-dwelling older adults met the inclusion and exclusion criteria (mean age 77.47, SD 7.25 years; n=41, 77% female; and n=21, 40% Hispanic). This study evaluated older adults using 3 different PPTs including the SPPB, 6MWT, and ISWT, as well as constructed multiple linear regression models with measures of physical activity, static balance, and fear of falling (FoF). The nongait measures included 7 days of physical activity monitoring using the ActiGraph GT9X Link instrument, objective measurement of static balance using the BTrackS Balance System, and FoF using the short Fall Efficacy Scale-International.

Results: The models revealed that the complete SPPB provided the most comprehensive value, as indicated by a greater R^2 value (0.523), and that performance on the SPPB was predicted by both moderate to vigorous physical activity (P=.01) and FoF (P<.001). The ISWT was predicted by moderate to vigorous physical activity (P=.02), BMI (P=.02), and FoF (P=.006) and had a similar R^2 value (0.517), whereas the gait component of the SPPB (P=.001) and 6MWT (P<.001) was predicted by only FoF and had lower R^2 values (0.375 and 0.228, respectively).

Conclusions: The results indicated the value of a multicomponent, comprehensive test, such as the SPPB, in evaluating the health of older adults. Additionally, a comparison of the 2 field walking tests (ISWT and 6MWT) further distinguished the ISWT as more responsive to overall health in older adults. In comparing these commonly used PPTs, clinicians and researchers in the field can determine and select the most optimal test to evaluate older adults in communities and research settings.

RenderX

Introduction

Older adults are a rapidly increasing population that experiences increased chronic health conditions [1] and decreased daily functioning [2] compared to the general population. Physical activity is a key intervention recommended by health care providers to decrease the incidence of chronic health conditions, increase the ability to perform activities of daily living, and improve overall quality of life [3-5]. As such, evaluating physical capacity and health is of critical importance in older adults. Various physical performance tests (PPTs) have been shown to be important predictors of mortality [6]; however, few studies have compared the relevance of different PPTs to older adults' physical activity, static balance, BMI, and fear of falling (FoF) within the same population of older adults. Here, this study aims to determine the PPT that is the most affected by overall physical capacity, performance, and other factors in older adults by comparing 3 commonly used tests (the Short Physical Performance Battery [SPPB], 6-minute walk test [6MWT], and Incremental Shuttle Walk Test [ISWT]).

Decreased physical performance in older adults has been associated with an increased risk of cardiovascular disease, physiological fall risk, and earlier onset of mental health conditions [7-9]. Cardiovascular disease is the leading cause of death in the United States [10]. For older adults specifically, declines in cardiovascular health have been shown to lead to further disability [7], highlighting the need for early detection using tests that are easy to perform. Time spent in moderate to vigorous physical activity (MVPA) is a cardioprotective measure associated with a lower incidence of cardiovascular disease and coronary heart disease in older adults [11,12]. However, measuring physical activity objectively requires equipment such as accelerometers or movement trackers. Similarly, 30% to 40% of older adults experience a fall yearly [13]. Identifying people at higher risk of falling has both social and financial incentives, as falls exacerbate existing health conditions, further decrease the quality of life for older adults, and cause injuries that pose a significant financial burden for the health care system [14]. Fall risk is assessed objectively by devices that test static balance and subjectively through questionnaires such as the short Fall Efficacy Scale-International (FES-I). Measuring both the physiological and perceived fall risk can help us understand the incongruence between balance performance and FoF in older adults to inform targeted fall prevention strategies [15]. Finally, physical performance has also been associated with mental health including earlier onset of depression in older adults with poor performance. However, most of these studies that outline the implications of changes in physical performance were performed using different tests in different populations, often relying on longitudinal or retrospective data. Given these implications, the tools used for the assessment of physical activity and fall risk are of paramount importance [16,17].

Three PPTs—the SPPB, 6MWT, and ISWT—are compared in their response to physical activity levels, static balance, and FoF in older adults. Each of these PPTs is commonly used by physicians and health care personnel in evaluating the physical fitness of older adults and recovering patients [18-20]. The SPPB is a PPT of lower mobility that has been shown to be associated with physical activity, static balance, and FoF [21-23]. The SPPB is composed of 3 different parts, including a gait speed component. The 6MWT is a gait measure associated with static balance and FoF [24,25]. Similarly, the ISWT is a more recent gait-related measure conducted incrementally and associated with physical activity and dynamic balance [26,27]. While the SPPB has been widely used as a measure of overall physical function and frailty, the use of 6MWT and ISWT has been predominantly limited to characterizing cardiopulmonary functional capacity and shown to be predictive of outcomes for patients with heart failure [28-30]. Some work has investigated the differences between the specified PPTs; however, this mainly consists of meta-analyses comparing multiple studies or studies that focus on the predictive value of the measure in health outcomes [6,31,32]. These PPTs were selected for their widespread use and similar purposes; by comparing their effectiveness when modeled by nongait components of physical health, we aim to determine which provides the most comprehensive value for the time and methods involved in each. As more studies are conducted on the aging population, researchers are likely to use one of the abovementioned PPTs to evaluate physical capacity and well-being in clinical and nonclinical older adults. By evaluating the more holistic SPPB alongside the gait component of SPPB, the 6MWT, and the ISWT, this study aimed to determine how the 3 PPTs are affected by overall physical capacity, performance, and other nongait factors in older adults.

Methods

Overview

In this cross-sectional study, 65 participants were recruited from Central Florida using word of mouth, announcements, and flyers. Participants were selected using purposive sampling, based on the following inclusion criteria: (1) aged 60 years or older, (2) being able to walk with or without an assistive device (but without the assistance of another person), (3) fluency in English or Spanish, and (4) living in their own homes or apartments. The exclusion criteria were (1) having a medical condition that may preclude participation in balance tests (eg, inability to stand on the balance plate) and physical activity (eg, shortness of breath, dizziness, and tightness in the chest or unusual fatigue at light exertion), (2) currently receiving treatment from a rehabilitation facility, and (3) having medical implants (eg, pacemakers).

Data Collection and Procedure

This study required 2 visits to the study site, and the data were collected from September 2022 to March 2023. In the first visit, participants completed a demographic survey and anthropometric measurements, followed by assessments of FoF and static balance. Then, participants completed the PPTs, including the SPPB, 6MWT, and ISWT.

At the end of the first visit, each participant was provided a wrist-worn accelerometer and wore it for 7-day physical activity monitoring in free-living conditions. On the second visit, participants returned the accelerometer and were compensated with a US $30 store gift card for their participation in the study.

Ethical Considerations

The study was approved by the Institutional Review Board at the University of Central Florida (protocol STUDY00004365). All participants provided written informed consent to participate. The data have been anonymized and deidentified. Participants were compensated with a US $30 gift card for their participation in the study.

Assessments

PPTs

For each of the following PPTs, trained research assistants demonstrated the procedure to the participant prior to the participant performing the test.

SPPB

The SPPB comprised 3 tests, which were performed in the following order: the standing balance test, the gait speed test, and the chair stand test [33].

The standing balance test took place in a quiet area with no visual distractions. Participants were instructed to wear comfortable footwear with a heel less than 3 cm (~1 inch) while performing three balance tests: (1) side-by-side stand: the participant attempted to stand with feet together, side-by-side, for 10 seconds; (2) semitandem stand: the participant attempted to stand with the side of the heel of one foot touching the big toe of the other foot for 10 seconds (participants were informed to start with the foot of their preference as per protocol [28]); and (3) tandem stand: the participant attempted to stand with the heel of one foot in front of and touch the toes of the other foot for about 10 seconds.

In the gait speed test, participants walked along a 4-meter course at their usual walk speed (ie, the pace walked from one place to another without urgency such as down a street or hallway). Participants were permitted to use assistive devices if required and completed the walk 2 times, for which the fastest attempt was recorded for scoring.

In the chair stand test, the participant was instructed to rise from a chair and sit down 5 times, as quickly as possible, without using their arms, and recorded the time required to complete the 5 chair stands. For each test, the experimenters demonstrated the task and guided the participant to the appropriate position, after which they started the test. Additionally, if the participant could not continue with the task for any reason, the test was terminated.

6MWT

Participants walked along a flat, straight corridor of 12 meters in length, back and forth, as many times as they could for 6 minutes at their own pace. Participants were encouraged every 60 seconds using standardized phrasing. After 6 minutes, the total distance walked was recorded [34].

ISWT

A 10-meter course was marked with 2 cones. Upon reaching the second cone, the participant turned around, as modeled by the experimenter. Audio recordings of standardized instructions were played for participants to indicate walking speed. Each time the participant reached a cone was considered as 1 shuttle (ie, representing a 10-meter distance) and every single bleep from the audio recording signaled the end of a shuttle. The walking speed was progressively increased every minute, indicated by a triple bleep, and the test ended when the participant was unable to reach the turnaround points within the required time [35].

Physical Activity

The participants were instructed to wear the ActiGraph GT9X Link instrument (ActiGraph LLC) on their nondominant wrists for 7 consecutive days in a free-living environment. The ActiGraph accelerometer has been validated for assessing free-living physical activity [36]. After 7 days, the accelerometers were removed, and the raw data were downloaded and processed in R statistical software (R Core Team) using the *GGIR* package [37].

The data processing steps included (1) the autocalibration of acceleration signals according to local gravity [38]; (2) nonwear time detection; and (3) the calculation of the Euclidean norm (ie, vector magnitude) of acceleration minus 1 g, expressed in milli-gravitational units or mg (described as the sum of the squared acceleration components [Euclidean norm] minus 1 g). The time periods spent in sedentary behavior (SB), light-intensity physical activity (LPA), and MVPA were estimated using the following nondominant wrist–specific Euclidean norm minus 1 g cutoff points for older adults, adopted from the literature: (1) SB<30 mg, (2) 30 mg≤LPA<100 mg, and (3) MVPA≥100 mg [38-41]. Participants with at least 4 valid days were included in the analysis, and only days during which the accelerometer was worn for at least 14 hours were counted as valid days [38].

Static Balance

Static balance was assessed using the BTrackS Balance System (BBS). The BBS includes a portable BTrackS Balance Plate (BBP) and BTrackS Assess Balance software running on a computer device. The BBP's dimensions were 15.5 × 23.5 × 2.5 in, weighing 6.58 kg (approved by the Food and Drug Administration). The participant stood as still as possible on the BBP for four 20-second trials. The software produced a normalized score using the BBS database to evaluate the performance of others of the same age and sex [42].

FoF

FoF was assessed using the short FES-I, which consists of a total of 7 items (eg, going in or out of a chair) on a 4-point scale,

measuring concerns about the possibility of falling when performing activities (eg, getting dressed), which have been validated for community-dwelling older adults [43,44]. Total scores range from 7 to 28, where higher total scores indicate higher FoF [45]. Participants completed the short FES-I in a quiet and private room prior to PPT testing.

BMI

Height and weight were measured by experimenters using a stadiometer, and BMI was calculated by dividing the weight (kg) by the square of the height (m^2) [46].

Data Analysis

All statistical analyses were performed in R statistical software (version 4.3.0). Pearson correlation coefficient is appropriate for linear relationships, assumes normality, and achieves efficiency when linearity and normality assumptions are met, whereas Spearman rank correlation coefficient is suitable for nonlinear relationships, ordinal or nonnormally distributed data, and is robust to outliers [47]. As such, the correlation analysis was performed using the Spearman correlation coefficient to maintain validity for both normally distributed and nonnormally distributed variables. The correlation matrix was produced using the R package *corrplot*. The normality of variables was tested using the Shapiro-Wilks test. The effects of race and sex on PPT results were tested separately using ANOVA and Kruskal-Wallis tests, for normal and nonnormally distributed variables, respectively.

Multiple linear regression analysis was conducted to investigate the relationship between each PPT (SPPB, ISWT, and 6MWT)

as outcome variables and the following predictors: physical activity (MVPA), static balance, FoF, BMI, and age. A priori sample size calculation for multiple linear regression revealed that the minimum number of samples for 5 explanatory variables at a statistical power level of 0.8, α=.05, and large effect size (Cohen f^2=0.35) would be 43; therefore, our sample size (ie, N=53) had sufficient statistical power for multiple regression.

Results

Overview

This study included 53 older adults (mean age 77.47, SD 7.25 years) who were 77% (n=41) female. The sample included 5 (9%) African American, 21 (40%) Hispanic, 26 (49%) White, and 1 (2%) other race older adults.

Correlation Analysis

Spearman correlation coefficients for measures of physical activity (SB, LPA, and MVPA) yielded significant correlations with all measures ($P<.05$), except static balance (BBS) and BMI. Among the PPTs, the SPPB showed significant correlations with all measures, except BMI; the ISWT was correlated with all measures except static balance; and the 6MWT was correlated with all except LPA, static balance, BMI, and age. FoF (FES-I) was correlated with all measures except static balance and BMI. Static balance and BMI were both only correlated with a few measures (MVPA, SPPB, and ISWT), and age was correlated with all except 6MWT, static balance, and BMI (Figure 1).

Figure 1. Correlation matrix between all collected and analyzed measures of physical performance tests. All values are significant ($P<.05$) Spearman correlation coefficients. Blank cells indicate insignificant relationships ($P>.05$). 6MWT: 6-minute walk test; BBS: BTrackS Balance System; FES-I: Fall Efficacy Scale-International; ISWT: Incremental Shuttle Walk Test; MVPA: moderate to vigorous physical activity; SPPB: Short Physical Performance Battery.
Effects of Sex and Race

The effects of sex and race were tested separately with ANOVA test and Kruskal-Wallis test for nonparametric variables, to evaluate differences in performance on the 3 PPTs, as shown in Table 1. For sex, the female group (n=41) was compared to the male group (n=12), finding no differences in the SPPB, 6MWT, or ISWT (P>.05; Table 1). Similarly, for race, the African American (n=5), Hispanic (n=21), and White (n=26) groups were compared, finding no differences in the SPPB, 6MWT, or ISWT (P>.05; Table 1). "Other" race was excluded in the tests as the sample size was 1. Based on these nonsignificant differences, sex and race were not included as covariates in the multivariable regression models below.

Table 1. ANOVA and Kruskal-Wallis tests comparing performance on PPT[a] by sex and by race.

Demographics effect and PPT	Test	P value
Sex[b]		
SPPB[c]	Kruskal-Wallis	.09
6MWT[d]	ANOVA	.34
ISWT[e]	ANOVA	.05
Race[f]		
SPPB	Kruskal-Wallis	.47
6MWT	ANOVA	.48
ISWT	ANOVA	.42

[a]PPT: physical performance test.

[b]Female (n=41) and male (n=12).

[c]SPPB: Short Physical Performance Battery.

[d]6MWT: 6-minute walk test.

[f]African American (n=5), Hispanic (n=21), and White (n=26).

Normality

The Shapiro-Wilks tests revealed that 4 of the 9 variables (SPPB, MVPA, static balance, and FoF) were not normally distributed.

Multivariable Linear Regression Models

The multivariable regression models were used on each PPT (SPPB, ISWT, and 6MWT), as well as the gait component of SPPB (SPPB-G; 4-meter gait speed test) to relate them to the following predictors: physical activity (MVPA), static balance, FoF, BMI, and age (years).

Performance on the SPPB was significantly predicted by MVPA and the FES-I (Table 2). Performance on the 6MWT was significantly predicted solely by the FES-I (Table 3).

Performance on the ISWT was significantly predicted by MVPA, BMI, and the FES-I (Table 4). Performance on the SPPB-G was similar to the 6MWT in that it was only predicted by the FES-I (Table 5). Supplemental analyses removing the FES-I as a covariate in the multivariable models showed no significant predictors for the 6MWT; however, the SPPB was then predicted by both MVPA and static balance, and the ISWT, as well as the SPPB-G, was predicted by MVPA, BMI, and age (Multimedia Appendix 1). Among the 3 models, the adjusted R^2 value for the SPPB (0.523; Table 2) was greater than those for the 6MWT (0.228), ISWT (0.517), and SPPB-G (0.375). The models without the FES-I as a predictor showed decreased adjusted R^2 values (all <0.500).

Discussion

Principal Findings

This study examined associations between several measures of physical performance and general physical health of older adults, including physical activity, static balance, FoF, and BMI. We found several significant correlations between PPTs and physical health measures and further explored these with multivariable regression models evaluating the health measures that are drivers of each PPT.

The full correlation analysis showed significant correlations (Figure 1) between most physical activity and PPTs, as well as the subjective measure of FoF (FES-I). By characterizing multiple measures of physical performance in the same sample, this study is the first to our knowledge to evaluate and compare the comprehensive value of 3 commonly used PPTs (SPPB, 6MWT, and ISWT). Among each test, the SPPB showed the greatest magnitude and consistency of significant correlations. Additionally, we note the similarity of significant correlations between objectively measured physical activity and subjectively measured FoF, emphasizing the value of subjectively collected measures in older adults.

The multivariable regression models further evaluated the comprehensive value and relevance of each PPT to the physical activity, balance, FoF, and BMI of older adults. The complete SPPB model (Table 2) was both predicted by more variables and characterized by a higher adjusted R^2 value than the models predictive of gait function only (SPPB-G, ISWT, and 6MWT), indicating a greater value in holistic testing. Performance on the SPPB was significantly predicted by the FESI-I; MVPA; and in the absence of the FES-I, static balance. Designed to assess lower extremity functioning, the SPPB includes measures of standing balance, 4-meter gait speed, and the time needed to rise from a chair 5 times. This multipart test is easy to perform and evaluates several parts of daily physical functioning, indicated by the static balance test, a field walking test, and a sit-to-stand test included in the protocol. As such, the SPPB was a more comprehensive measure of older adults' physical health, evidenced by its associations with MVPA and static balance. Separating the SPPB-G provided a foundation upon which to compare the gait-based PPTs. In Table 5, the gait speed on the 4-meter course was predicted by the FES-I. Very similarly, the 6MWT (Table 3) was only predicted by the FES-I, suggesting that performance on this test is more related to the effect of subjective FoF and its impact on willingness to participate in physical activity. Furthermore, the 6MWT is limited by several factors, including variable standardization of testing and the learning effect, where repeated administration influences performance on the test [48-50]. The 6MWT is focused on lower limb mobility as a PPT [25], and as such, may be more of an indicator of gait performance and variables related to mobility rather than overall health. This focus on mobility is observed in the relationship between 6MWT performance and its only significant predictor, the FES-I.

The ISWT was similar to the 6MWT in its aim of assessing gait; however, the ISWT is performed incrementally and externally paced. As such, it was expected to be more integrative of overall health, supported also by a higher magnitude of correlation coefficients for the ISWT than for the 6MWT. We found that the ISWT was predicted by 3 components of overall health in older adults: MVPA, BMI, and the FES-I (Table 4). While the ISWT was more parsimonious in nature than the SPPB, as shown by its multiple predictors, disadvantages include the intensity and fatiguing nature of the ISWT. The similarity of the ISWT to the 6MWT validated its link with FES-I scores, although this has not been validated in the literature for the ISWT. Additionally, the R^2 values for the ISWT were more similar but not as large as the complete SPPB, and larger than the values for the SPPB-G and 6MWT, indicating its possible superiority as a comprehensive PPT. The implications of such a finding are its increased use as a standardized tool in geriatric clinician visits or preferential use of a more robust measure when evaluating gait. The broader impact of using the ISWT relates to that it is cost-effective and relatively user-friendly, not requiring significant training to administer.

Comparison to Previous Work

Our finding of associations between physical activity and FoF is consistent with previous literature [21-23] indicating the

effectiveness of PPTs in evaluating overall physical health. Among the specific PPTs, the relationship between the 6MWT and FoF is also supported by previous literature, which has found that performance on the 6MWT has previously been associated with both physiological fall risk [51] and more subjective responses to FoF, as measured by the FES-I [52]. However, this study found a lack of other significant predictors of performance on the 6MWT, which could contribute to its decreased potential for assessing the overall health of older adults in research and outpatient settings. The multiple predictors of the ISWT are more difficult to justify based on previous literature, which shows mixed results between physical activity and ISWT performance. One study among patients with heart failure has reported significant correlations between performance on the ISWT and physical activity levels [26]. However, another study in patients with chronic obstructive pulmonary disease did not find a relationship between physical activity and ISWT distance [53]. The relationship of the ISWT with BMI is notable, in that it is indicative that the more incremental approach to the walk test may be representative of overall body composition and mass. This finding has previously been reported as the result of increased exertion during the ISWT than during the 6MWT, evidenced by a higher peak heart rate [54,55]. However, the administration of the ISWT involves an externally set pace and is typically used for adults with chronic obstructive pulmonary disease; this may limit the applicability of this test for older adults with impairments, as shown by studies demonstrating decreased walking distance on the ISWT compared to the self-paced 6MWT for adults with disabilities [56].

Strengths and Limitations

First, this study was limited by a small sample size to represent several variables of overall health. This was evident in the power analysis with a large, anticipated effect size. However, the depth of data collected on each participant is a clear strength that reflected the contribution of this work to the body of literature on PPTs. Each participant completed 3 PPTs, physical activity monitoring for several days, static balance testing, an FoF questionnaire, and BMI measurement. In doing so, this study allowed for direct comparisons of PPTs conducted in the same sample. Second, the study sample consisted of predominantly female participants (41/53, 77%). While this is representative of the population of community-dwelling older adults who attend community centers, it is an additional factor that may impact the results. To address this, separate ANOVAs and Kruskal-Wallis tests were conducted to evaluate the effect of sex and age and include them as appropriate in the analysis.

The results of this study emphasized the value of the SPPB as an indicator of overall physical health in older adults. As this population grows in size, it is critical to determine optimal standards of physical health assessment. In identifying the SPPB as an optimal indicator, the authors not only validated its use in both identifying older adults at higher risk for falls and adverse health events but also set a standard for future research in older adults. Additionally, while the 6MWT and ISWT are both field walking tests, a comparison between these 2 tests provided clarification on the response of the ISWT to measures beyond its primary variable of interest, aerobic capacity. By consolidating various measures of PPT into a single, more comprehensive test, experimental and epidemiological studies are more easily compared and reproduced.

Future Directions

To expand this work, further studies should validate these findings in older adult samples from different communities to evaluate the external validation, as well as clinical differences over longitudinal data collection. Additionally, the mechanisms behind how each of the physical health measures affects the PPTs remains unknown. Interdisciplinary work can evaluate the multifaceted drivers of physical performance and their physiological mechanisms. Understanding these may provide further support and additional interventions for older adults.

Conclusions

This study found that the SPPB was more comprehensive and responsive to overall physical health compared to the 6MWT and ISWT in older adults. In particular, the SPPB was predicted by both physical activity levels and FoF. It assessed balance, gait speed, and lower extremity strength through its inclusion of standing balance tests, walking, and chair stands. In contrast, field walking tests, like the 6MWT and ISWT, were more limited in their associations. These findings suggested that the SPPB should be standardized as the optimal physical performance measure in geriatric research and care, as it allows earlier identification of those at risk of functional decline. However, the ISWT may still provide value in revealing limitations at higher exertion capacities that are not apparent with the SPPB. More comparative research is warranted to develop the best assessment battery for evaluating multifaceted geriatric health.

Data Availability

The datasets generated during or analyzed during this study are available in the Open Science Framework repository Comparison of Physical Performance Tests in Older Adults [57].

Authors' Contributions

JHP, LT, RX, and DHF contributed to the funding acquisition, conceptualization, and study design. RC, JHP, LT, DHF, and JRS coordinated the study and collected data. CB, JHP, and RX contributed to the data analysis. CB wrote the original draft, and RC, JHP, RX, DHF, JRS, and LT contributed to the revision of the original draft. All authors have agreed to the final version of the paper.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Supplementary analyses investigating the significance of each linear regression model for the physical performance tests (SPPB, SPPB-G, 6MWT, and ISWT) without fear of falling as a predictor. 6MWT: 6-minute walk test; ISWT: Incremental Shuttle Walk Test; SPPB: Short Physical Performance Battery; SPPB-G: gait component of the Short Physical Performance Battery.

Abstract

Background: Anterior chamber–associated immune deviation (ACAID) is an active immunotolerance mechanism, which is induced by placing antigen into the anterior eye chamber as long as a major surgical trauma is avoided. For this reason, ACAID may be a major contributor to the favorable immunologic outcomes in Descemet membrane endothelial keratoplasty (DMEK). Rodent models have demonstrated the importance of a functional spleen for the development of an ACAID.

Objective: This study aimed to investigate whether splenectomy leads to increased rejection rates after DMEK in humans.

Methods: A retrospective evaluation was conducted on the course following DMEK at the Eye Center, Medical Center, University of Freiburg, for patients with a self-reported history of splenectomy compared to patients without this condition. Potential study patients were contacted by mail. A questionnaire to self-report splenectomy and the time thereof was sent out. The medical records of all consenting patients at the Eye Center were reviewed for graft survival and immune reactions.

Results: We asked 1818 patients after DMEK to report their history of splenectomy. A total of 1340 patients responded and were included in the study. Of these 1340 patients, 16 (1.2%) reported a history of splenectomy (ie, 26 DMEKs, with 10 patients being transplanted in both eyes and 6 patients being transplanted in 1 eye; median age at surgery 73.7, range 66.7-76.1 y). The remaining patients (1324 patients, ie, 1941 eyes) served as controls, with 1941 DMEKs (median age at surgery 71.5, range 64.1-77.2 y). Five (19%) out of the 26 eyes from the splenectomy group required a second transplant due to dislocation (n=2.8%), failure (n=2.8%), and rejection (n=1.4%). Kaplan-Meier analysis revealed no relevant difference compared with controls.

Conclusions: Our results suggest that splenectomy has no major effect on the outcome following DMEK. Subsequent, ACAID may not be the main reason for the favorable immunological outcomes in DMEK, or the camero-splenic axis may be subordinate in humans. However, we only included 16 patients who underwent splenectomy, so it might be possible that we missed a minor effect.

Introduction

Nowadays, corneal transplantation is one of the most common and successful forms of tissue transplantation worldwide, and in the vast majority of cases, it occurs without a human leukocyte antigen match [1]. Since not only can penetrating keratoplasty be performed but lamellar surgery techniques (such as Descemet membrane endothelial keratoplasty [DMEK]) are also available, the proportion of penetrating keratoplasties is decreasing while the number of DMEKs performed is increasing [2]. Approximately 2% to 7% of normal-risk patients after a DMEK and about 18% after a penetrating keratoplasty

experience immunologic rejection [3-5]. At present, it remains unclear why there is less rejection in DMEK transplantation; consequently, a hypothesis arose—that the anterior chamber–associated immune deviation (ACAID) phenomenon may contribute significantly to the favorable immunologic outcomes in DMEK. As of today, there are practically no clinical data on this topic.

The fact that corneal transplantation can be effective was demonstrated by various surgeons and ophthalmologists in animal models as early as 1818 (on rabbits) [6]. The first successful corneal transplantation in humans was performed by Austrian surgeon Eduard Zirm [7] in 1906. In comparison, the first successful kidney transplantation was performed almost 50 years later, in 1953 [8]. Corneal transplants were much less likely to be rejected compared to organ transplants at very early stages after transplantation. The reason why the corneal tissue was not rejected directly led to many hypotheses about the immunology of the eye that allows this [9]. Considering these questions, clinicians as well as researchers began to investigate ACAID [10,11]. The immune system is able to prevent immune reactions against foreign antigens within the eye. In the rodent model, it has been found that this principle works only if the antigens are injected atraumatically into the eye [12]. The removal of the spleen prevents the development of ACAID in the rodent model, resulting in an increased rejection rate after corneal transplantation [13]. This is currently explained by the so-called camero-splenic axis. Antigen-presenting cells most likely derived from the iris and ciliary body take up antigens placed in the anterior chamber and migrate via the trabecular meshwork and collector veins through the blood into the spleen. Within the spleen, these antigen-presenting cells induce the differentiation of antigen-specific regulatory T cells, forming the cellular arm of ACAID [14]. However, there is currently no proof of this theory; human data on the presence of ACAID or the camero-splenic axis are lacking.

The primary objective of this retrospective study was to compare outcomes between human patients with and without splenectomy, specifically graft rejection and failure, following DMEK surgery. For this purpose, all reachable patients who underwent DMEK at the Eye Center, Medical Center, University of Freiburg, during the last 12 years (2734 eyes in total) were sent a questionnaire to self-report whether they underwent splenectomy and the time thereof. We herein investigate the potential role of ACAID in the excellent immunological prognosis of DMEK. This could provide initial evidence on the contribution of ACAID to the success rates of DMEK.

Methods

Study Design

This was a retrospective study evaluating the course following DMEK at the Eye Center, Medical Center, University of Freiburg, for patients with a self-reported history of splenectomy compared to patients without this condition.

Data Collection

A total of 2734 DMEKs were performed between 2010 and 2022 at the Eye Centre, Medical Center, University of Freiburg.

Patients who underwent DMEK during this period were eligible for inclusion. We were able to contact 1818 patients from this pool. They were sent a cover letter by mail, including patient information about the study, a consent form, and a questionnaire to self-report splenectomy and the time thereof. This questionnaire formed the basis of consent in our study. Patients who did not respond to the questionnaire or did not wish to participate in the study were excluded from the analysis.

The exposure of interest was a self-reported history of splenectomy, which was assessed through the questionnaire sent to patients. Data collected through the questionnaire included self-reported history of splenectomy and the time thereof.

The questionnaire was a simple 1-question survey asking patients to self-report whether they had undergone splenectomy and when. The questionnaire was developed by the research team and reviewed and approved by the ethics committee to ensure clarity and comprehensibility.

After submitting the questionnaire, patients cannot withdraw their participation in the research project, as we irreversibly anonymize their identity and destroy their questionnaire in accordance with data protection regulations once their information have been transferred for the statistical analysis. Therefore, individual study participants cannot be identified when publishing the study results.

Data collected from electronic health records included demographic information, indication for DMEK, and postoperative outcomes such as graft rejection and failure.

The medical records of all consenting patients were reviewed for graft survival and immune reactions. All patients are scheduled postoperatively for follow-up in our clinic, so it is highly likely that we have captured almost all immune reactions. These data were linked to the questionnaire responses to compare patients who underwent splenectomy to the remainder who served as controls.

DMEK surgery was executed per standards as previously described [3]. Briefly, a trephine was used to punch the grafts, which were stained with trypan blue 0.6 mg/mL. Subsequent to descemetorhexis and insertion of the graft into the anterior chamber, the graft was unfolded and centered. Next, complete air filling of the anterior chamber connected the graft to the posterior stroma. Postoperatively, patients were requested to remain supine for 3 days. Postoperative local therapy consisted of topical dexamethasone 5 times daily and tapered over 5 months to once daily, which was recommended for up to 24 months or longer. There was no evidence of any difference in postoperative medical aftercare between patients who under splenectomy and the controls.

Patients with postoperative epithelial defects were initially treated with dexpanthenol and ofloxacin ointment alternately every hour until epithelial closure, before the aforementioned treatment was started.

The main outcomes were graft rejection and failure.

Graft rejection was determined by reviewing medical records for signs of rejection, such as newly appearing endothelial

precipitates on the graft [5]. Other clinical signs of graft rejection may include cells in the anterior chamber or otherwise unexplained corneal edema [15].

Corneal grafts that were not adherent and/or did not result in corneal transparency were classified as graft failures.

Ethical Considerations

The study protocol was approved by the ethics committee of the Albert Ludwigs University of Freiburg (21-1472). Informed consent was obtained from all participants, and they had the ability to opt out of the study. Data were anonymized, and protective measures were in place to safeguard participant information. No compensation was provided to participants in this study.

Data Presentation and Statistical Analysis

Descriptive statistics summarized baseline characteristics between the splenectomy and control groups. Median and IQR were reported for continuous variables, and percentages were reported for categorical variables. Differences were assessed using ANOVA for continuous data and Pearson chi-square tests for categorical outcomes.

Time-to-event analysis was performed using Kaplan-Meier curves depicting the risk of immune reactions, graft failure (as operationalized by regrafting), and rejection-free graft survival (a combination of the 2 aforementioned end points) between the splenectomy and control groups. Additionally, we also conducted another analysis by excluding early regrafting (during the first few postoperative days) due to technical failures. Groups were compared using the log-rank test. Multivariable Cox proportional hazard models were constructed to determine the independent association of splenectomy on outcomes after adjusting for potential confounding factors such as recipient age, sex, baseline diagnosis, and triple surgery (ie, cataract surgery in combination with DMEK). Hazard ratios with 95 CIs were reported.

Two-sided P values <.05 were considered statistically significant for all analyses, which were performed with R software (version 4.1.3; R Foundation for Statistical Computing) [16].

Results

Of the 1818 patients contacted, 1311 (72.1%) responded by returning the questionnaire. Additionally, 11 (0.6%) patients responded by email, and 18 (1%) responded via telephone. This yielded a response rate of 73.7% (1340/1818). Among the 1340 respondents, 16 (1.2%) reported a history of splenectomy. Only 5 other patients reported back and did not want to be included in the study. The family members of 27 patients contacted us to inform us that the patient had died and that no information about splenectomy was available; thus, these patients were not included in the study.

Of the 1324 patients who did not undergo splenectomy, we performed DMEKs on both eyes among 617 patients, so a total of 1941 eyes could be included in the control group.

Of the patients who underwent splenectomy, some had received DMEKs on both eyes at our hospital, yielding a total of 26 DMEK procedures. Of the 16 patients who underwent splenectomy, 11 (69%) were able to recall the time of the surgery. The remaining 5 (31%) patients could not give information about the time of surgery. Only 2 patients (each having had a DMEK on only 1 eye) underwent the splenectomy after the DMEK (see Multimedia Appendix 1). Median age at transplantation was similar between the groups. However, there was a lower proportion of female patients (9/26, 35% vs 1129/1941, 58.2%) and a higher rate of triple surgery (20/26, 77% vs 1139/1941, 58.7%) in the splenectomy group.

After reviewing the medical records, we found that of the 26 DMEKs (16 patients) in the splenectomy group, 5 (19%) eyes required regrafting. Two of these repeated DMEKs were performed for technical reasons because of incomplete graft attachment. Only 1 patient presented the defined signs of endothelial graft rejection, and the remaining 2 patients showed unspecific late endothelial graft failure (see Table 1 and Multimedia Appendix 2).

Table 1. Summative evaluation of the Descemet membrane endothelial keratoplasties (DMEKs) of the 16 patients who underwent splenectomy.

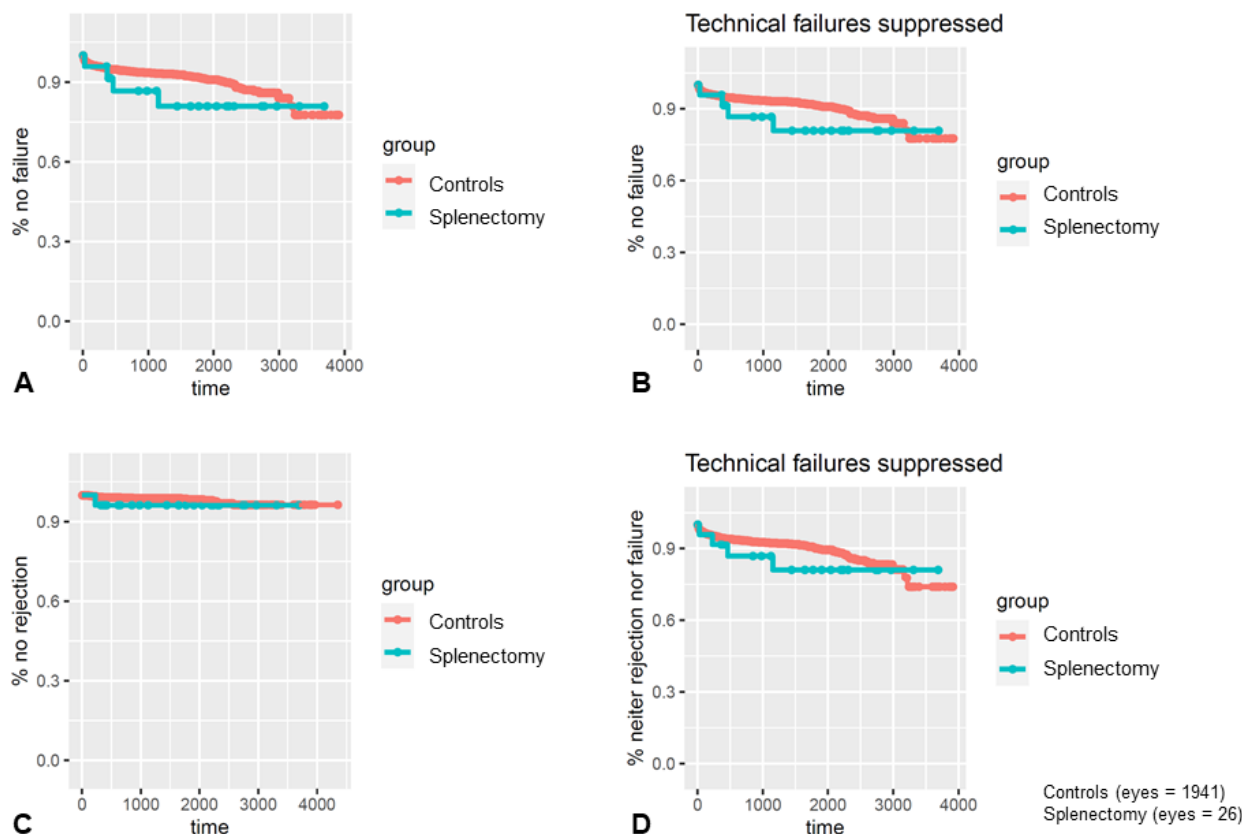
Variable	Value
Patients who underwent splenectomy, n	16
DMEKs, n	26
Repeat DMEKs (n=26 eyes), n (%)	5 (19)
Graft dislocation	2 (8)
Graft failure	2 (8)
Graft rejection	1 (4)

In the control group, graft failure occurred in 153 (7.9%) out of 1941 eyes, and rejections were observed in 26 (1.3%) eyes. We additionally compared the indication for DMEK between the patients who underwent splenectomy and the controls (see Multimedia Appendix 2). Of the 26 DMEKs in patients who underwent splenectomy, 24 (92%) had Fuchs endothelial dystrophy. Two patients had previously received penetrating keratoplasty and required a DMEK for graft failure. Precisely, these 2 cases required a second DMEK, both due to endothelial graft failure.

Kaplan-Meier analysis (Figure 1) and multivariable Cox proportional hazards models adjusting for age, sex, baseline

diagnosis, and triple surgery revealed no statistically significant differences in the risk of regrafting, failure, rejection, or

combined end points between groups (all *P*>.05).

Figure 1. Survival analyses. (A) The percentage of patients who did not need a repeat keratoplasty shown over time in days. The patients who underwent splenectomy are presented in blue and the control group is shown in red. The splenectomy group includes the 2 cases of graft dislocation. (B) Without these technical failures, a slight trend of patients who underwent splenectomy toward the need of a second keratoplasty may be seen. The same plots are shown for (C) the rejection-free time and (D) without the technical failures. Included in these lower 2 curves is 1 rejection case that did not require repeat keratoplasty. Again, one could assume a trend here.


Survival analyses comparing graft rejection rates, the need for repeat keratoplasties, and the combined results between groups are shown in Figure 1. The control group is considerably larger than the splenectomy group for obvious reasons. When counting the early repeat DMEKs from graft dislocation, the splenectomy group showed a trend toward a slightly worse performance compared to the controls (see Figure 1A). However, this is abrogated when counting only events that could theoretically be caused by immune reactions (see Figure 1B). In the comparison of the DMEK grafts without rejection reaction, almost no difference between the groups is discernable (see Figure 1C). Ignoring technical failures when regarding the combined results (see Figure 1D), a slight trend may be inferred toward the splenectomy group performing worse than the controls.

Specifically, the adjusted hazard ratio for the risk of graft failure comparing patients who underwent splenectomy to controls was 1.91 (95% CI 0.25-14.31; *P*=.53). Similar nonsignificant findings were observed for rejection and combined outcome models.

Discussion

Principal Findings

Our study was designed to investigate the effects of splenectomy on rejection after DMEK. Based on the data presented here, the spleen does not appear to have a major influence on the survival or rejection of DMEK grafts, so the significance of ACAID for human DMEK may be subordinate.

Animal models theorize that the spleen is essential in the induction of ACAID [13,14]; evidence to support this theory does not exist from clinical studies. This study is the first large-scale study to examine this in a retrospective clinical setting. We found no evidence to support these hypotheses.

It is still unclear whether ACAID and immune privilege for corneal transplantation established in animal models also applies to human keratoplasty and more specifically to DMEK. The low risk of allograft rejection after corneal endothelial transplantation is thought to be due to the ACAID phenomenon after the introduction of antigens into the anterior chamber [17]. As early as 1966, Streilein et al [18] demonstrated that external corneal procedures, such as keratoplasty, corneal cauterization, and corneal sutures, lead to inflammation that prevents the induction of ACAID. Yamada et al [19] examined the allogeneic

response in the anterior chamber after the transplantation of corneal endothelial cells in a mouse model. Both intracameral injection of splenocytes and corneal endothelial cells induced ACAID with the suppression of the delayed hypersensitivity reaction. However, this could not be detected in inflamed eyes by cryoinjury, so the loss of the delayed hypersensitivity reaction does not seem to be regulated by ACAID.

Not all animal studies showed an effect of splenectomy on corneal graft survival. Bourne et al [20] performed corneal transplants in 19 rabbits each with and without splenectomy and found no significant difference in graft survival. In 2017, Vendomèle et al [11] summarized the evidence on ACAID and noted that several factors raised questions about the reliability and validity of studies using knockout mouse models. In particular, physiological relevance and transferability to humans must be considered critically.

To our knowledge, our study is the first with such a high number of patients who underwent both splenectomy and DMEK. Hos et al [21] followed a single case of a patient who underwent splenectomy for 4 years after DMEK. During this time, they noted no corneal graft rejection and assumed that the spleen was not necessary for graft acceptance.

Of our 26 DMEK transplants, 1 case developed graft rejection and 2 cases developed graft failure. In relation to the control group, this may suggest that splenectomy possibly does lead to a slight tendency of poorer graft acceptance. However, it has to be considered that the 2 graft failures are part of the high-risk group, because the indication for DMEK was the failure of a previously performed penetrating keratoplasty. Thus, from the data presented here, splenectomy does not appear to have a clear effect on the immunologic response to corneal transplantation. Furthermore, it should be noted that of all participating patients, only 16 patients who underwent splenectomy were included; thus, it is possible that we missed finding an influence on graft rejection after DMEK. The validity and reliability of the basic questionnaire was not formally tested. This is a limitation given the self-reported nature of the splenectomy history but is mitigated by the minimalistic (only 1 question) nature of this document. Additionally, we can conclude that undergoing splenectomy after DMEK does not have any influence either, since 2 of our patients showed such a course.

Conclusion

As described previously, there is controversy about the relevance of the spleen in animal models investigating corneal graft rejection. The importance of the spleen in humans has not yet been investigated. Our results suggest that splenectomy does not substantially impact DMEK outcomes after accounting for potential confounding factors. However, given the limited sample size of patients who underwent splenectomy, a clinically meaningful effect cannot be definitively excluded. Nonetheless, ACAID may either not fully explain favorable immunologic outcomes following DMEK based on current evidence or the camero-splenic axis may be subordinate in humans.

Abstract

Background: The interrelation between COVID-19 and various cardiovascular and metabolic disorders has been a critical area of study. There is a growing need to understand how comorbidities such as cardiovascular diseases (CVDs) and metabolic disorders affect the risk and severity of COVID-19.

Objective: The objective of this study is to systematically analyze the association between COVID-19 and cardiovascular and metabolic disorders. The focus is on comorbidity, examining the roles of CVDs such as embolism, thrombosis, hypertension, and heart failure, as well as metabolic disorders such as disorders of glucose and iron metabolism.

Methods: Our study involved a systematic search in PubMed for literature published from 2000 to 2022. We established 2 databases: one for COVID-19–related articles and another for CVD-related articles, ensuring all were peer-reviewed. In terms of data analysis, statistical methods were applied to compare the frequency and relevance of MeSH (Medical Subject Headings) terms between the 2 databases. This involved analyzing the differences and ratios in the usage of these terms and employing statistical tests to determine their significance in relation to key CVDs within the COVID-19 research context.

Results: The study revealed that "Cardiovascular Diseases" and "Nutritional and Metabolic Diseases" were highly relevant as level 1 Medical Subject Headings descriptors in COVID-19 comorbidity research. Detailed analysis at level 2 and level 3 showed "Vascular Disease" and "Heart Disease" as prominent descriptors under CVDs. Significantly, "Glucose Metabolism Disorders" were frequently associated with COVID-19 comorbidities such as embolism, thrombosis, and heart failure. Furthermore, iron deficiency (ID) was notably different in its occurrence between COVID-19 and CVD articles, underlining its significance in the context of COVID-19 comorbidities. Statistical analysis underscored these differences, highlighting the importance of both glucose and iron metabolism disorders in COVID-19 research.

Conclusions: This work lays the foundation for future research that utilizes a knowledge-based approach to elucidate the intricate relationships between these conditions, aiming to develop more effective health care strategies and interventions in the face of ongoing pandemic challenges.

Introduction

The SARS-CoV-2 virus, which causes the disease COVID-19, has impacted all areas of our lives. The scientific community has shown an unprecedented and coordinated response to this global pandemic [1,2]. This has led to a rapid acquisition of new knowledge in a wide range of scientific fields and, simultaneously, to new questions that needed to be answered [3-5]. Some of the most important questions concern the origins and causes leading to the severe form of COVID-19 or even death [6,7]. One of the most important pathological aspects of COVID-19 disease is its impact on the cardiovascular system, more specifically cardiovascular disease (CVD) [8-11]. The link between COVID-19 and CVD has been demonstrated and confirmed in numerous studies. A recent scientific review article by Vosko et al [12] offers an extensive overview of the literature on the interaction between COVID-19 and CVDs. The authors describe how COVID-19 can act as a yet unrecognized risk modifier for CVD, including risk factors such as diabetes mellitus [13] or arterial hypertension [14]. In the study by Vosko et al [12], an increased incidence of CVD and poorer clinical outcomes were observed in individuals with preexisting CVD, noting conditions like myocarditis, acute coronary syndrome, heart failure, thromboembolic complications, and arrhythmias. Furthermore, the article by Vosko et al [12] summarizes the mechanisms through which COVID-19 can affect CVD, including the impact on endothelial cells and inflammation, which can increase the risk for atherosclerosis and other cardiovascular events. Additionally, a review study [15] was conducted to demonstrate the connection between COVID-19 and CVD. This study provides a detailed examination of the impact of COVID-19 on different cells in myocardial tissue and offers an overview of the clinical manifestations of cardiovascular involvement in the pandemic.

The most striking link between COVID-19 and CVD involves the angiotensin-converting enzyme 2 (ACE2), which is the main receptor for the glycoprotein membrane spike of SARS-CoV-2 [16-18]. ACE2 is bound to cell membranes in various tissues of the vascular system [19]. Considering its importance in CVD, a population-based study showed that higher ACE2 plasma levels are associated with a greater risk of severe CVD [20]. COVID-19 has been found to increase the risk of cardiogenic shock [21,22], cardiac arrhythmias [23,24], acute myocardial injury [25,26], and sometimes sudden death in patients with CVD [15,27,28], and at the same time, patients with CVD have a higher risk of mortality due to COVID-19.

ACE2 is an important down-regulator of the renin-angiotensin-aldosterone system (RAAS), which plays a significant role in controlling arterial blood pressure [29]. Various studies have investigated the dysregulation of ACE2 in different cells of patients with CVD, indicating an involvement of the RAAS [30,31]. For example, downregulation was found primarily in fibroblasts and the vascular smooth muscle of ventricles with dilated or hypertrophic cardiomyopathy [32,33]. Conversely, an upregulation of ACE2 is mainly observed in the cardiomyocytes of patients with ischemic and non-ischemic cardiomyopathy [32-34], It is also noted in the lungs of patients with hypertension, cerebrovascular

disease, coronary artery disease, and other comorbidities such as diabetes [35], which may be attributable to the joint treatment of such comorbidities in addition to the disease itself [36].

This correlation is further supported by biochemical and genetic analyses, as patients with heart failure show increased ACE2 expression. ACE is found in 7.6% of all heart cells, compared to only 5.88% in healthy individuals. This is even more pronounced in cardiomyocytes, where 9.87% of all cardiomyocytes in heart failure express ACE2, whereas in healthy hearts, the figure is 6.75% of cardiomyocytes. This is reversed in arterial vascular cells: heart failure shows positive ACE2 expression in 7.93% of vascular cells and 19.4% in healthy individuals [37]. The invasion of SARS-CoV-2 upregulates the activity of the protease ADAM17, which in turn downregulates ACE2 by cleaving it from the cell surface. This process, known as "shedding," and is very important for understanding the cardiovascular effects of COVID-19. Recognizing the beneficial effects of Ang-1-7 signaling, we understand that disruption of this pathway through shedding leads to the predominance of the RAAS, causing hypertension, fibrotic remodeling, inflammation, and sodium retention [38,39].

Novel big data streams have created interesting opportunities to synthesize research and identify hotspots of big data in infectious disease epidemiology [40]. Furthermore, big data bibliometric analyses can reveal trends and project future developments in each scientific discipline [41-43]. Thus, based on bibliometric analysis, a study was conducted [44], that aimed to investigate the international scientific output on the relationship between COVID-19 and CVDs. The findings revealed that the United States and China are at the forefront in both the quantity and quality of publications in this area. Additionally, the analysis indicated that researchers have paid special attention to cardiovascular comorbidities, outcomes, and regenerative medicine in the context of COVID-19. Such innovative analytical approaches, which leverage extensive big data resources, are particularly crucial for deciphering the complex dynamics of comorbidity patterns observed in COVID-19 and CVDs. By integrating big data insights with traditional epidemiological methods, our study not only contributes to a deeper understanding of these comorbidities but also opens new avenues for predictive analytics in health care.

Considering all this evidence, a critical interface between the virus and CVD has emerged, posing unique challenges to health care systems worldwide. This study aims to unravel the complex relationship between COVID-19 and CVD, addressing a significant gap in our current understanding of the comorbidity dynamics of these diseases. Utilizing a novel approach with MeSH (Medical Subject Headings) descriptors, we systematically analyze a wide range of literature to identify key patterns and themes. Our study not only sheds light on the increased risks and outcomes associated with these comorbidities, but also paves the way for future research methods. This manuscript is organized to first explain our methodological approach, followed by a presentation of our findings, a discussion of their implications, and concludes with insights that have the potential to inform future health care strategies and interventions.

Methods

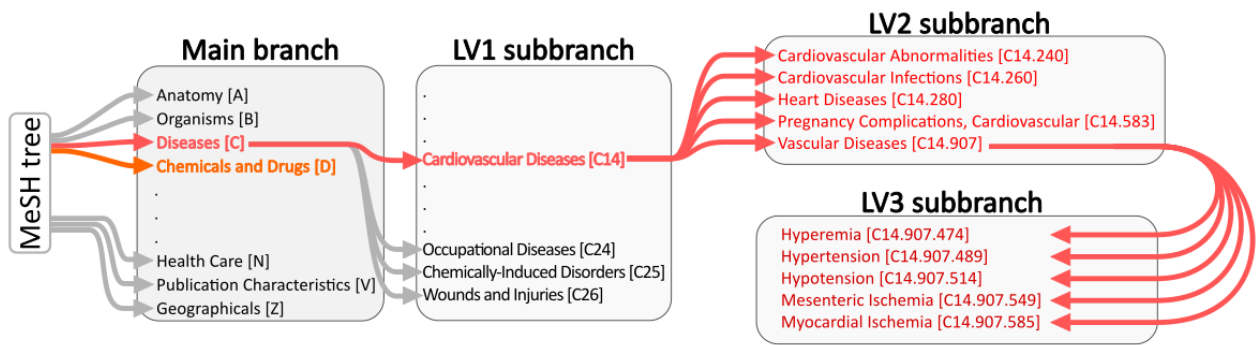
Overview

We conducted a search on PubMed [45] with specific search queries on CVD and SARS-CoV-2 and limited our search to articles published from the year 2000 onwards. Between January 1, 2000, and September 30, 2021, we collected all relevant entries in PubMed. From these entries, we selected only peer-reviewed scientific publications. We then created 2 databases: one for articles related to COVID-19 (the COVID-19 database) and another for articles related to CVDs (the CVD database). The databases had a similar organization and stored 2 primary pieces of information: the PubMed identifier (PMID) and all the MeSH descriptors provided for an article. The following sections describe in detail the creation of the databases, the use of the MeSH classification scheme, and the analyses performed.

MeSH Classification

The MeSH thesaurus is a controlled and hierarchically organized vocabulary developed and curated by the National Library of Medicine (NLM). The assignment of MeSH descriptors to papers by professional indexers at the NLM is highly consistent and an efficient method for describing the main topics of an article. Consequently, the MeSH classification system offers an organized approach for sorting and accessing medical knowledge. This knowledge is represented by MeSH descriptors or MeSH terms, which are organized hierarchically to facilitate efficient retrieval of biomedical and health-related information from the NLM databases.

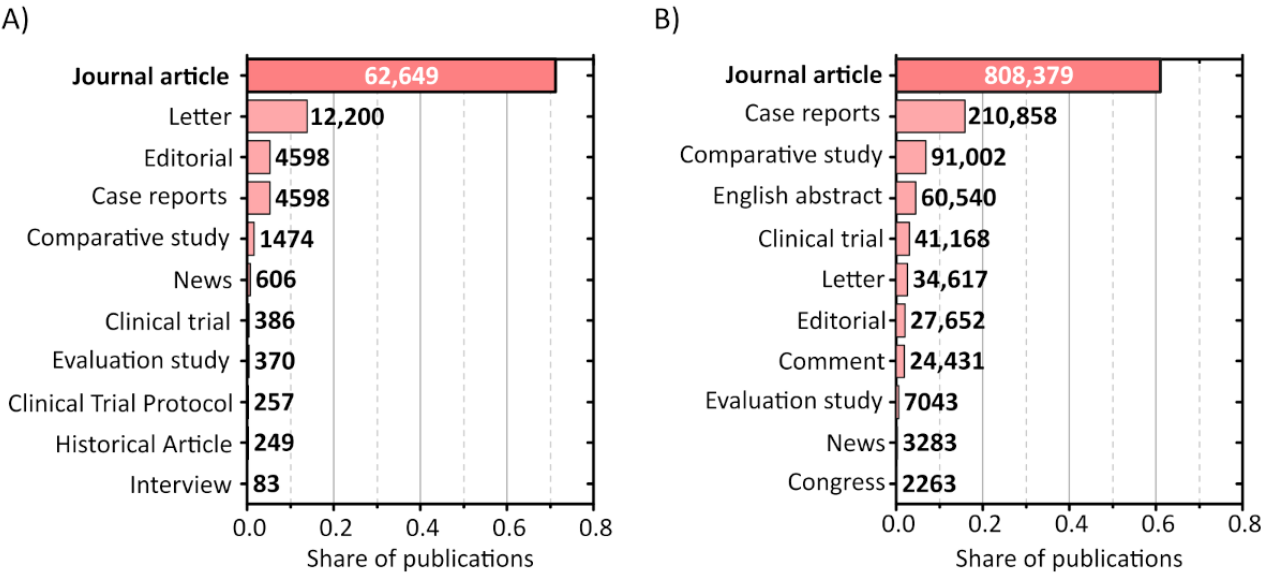
In the MeSH tree, the 16 main categories form the foundation of its hierarchical structure. Each main category branches into level 1 (LV1) subbranches, representing more specific aspects of the primary category. These LV1 subbranches further divide into level 2 (LV2) subbranches, offering an even more detailed classification. This pattern continues, with each subsequent level—level 3 (LV3), level 4, and so forth—delving deeper into specialized topics, ensuring a comprehensive and nuanced organization of medical subjects. Overall, the MeSH descriptors are structured hierarchically across 13 levels of subbranches. The coding of MeSH descriptors involves assigning unique alphanumeric identifiers to each descriptor in the MeSH database. These codes serve as precise references, facilitating information retrieval and classification in medical and health-related databases. Typically, MeSH codes consist of a combination of letters and numbers. The letters often represent the main category or aspect of health or medicine the descriptor pertains to, while the numbers provide a unique identifier within that category. Figure 1 presents a schematic representation of the MeSH tree.

Figure 1. A schematic representation of the hierarchical structure within the MeSH (Medical Subject Headings) tree, illustrating the organization from main branches to more specific sub-branches. The main branch example shown here includes categories like Anatomy [A], Diseases [C], and Chemicals and Drugs [D]. It details the progression from a main branch (Diseases [C]) to a LV1 sub-branch (Cardiovascular Diseases [C14]), to more refined LV2 and LV3 sub-branches, which specify narrower topics such as Heart Diseases [C14.280] and further down to Hypertension [C14.907.489] within the LV3 sub-branch. Each descriptor or topic is paired with a unique alphanumeric code that facilitates indexing and retrieval in medical databases. LV1: level 1; LV2: level 2; LV3: level 3.


For our analysis, we developed a Python script capable of mining relevant publications from PubMed through their API. It extracts the MeSH descriptors associated with an article, along with its unique PMID, and translates a given MeSH descriptor code to the corresponding MeSH descriptor name. Since the code of the MeSH descriptor embeds the location of the term in the MeSH tree, our script can determine the branches from which a MeSH descriptor originates. Our analysis primarily focuses on the "Diseases" main branch (denoted by the letter C), especially the "Cardiovascular Diseases" subcategory (LV1 subbranch C14; Figure 1). The hierarchical structure of the MeSH tree enables an in-depth analysis of topics at different levels of specificity, as illustrated in Figure 1. A more detailed description of the algorithm is given in the subsequent sections.

Creation of the Database

Using Python and the PubMed API, Entrez, our algorithm retrieved relevant information from the PubMed database on COVID-19 and CVDs. We utilized MeSH descriptors as search parameters. For the CVD database, our search query was "Cardiovascular Diseases [MeSH Terms]," while for the COVID-19 database, it was "COVID-19 [MeSH Terms]." Our inclusion criteria were limited to articles from peer-reviewed journals. Figure 2 provides a comprehensive breakdown of the records obtained for each query, categorized by publication type, focusing on the PMID and associated MeSH terms.

Figure 2. Publication type prevalence in the (A) COVID-19 and (B) cardiovascular disease (CVD) data sets.


For the selected publications, we retrieved raw XML data from PubMed and extracted 2 pieces of information from each XML file: all MeSH descriptors and the PMID. The latter was used to remove duplicate entries. Following this procedure, we created 2 databases: one for the COVID-19 query and another for the CVD query. In addition to these databases, we also developed a graph of MeSH descriptors, which was used for information retrieval.

Data Analysis

For each database, we performed statistical analyses using Python [46] and its associated libraries: pandas [47] for data manipulation, SciPy [48] for statistical calculations, and Matplotlib [49] for data visualization.

Our initial step in the analysis involved calculating the relative frequency of each MeSH descriptor within a specified branch level, ranging from the "Disease" main branch to subsequent levels such as the LV1 subbranch and beyond. We accomplished this by tallying the occurrences of each MeSH term across all publications in our database. After obtaining these raw counts, we moved to a critical phase of normalization. We normalized each count by the total number of articles within the database, thus converting raw frequencies into proportional measures. This adjustment allows the data to accurately reflect the prevalence of each descriptor within the context of the overall literature corpus.

For a more granular analysis of specific subbranches (i.e., LV1, LV2, etc), we refined our approach. We quantified the number of articles associated with each MeSH descriptor within the subbranch of interest. This time, however, the normalization process took into account the total number of articles relevant to that particular subbranch, thus ensuring that our statistical insights were accurately contextualized within the scope of the subbranch's literature.

To ascertain the relative significance of specific MeSH descriptors within our databases, we denoted the frequency of each MeSH term within a database (DB) as f_{DB} (MeSH). This measure allows us to conduct a comparative analysis to determine the prominence of each descriptor in the COVID-19 database relative to the CVD database. We measure the disparity in usage frequency of a MeSH term between the 2 databases by calculating the difference , expressed as:

$$\Delta f(MeSH) = f_{COVID}(MeSH) - f_{CVD}(MeSH) \text{ (1)}$$

This difference, $\Delta f(MeSH)$, provides an indication of whether a MeSH descriptor's presence is more pronounced (up-regulated) or less pronounced (down-regulated) in the COVID-19 database as compared to the CVD database. A positive difference signifies a MeSH term's greater relevance to the COVID-19 corpus, while a negative value indicates lesser importance.

However, the difference in frequencies can be misleading if the absolute values are too large or small. This difference might not accurately represent the term's practical significance. To address this, we also calculated the ratio, $R(MeSH)$, defined as:

(2)

This ratio offers insight into the relative usage of each MeSH descriptor. A ratio near 1 suggests comparable usage in both databases, while ratios significantly greater or less than 1 imply a disparity in descriptor usage.

By integrating both the difference, $\Delta f(MeSH)$, and the ratio, $R(MeSH)$, of frequencies, we achieved a more nuanced understanding of the role and emphasis of MeSH terms in the COVID-19 database in contrast with the CVD database. This dual-parameter approach allows for a more detailed and representative interpretation of the importance of specific MeSH descriptors in relation to the topics under investigation, such as hypertension.

Statistical Analysis

To pinpoint the most significant MeSH topics within the context of the 3 most prominent CVDs in relation to COVID-19, we employed a statistical approach. We conducted a chi-square test

of independence. This statistical test was employed to assess whether the occurrence of specific MeSH terms shows a significant difference when comparing the COVID-19 database with the CVD database.

The chi-square test is particularly suited for this analysis as it helps determine if there is a significant association between the type of database (COVID-19 or CVD) and the frequency of particular MeSH terms. A significant result from this test implies that the likelihood of a MeSH term's occurrence is dependent on the database, indicating a specific relevance to either COVID-19 or CVD-related articles.

Such a methodological approach allows us to identify and highlight those MeSH terms that are disproportionately represented in one database compared to the other, thereby providing insights into the intersection of COVID-19 with prominent cardiovascular conditions. This analysis not only enhances our understanding of disease dynamics but also potentially guides future research directions in these intersecting medical areas.

Results

Our analysis begins with a thorough examination of the "Disease" main branch in the MeSH tree. Specifically, our interest lies in the corresponding MeSH descriptors found within the LV1 subbranches. These LV1 subbranches are particularly notable as they encompass the primary disease descriptors, which are the fundamental classifications for various diseases.

In Figure 3, we show the frequency with which primary disease descriptors are used in COVID-19 articles, $f_{COVID}(MeSH)$. Additionally, we analyze articles that have been assigned the MeSH term "Comorbidity," focusing exclusively on the frequency of disease descriptors within this subset. We compute the relative importance as defined in equation (1) to assess the importance of each LV1 disease descriptor in the context of comorbidity-related articles.

Overall, we find that all COVID-19 articles are labeled with the LV1 disease descriptor "Infections." The second most common LV1 disease descriptor is "Respiratory Diseases," which appears in 26.7% of all articles. The third descriptor, "Pathological Conditions, Signs and Symptoms," was found in about 20% of all COVID-19 articles. The MeSH term "Cardiovascular Diseases" is the fourth most used descriptor, found in 7% of all articles. The top ten LV1 disease descriptors found in COVID-19 articles are shown in Figure 3A. In contrast, the results in Figure 3B illustrate the relative importance of the disease descriptors in a subset of COVID-19 articles related to comorbidities, considering the baseline frequency shown in Figure 3A. Therefore, the results in Figure 3B evaluate the importance of each LV1 disease descriptor specifically for these selected articles. As can be seen in Figure 3B, "Cardiovascular Diseases" has the highest relative importance among LV1 disease descriptors in COVID-19 articles examining comorbidity. This MeSH term has a 17.4% higher frequency of occurrence among COVID-19 articles related to comorbidities. It is also interesting to note that the MeSH term "Nutritional and Metabolic Diseases" ranks second.

In continuation, we focus on the first- and second-ranked MeSH descriptors in Figure 3B. To describe the disease terms in more detail, we repeat the analysis at the second level of the MeSH disease tree. Again, we separately calculated the proportion of items with a given LV2 disease descriptor and the relative importance of these descriptors within COVID-19 articles related to comorbidities. The results are shown in Figure 4.

From the results shown in Figure 4A, we see that "vascular disease" and "Heart Disease," which belong to "Cardiovascular Diseases," are among the 10 most frequently used LV2 disease descriptors. For COVID-19 articles related to comorbidity, both "Vascular Disease" and "Heart Disease" gain prominence (Figure 4B). The LV1 subbranch "Cardiovascular Diseases" is divided into 5 MeSH descriptors at the second level (Cardiovascular Abnormalities, Cardiovascular Infections, Heart Diseases, Pregnancy Complications, Cardiovascular and Vascular Diseases). In contrast, the disease branch "Nutritional and Metabolic Diseases" is divided into 2 descriptors at the second level (Metabolic Diseases, Nutritional Disorders). This should be considered as it could lead to a bias in the frequency of occurrence of a descriptor caused by the number of terms available in each subbranch. However, since we are interested in their relative importance, we can circumvent these biases and reveal the distributed or concentrated importance of the descriptors. Therefore, we continue our analysis at the third level of the MeSH tree of diseases. Since we found that at the second level of the MeSH tree, the LV1 subbranch "Cardiovascular Diseases" and "Nutritional and Metabolic Diseases" have the highest relative importance, we continue our investigation in this direction. The results are shown in Figure 5.

Figure 5A reveals that "Disorders of Glucose Metabolism" top the list as the most frequently mentioned LV3 MeSH term within the COVID-19 data set, followed by "Hypertension" and "Disease Attributes." This figure provides an overarching view of the commonality of these terms across all research articles.

Figure 5B delves into the LV3 MeSH descriptors that stem from the LV2 subbranch of "Metabolic Diseases". The data clearly indicate that disorders of glucose and lipid metabolism are the most recurrent topics within the LV3 subbranch, underscoring their significance in the discourse on metabolic diseases.

Figure 5C illustrates that within the realm of CVDs, "Embolism and Thrombosis" emerges as the most prevalent LV3 MeSH descriptor utilized in the literature, followed by "Hypertension" and "Heart Failure," among others, in descending order of frequency.

By comparing Figure 5B and 5C, we observe a less diverse distribution of the embedded MeSH terms. The LV3 descriptors within the CVD subbranch are more specifically clustered, pointing to a narrower focus within CVD research in relation to COVID-19, as opposed to the broader range of topics covered under metabolic diseases.

Figure 5D presents a detailed ranking of LV3 MeSH descriptors within the CVD domain as they appear in the context of comorbidity research. Figure 5D specifically highlights which cardiovascular conditions are most frequently discussed in

conjunction with other health issues, shedding light on the patterns of comorbidity that are prevalent in the current body of literature. It allows researchers to identify which cardiovascular disorders are most considered in studies that address the complexities of patients presenting with multiple concurrent health challenges. The data presented in Figure 5D identifies "Hypertension" as the most used LV3 MeSH descriptor within articles that discuss comorbidities, with "Heart Failure" following in frequency. Based on these observations from Figure 5, the subsequent analysis concentrates on 3 critical LV3 MeSH terms: "Hypertension," "Heart Failure," and "Embolism and Thrombosis."

In our analysis of the COVID-19 and CVD databases, we use the frequency of LV3 MeSH descriptors to represent the focus of research. We started by examining "Embolism and Thrombosis," a common CVD descriptor (Figure 5C). Our results (Figure 6A) indicate that "Embolism and Thrombosis" is most frequently associated with "Disorders of Glucose Metabolism" in the COVID-19 database. "Disorders of Iron Metabolism" (with an increase of Δf[MeSH]=0.16% and a ratio of R[MeSH]=5.64) and "Disorders of Acid-Base Balance" are also significant but less frequent. "Disorders of Iron Metabolism" have seen the largest increase, ranking it at the top in the COVID-19 database. "Disorders of Glucose Metabolism" follow (with an increase of Δf[MeSH]=1.14% and a ratio of R[MeSH]=2.46), and "Disorders of Acid-Base Balance" come in third (with an increase of Δf[MeSH]=0.06% and a ratio of R[MeSH]=1.47).

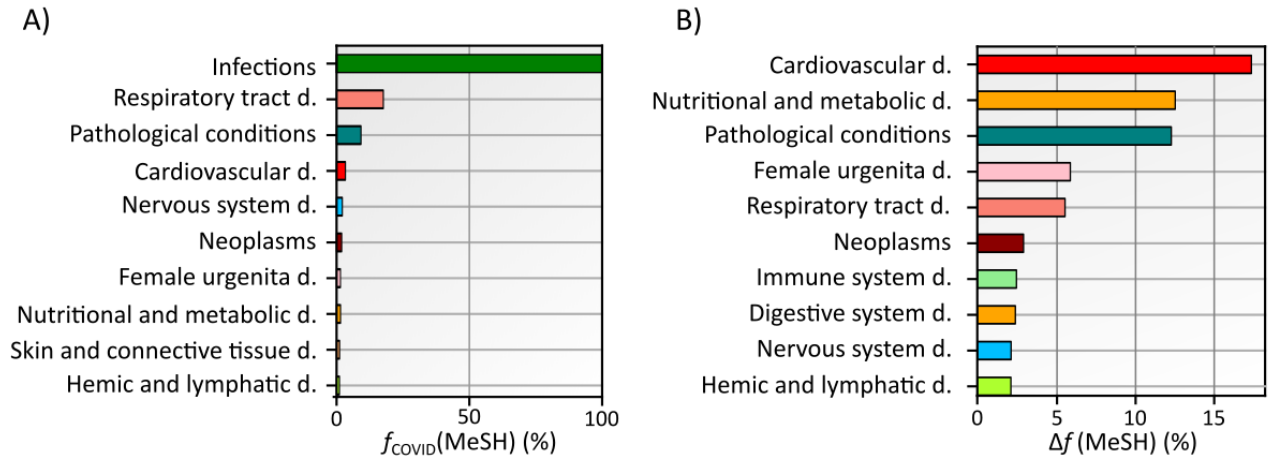
Figure 3. Comparative analysis of level 1 (LV1) subbranch disease descriptor frequencies in COVID-19–related articles. Panel A presents the distribution within the COVID-19 data set, while Panel B focuses on the subset of COVID-19 articles tagged with the "Comorbidity" MeSH (Medical Subject Headings) term. Each bar's color corresponds to a specific disease descriptor and maintains consistency throughout the manuscript.


Figure 4. Most important level 2 (LV2) disease descriptor. Results are computed for (A) the entire COVID-19 data set and (B) for the subset of COVID-19 articles related to comorbidities. Each bar's color corresponds to a specific disease descriptor, as defined in Figure 3. MeSH: Medical Subject Headings.
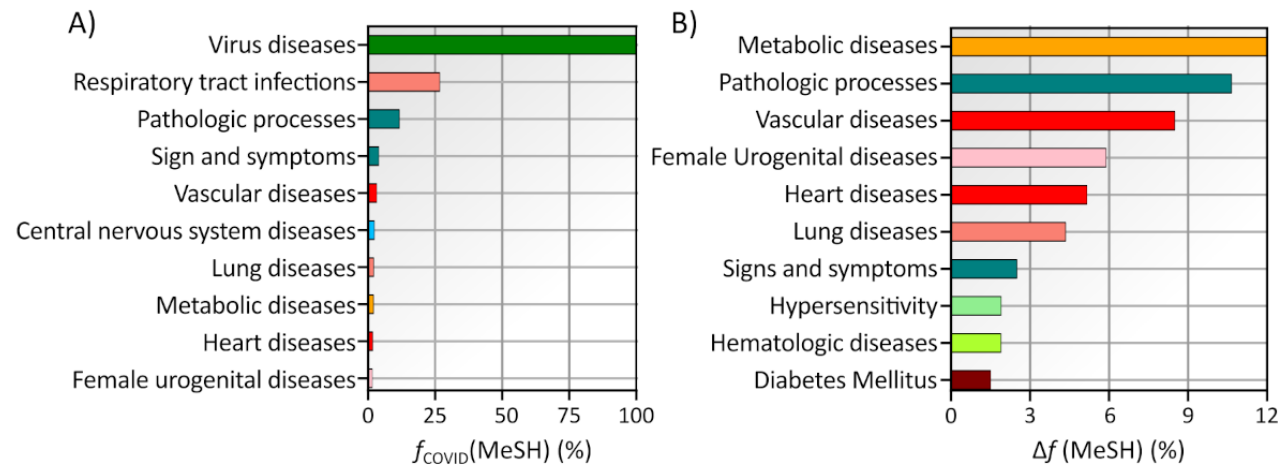

Figure 5. Ten most important level 3 (LV3) disease descriptors for COVID-19–related articles. Results are computed for (A) all LV3 disease descriptors, (B) only for LV3 disease descriptors originating from the "Nutritional and Metabolic Diseases," (C) only for the LV3 "Cardiovascular Diseases" branch, and (D) only for the LV3 "Cardiovascular Diseases" branch obtained for the COVID-19 sub-set of articles considering comorbidities. Each bar's color corresponds to a specific disease descriptor, as defined in Figure 3. MeSH: Medical Subject Headings.
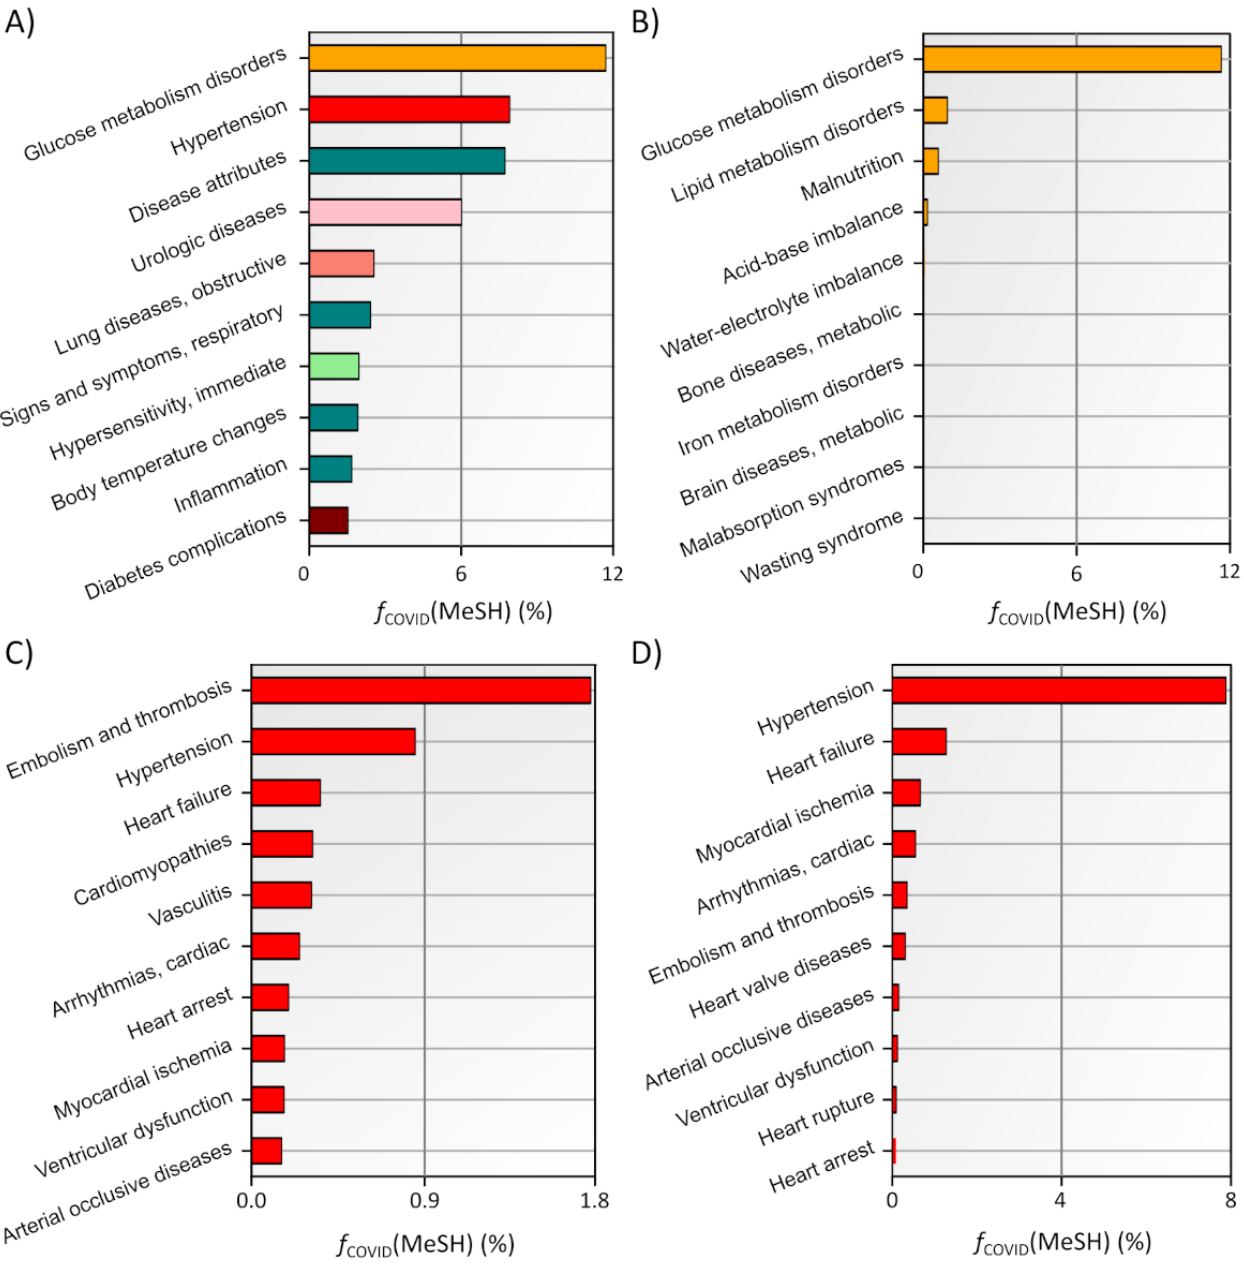

Figure 6. A comprehensive comparison of the absolute and relative changes in the frequency of level 3 (LV3) MeSH (Medical Subject Headings) descriptors in the COVID-19 database relative to the cardiovascular disease (CVD) database, focusing on 3 specific cardiovascular diseases: Embolism and Thrombosis (panels A and B), Hypertension (panels C and D), and Heart Failure (panels E and F). The figure displays the top 15 MeSH descriptors for each condition. Notably, the bars corresponding to "Iron Metabolism Disorders," "Glucose Metabolic Disorders," "Acid-Base Imbalance," and "Disorders of Lipid Metabolism" are distinctly color-coded in black, red, green, and orange, respectively, allowing for easy identification and comparison of these key terms across different cardiovascular conditions.
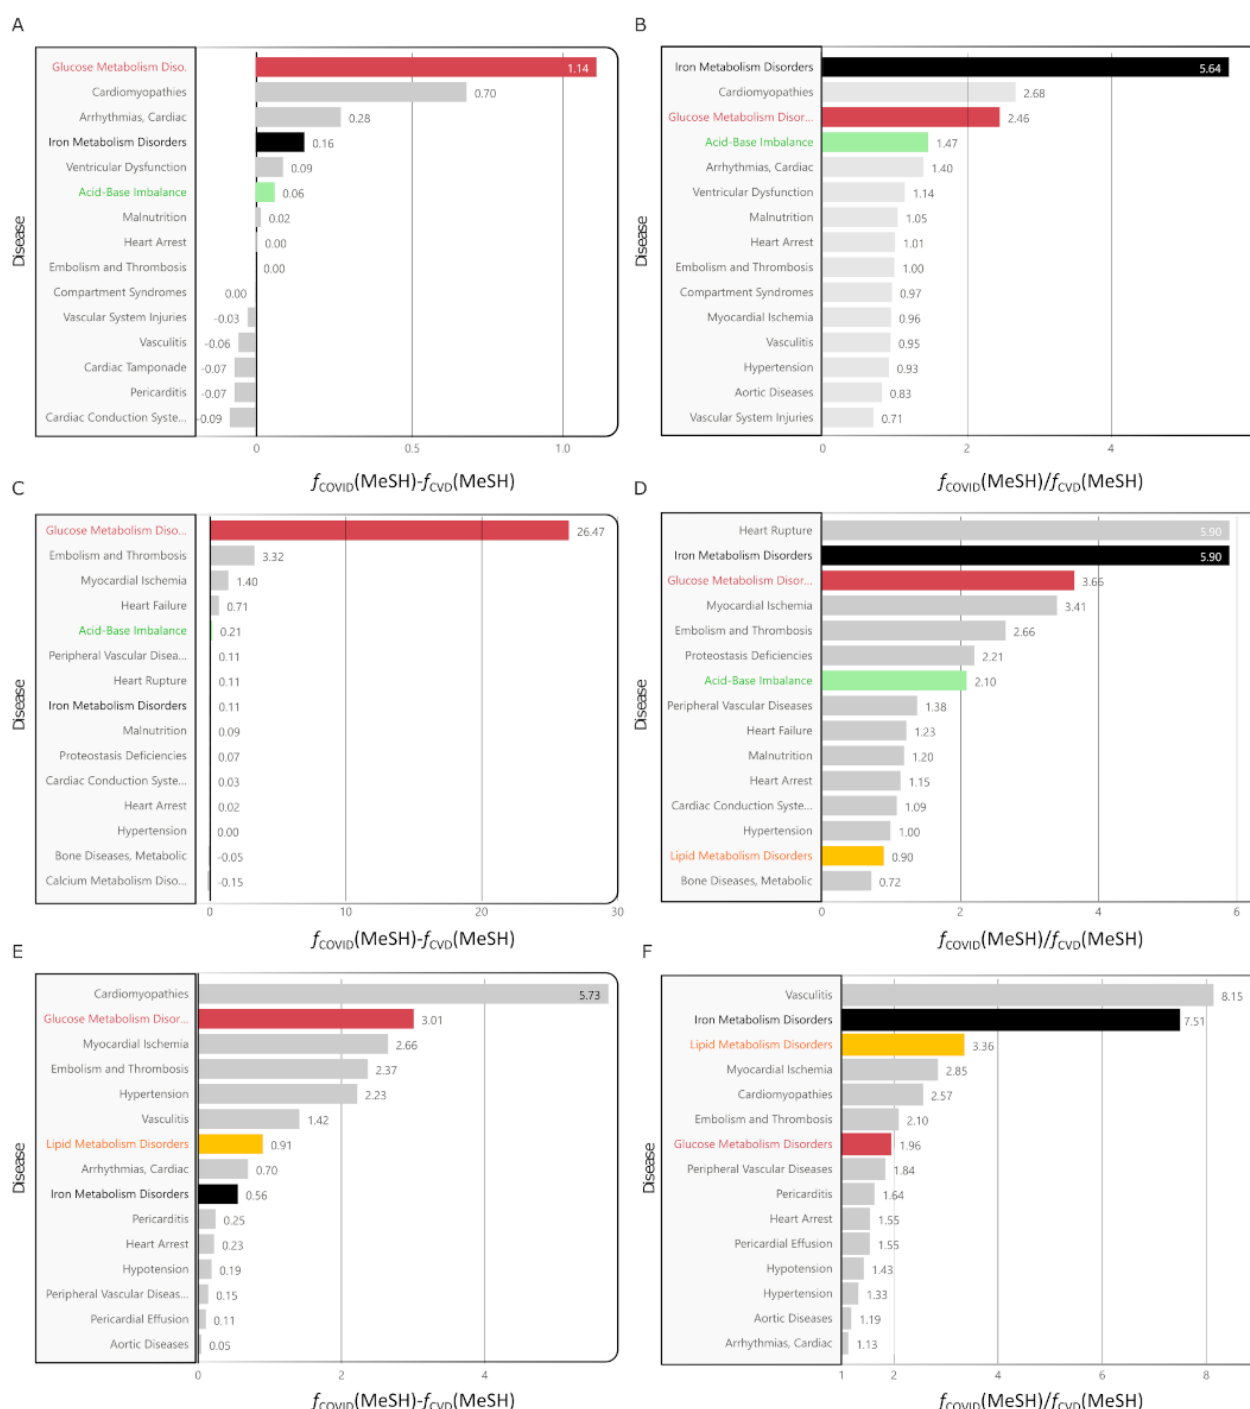

For high blood pressure ("Hypertension"), the MeSH term "Disorders of Glucose Metabolism" is most significant in frequency difference, followed by "Acid-Base Imbalance" and "Iron Metabolism Disorders" (Figure 6C). Interestingly, "Iron Metabolism Disorders" show a smaller overall frequency difference (Δf[MeSH]=0.11%) but a higher ratio (R[MeSH]=5.90), indicating they are used more frequently in COVID-19 research compared to CVD research. "Disorders of Glucose Metabolism" take the second spot (with a substantial increase of Δf[MeSH]=26.47% and a ratio of R[MeSH]=3.66), and "Acid-Base Imbalance" is third (Δf[MeSH]=0.21% and R[MeSH]=2.10) based on their relative frequencies.

In the third part of our analysis, we focused on heart failure, with the findings illustrated in Figure 6E and 6F. Among the various MeSH terms, "Glucose Metabolic Disorders" emerged as the second most frequent term in the comparison between the COVID-19 and CVD databases. While "Iron Metabolic

Disorders" and "Acid-Base Imbalance" are also relevant, they are positioned at 17th, explaining their absence from the figure due to their lower frequency. Notably, "Iron Metabolism Disorders" feature more prominently in the COVID-19 database than in the CVD database, ranking tenth in frequency difference. Significantly, as Figure 6F reveals, "Iron Metabolism Disorders" rank second in relative importance among all LV3 MeSH descriptors in the COVID-19 database, compared to the CVD database. "Disorders of Lipid Metabolism" also show considerable relevance, ranking third, whereas "Disorders of Glucose Metabolism" are positioned seventh. Despite its lower frequency, "Acid-Base Imbalance" maintains a high relative importance, coming in at 17th. These results underscore the shifted focus in medical research on specific metabolic disorders

in the context of COVID-19, particularly in relation to heart failure.

To build upon these findings, we applied the chi-square test to validate whether the observed differences in LV3 MeSH descriptor frequencies between COVID-19 and CVD databases are statistically significant. This test helped us determine if the occurrences of 4 specific MeSH terms—"Disorders of Glucose Metabolism," "Iron Metabolism Disorders," "Acid-Base Imbalance," and "Disorders of Lipid Metabolism"—in the COVID-19 database are significantly different from their occurrences in the CVD database. We also employed multiple P values to strengthen our assessment of significance. The findings are detailed in Table 1.

Table 1. Statistical significance of selected MeSH (Medical Subject Headings) terms in 3 subsets of COVID-19 articles related to cardiovascular diseases (CVDs)[a].

LV3[b] MeSH terms	Embolism and thrombosis, P value	Hypertension, P value	Heart failure, P value
Glucose Metabolism Disorders	<.001	<.001	<.05
Iron Metabolism Disorders	<.01	.525	.116
Acid-Base Imbalance	.103	.42	.585
Lipid Metabolism Disorders	.94	.53	.05

[a]The P values signify whether the appearance of a MeSH term in the COVID-19 database is significantly different compared to the appearance in the CVD database.
[b]LV3: level 3.

In the context of "Embolism and Thrombosis," our analysis reveals that the frequencies of both glucose and iron metabolism disorders show a statistically significant difference when comparing the COVID-19 and CVD databases across all 3 subdata sets.

For "Hypertension," the scenario is slightly different. Here, the incidence of glucose metabolism disorders stands out as the only descriptor with a significant difference in frequency between the COVID-19 and CVD databases.

Lastly, regarding "Heart Failure," we again note a significant difference for glucose metabolism disorders, although with a P value of <.05. This pattern highlights a specific focus or heightened research interest in glucose metabolism disorders within the context of COVID-19, particularly when comorbid with CVDs such as embolism, thrombosis, hypertension, and heart failure.

Discussion

Principal Results

The aim of this study was to analyze all available peer-reviewed articles from the PubMed database to identify the most relevant topics regarding the relationship among COVID-19, CVDs, and comorbidity. For this purpose, we used the MeSH term descriptors, which are the most important topics covered in an article in a standardized form. In COVID-19–related research that considers comorbidity, we found the most relevant MeSH descriptors are CVDs and nutritional and metabolic diseases. Since both terms are quite broad, we continued our analysis one branch deeper in the MeSH tree and found that the

corresponding significant topics are related to metabolic disorders, vascular diseases, and heart diseases. Advancing one level deeper in the MeSH tree, we investigated the meaning of more specific terms related to CVD and metabolic disease. We determined that the most significant CVDs related to comorbidity and COVID-19 are embolism and thrombosis, hypertension, and heart failure. Given the prominence of metabolic disorders in our analysis, we also explored which specific metabolic disorders were most significant and found that glucose metabolism disorders were the most notable. However, we also noted a significantly increased frequency of the term iron metabolism disorders in COVID-19 articles related to embolism and thrombosis compared to CVD articles related to embolism and thrombosis.

Limitations

Using the methodology presented here, we were able to identify the most important issues relevant to comorbidities and COVID-19. Although the methodology can be applied to any major topic and its corresponding subtopic, it has some limitations. The main limitation is its inability to find relationships between themes. This was addressed by selecting relevant subtopics through iteratively evaluating the results at each level of the MeSH tree. However, in future studies, we intend to incorporate a knowledge graph-based approach by mapping relationships between topics. This would in turn allow us to consider not only the frequency of the occurrence of a topic but also to evaluate the co-occurrence of topics. Consequently, this would allow us to automatically find highly related pairs of topics and eventually create a more detailed and complex description of the item database under consideration.

Comparison With Prior Work

In relation to COVID-19, individuals with certain comorbidities have been shown to have a higher likelihood of developing a severe form of this disease and have a higher mortality rate. COVID-19 has been associated with an increased prevalence of CVD, suggesting that CVD may be a risk factor for the disease [50]. According to mortality data from China's National Health Commission, 17% and 35% of individuals with COVID-19 had a history of coronary heart disease and hypertension, respectively [51]. Li et al [52] showed that the presence of cardio-cerebrovascular disease, diabetes, and hypertension increased the risk of severe COVID-19 by threefold, twofold, and twofold, respectively. A larger study from the Chinese Center for Disease Control and Prevention, which examined the clinical outcomes of 44,672 confirmed COVID-19 cases, found that the case fatality rate was 2.3% in the entire cohort, but was significantly higher (6%, 7.3%, and 10.5%, respectively) in individuals with hypertension, diabetes, and CVD [53]. Several smaller cohort studies have also presented similar reports, suggesting a higher risk of an adverse episode in patients with COVID-19 with underlying CVD [54-56]. Cardiac injury (characterized by elevated troponin levels), myocarditis, and acute respiratory distress syndrome have been reported as strong, independent risk factors associated with mortality in patients with COVID-19 [57]. According to the Pneumonitis Diagnosis and Treatment Program for Novel Coronavirus Infections, the likelihood of COVID-19 infection is higher in older people (>60 years) with pre-existing conditions, especially in patients with hypertension, coronary heart disease, or diabetes [51]. Thus, advanced age, male gender, and the presence of preexisting conditions are the main risk factors for COVID-19 mortality [57].

Given the increasing evidence of iron status' importance for immunity, it is not surprising that biomarkers of iron metabolism have been investigated in several studies on patients with COVID-19 [58]. COVID-19 is also characterized by a cytokine storm, leading to increased production of hepcidin, the primary hormone regulating iron metabolism, in response to heightened proinflammatory cytokines [59]. Patients with low serum iron status were likely to suffer from severe conditions and multiple organ damage in COVID-19 [60]. In addition, both iron deficiency (ID) and iron overload are commonly observed in a variety of CVDs and contribute to the onset and progression of these diseases. One of the devastating consequences of iron overload is the induction of ferroptosis, a newly defined form of regulated cell death that severely impairs cardiac function through ferroptotic cell death in cardiomyocytes [60]. Our results show that the term iron metabolism disorder occurs significantly more frequently in COVID-19 articles related to heart failure than in CVD articles on the same topic. Interestingly, ID is frequently observed in patients with heart failure [61-63]. Furthermore, ID correlates with an increased incidence of right ventricular failure in patients with acute HF [64,65]. ID also contributes to impaired functioning of the respiratory chain complexes (complex I to V), leading to altered myocardial metabolism, ROS formation, and ultimately advanced HF. Impaired mitochondrial function is one of the underlying mechanisms of ID-induced HF [66,67].

Clinical Implications of Our Findings

Our research has highlighted the critical intersection between COVID-19 and severe cardiovascular conditions, notably embolism and thrombosis. The urgency of identifying and managing these conditions is of paramount importance, as they present immediate life-threatening risks and their symptoms often overlap with those of COVID-19, especially pulmonary thromboembolism [68]. Our findings underscore the vital importance of vigilant monitoring for individuals affected by COVID-19 to prevent these severe outcomes.

A primary tool in this monitoring process is the serial measurement of D-dimer levels, which has been shown to strongly correlate with an increased risk of disease progression, critical illness, and mortality. D-dimer levels also serve as a reliable predictor of venous thromboembolism when measured at admission, and levels at discharge are associated with a higher 1-year mortality risk [69]. Current guidelines recommend thromboprophylaxis for all hospitalized patients with COVID-19, except those with an increased risk of bleeding [68]. While further research is necessary to determine the optimal anticoagulation dosage, standard doses of LMWH are generally recommended for most patients, with intermediate doses for those who are critically ill or obese [70]. Routine screening for deep vein thrombosis with Doppler ultrasonography is not currently advised for thromboembolism screening, as rapidly increasing D-dimer levels and worsening oxygenation have been found to be more successful [71].

We have also uncovered a significant correlation between COVID-19 and glucose metabolism disorders. Increasing evidence suggests a bidirectional relationship between diabetes and SARS-CoV-2 infection. This indicates that patients with diabetes are at a higher risk of developing a severe form of COVID-19, while individuals with COVID-19 are more likely to develop metabolic disorders. Shared pathogenic mechanisms, such as general inflammation, a pro-thrombotic state, and atherosclerosis, likely contribute to this association [72].

Analysis of the GTEx database revealed higher ACE2 expression in the pancreas than in the lungs. Liu et al. analyzed pancreatic injury following SARS-CoV-2 infection and found that such injuries predominantly occurred in patients with severe COVID-19 [73]. Therefore, special attention is warranted for patients with metabolic disorders, including priority for vaccination and rigorous monitoring in the event of infection, with a low threshold for intensifying care. Preventive measures for detecting metabolic disorders should be implemented in individuals after a severe SARS-CoV-2 infection. This includes monitoring blood glucose levels, lipids, and biochemical markers for pancreatic injury.

Additionally, our results underscore the importance of iron metabolism, a factor currently underrepresented in clinical practice, underscoring the need for further trials to integrate it into care for patients with COVID-19. Research indicates that ferritin levels can be used to estimate disease severity, providing useful cutoff values. These could complement other initial screening methods in predicting the necessary level and intensity of patient care [74]. There is also an underexplored therapeutic potential in manipulating iron levels, either by using chelators

like deferoxamine to lower them or through iron supplementation to raise them in patients with inappropriate values. Before this approach can be widely adopted in practice, further research is essential to determine the optimal levels. Reducing iron in patients with highly active hepcidin due to inflammation could impede recovery [75]. Nonetheless, the importance of iron metabolism extends beyond coagulation disorders to metabolic disorders, with iron overload contributing to the development of these diseases [76,77].

In summary, the insights from our study have critical implications for clinical practice. By identifying key biomarkers and conditions associated with severe COVID-19 outcomes, we provide a foundation for improving patient monitoring, treatment strategies, and, ultimately, patient outcomes during the pandemic. Our findings urge health care professionals to incorporate these insights into their clinical practice, promoting a proactive and informed approach to managing COVID-19 and its cardiovascular complications.

Conclusions

Our study represents a crucial step toward understanding the complex interplay between COVID-19, CVD, and metabolic disorders, highlighting in particular the role of embolism, thrombosis, and iron metabolism disorders. The method we adopted, using MeSH term descriptors to dissect the different levels of related topics, has furnished a comprehensive overview of the main comorbidities influencing COVID-19 outcomes. Importantly, this approach can be adapted and applied to other important health topics and their subcategories, despite its current limitation in directly mapping topic relationships. Future research efforts should aim to incorporate a knowledge graph–based methodology, enabling a more detailed analysis of topic co-occurrences and their relationships. Such advancements are essential for deciphering complex disease dynamics, particularly in the context of emerging infectious diseases such as COVID-19.

The knowledge gained from this study is invaluable for the development of more effective clinical practices and public health strategies. By identifying key comorbidities and their impact on COVID-19, we are better positioned to tailor treatments and interventions for patients affected by these conditions. Additionally, understanding the role of specific metabolic disorders, such as those affecting glucose and iron metabolism, opens up potential therapeutic targets and preventive measures. In managing the current pandemic and preparing for future viral outbreaks, the findings from this study are crucial in guiding medical advancements, improving patient outcomes, and increasing the resilience of the health care system. This work not only contributes to our immediate fight against COVID-19 but also creates a foundation for more informed and effective responses to similar health crises in the future.

Authors' Contributions

MM, RM, and VG were involved in the design of this study. RM, LT, TT, and MM wrote the introduction. Datamining and data analysis were performed by RM. Data visualization was performed by RM and VG. All authors critically revised the manuscript. The final manuscript has been read and approved by all authors.

Abstract

Background: Thyroid disease (TD) is a prominent endocrine disorder that raises global health concerns; however, its comorbidity patterns remain unclear.

Objective: This study aims to apply a network-based method to comprehensively analyze the comorbidity patterns of TD using large-scale real-world health data.

Methods: In this retrospective observational study, we extracted the comorbidities of adult patients with TD from both private and public data sets. All comorbidities were identified using ICD-10 (International Classification of Diseases, 10th Revision) codes at the 3-digit level, and those with a prevalence greater than 2% were analyzed. Patients were categorized into several subgroups based on sex, age, and disease type. A phenotypic comorbidity network (PCN) was constructed, where comorbidities served as nodes and their significant correlations were represented as edges, encompassing all patients with TD and various subgroups. The associations and differences in comorbidities within the PCN of each subgroup were analyzed and compared. The PageRank algorithm was used to identify key comorbidities.

Results: The final cohorts included 18,311 and 50,242 patients with TD in the private and public data sets, respectively. Patients with TD demonstrated complex comorbidity patterns, with coexistence relationships differing by sex, age, and type of TD. The number of comorbidities increased with age. The most prevalent TDs were nontoxic goiter, hypothyroidism, hyperthyroidism, and thyroid cancer, while hypertension, diabetes, and lipoprotein metabolism disorders had the highest prevalence and PageRank values among comorbidities. Males and patients with benign TD exhibited a greater number of comorbidities, increased disease diversity, and stronger comorbidity associations compared with females and patients with thyroid cancer.

Conclusions: Patients with TD exhibited complex comorbidity patterns, particularly with cardiocerebrovascular diseases and diabetes. The associations among comorbidities varied across different TD subgroups. This study aims to enhance the understanding of comorbidity patterns in patients with TD and improve the integrated management of these individuals.

Introduction

Thyroid disease (TD) is a prominent endocrine disorder and has become an increasing public health concern worldwide. In the United States, its prevalence rose from 2.54% in 1999-2002 to 5.05% in 2015-2018 [1]. Thyroid cancer (TC) is considered the 9th most common malignancy and the most common endocrine cancer, accounting for over 586,000 cases and 43,600 deaths annually [2]. In China, thyroid nodules (TNs) were the most common form of TD, affecting about 36.9% of the population in 2017 [3]. The incidence of TC in China is nearly 2 times the global average, with 11.3 versus 6.6 cases per 100,000 people [4].

TD is intricately linked to multiple diseases and health conditions [5,6]. A comprehensive understanding of the interactions and overlapping symptoms among these diseases can enhance clinicians' diagnostic accuracy and personalize treatment plans [7]. However, previous studies have mostly focused on the correlation between a single disease and a specific type of TD [6,8], neglecting the simultaneous consideration of multiple diseases. Consequently, the underlying patterns of TD's multiple comorbidities are far from fully elucidated.

Advancements in network theory offer fresh insights into understanding the intricate relationships among comorbidities. Recently, the phenotypic comorbidity network (PCN) has gained popularity in exploring associations and disparities across multiple diseases. In the PCN, coexisting diseases are represented as nodes, with edges indicating their connections. These edges can be assigned weights to reflect the frequency of their coexistence. The PCN uncovers hidden disease patterns, facilitating enhanced comorbidity risk assessments and future disease predictions for individuals. Recently, researchers have used the PCN to reveal comorbidity patterns for specific diseases such as diabetes [9], colorectal cancer [10], and heart failure [11].

Electronic medical records (EMRs), a typical real-world data set, are increasingly mined for valuable insights enriched with clinical history information to enhance decision-making [12]. As a crucial component of EMR, discharge diagnoses reflect patients' co-occurring diseases and health status during hospitalization, offering insights into comorbidity associations. These disease diagnoses are typically identified by standardized International Classification of Diseases (ICD) codes, which have proven effective in elucidating comorbidity patterns among diseases in prior studies [7,10,13].

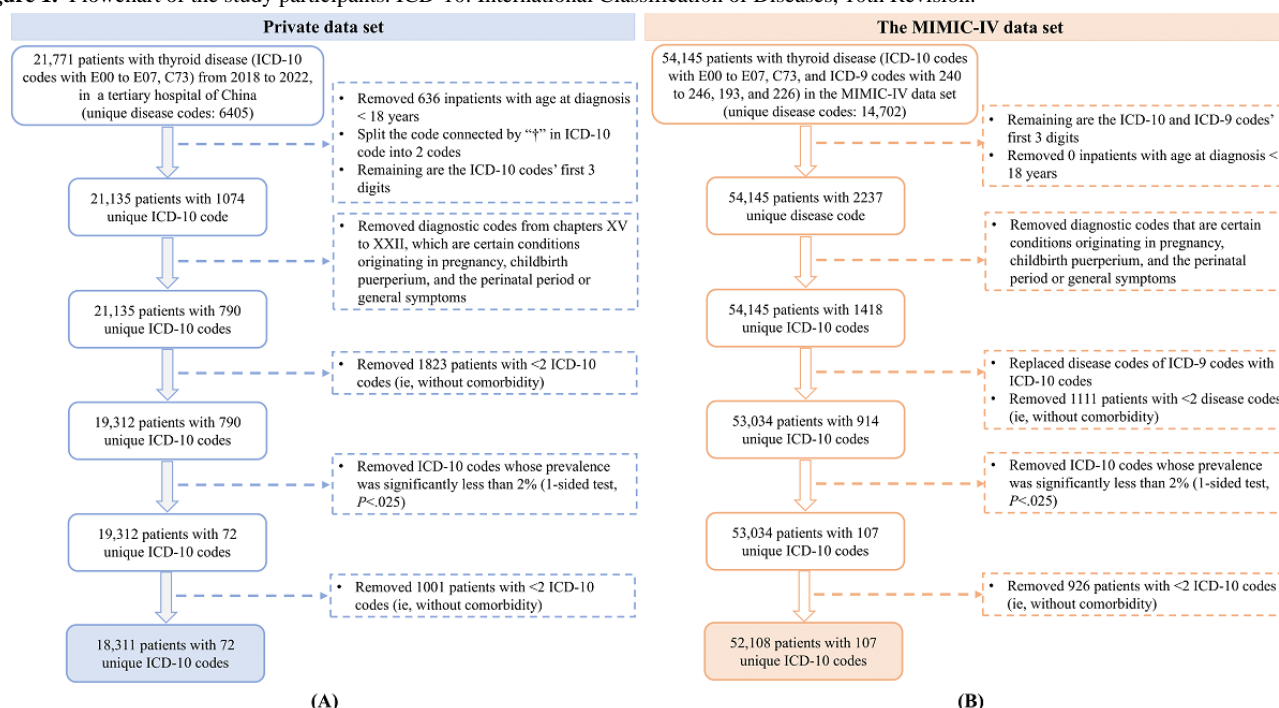
In this study, we aimed to leverage a network-based method to systematically investigate comorbidity patterns in a general population of patients with TD, using disease codes from large-scale real-world EMR data from both private and public data sets. We hope to uncover previously recognized or unrecognized relationships among multiple comorbidities of TD.

Methods

Study Populations

We conducted a retrospective cohort study using EMR data from both private and public data sets. Age, sex, and ICD codes were extracted. The private data set, covering 2018-2022, was obtained from a tertiary hospital in Guangxi, China, and included 21,771 hospitalizations and 6405 distinct ICD-10 (10th Revision) codes. Patients with TD were identified by ICD-10 codes E00-E07 (benign TD [BTD]) or C73 (TC). We treated each hospitalization record as an independent individual, considering that patients may have different health states and disease progression during different hospitalizations. The data cleaning process to identify the study cohort was as follows: (1) included adult patients aged ≥18 years; (2) excluded diagnostic codes from chapters XV to XXII, which pertain to pregnancy, childbirth, puerperium, perinatal conditions, and general symptoms; (3) excluded patient records with fewer than 2 ICD-10 codes; and (4) excluded rare diseases with a prevalence <2%. Ultimately, the study population comprised 18,311 patients in the private data set (Figure 1A).

Additionally, we validated our study using the Medical Information Mart for Intensive Care (MIMIC)-IV data set, a public clinical database containing over 73,000 admissions from 2008 to 2019. Diseases were initially coded using ICD-10 and ICD-9 (9th Revision) codes. To ensure consistency, we standardized all disease codes to 3-digit ICD-10 codes. Ultimately, we extracted data for 52,108 patients with TD from the MIMIC-IV data set (Figure 1B).

Figure 1. Flowchart of the study participants. ICD-10: International Classification of Diseases, 10th Revision.


Ethical Considerations

The original data collection for this study was approved by the Medical Ethics Committee of the First Affiliated Hospital of Guangxi Medical University (approval number 2023-E592-01), and the Ethics Committee waived the requirement for a consent form. Informed consent from patients to use their data could not be obtained because the study is retrospective, observational, and population based. The analysis of the information was anonymized, with no variables that could identify individual patients. Additionally, we collected public clinical data from the MIMIC database after completing the web course (certification number 57439457). Given that the MIMIC-IV database consists of deidentified data and is publicly accessible, and as the collection of patient information and the creation of the research resource were reviewed by the Institutional Review Board at Beth Israel Deaconess Medical Center, which granted a waiver of informed consent and approved the data-sharing initiative [14], this study was not subject to specific ethical review.

Comorbidity Prevalence

We stratified the population by sex (male or female) and disease type (TC or BTD). The prevalence of all diseases with ICD-10 codes and the 95% CI were calculated. We excluded diseases with a prevalence of <2% ($P<.03$, 1-sided test) in any subgroup to avoid including rare diseases. The lists of 72 and 107 diseases from the private and MIMIC-IV data sets are presented in Tables S1 and S2 in Multimedia Appendix 1, respectively. TDs, including TC (C73), nontoxic goiter (E04), hypothyroidism (E02 and E03), hyperthyroidism (E05), and other BTDs (E06), were excluded from the list of diseases, resulting in a final count of 67 and 102 comorbidities in the private and MIMIC-IV data sets, respectively. After comparing the comorbidity differences between the TC and BTD subgroups, we analyzed the comorbidity differences between patients with TC and those

with specific typical BTDs (nontoxic goiter, E04; hypothyroidism, E02 and E03; and hyperthyroidism, E05). Subgroup details are presented in Figure S1 in Multimedia Appendix 1.

To evaluate the differences in comorbidity prevalence by sex and disease type, we calculated relative differences and used a Z-test for significance. The calculation for the relative difference by sex is based on equation (1) [10]:

$$d = (P_{male} - P_{female})/[(P_{male} + P_{female})/2] \quad \textbf{(1)}$$

where P_{male} and P_{female} represent the prevalences of comorbidities in males and females, respectively.

We considered comorbidity prevalence to be significantly different if the relative difference exceeded 0.1 [10] and the absolute difference was statistically significant. Among these, comorbidities with a ≥0.5-fold prevalence increase were deemed enriched. We used Spearman correlation to assess comorbidity prevalence trends with age and applied K-means clustering to group comorbidities by age-related prevalence.

Phenotypic Comorbidity Network Construction

We constructed a PCN to capture the coexistence of multiple diseases. In the PCN, nodes represent disease codes (ICD-10 codes at 3 digits) that are connected by edges. Node sizes are proportional to disease prevalence, and node colors represent the ICD-10 categories. The cosine index was applied to quantify the comorbidity strength of coexisting diseases, taking into account the co-occurrence and prevalence of comorbidities, thereby minimizing the influence of sample size. We defined a cutoff value to detect comorbidity coexistence measured by the cosine index by assessing the relationship between the Pearson correlation and cosine index, where the number of significant coexisting comorbidities was equal in both networks as measured by the cosine index and Pearson correlation. The cosine index and Pearson correlation coefficient are defined in

equations (2) and (3), respectively, and the significance of was determined by performing a *t* test (2-tailed), calculated according to equation (4) [10].

where *N* is the total number of patients with TD; and n_a, n_b, and n_{ab} are the number of patients with disease a, disease b, and both diseases, respectively.

Four structural properties of the PCN were measured using network indices, including network density, degree, average degree of neighbors, and betweenness centrality [15]. Network density measures the compactness of a network by calculating the ratio of significant connections to all potential ones. A denser network indicates more connections among comorbidities. The degree of the PCN reflects its number of connections with other comorbidities. When a comorbidity is directly connected to others, those are referred to as neighbors. We calculated the average degree of neighbors to measure neighbor connectivity. Betweenness centrality represents the number of shortest paths between any 2 comorbidities. A high betweenness centrality indicates a greater likelihood of forming bridges between other comorbidities or serving as endpoints for many comorbidities [10].

To identify the most important comorbidity in the PCN, we applied the PageRank algorithm, which considers edge weights [16]. The PageRank algorithm calculates the importance of each node in a network by assigning ranks. Nodes that are connected to other nodes with a high rank receive a higher weight and are considered more central, while a higher PageRank value for a node indicates greater influence within the network.

Comorbidities with the top 5 PageRank values were defined as the most important comorbidities in the PCN.

We constructed 4 separate PCNs for males, females, patients with TC, and patients with BTD. We then compared comorbidity strengths to measure disparities by sex and disease type. When a coexisting disease was unique or enriched (with a comorbidity strength of at least 0.05 higher than that of another) in a given subgroup, the difference was considered significant and was defined as an abundant connection [10].

Analyses and visualizations were performed using R 4.3.1 (R Foundation) and Python 3.7 (Python Foundation), leveraging the igraph and ggraph libraries for network visualization and property computation in R, and the pyecharts package for generating Sankey diagrams in Python.

Results

Characteristics of Patients With Thyroid Disease

In the private data set, the median age of patients with TD was 58 years, with 61.09% (11,187/18,311) being female and 6.25% (1144/18,311) having TC (Table 1). By contrast, in the MIMIC-IV data set, patients with TD were older, with a median age of 67 years; among them, 71.74% (37,384/52,108) were female and less than 0.93% (482/52,108) had TC. Patients with TD exhibited a high comorbidity burden, with a median number of comorbidities of 5 in the private data set and 7 in the MIMIC-IV data set. Males had more comorbidities than females, with the median number of comorbidities significantly higher in males than in females (6 vs 4, *P*<.001, and 8 vs 7, *P*<.001, in the private and MIMIC-IV data sets, respectively). Patients with TC were younger and had fewer comorbidities than patients with BTD. The median age of patients with TC was 16 and 11 years younger than that of patients with BTD, and the median number of comorbidities in patients with TC was 2 and 3 fewer than that in patients with BTD, in the private and MIMIC-IV data sets, respectively.

Table 1. Characteristics of patients with thyroid disease on the 2 data sets.

Demographic and clinical factors	Private data set					MIMIC[a]-IV data set				
	Overall	Male	Female	TC[b]	BTD[c]	Overall	Male	Female	TC	BTD
Number of patients	18,311	7124	11,187	1144	17,167	52,108	14,724	37,384	482	51,626
Age (years), median (IQR)	58 (49-67)	59 (51-68)	57 (47-66)	43 (34-53)	59 (50-67)	67 (55-78)	68 (57-78)	67 (55-79)	56 (45-70)	67 (55-79)
Number of comorbidities, median (IQR)	5 (3-7)	6 (4-8)	4 (3-6)	3 (2-4)	5 (3-7)	7 (5-10)	8 (5-11)	7 (5-10)	4 (3-6)	7 (5-10)

[a]MIMIC: Medical Information Mart for Intensive Care.

[b]TC: thyroid cancer.

[c]BTD: benign thyroid disease.

The mean number of comorbidities increased with age in both males and females across both data sets (Figure 2A and 2C). In the private data set, the percentage of patients with TD decreased as the number of comorbidities increased, both overall and among females. By contrast, in the MIMIC-IV data set, the percentage of patients exhibited a trend of initially increasing

and then decreasing with the number of comorbidities (Figure 2B and 2D).

The incidence of patients with different types of TDs varied between the 2 data sets (Figure 3). In the private data set, nontoxic goiter was the most common BTD, affecting 67.77% (12,410/18,311) of patients, whereas in the MIMIC-IV data set, hypothyroidism was prevalent in 86.36% (44,999/52,108) of

patients. In most patient subgroups, the percentage of patients decreased with the number of comorbidities in the private data set, while in the MIMIC-IV data set, the percentage of patients initially rose and then declined as the number of comorbidities increased (Figure 3B and 3E). However, across all TD subgroups within both data sets, the mean number of comorbidities increased with age, with Spearman correlations of 0.993 ($P=.001$) and 0.955 ($P<.001$) in the private and MIMIC-IV data sets, respectively (Figure 3C and 3F).

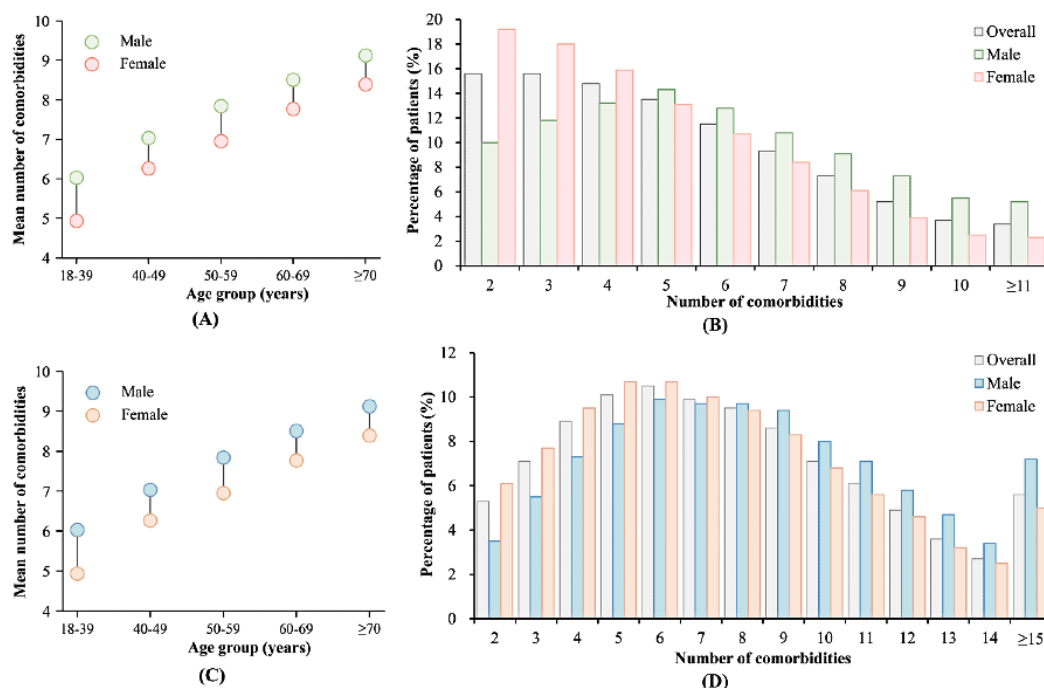
Figure 2. Comorbidity and age distributions in different subgroups of patients with thyroid disease. (A) Age-specific mean number of comorbidities and (B) frequency of patients per distinct number of comorbidities per patient on the private data set, respectively. Panels (C) and (D) are the counterparts of (A) and (B) on the MIMIC-IV data set, respectively. MIMIC: Medical Information Mart for Intensive Care.


Figure 3. (A-C) The number of patients across different age groups, the percentage of patients with varying numbers of comorbidities, and the mean number of comorbidities for each thyroid disease subgroup, respectively, based on the private data set. (D-F) The corresponding data for patients from the MIMIC-IV data set. MIMIC: Medical Information Mart for Intensive Care.
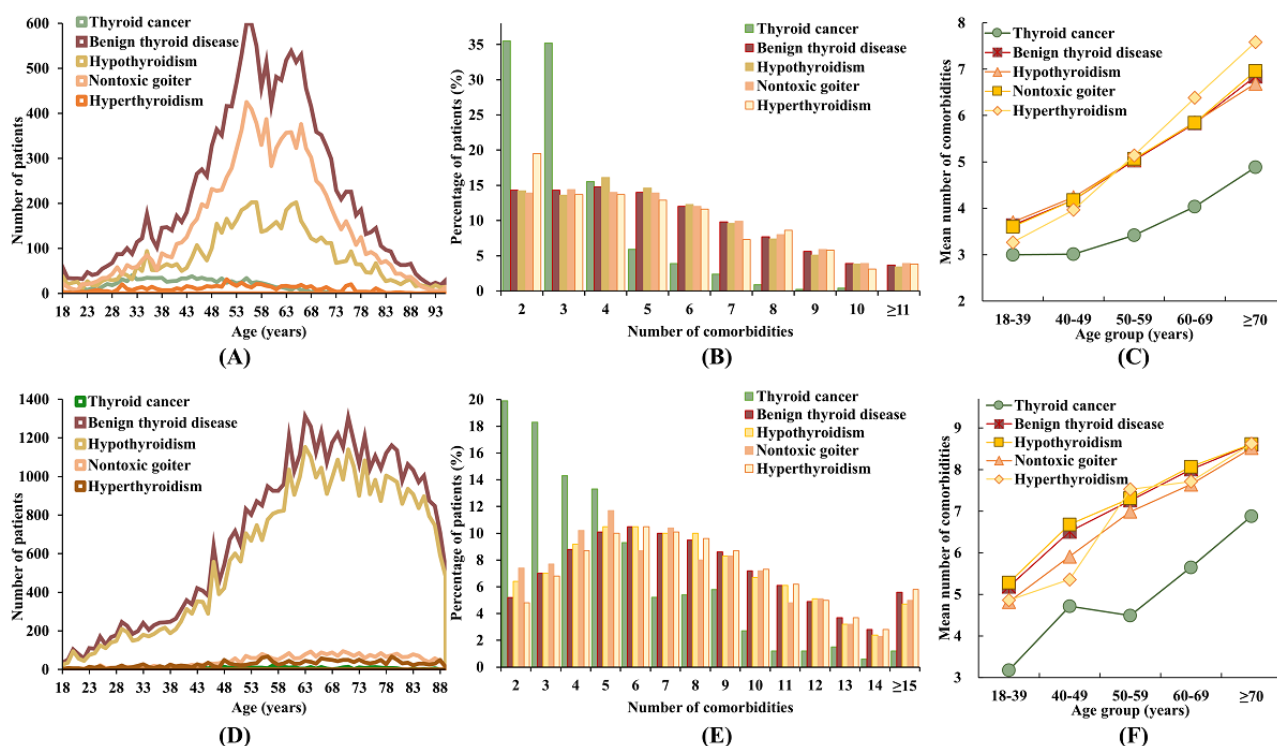

Comorbidity Prevalence and Differences Between Subgroups

Figure 4 displays the top 15 diseases with the highest prevalence. In the private data set, the most prevalent comorbidities were hypertension, liver disease, and diabetes, with prevalences of 35.14% (6435/18,311), 21.97% (4023/18,311), and 16.82% (3080/18,311), respectively. In the MIMIC-IV data set, hypertension and diabetes were also among the most common comorbidities, with prevalence rates of 42.13% (21,951/52,108) and 20.39% (10,627/52,108), respectively. Additionally, disorders of lipoprotein metabolism (E78) showed high prevalence, at 15.29% (2800/18,311) in the private data set and 44.37% (23,120/52,108) in the MIMIC-IV data set.

Among comorbidities with significant differences ($P<.05$) in prevalence, the differences were substantial, with some comorbidities enriched in specific subgroups (Table 2). In the private data set, diabetes (E11), cerebrovascular diseases (I63 and I69), heart diseases (I11, I20, I25, I48, and I50), chronic obstructive pulmonary disease (J43 and J44), renal diseases (N04, N18, N20, and N28), and gout (M10) were enriched in males. Conversely, systemic connective tissue disorders (M35), dorsopathies (M48 and M50), and disorders of bone density and structure (M80 and M81) were enriched in females.

Most comorbidities had higher prevalence and were even enriched in patients with BTD, including heart disease (I20, I25, and I50), cerebrovascular disease (I63, I65, and I67), hypertension (I10), diabetes (E11), liver disease (K74), gastritis and duodenitis (K29), and renal disease (N18, N20, and N08). Notably, malignant neoplasms were enriched in the TC group, including nasopharyngeal carcinoma (C11), bronchus and lung cancer (C34), and lymph node cancers (C77). Tables S3 and S4 in Multimedia Appendix 1 present the complete prevalence differences of enriched comorbidities in the subgroups of patients with TD from the private and MIMIC-IV data sets, respectively.

Age-specific comorbidities were clustered into 3 groups in the private data set and 4 groups in the MIMIC-IV data set (Figure 5). Most comorbidities' prevalence generally increased with age, although the rates varied by cluster. In the private data set, cluster 1 comprised 55 comorbidities with low, mostly stable prevalence. Cluster 2 included 11 comorbidities with moderate prevalence and high growth rates, such as atherosclerosis (I70), ischemic heart disease (I25), and diabetes (E11). Cluster 3 contained a single comorbidity (hypertension, I10) with the highest growth rate with age. In the MIMIC-IV data set, cluster 1 included 2 comorbidities (lipoprotein metabolism disorder, E78, and hypertension, I10) that showed significant age-related increases. Cluster 2 had 9 comorbidities with moderate increases, while clusters 3 and 4 comprised 22 and 70 comorbidities with low prevalence, respectively.

Figure 4. The top 15 comorbidities with the highest prevalence of patients with thyroid disease on the (A) private and (B) MIMIC-IV data sets. MIMIC: Medical Information Mart for Intensive Care.
Table 2. Absolute prevalence differences of enrichment comorbidities in subgroups of patients with thyroid diseases on the private data set.

ICD-10[a] code	Enrichment comorbidity	Crude prevalence (95% CI)	Absolute prevalence difference, value (95% CI)	
			Male – Female	TC[b] – BTD[c]
A49	Bacterial infection	2.7 (2.5 to 3.0)	N/A[d]	–2.6 (–3.0 to –2.2)
B66	Fluke infections	3.4 (3.1 to 3.6)	5.1 (4.5 to 5.7)	–3.0 (–3.5 to –2.5)
C11	Nasopharyngeal carcinoma	1.7 (1.5 to 1.9)	2.2 (1.8 to 2.6)	–1.7 (–2.0 to –1.4)
C22	Malignant neoplasm of the liver and intrahepatic bile ducts	1.7 (1.5 to 1.9)	1.8 (1.4 to 2.2)	–1.8 (–2.0 to –1.6)
C34	Bronchial and lung cancer	7.8 (7.4 to 8.1)	3.7 (2.9 to 4.5)	–7.5 (–8.1 to –6.9)
C50	Malignant neoplasm of the breast	2.4 (2.2 to 2.6)	–3.9 (–4.3 to –3.5)	–2.5 (–2.8 to –2.2)
C77	Secondary lymph node carcinoma	9.2 (8.8 to 9.7)	4.0 (3.1 to 4.9)	31.9 (29.0 to 34.8)
C78	Secondary malignant neoplasm of the respiratory and digestive organs	6.4 (6.1 to 6.8)	N/A	–3.0 (–4.1 to –1.9)
C79	Secondary malignant neoplasm	5.3 (5.0 to 5.6)	2.9 (2.2 to 3.6)	–3.2 (–4.1 to –2.3)
C90	Multiple myeloma and malignant plasma cell neoplasms	1.7 (1.5 to 1.9)	1.9 (1.5 to 2.3)	–1.8 (–2.0 to –1.6)

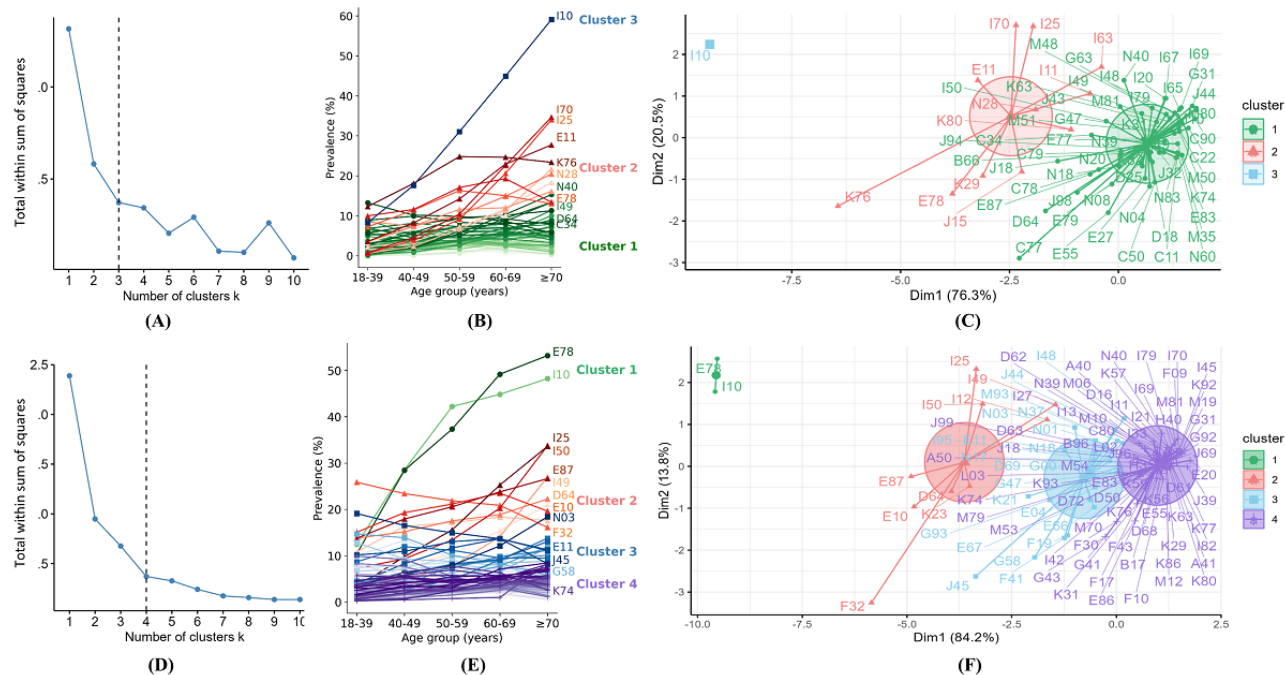
[a]ICD-10: International Classification of Diseases, 10th Revision.

[b]TC: thyroid cancer.

[c]BTD: benign thyroid disease.

[d]Not applicable, as the comorbidity was not enriched in this subgroup.

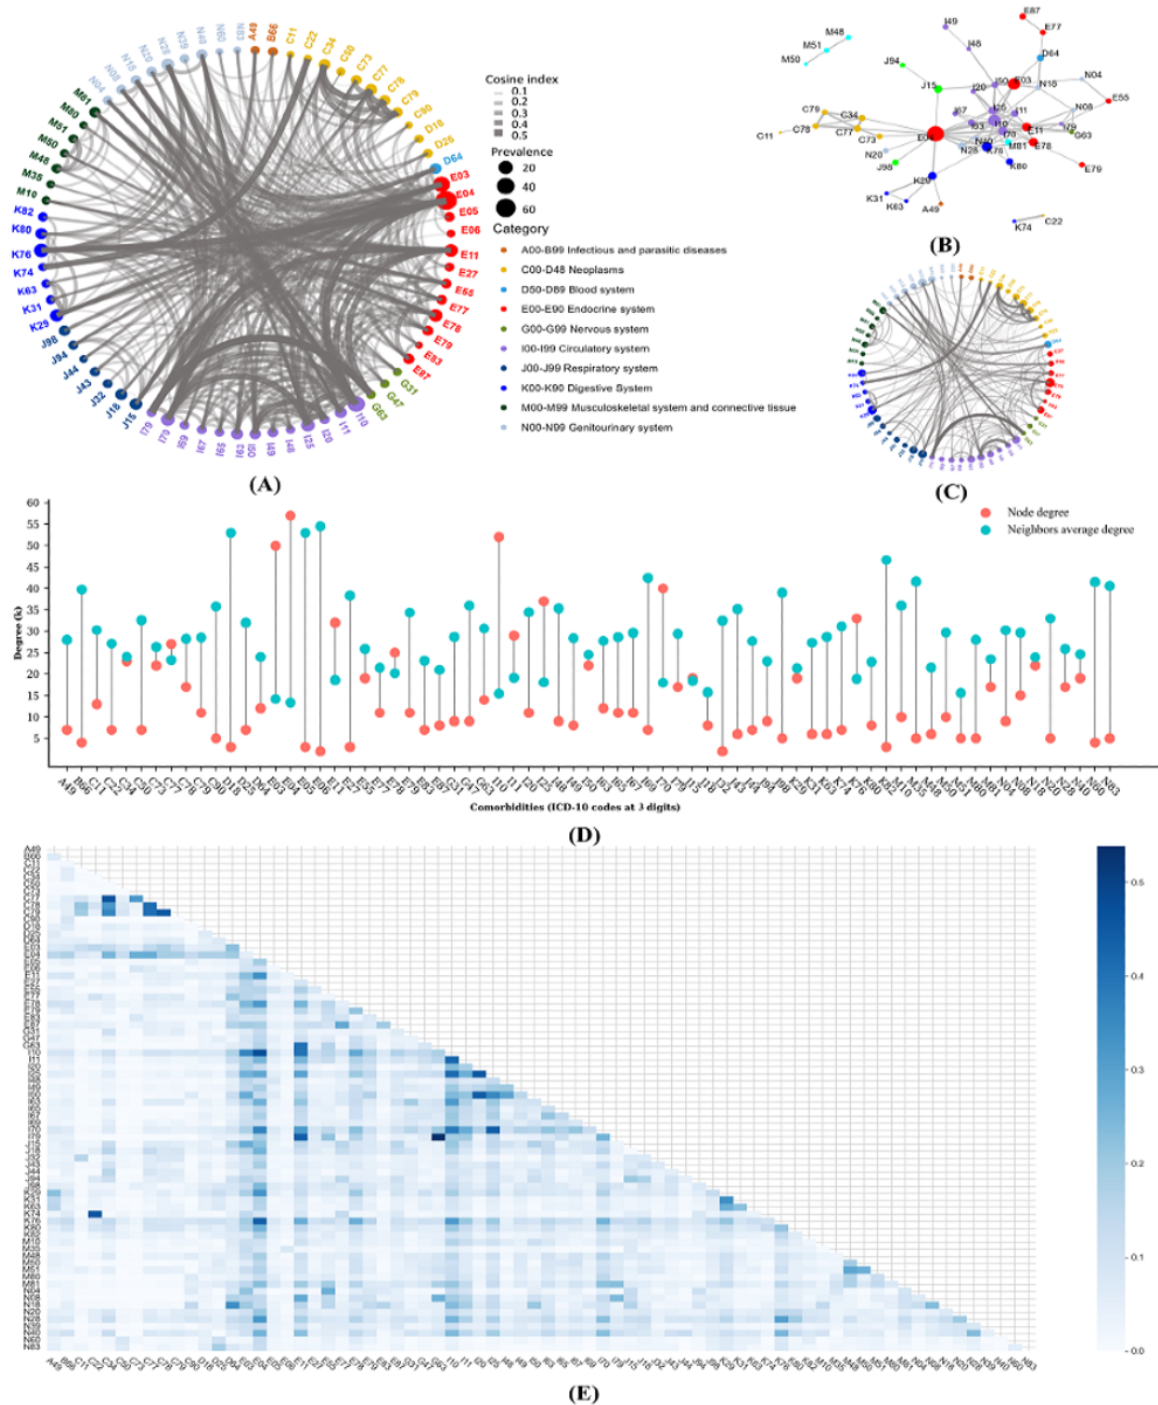
Figure 5. (A) and (D) The optimal number of clusters identified using the K-means clustering algorithm. (B) and (E) The age-specific prevalence of comorbidities within each cluster. (C) and (F) The cluster plots, where comorbidity prevalence in the 5 age groups (18-39, 40-49, 50-59, 60-69, and ≥70 years) has been reduced to 2 dimensions (x-axis and y-axis) through principal component analysis. Panels A-C are based on the private data set, while panels D-F correspond to the MIMIC-IV data set. A detailed list of ICD-10 codes is provided in Tables S1 and S2 in Multimedia Appendix 1. ICD-10: International Classification of Diseases, 10th Revision; MIMIC: Medical Information Mart for Intensive Care.


Phenotypic Comorbidity Network in Patients With Thyroid Disease

In the private data set, the PCN of patients with TD contained 72 diseases and 492 disease pairs (Figure 6A). Each disease shared a median of 13.7 significant correlations with other comorbidities. Nontoxic goiter (E04), hypothyroidism (E03), and TC (C73) were prevalent TDs, with degrees of 50, 57, and 22, respectively (Figure 6D). Hypothyroidism (E03) was strongly linked to hypertension (I10), bacterial pneumonia (J15), heart failure (I50), ischemic heart disease (I25), and anemias (D64), with cosine indexes ranging from 0.23 to 0.36 (Figure 6A and 6E). By contrast, nontoxic goiter (E04) was associated with hypertension (I10; cosine index=0.47), liver disease (K76; cosine index=0.44), atherosclerosis (I70; cosine index=0.37), gastritis and duodenitis (K29; cosine index=0.33), and disorders of the renal and ureter (N28; cosine index=0.33), differing from those of hypothyroidism (E03). Nontoxic goiter (E04) and secondary lymph node carcinoma (C77) showed the highest correlation with TC (C73), with cosine indexes of 0.32 and 0.27, respectively, while other comorbidities had a cosine index of less than 0.06 with TC.

In the private data set, hypertension (I10), atherosclerosis (I70), ischemic heart disease (I25), diabetes (E11), and liver diseases (K76) were the top 5 comorbidities with high degrees (range 32-52) and betweenness centrality (range 47.1-385.2), reflecting their frequent coexistence and mediating role in disease correlations. Among the top 103 comorbid disease pairs with a cosine index of 0.20 or higher, some connections were within the same disease system, such as 50 and 12 connections within circulatory system diseases (ICD-10 codes starting with I) and malignant neoplasms (ICD-10 codes starting with C). When the diseases mentioned above (ie, E03, E04, I10, I70, I25, E11, and K76), which account for about 10% (7/72) of the diseases in the PCN, were removed, the scale of the PCN (Figure 6C) decreased significantly, with the number of significant comorbid disease pairs dropping by 57.5% (283/492).

In the MIMIC-IV data set, there were 107 diseases with 1819 disease links in the PCN, as shown in Figure S2 in Multimedia Appendix 1. Hypertension (I10), ischemic heart disease (I25), heart failure (I50), diabetes (E10 and E11), and esophageal disease (K23) were closely connected with TDs, with the highest cosine index values of 0.60, 0.48, 0.46, 0.42, and 0.39, respectively. Figures S3 and S4 in Multimedia Appendix 1 display the PCN for each subgroup in the private and MIMIC-IV data sets, respectively.

Figure 6. Phenotypic comorbidity network (PCN) in patients with thyroid disease (TD) on the private data set. (A) The PCN of patients with TD. Nodes represent comorbidities. The node size is proportional to the comorbidity prevalence in patients with TD and its color is used to identify the disease category. Link weights are proportional to the magnitudes of the cosine index which are >0. (B) The 103 edges in the PCN, for which the cosine index values are ≥0.20. (C) PCN of dropping the top 7 diseases with the highest degree and the highest betweenness centrality. (D) The degree distribution of the node and its neighbors. (E) Correlations measured by the cosine index between diseases. The disease codes are listed in Table S1 in Multimedia Appendix 1.


Differences in Phenotypic Comorbidity Networks Between Subgroups

In both data sets, the comorbidity coexistence relationships were more complex in males than in females and in patients with BTD compared with those with TC (Table 3). In the private data set, males had 60 comorbidities and females had 63, with the median numbers of connections for comorbidities of 14.0 and 11.5, respectively. Patients with TC had fewer comorbidities

(lower degrees) than those with BTD. As patients aged, the PCNs exhibited an increasing average degree of nodes and their neighboring nodes across the 5 age groups, indicating increasingly complex comorbidity coexistence relationships.

Figure 7 displays the top 10 important comorbidities with the highest PageRank values in different patient groups. In both data sets, cardiovascular and cerebrovascular diseases (colored in blue, ICD-10 codes with I), such as hypertension (I10 and I11) and ischemic heart disease (I25), along with endocrine and

metabolic diseases (colored in orange, ICD-10 codes with E), such as diabetes (E10 and E11) and lipoprotein metabolism disorder (E78), showed high PageRank values, indicating their significance in the PCN of patients with TD. Notably, secondary lymph node carcinoma (C77) exhibited a particularly high PageRank value within the PCN of patients with TD in the private data set, especially among patients with TC.

Figure 8 illustrates the abundant connections among patients with TD in the private data set. In the sex-specific PCN, there were 103 connections involving 55 comorbidities common to both sexes. Abundant connections in females were primarily linked to atrial fibrillation and flutter (I48), heart failure (I50), diseases of the stomach and duodenum (K29 and K31), and

renal failure (N18). By contrast, abundant connections in males were mainly associated with various cardiocerebrovascular diseases (ICD-10 codes with I), malignant neoplasms (ICD-10 codes with C), bacterial pneumonia (J15), disorders of the ureter (N28), and cholelithiasis (K80). Differences in connections based on disease type were relatively minor, with 2 abundant connections in patients with TC and 5 in those without. The abundant connections in patients with TC were primarily linked to metabolic disorders (E78 and E79). By contrast, patients with BTD exhibited several abundant connections, including hypertension (I10), diabetes (E11), pneumonia (J18), and cholelithiasis (K80). The abundant connections within a specific subgroup of patients with TD from the MIMIC-IV data set are shown in Figure S5 in Multimedia Appendix 1.

Table 3. Phenotypic comorbidity network structures in subgroups of patients with thyroid disease.

Subgroup	Nodes, n		Density		Degree, median (IQR)		Degree of neighbors, median (IQR)

[a]MIMIC: Medical Information Mart for Intensive Care.

[b]TC: thyroid cancer.

[c]BTD: benign thyroid disease.

Figure 7. Sankey diagrams of the top 10 important comorbidities of patients with thyroid disease in subgroups on the 2 data sets. The links between the subgroups and comorbidities were proportional to the PageRank values. The higher the PageRank value, the stronger the connection, and the more significant the comorbidity. MIMIC: Medical Information Mart for Intensive Care.

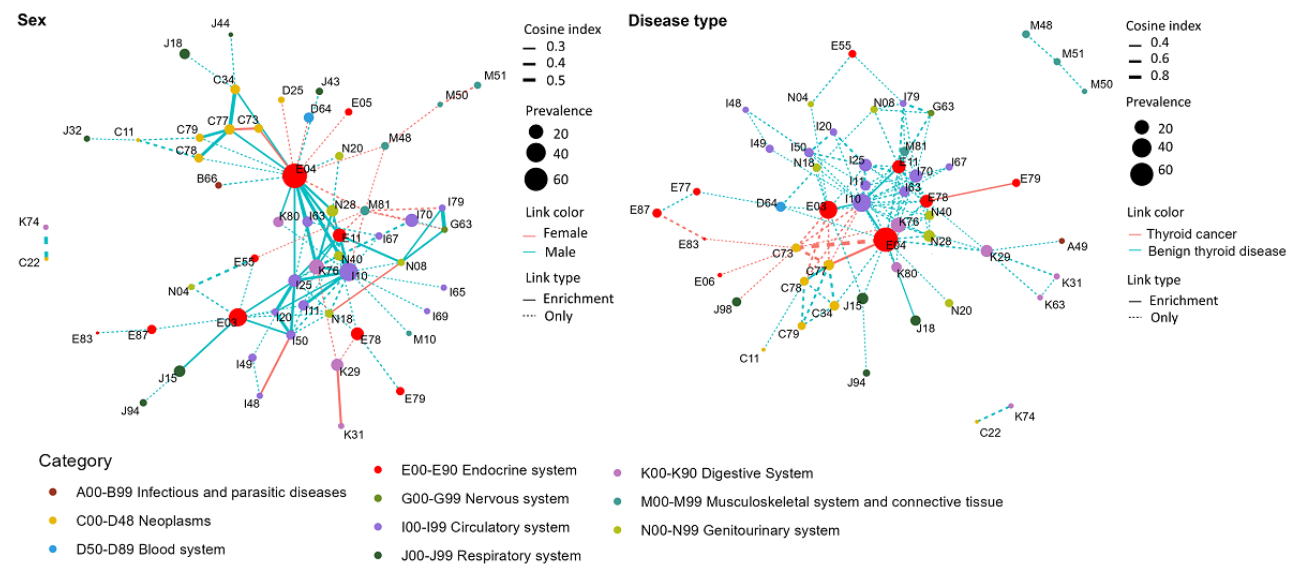

Figure 8. Abundant connections by sex and disease type in patients with thyroid disease on the private data set. Except for those common to both subgroups (link weight difference, ie, cosine index <0.05), disease pairs were identified as abundant edges in 1 subgroup, including enrichment (solid lines) or only occurrence (dotted lines).

Discussion

Principal Findings

In this population-based cohort study, we used a network-based approach to reveal the comprehensive comorbidity patterns in patients with TD, highlighting differences across sex, age, and TD types. Comorbidities were prevalent among patients with TD, with variations in prevalence and complex coexistence relationships influenced by sex, age, and the type of TD. Nontoxic goiter, hypothyroidism, hyperthyroidism, and TC were identified as the most common TDs. The top 5 comorbidities with the highest prevalence were hypertension, liver disease, diabetes, atherosclerosis, and disorders of lipoprotein metabolism. The number of comorbidities increased with age across all patients with TD and subgroups. Males and patients with BTD demonstrated higher rates of comorbidity, greater disease diversity, and stronger associations compared with females and patients with TC.

In this study, hypertension emerged as the most significant comorbidity, affecting 35.14% (6435/18,311) of patients with TD in the private data set. A previous study has demonstrated a positive correlation between blood pressure and thyroid-stimulating hormone levels [17]. Additionally, both blood pressure and dyslipidemia have been strongly associated with TNs [18]. Consistent with previous studies [5,19-22], we found a strong link between TD and diabetes. Specific thyroid

disorders, such as TNs [22], hypothyroidism [19], thyroid dysfunction [5], and thyroid disorders [20], have been linked to diabetes. Furthermore, thyroid function significantly impacts the cardiovascular system [23]. Both hyperthyroidism and hypothyroidism are associated with increased cardiovascular morbidity and mortality, and abnormal thyroid function elevates the risk of coronary heart disease [6,24]. Our findings also revealed high PageRank values for ischemic heart diseases within the PCN of patients with TD. Additionally, thyroid hormones regulate metabolism, linking metabolic syndrome and thyroid dysfunction to significant morbidity and mortality [23]. We also observed that metabolic disorders, such as disorders of lipoprotein metabolism, were closely associated with patients with TD. Moratalla et al [8], exploring the comorbidity network of hypothyroidism, showed strong links to thyroid/larynx cancer, hyperthyroidism, anemia, and goiter. We similarly found associations with nasopharyngeal carcinoma, secondary respiratory cancers, anemia, hyperthyroidism, and nontoxic goiter. However, we revealed that hypothyroidism was strongly associated with hypertension and pneumonia, which was unreported in the study by Moratalla et al [8].

In this study, females exhibited a higher TD burden than males, especially among younger individuals. Similar findings have been widely reported in several studies [22,25]. Consistent with previous studies [22,25], TDs were more prevalent in females than males [1], and the incidence of TC was significantly higher among females, with a ratio of 2.36 in 2017 [26]. This could be attributed to factors such as physiology, pregnancy, and estrogen exposure [27,28]. Estrogen, which is higher in females, can lead to thyroid gland changes, increasing the risk of TDs [27]. Therefore, greater attention should be paid to thyroid gland examination in females.

Further, our findings revealed sex-specific comorbidity patterns in patients with TD. Males, despite lower TD incidence, tended to have more comorbidities than females, with 31 enriched disease pairs in males' PCN compared with only 5 in females on the private data set. Moratalla et al [8] also found that comorbidity networks showed more and stronger connections in males than in females. Notably, cancers, especially malignant neoplasms of lymph nodes, bronchus and lung, and respiratory and digestive organs, demonstrated enriched connections with TC in the PCN of males. Moreover, despite evidence of higher primary TC incidence among females [26,29], males faced a greater risk of developing second primary TC compared with females [30-32]. For instance, males had a higher risk of head and neck cancer than females [30]. Our results confirmed that males were more likely to have concurrent cancers other than TC than females. Besides, males exhibited enrichment in multiple cardiocerebrovascular diseases, while females displayed fewer heart disease associations. Understanding these sex-specific comorbidity patterns aids in developing tailored treatment plans for patients with TD.

Our findings showed that older patients with TD, regardless of sex or TD type, tend to have more comorbidities, which increase with age. This aligns with previous research, including Stenholm et al [33], who reported a rise in diseases and physical difficulties with age, and Xu et al [22], who found a similar trend in TNs' prevalence. Therefore, enhanced nursing and care

for older adult patients with TD is crucial to reduce comorbidities, improve quality of life, and ease medical burdens.

Notably, the average age of patients with TC in this study was 44 years, the same for both genders. A previous study [34] also found that 45-year-old women are the most prone to papillary thyroid carcinoma, while another study [26] reported peak ages of 50-69 years for males and 15-49 years for females. However, Huang et al [2] found that the incidence of TC increased in populations aged under 40 years in China, with males showing a higher growth rate (18.6 vs 13.3). Some researchers suggested that young patients may delay seeking treatment due to underestimating the cancer risk [35]. We speculated that high workload and mental stress in young people may cause endocrine issues and hormone imbalances, contributing to TC's younger trend. Given the link between neuropsychological functions and thyroid health [36,37], extra care is needed for young patients with TD to prevent cancer.

Besides, we observed that patients with TC, despite having a relatively low median comorbidity count (3 and 4 on the private and MIMIC-IV data sets, respectively), exhibited severe comorbidities such as cancer, heart failure, cerebral infarction, and pneumonia. This severity may stem from the aggressive nature of cancer and its tendency to metastasize, leading to life-threatening complications. Prior studies have shown higher risks of papillary TC following other neoplasms, particularly renal and breast cancers, as well as leukemias/lymphomas [38,39]. Similarly, Lian et al [40] found that subclinical hypothyroidism was common in patients with nasopharyngeal carcinoma within a year and that thyroid volume is a risk factor for radiation-induced hypothyroidism. Given these findings, heightened vigilance is necessary to prevent cancer progression and deterioration in patients with TC.

From a methodological perspective, we used cosine similarity and Pearson correlation indices to quantify node connectivity, considering disease prevalence and minimizing sample size biases. Cosine similarity effectively captured significant comorbidities in this study, as well as in previous analyses of comorbidities associated with colorectal cancer [10] and idiopathic cardiomyopathy [41]. Other similarity metrics, such as the Jaccard index [42], which quantifies the overlap between disease sets, and the observed-to-expected ratio, which considers the observed prevalence of disease pairs relative to the expected prevalence [7], were utilized in constructing cardiovascular comorbidity networks [7,42]. Additionally, various network properties were used to computationally identify key comorbidities. We applied the PageRank algorithm, which considers the number and weight of edges, the number of neighbor edges, and the centrality of neighbors, to assess the importance of comorbidities. In the comorbidity networks of both data sets in this study, the comorbidities selected by PageRank were similar, including hypertension and diabetes. PageRank has also been utilized in constructing comorbidity networks for patients with colorectal cancer [10], general patients [16], and hypothyroidism patients [8]. Additionally, other properties, such as degree [11] and degree centrality [42], have been used to identify important comorbidities and their connections.

Limitations

This study has several limitations. First, apart from the MIMIC-IV data set, we collected data and conducted analyses solely in a general tertiary hospital in China, which may introduce selection bias, particularly concerning geographical and population factors. Utilizing multicenter data could yield more representative and robust results. Second, our analysis focused solely on the coexistence of comorbidities without considering their causal relationships, and many network properties remain unexplained in clinical or biological contexts. Some diseases may share common pathophysiological mechanisms or causes, leading to mutual influence. In some cases, one disease may promote the occurrence and progression of another. Therefore, further analysis is needed to explore the deeper and more detailed causal relationships between thyroid disorders and their comorbidities. Third, relying solely on ICD-10 codes for disease identification may not fully capture all cases related to thyroid disorders, potentially leading to missing information. Additionally, some diagnoses may be subject to overdiagnosis or underdiagnosis due to the complexity of clinical issues. Certain diseases may not be frequently coded, and broad categorization may obscure differences among heterogeneous conditions. Finally, we conducted only a cross-sectional analysis and did not consider the temporality and sequence of comorbidities when constructing comorbidity profiles. These patterns may change as diseases progress. By collecting more data over longer periods from multiple hospitals, a more detailed analysis could provide deeper insights into the comorbidity patterns of patients with thyroid disorders.

Conclusions

This data-driven exploration of comorbidity patterns among all patients with thyroid disorder and their subgroups aims to provide valuable clinical and foundational insights into the comorbidities associated with thyroid disorders. It enhances our understanding of thyroid disorders as a whole and may inform the development of more effective and integrated therapeutic strategies for patients. Additionally, the network-based methodology utilized in this study has the potential to uncover comorbidity patterns in other diseases. In the future, we plan to incorporate a wider variety of data to construct more comprehensive networks. By extracting features from these networks, we aim to leverage medical knowledge to develop machine learning–based prediction models for patients with thyroid disorders.

Data Availability

The MIMIC-IV data sets used in this study are available online [43]. However, the private data set generated or analyzed in this study is not publicly available as these are restricted by the Medical Ethics Committee of the First Affiliated Hospital of Guangxi Medical University.

Abstract

Background: Health care workers (HCWs) in Canada have endured difficult conditions during the COVID-19 pandemic. Many worked long hours while attending to patients in a contagious environment. This introduced an additional burden that may have contributed to worsened mental health conditions.

Objective: In this study, we examine the factors associated with worsened mental health conditions of HCWs as compared to before the start of the pandemic.

Methods: We use data from a survey of HCWs by Statistics Canada. A regression model is used to estimate the odds ratios (ORs) of worsened mental health after the start of the pandemic. The estimated odds ratio (OR) is associated with different independent variables that include demographics (age, sex, immigration status, and geographic area), occupational factors (work status, occupational group, and exposure category), and different access levels to personal protective equipment (PPE).

Results: Of 18,139 eligible participants surveyed, 13,990 (77.1%) provided valid responses. We found that HCWs younger than 35 years old were more likely (OR 1.14, 95% CI 1.03-1.27; P=.01) to exhibit worsened mental health as compared to the reference group (35-44 years old). As for sex, male HCWs were less likely (OR 0.76, 95% CI 0.67-0.86; P<.001) to exhibit worsened mental health as compared to female HCWs. Immigrant HCWs were also less likely (OR 0.57, 95% CI 0.51-0.64; P<.001) to exhibit worsened mental health as compared to nonimmigrant HCWs. Further, HCWs working in Alberta had the highest likelihood of exhibiting worsened mental health as compared to HCWs working elsewhere (Atlantic provinces, Quebec, Manitoba, Saskatchewan, Ontario, British Columbia, and Northern Territories). Frontline workers were more likely (OR 1.26, 95% CI 1.16-1.38; P<.001) to exhibit worsened mental health than nonfrontline HCWs. Part-time HCWs were less likely (OR 0.85, 95% CI 0.76-0.93; P<.001) to exhibit worsened mental health than full-time HCWs. HCWs who reported encountering COVID-19 cases were more likely (OR 1.55, 95% CI 1.41-1.70; P<.001) to exhibit worsened mental health as compared to HCWs who reported no contact with the disease. As for PPE, HCWs who never had access to respirators, eye protection, and face shields are more likely to exhibit worsened mental health by 1.31 (95% CI 1.07-1.62; P<.001), 1.51 (95% CI 1.17-1.96; P<.001), and 1.41 (95% CI 1.05-1.92; P=.02) than those who always had access to the same PPE, respectively.

Conclusions: Different HCW groups experienced the pandemic differently based on their demographic and occupational backgrounds as well as access to PPE. Such findings are important to stakeholders involved in the planning of personalized support programs and aid mental health mitigation in future crises. Certain groups require more attention.

Introduction

On March 11, 2020, the World Health Organization declared COVID-19 a global pandemic. The pandemic resulted in devastating health impacts on populations and a crisis within the health care system [1]. This health care system was tasked to handle the unprecedented inflow of patients. Functions within the system that were impacted include emergency departments, intensive care units, physician services, and long-term care units [2]. Health care workers (HCWs) of different occupational groups battled the pandemic. Overwhelmed hospitals in Canada canceled less urgent surgeries by up to 80% by June 2020 [3]. These patterns shifted the workload on HCWs and had an impact on the overall health care system. These conditions not only demanded more hospital capacity but also put an overwhelming strain on HCWs [4]. In addition to the operational pressure, HCWs also suffered from the lack of personal protection equipment (PPE), especially at the beginning of the pandemic [5]. HCWs were at the frontline in battling this pandemic. This battle has put pressure on their mental health conditions [6-8].

In this paper, we assess the various factors associated with worsened HCWs' mental health conditions as compared to before the start of the pandemic. Although experiencing mental health conditions may be a daily occurrence for some HCWs, the duration and severity during the pandemic were different. HCWs were also at a higher risk of infection, adding to the risk of further mental health conditions [9]. In the past, HCWs have experienced mental health problems during other outbreaks, including the Middle East respiratory syndrome and the severe acute respiratory syndrome [10]. Such conditions have been studied in the literature [11]. In this study, we use a recent data set by Statistics Canada from a national cross-sectional survey that was conducted in the fall of 2020 to assess the impact of COVID-19 on HCWs. Unlike work in the literature, we comprehensively assess the impact of demographic and occupational factors as well as the availability of PPE on HCWs' mental health conditions [9,12,13].

In the global literature, authors assessed the mental health conditions of HCWs during such outbreaks globally [14-16]. The impact of demographic, social, and occupational factors was reportedly linked to various mental health conditions. Researchers also assessed the prevalence of stress, anxiety, and other psychological well-being indicators of HCWs in Oman during the pandemic [12]. The focus was on young female HCWs who encountered confirmed or suspected COVID-19 cases during their work. Another study in Turkey examined the relationship between the perceived risk of infection and the mental health conditions of HCWs during the COVID-19 pandemic [13]. In addition, a study in the Chinese province of Hubei was conducted early in the pandemic to assess the psychological impact of the pandemic on the frontline medical staff [9]. The study measured the association of factors including professional group, age, and sex factors with work stress.

Our study is among the first to highlight the association of diverse demographic and occupational factors with the mental health condition of HCWs during the pandemic in Canada. We also considered the role of access to PPE on HCWs' mental health conditions. Unlike existing literature, we studied the individual impact of each of the following factors on the mental health of HCWs while holding the rest constant. Demographic factors include age group, sex, province of the workplace, and immigration status. Occupational factors include work status, frontline category, and exposure to confirmed or suspected COVID-19 cases. Finally, we also considered access to several PPE. The findings of the study will be of prime importance to key stakeholders, including mental health support program planners, health care policy makers, HCWs themselves, and researchers in the area. The goal of this paper is to understand which factors were associated with worsened mental health conditions in HCWs after the start of the pandemic.

Methods

Data Sources, Study Procedure, and Participants

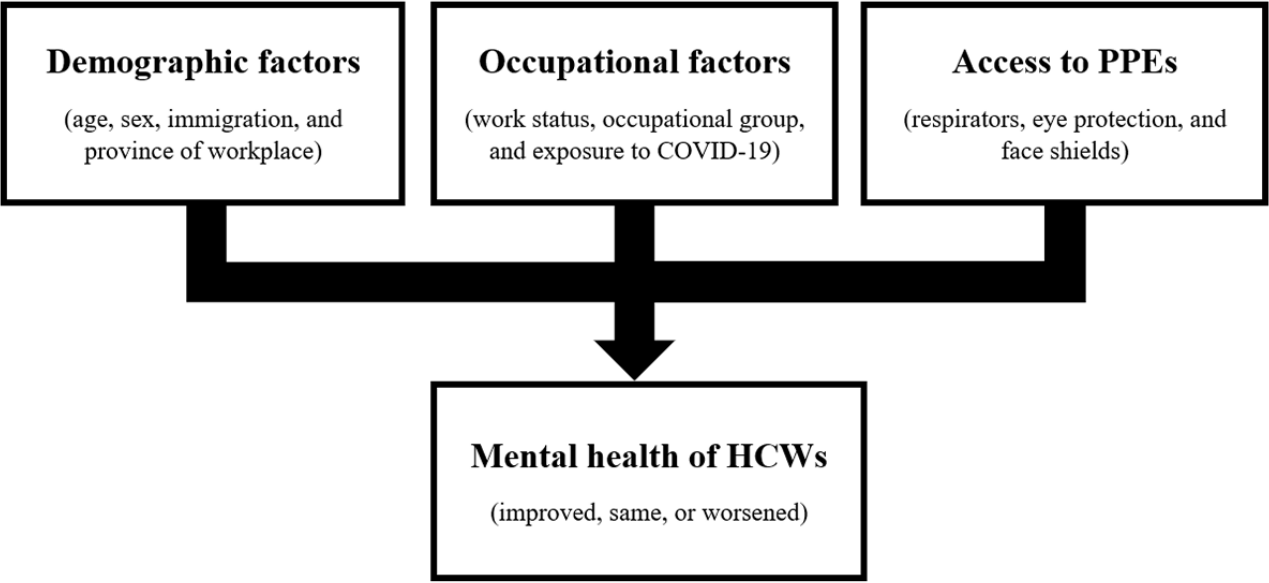
We used a data set from a recent cross-sectional survey by Statistics Canada on the impacts of COVID-19 on HCWs. Unlike other traditional Statistics Canada surveys, a random selection of participants was not used. Instead, Statistics Canada sent an email invitation to HCWs across Canada. Then, a snowball sampling procedure was used. The invitation included a link to a web-based survey that was available through Statistics Canada's web page. Accordingly, 18,139 responses were collected between November 24 and December 13, 2020, across 7 provincial and territorial regions in Canada. No data were collected for this survey beyond these dates. Only responses by HCWs were included in the data set. The responses were completely anonymized by Statistics Canada.

The questionnaire asked HCWs for information related to the job environment, demographics, geography, and information on access to PPE as background information. Adaptive questioning was used. Our study was limited to these 3 factors categories only: demographics, occupational, and access to PPE based on the available data from Statistics Canada. In assessing mental health well-being, the survey asked HCWs: compared to before the COVID-19 pandemic, how would you say your mental health is now? HCWs self-reported their perceived mental health on a 5-point Likert scale: much better now, somewhat better now, about the same, somewhat worse now, much worse now.

Statistical Analysis Strategy

Our study uniquely studied the association of various interesting factors, as depicted in Figure 1, with HCW mental health conditions as compared to before the start of the pandemic. To consider each factor separately, we used a multivariate ordinal logistic regression [17,18]. The model is defined in Multimedia Appendix 1. The dependent variable is the state of mental health

of the respondents. We reduced the mental health state categories from the 5 mentioned above to 3 (improved, same, or worsened) to yield statistically significant model estimates. The independent variables include demographics such as age, sex, immigration status, and the province of the workplace. Occupational variables include work status, occupational group, and exposure to COVID-19 cases. The model also estimated the association of HCWs' access to a variety of PPE, such as respirators, eye protection, and face shields. Access to PPE is also reported by the HCW on a 5-point Likert scale, which we reduced to 3 categories (always available, sometimes available, or never available) to yield statistically significant model estimates. All responses are self-reported. Analyses were conducted in RStudio (version 1.4.1717; Posit, PBC).

Figure 1. Factors associated with the mental health of HCWs. HCW: health care worker; PPE: personal protective equipment.


Ethical Considerations

Data collected by Statistics Canada were reviewed based on the following principles: privacy, security, transparency, accountability, trust, sustainability, data quality, and fairness, as well as well vetted to be harmless to participants or the public. All ethical approvals were considered by Statistics Canada. No further ethical approval to use these data was required by the authors and the survey is made available to the public. This study is exempt from further ethical approval. Furthermore, the authors also did not have access to information related to the development and testing of the survey. The authors are also not aware of any compensation provided to survey participants.

Results

Participant Profile

From the full data set of 18,139 responses, we considered nonduplicate responses that provided valid answers to all questions of interest to this study (N=13,990). The remaining responses contained missing or invalid responses. For the considered population, Table 1 outlines the number of observations and percentages for different demographic factors such as age group, sex, and immigration status. The number of observations and percentages were also calculated for occupational factors including the province of the primary workplace, work status (full-time vs part-time), frontline work status, occupational group, and exposure to confirmed or suspected COVID-19 cases. Additionally, the last 3 rows of Table 1 outline PPE access levels for 3 different PPE: face shields, eye protection, and respirators. Overall 4261 (31%) HCWs were younger than 35 years. The majority were female participants (n=12,682, 91%). In total, 12,510 (89%) HCWs were nonimmigrant. HCW workers were distributed across 7 regions, with the largest group of 6626 (47%) working in Ontario. The majority (n=10,152, 73%) of HCWs worked full-time and 5511 (39%) were nonfrontline allied health professionals. A total of 8188 (59%) HCWs did not report exposures to confirmed or suspected COVID-19 cases. As for access to PPE, 10,758 (77%) HCWs always had access to face shields, 10,118 (72%) always had access to eye protection, and 6898 (49%) always had access to respirators.

Skipped answer	5047 (36.1)

[a]PPE: personal protective equipment.

Analysis Results

In the following, we present the results for estimating the associations between the various factors and the likelihood of worsened mental health conditions for HCWs.

Demographic Factors

Model estimates are expressed as odds ratios (ORs), as presented in Table 2. These ORs indicate the odds of worsened mental health conditions as compared to before the start of the pandemic. Based on the ORs in Table 2, HCWs who are younger than 35 years old were more likely (OR 1.14, 95% CI 1.03-1.27; P=.01) to exhibit worsened mental health conditions than the reference group (35 to 44 years old). Furthermore, those aged 45-54 years and 55 years and older were less likely to exhibit worsened mental health conditions than the reference group (OR 0.71, 95% CI 0.64-0.78; P<.001; and OR 0.55, 95% CI 0.49-0.61; P<.001, respectively). Hence, the older the HCW, the lower the likelihood of worsened mental health conditions. As for sex, male HCWs were less likely (OR 0.76, 95% CI 0.67-0.86; P<.001) to exhibit worsened mental health conditions than their female counterparts. Immigrant HCWs were also less likely (OR 0.57, 95% CI 0.51-0.64; P<.001) to exhibit worsened mental health conditions than nonimmigrants. Geographically, HCWs working in Alberta have the highest likelihood of worsened mental health conditions. HCWs living in Alberta were most likely to exhibit worsened mental health conditions.

Table 2. Estimates for the ordinal regression model for various factors associated with the mental health conditions of HCWs[a].

[a]HCW: health care worker.

[b]OR: odds ratio.

Occupational Factors

Frontline HCWs, such as physicians, nurses, and emergency medical personnel, were more likely (OR 1.26, 95% CI 1.16-1.38; $P<.001$) to exhibit worsened mental health conditions than nonfrontline workers (personal support workers, allied health professionals, laboratory workers, pharmacists, and professionals). Part-time HCWs, however, were less likely (OR 0.85, 95% CI 0.76-0.93; $P<.001$) to exhibit worsened mental

health conditions. Furthermore, HCWs who reported encountering suspected or confirmed COVID-19 cases were more likely (OR 1.55, 95% CI 1.41-1.70; $P<.001$) to exhibit worsened mental health conditions.

Access to PPE

HCWs who never had access to PPE such as respirators, eye protection, and face shields exhibited the highest likelihood of worsened mental health conditions than those who always had

access to such PPE. For instance, HCWs who never had access to respirators were more likely (OR 1.31, 95% CI 1.07-1.62; *P*<.001) to exhibit worsened mental health conditions than those who did not need this PPE. Similar trends were exhibited with access to eye protection (OR 1.51, 95% CI 1.17-1.96; *P*<.001) and face shields (OR 1.41, 95% CI 1.05-1.92; *P*=.02).

Discussion

Principal Findings

The statistical analysis in this study found that HCWs who are younger than 35 years old were found to be more likely to exhibit worsened mental health conditions than HCWs aged 35-44 years. Male HCWs were less likely to exhibit worsened mental health conditions than female HCWs. Immigrant HCWs were also less likely to exhibit worsened mental health conditions than nonimmigrant HCWs. In contrast, HCWs working in Alberta had a higher likelihood of worsened mental health conditions than HCWs working elsewhere (Atlantic provinces, Quebec, Manitoba, Saskatchewan, Ontario, British Columbia, and Northern Territories). Frontline workers were more likely to exhibit worsened mental health conditions than nonfrontline HCWs. Part-time HCWs were less likely to exhibit worsened mental health conditions than full-time HCWs. HCWs who reported encountering COVID-19 cases were more likely to exhibit worsened mental health conditions than HCWs who reported no contact with the disease. As for PPE, HCWs who never had access to respirators, eye protection, and face shields were more likely to exhibit worsened mental health conditions than those who always had access to the same PPE, respectively.

Comparison With Prior Work

Previous research has shown that shock events can result in psychological trauma to HCWs [19-21]. To the best of our knowledge, our study is the first to assess the association of a comprehensive variety of factors (demographics, occupational factors, and access to PPE) independently with the mental health conditions of HCWs.

With regard to demographic factors, a study found sex to be associated with worsened mental health conditions of HCWs. Female medical staff exhibited a higher incidence of severe anxiety than their male counterparts [22]. Sex was also found as a predictor of increased anxiety and distress in a study that found female HCWs more vulnerable to such conditions than male HCWs [23]. Our study findings corroborate these previous findings. Similarly, for age, our results demonstrated that older HCWs exhibited less likelihood of worsened mental health conditions. This agrees with findings from a study in the Middle East that found older workers enjoyed better mental health conditions than younger workers [24]. Older HCWs with longer work experience seemed to have handled the pandemic better than their younger counterparts. Another study found that HCWs 40 years or older were less likely to report higher anxiety during the pandemic than younger HCWs [25]. Our results confirm such findings as well.

As for occupational factors, our findings align with a cross-sectional study conducted in Oman, which found frontline workers to be more likely to have anxiety and sleep problems

[26]. This was attributed to frontline workers' increased awareness of the mortality rate of COVID-19 and their fear of contracting the virus. Similar findings were reported by a study conducted in China as well [27]. Exposure to COVID-19 cases has been recognized as a risk factor associated with an increased likelihood of mental health issues in the literature. For instance, in France, female urologists working on the frontline were 1.41 times more likely to feel a degree of stress during their duties. Of this group, those who worked in a department where patients with COVID-19 are treated were 1.85 times more likely to report a degree of stress during work duties [28]. This was attributed to the workers' fear of infection and the spread of the virus. Direct involvement with COVID-19 care is also found to be highly associated with fear, depression, and anxiety as compared with those working under lower risk conditions [29]. The authors attributed this to the workers' fear of bringing the virus to their families at home.

As for the work setting, contrary to our findings, the literature reports higher levels of fear and anxiety among part-time HCWs than among full-time [30]. Another study in France found part-time HCWs to exhibit a greater association with distress [31]. Given the small number of part-time HCWs in our study, caution should be observed in interpreting the results. Regarding factors related to access to PPE, access to PPE was found to be associated with better health and less stress [24]. Lack of access to PPE was found to be a major source of HCW stress in a study that surveyed emergency physicians [32]. In Canada, a study found that inadequate PPE supply is associated with increased symptoms of anxiety and depression among HCWs [33]. Workers were concerned about the ability to access sufficient PPE during work hours. These findings are in line with our results. Compared to studies in the literature, our study is the first comprehensive study that assesses the association of a diverse pool of factors including demographics, occupational, and access to PPE, with HCWs' mental health conditions.

Implications: Mental Health Programming

Our comprehensive study sheds light on the association of various factors with HCWs' mental health after the start of the pandemic. It helps in understanding the vulnerability of various HCW groups to mental health during such events. Certain groups were at substantially higher risk of exhibiting worsened mental health conditions after the pandemic, hence the need for a specialized support program to target this group. As a direct implication, the findings can be used to inform guidelines for mental health support for HCWs during future public health emergencies. Such mental health support may be directed more specifically to more vulnerable groups. Literature has pointed to the importance of an evidence-based approach to designing mental health support programs for HCWs [34,35]. For instance, a study in Alberta during the pandemic pointed to the importance of understanding HCWs' occupational settings and mental health mitigation techniques [16]. Others have discussed the importance of support programs for HCWs during the pandemic based on need and background [36,37]. More importantly, many studies highlighted the importance of designing personalized mental health support programs based on various factors including demographic and occupational factors [38,39]. Some of these programs used mobile technology to offer mental health

support to HCWs [35,40]. As such, our study aims to inform stakeholders of such factors associated with HCW groups most vulnerable to future events such as the pandemic and health crises.

Limitations and Future Directions

This study has several limitations. First, the scope of the study was limited to assessing mental health in general without measuring different mental condition forms such as depression, anxiety, and fear. This is due to the limited data offered by the survey we used. Second, participants were asked, "Compared to before the COVID-19 pandemic, how would you say your mental health is now?" That is, HCWs had to objectively compare their mental health state from the time they received the survey to sometime in the past. There may be some variation in how HCWs perceive this comparison. Third, data collected were at a single point in time, which limits the ability to compare mental health assessments to later periods in the pandemic and during subsequent pandemic waves. Fourth, no information about HCW medical history is collected in this survey. In future research, we recommend collecting data at different points in the given event to allow for a time-series analysis and comparison at different crucial points of the event. We also suggest the collection of distress information and whether the

conditions persisted beyond the initial shockwave. HCWs' years of work experience and ethnicity information can also be useful in future studies. We also believe medical history, particularly a preexisting history of mental health disorders, is an important factor associated with the mental health conditions of HCWs and should be considered in future studies.

Conclusions

This study investigated the factors associated with worsened mental health conditions of HCWs in Canada during the pandemic. Our study suggested the association of various factors with the likelihood of HCWs exhibiting worsened mental health conditions as compared to feeling neutral and better. In agreement with the literature, our findings concluded that younger (vs older), female (vs male), nonimmigrant (vs immigrant), full-time (vs part-time), and frontline (vs nonfrontline) HCWs living in Alberta (vs other provinces) exhibited a higher likelihood of worsened mental health conditions than those who felt neutral or better. Those who reported concerns about access to PPE also exhibited the same trend. Such findings can guide the future development of health care programming and inform mental health support planning for HCWs. COVID-19 is a shocking event that introduced uncertainty to the health care system.

Data Availability

The data that support the findings of this study is available through Statistics Canada.

Authors' Contributions

AA processed and cleaned the data and wrote the first draft of the manuscript with guidance from ZAB. BC and SD conducted iterative reviews and suggested revisions to the draft. All authors offered substantial contributions to the discussion and analysis presented in this manuscript. All authors agreed to publish the final draft of this paper.

Conflicts of Interest

None declared.

Abstract

Background: Individuals with severe mental illness living in supported accommodation are often socially excluded. Social inclusion is an important aspect of recovery-based practice and quality of life. The Social Inclusion Questionnaire User Experience (SInQUE) is a measure of social inclusion that has been validated for use with people with mental health problems. Previous research has suggested that the SInQUE could also help support care planning focused on enabling social inclusion in routine mental health practice.

Objective: This study aims to develop a web-based version of the SInQUE for use in mental health supported accommodation services, examine its acceptability and perceived usefulness as a tool to support care planning with service users, determine the extent of uptake of the tool in supported accommodation settings, and develop a program theory and logic model for the online SInQUE.

Methods: This study involved a laboratory-testing stage to assess the acceptability of the SInQUE tool through "think-aloud" testing with 6 supported accommodation staff members and a field-testing stage to assess the acceptability, utility, and use of the SInQUE tool over a 5-month period. An implementation strategy was used in 1 London borough to encourage the use of the SInQUE. Qualitative interviews with 12 service users and 12 staff members who used the tool were conducted and analyzed using thematic analysis. The use of the SInQUE was compared with that in 2 other local authority areas, 1 urban and 1 rural, where the tool was made available for use but no implementation strategy was used.

Results: Overall, 17 staff members used the SInQUE with 28 different service users during the implementation period (approximately 10% of all service users living in supported accommodation in the study area). The staff and service users interviewed felt that the SInQUE was collaborative, comprehensive, user-friendly, and relevant. Although some staff were concerned that particular questions might be too personal, service users did not echo this view. Participants generally felt that the SInQUE could help identify individuals' priorities regarding different aspects of social inclusion by prompting in-depth conversations and tailoring specific support to address service users' inclusion goals. Some interviewees also suggested that the tool could highlight areas of unmet or unmeetable needs across the borough that could feed into service planning. The SInQUE was not used in the comparison areas that had no implementation strategy.

Conclusions: The online SInQUE is an acceptable and potentially useful tool that can be recommended to assess and support care planning to enable social inclusion of people living in mental health supported accommodation services. Despite this, uptake rates were modest during the study period. A concerted implementation strategy is key to embedding its use in usual care, including proactive endorsement by senior leaders and service managers.

Introduction

Background

Social inclusion refers to an individual's ability to participate in important societal activities and their sense of community belonging [1,2]. Someone may feel socially excluded if they do not have opportunities for societal involvement and integration, often because of external factors that are beyond their control [3]. Social exclusion is a multifaceted continuum [2], typically signified by poverty, unemployment, inequality, and poor health [4].

People with serious mental illness are thought to be among the most socially excluded groups in society [5]. Individuals with this type of mental health problems often have smaller and less satisfying social networks [6], lower household income [7], and lower levels of employment [8,9] and experience more criminal and violent victimization [10,11] than those in the general population. Social exclusion can be conceptualized as both a cause and a consequence of mental illness [12]. Furthermore, greater social inclusion is associated with better quality of life and lower levels of loneliness among those with severe mental illness, suggesting that social exclusion is an important area for mental health practitioners to try to address [13,14].

Mental health supported accommodation services provide care and support to individuals with particularly severe and complex mental health problems as a way of supporting recovery in the community [15]. It is estimated that there are approximately 100,000 people living in mental health supported accommodation in England. Services are typically staffed by support workers, with additional specialist clinical input provided by National Health Service (NHS) community mental health teams [16]. In England, three main types of supported accommodation are provided: (1) residential care homes for those with the highest needs that comprise 24-hour–staffed communal facilities where placements are not time limited, with meals, supervision of medication, cleaning, and activities provided to service users; (2) supported housing services that provide shared or individual, self-contained, and time-limited tenancies with staff based on-site up to 24 hours a day to assist service users in gaining skills to move on to less supported accommodation; and (3) floating outreach services that provide visiting support for a few hours per week to people living in permanent, self-contained, and individual tenancies with the aim of reducing support over time to zero [16].

Service users living in supported accommodation are often socially isolated, with low levels of employment and little involvement in civil and political processes [17]. Many report feeling lonely and isolated and experiencing a high level of stigma that causes them to become more socially isolated [18]. There is evidence that users of mental health supported accommodation services report a variety of unmet needs, such as accessing employment opportunities and forming intimate relationships [19,20]. However, relatively little research has been conducted to determine the precise needs of service users living in supported accommodation [21], and a greater focus on this group is needed to identify and implement interventions that are likely to be the most useful for them [22].

Supporting service users to work toward desired goals and community engagement is highly congruent with recovery-based practice in mental health. Recovery-based practice recognizes and builds on service users' strengths and promotes empowerment through collaboration between them and staff to identify and work toward specific goals [23]. Many of the identified goals are markers of social inclusion, such as employment, social network development, and participation in community activities [24]. There is qualitative evidence from a large national research program suggesting that staff working in mental health supported accommodation services operate with a considerable degree of recovery orientation [24,25], and the more recovery-orientated these services are, the more likely people are to move on successfully to more independent settings [26].

People living in mental health supported accommodation have expressed a strong preference for individually tailored services that offer choice and promote autonomy, consistent with a recovery-based approach [18]. Patient-reported outcome measures have been recommended to inform this individualized approach by directly capturing service users' perspectives on constructs such as goal attainment, quality of life, and social inclusion [27]. Such measures enable service users to make informed decisions about their own support and care planning, in line with World Health Organization recommendations for recovery-based practice in community care provision [28]. Resources delivered across web-based platforms, particularly those that offer guided support, have been established as accessible, acceptable, and effective for use by participants with severe mental illness [29,30]. A tailor-made web-based assessment tool, the Quality Indicator for Rehabilitative Care for supported accommodation, has also been successfully used by managers of supported accommodation services, suggesting that these settings have the required resources and expertise to implement online measures [31].

The Social Inclusion Questionnaire User Experience (SInQUE) was developed as a measure of social inclusion for individuals with severe mental illness [32]. The measure has been validated across a range of mental health populations, has established reliability, is considered acceptable to service users, and has been proposed as being potentially cross-culturally suitable [32-34]. To date, the SInQUE has been used solely in offline research contexts. However, stakeholder feedback from a previous study testing the SInQUE indicated that the measure may be useful in clinical practice to assess social inclusion, facilitate important conversations with service users, and guide care and support planning [34]. Furthermore, a consistent research recommendation from the developers of the SInQUE

tool has been to investigate whether the measure has utility as a care-planning tool to promote social inclusion in routine mental health practice [13,34].

This study aimed to develop a web-based version of the SInQUE for use in mental health supported accommodation services. We sought to examine the acceptability and perceived usefulness of this tool among supported accommodation staff and service users as a means to assess their needs for greater social inclusion and promote care planning.

Aims

The study aims were as follows:

1. To develop and refine a web-based version of the SInQUE social inclusion assessment tool tailored for use in mental health supported accommodation settings.
2. To investigate the acceptability and perceived utility of the online SInQUE tool among supported accommodation staff and service users.
3. To determine the extent of uptake of the tool in supported accommodation settings with and without a locally developed implementation strategy to support its use.
4. Informed by the study findings, to develop a program theory and logic model for the online SInQUE specifying its anticipated outcomes, the mechanisms through which they may be achieved, and contextual factors affecting the use and experience of the SInQUE.

Methods

Study Design

This study comprised two stages conducted in 1 inner London borough:

1. A laboratory-testing stage to assess initial acceptability of the tool and develop it through "think-aloud" testing and semistructured interviews with supported accommodation staff.
2. A field-testing stage to assess wider acceptability, feasibility, and use of the tool. Semistructured interviews were conducted with staff and service users who had used the online SInQUE during this stage.

The 5-month field-testing stage was supported by a local implementation strategy developed in collaboration with local service leads to support the use of the online SInQUE by supported accommodation staff in the participating London borough. The online SInQUE was also made available to supported accommodation services by local service leads in 2 other areas without any accompanying implementation strategy.

Description of the SInQUE Tool

The web-based version of the SInQUE [35] can be used to assess social inclusion and inform support and care planning for people with mental health problems. It is designed to be used by staff as part of routine care planning to be completed collaboratively with service users. It can be used on a computer, tablet, or mobile device. Staff are required to register for an account on the SInQUE site using their work email address and details of their organization and can then use the tool for free. No personal

data identifying service users are logged or stored on the SInQUE platform. The online SInQUE generates a unique reference number for each new service user, which is retained by the staff member completing the assessment for future reference and to link any repeat assessments.

The online tool developed for laboratory testing in our study included the 46-item version of the validated SInQUE social inclusion questionnaire, which was refined following stakeholder feedback at the end of the previous measure development study [34]. For this study, we removed 1 question from the SInQUE that asked whether the respondent was living alone as this was considered redundant for people living in residential care and supported housing. The SInQUE's psychometric properties have been established among people with a range of mental health problems receiving input from community mental health services in previous studies [13,32,34]. Although the removal of a question from the original SInQUE questionnaire compromised its established psychometric properties, this minor adaptation is unlikely to have disrupted them substantially. We wanted to minimize changes to maintain the online SInQUE's similarity to the validated measure and did not aim to make further significant refinements to the content of the tool. Instead, we wanted to gain feedback on its acceptability and feasibility for use in its digital format among staff and users of mental health supported accommodation services to assist in care and support planning.

The online SInQUE questionnaire yields a total score of 0 to 75, with a higher score indicating greater social inclusion. The questions and subscale scores are grouped into 9 different areas of social inclusion: leisure, social relationships, religious and cultural activities, education and employment, transport, health, crime victimization, home life and housing, and civic duties. These areas cover the 5 social inclusion domains of the validated SInQUE (social integration, productivity, consumption, access to services, and political engagement), but the aforementioned 9 areas were considered more immediately understandable for use in practice.

Using the service user's responses, the online SInQUE generates a list of areas in which the person has said that they would like to be more socially included. It then offers a prompt for the service user and staff member to collaboratively select up to 3 priority areas that they would like to integrate into the person's support plan. Once the assessment is completed, a summary report is generated. If the assessment is repeated with the same service user in the future, this report will also display changes in their social inclusion over time. The tool can generate management-level summary reports for each organization that is registered with it and commissioner-level summary reports of services using the tool across an entire area (such as a London borough). Multimedia Appendix 1 provides a full description of the SInQUE using the TIDieR (Template for Intervention Description and Replication) checklist [36].

Setting

This study took place in mental health supported accommodation services across 1 inner London borough. There are 21 such services in the borough run by 6 different voluntary sector organizations. They offer varying degrees of support to >270

service users who are also supported by local NHS secondary mental health services. In the borough, there are approximately 24 service users living in residential care, 159 living in supported housing, and 89 who receive floating outreach support. Supported housing services offer 24-hour support to 119 people and "9 to 5" support to 40 individuals.

Laboratory-Testing Stage: Recruitment, Data Collection, and Analysis

In total, 6 supported accommodation staff members were recruited to provide initial impressions of the online SInQUE tool. We discussed the study with service managers working in 3 different services and asked them to nominate 2 staff members each from their service who were interested in taking part. Participants were purposively sampled to include staff working in floating outreach support, 24-hour supported housing, and residential care. We asked the managers of each of the 3 services to ask for volunteers from their staff teams. Interviews were arranged with the first 2 staff members identified by the manager of each service.

Data were collected between January 2022 and February 2022. All 6 think-aloud interviews with staff members were conducted and recorded using Microsoft Teams (Microsoft Corp). The researcher first discussed the information sheet with each participant and gave them the opportunity to ask questions. Following this, participants' consent was verbally collected and audio recorded separately from the main part of the interview. Participants were then asked to fill out a short online form providing their demographic information before beginning the interview.

We conducted "think-aloud" testing of the online tool with staff using a semistructured topic guide developed by the study team (Multimedia Appendix 2). Following a process used previously in developing web-based tools [37], participants were asked to complete set tasks using the online SInQUE tool while providing a continuous commentary on their thoughts. They were asked to open the SInQUE website, register for an account, and complete an assessment as they would with a service user. At all stages, they were prompted to share their thoughts as they navigated the website and offer their initial impressions on how easy it was to understand and use and its potential suitability for their work. Once participants had completed the questionnaire, the researcher asked broader questions about their experience using the tool and any ways in which it could be improved. Throughout these interviews, participants were asked to focus on their experience using the SInQUE tool rather than offering specific feedback on individual SInQUE items. This was because we did not intend to make substantial modifications to the SInQUE questions to maintain their scope and similarity to those of the validated SInQUE measure.

Identified problems and suggestions for improvements to the online tool were collated by the researcher following the interviews. They were then reviewed by the study team, decisions about refinements to the online SInQUE were agreed upon, and the tool was revised accordingly.

Field-Testing Stage: Recruitment, Data Collection, and Analysis

Local Implementation Strategy

The revised version of the tool was made available for use in mental health supported accommodation services across the participating inner London borough. We iteratively developed and implemented a strategy to encourage and support its use by supported accommodation staff in the borough over a 5-month period beginning on May 11, 2022. This implementation strategy was informed by consultation with supported accommodation service managers and clinicians working in the Islington community mental health rehabilitation team and by individual interviews conducted with supported accommodation service users and staff.

Interviews With Field-Testing Participants

Participants and Recruitment

Individual interviews with service users (n=12) and staff (n=12) who tried out the SInQUE tool were conducted from late May 2022 to September 2022. This number was chosen to explore the views of staff and service users from a variety of supported accommodation types and service providers. Following our implementation strategy, we asked staff members to alert the study researcher once they had tried the tool in practice. Any staff member or service user in supported accommodation who tried the SInQUE tool was eligible to participate in an individual interview.

Once a staff member informed the study researcher that they had tried the tool, we asked them whether they would like to participate in an individual interview about their experience. We also invited staff to pass on information about the study to the service users with whom they had used the tool and ask them whether they would like to participate in an interview about their experience. If the service user was interested in taking part, the researcher communicated with them either directly or through the staff member they had completed the SInQUE assessment with depending on their preference. Toward the end of the recruitment stage, we recruited the final few staff members and service users purposively to ensure that participants were from a range of supported accommodation types and provider organizations.

One service user interview and 1 staff member interview were conducted online via Microsoft Teams; all other interviews were carried out in person according to participants' preferences. In-person interviews were conducted by the study researcher at the staffed supported accommodation sites, aside from 1 interview with a service user receiving floating outreach support, which was conducted at their home.

Measures and Procedures

The researcher first discussed the information sheet with the participants and gave them the opportunity to ask questions about the study. For in-person interviews, informed consent was collected via a paper consent form; for online interviews, verbal consent was audio recorded. Participants were then asked to answer brief demographic questions about themselves and their associated services. Following this, the researcher asked

each participant questions about their experience using the SInQUE; whether there were any ways in which it could be improved; the appropriateness of the online tool for use in their work; and what impacts, if any, they thought it might have on care provision and service users' experience. The interview topic guides (one for staff participants and one for service user participants) were developed by the study team as semistructured interviews—they are provided in Multimedia Appendix 3. In-person interviews were recorded using a digital voice recorder; online interviews were recorded on Microsoft Teams. Interview audio recordings were transcribed by a professional transcription company with which University College London (UCL) had a data-sharing and privacy agreement. Interview transcripts were then checked by the study researcher for accuracy. Any potentially identifiable text was anonymized. The resulting cleaned transcripts were then securely stored on the UCL university system.

Analysis

The analysis of the interviews comprised 2 stages. First, the study researcher noted any problems experienced by participants and recorded improvements to the online SInQUE they suggested. These issues and the suggested changes were reviewed by the study team, as in the previous laboratory-testing phase. Minor modifications to the online SInQUE were agreed upon, and we made adjustments to the tool in line with this.

Second, transcripts were uploaded to NVivo (version 12; QSR International) for qualitative analysis. As we aimed to develop a program theory for the online SInQUE intervention, we initially coded data into a deductively derived framework that used an intervention-context-actor-mechanism-outcome (ICAMO) configuration, with each component of this ICAMO framework representing a primary theme [38]. Within each of these 5 primary themes, we inductively derived subthemes from the data using thematic analysis. The initial coding was conducted by the lead author (SE) and was then reviewed and adjusted collaboratively by the study team. This included gaining lived-experience perspectives from a researcher with experience of mental health service use (JC) and clinical insights from a senior clinical academic working in the participating borough as a consultant rehabilitation psychiatrist supporting service users who live in supported accommodation (HK). The team brought in further perspectives from those with backgrounds in social work (BLE), clinical psychology (PM), and forensic psychiatry (GM) and from the community rehabilitation team in the borough (MD).

Data Use Monitoring

Data on the uptake and use of the online SInQUE tool were collected from the online SInQUE informatics for the 5-month field-testing period from May 11, 2022, to October 11, 2022.

At the start of this period, the study team also contacted local mental health service rehabilitation and housing leads in 2 other areas: another inner London borough and a rural county in the west of England. These service leads contacted local supported accommodation managers and invited them to use the online SInQUE in their service if they wished. The tool was made available to 7 supported accommodation services in the London borough and 10 in the rural county. No further encouragement to use the tool or implementation support was provided. This allowed us to monitor uptake and use of the tool in 2 areas without an associated implementation plan, thus making inferences about the necessity and impact of the strategy we developed.

Logic Model Development

The study team developed a preliminary logic model for the online SInQUE in planning this study. We used the findings of the aforementioned research activities to review and refine this logic model and develop an updated theory about the potential outcomes for service users and organizations from using the online SInQUE; mechanisms through which these outcomes are achieved; and factors influencing the uptake, experience, and impact of the online tool. Factors were related to (1) the intervention itself, (2) the characteristics and attitudes of staff and service users using the online SInQUE, and (3) the broader organizational and societal context. This was summarized in a logic model in the form of an "ICAMO map" [38], which was developed and refined iteratively through discussion with the study team.

Ethical Considerations

The initial laboratory-testing phase of this study (Supporting social inclusion for people with serious mental illness living in supported housing [SUSHI] phase 1) was approved by the UCL Research Ethics Committee (REC) on June 18, 2021 (REC reference 6711/002). The subsequent field-testing phase (SUSHI phase 2) was approved by the London – Camden and Kings Cross NHS REC on November 4, 2021 (REC reference 21/LO/0657). Written or audio-recorded informed consent was obtained from all participants before they took part, and they were clearly informed that they could opt out of the study at any time. All the study data were carefully deidentified. Service user participants were offered a £20 (US $25.14) shopping voucher to thank them for their time.

Results

Participants

We recruited 6 supported accommodation staff members for the "think-aloud" interviews during the laboratory-testing stage. We recruited a further 12 staff members and 12 supported accommodation service users for the individual interviews as part of the field-testing stage. Participant characteristics for both stages are summarized in Table 1.

Table 1. Laboratory testing and field testing of the online Social Inclusion Questionnaire User Experience—characteristics of participants.

Participant characteristics	Laboratory testing	Field testing	
	Staff (n=6), n (%)	Staff (n=12), n (%)	Service users (n=12), n (%)
Gender			
Male	2 (33)	5 (42)	11 (92)
Female	4 (67)	6 (50)	0 (0)
Nonbinary	0 (0)	1 (8)	1 (8)
Age group (y)			
18-30	0 (0)	8 (67)	4 (33)
31-50	2 (33)	2 (17)	3 (25)
≥51	4 (67)	1 (8)	4 (33)
Prefer not to say	0 (0)	1 (8)	1 (8)
Ethnicity			
Asian/Asian British	1 (17)	0 (0)	1 (8)
Black/Black British	3 (50)	2 (17)	4 (33)
White/White British	2 (33)	8 (67)	1 (8)
Mixed/multiple ethnic groups	0 (0)	1 (8)	6 (50)
Other ethnic background	0 (0)	1 (8)	0 (0)
Sexual orientation			
Heterosexual	N/A[a]	N/A	6 (50)
Gay/lesbian	N/A	N/A	1 (8)
Bisexual	N/A	N/A	2 (17)
Prefer not to say	N/A	N/A	3 (25)
Type of supported accommodation lived or worked in			
Floating outreach support	2 (33)	2 (17)	2 (17)
9-to-5 supported housing	2 (33)	1 (8)	2 (17)
24-h supported housing	2 (33)	7 (58)	8 (67)
Residential care	0 (0)	2 (17)	0 (0)
Length of time worked or lived in supported accommodation (y)			
<2	1 (17)	7 (58)	5 (42)
2-5	3 (50)	3 (25)	5 (42)
6-10	1 (17)	2 (17)	0 (0)
≥10	1 (17)	0 (0)	1 (8)
Prefer not to say	0 (0)	0 (0)	1 (8)

[a]N/A: not applicable; staff were not asked about their sexual orientation.

Changes Made to the SInQUE

Following phase 1 laboratory testing and phase 2 field-testing, suggestions that participants made for how the tool could be improved were collated and reviewed by the team. Accordingly, adjustments were made to the online SInQUE after each stage, an overview of which can be found in Table 2. This addressed aim 1 of this study.

Table 2. Changes made to the online Social Inclusion Questionnaire User Experience (SInQUE) following phase 1 and phase 2 testing. All changes were made following the initial laboratory-testing stage unless indicated otherwise.

Section of the SInQUE affected	Explanation of the problem	Resolution	Justification for the change
Registration and use changes			
The online SInQUE home page	Some staff members and service users suggested developing additional materials to help explain the SInQUE[a].	Developed a guidance manual for service managers and commissioners with information on using the SInQUE as well as an informational leaflet and poster aimed at service users about the SInQUE.	It is easier for managers, commissioners, staff, and service users to understand and use the SInQUE.
The initial page where staff members are asked to register for the SInQUE	Staff were asked to enter the organization they worked for in a free-text box. Some found it confusing to know which organization name they should enter.	Changed response options to a fixed-response drop-down menu with all housing providers in the borough and an "other" free-text option.	Allows for compilation of service-level data and is easier for staff to navigate.
The page where staff members enter details to set up a new SInQUE assessment	Some staff members thought that further information on the exact purpose of the questionnaire and how it should be administered would be useful in the introductory paragraph describing the assessment.	Additional guidance on how the questionnaire should be administered was added to the introduction paragraph of the SInQUE.	Important contextual information for the questionnaire was explicitly clarified.
The page where staff members enter details to set up a new SInQUE assessment	Some staff members found the wording of the following question—"Please select the type of accommodation in which the service user is living from the list below"—to be ambiguous and confusing.	Changed the wording of the question to the following: "Please select the type of housing support the service user receives from the list below."	The clarity of the question improved.
Changes to the wording of SInQUE questions			
The section covering "leisure" questions	Some staff members felt that it was unclear what the "Other" option meant in the context of question 3f: "Over the past year have you been to...Other?"	Changed the wording of this subquestion to the following: "Other leisure activity?"	The clarity of the question improved.
The section covering "leisure" questions	Some staff members and service users felt that question 7—"Do you spend time in pubs or cafés?"—was worded in a way that was potentially inappropriate for people who do not drink alcohol[a].	Changed the wording of the question to the following: "Do you go out for a coffee/drink (e.g. to a café or pub, etc) at least once a week?"	The clarity and appropriateness of the question improved.
The section covering "social" questions	Some staff members were unsure whether question 9—"How many people, outside those in your care team, could you confide in?"—related to a professional or personal care team.	Changed the wording of the question to the following: "How many people, outside the workers in your care team, could you confide in?"	The clarity of the question improved.
The section covering "home life/housing" questions	Some staff members thought that question 36—"What kind of accommodation do you live in?"—was worded ambiguously.	Changed the wording of the question to the following: "What type of housing support do you receive?"	The clarity of the question improved.
The section covering "home life/housing" questions	A statement alerting users that question 38 had been omitted from the online SInQUE, which read the following—"Not relevant for supported accommodation contexts -omitted."—was confusing.	Changed statement to the following: "Question omitted, not included in the online SInQUE."	The clarity of the question improved.
Changes to the SInQUE summary outputs			
The SInQUE summary report	Some staff members found the spider graph to be confusing to interpret as the numbers summarizing scores in each section were not standardized and, therefore, it was difficult to tell which domains scored lower than others.	Simplified the spider graph to show percentage of total score in the graph instead of frequency.	It was easier to interpret the graph as sections with different totals became standardized.
The SInQUE summary report for multiple assessments completed with the same service user	In the section summarizing scores across multiple time points, staff members thought that a visual depiction of this comparison would be useful.	Made comparative bar charts of multiple scores across time with the same service user available on the summary report.	It was easier to understand and relay the results.

[a]Changes were made following the field-testing stage.

XSL•FO

RenderX

Overall, the changes made to the online SInQUE were relatively few and minor. Following initial laboratory testing, additional information and guidance for users was added, and minor revisions to the wording of questionnaire items were made to improve clarity. Modifications to the visual representation of scores in the summary reports were also made to aid ease of interpretation. During the field-testing stage, very few suggested changes to improve the usability of the online SInQUE were made by staff or service user participants. Further changes made at this stage included a minor wording adjustment to one question to ensure its cross-cultural appropriateness. Changes were made exclusively to the web-based version of the SInQUE and did not affect the existing SInQUE measure. We also developed an additional guidance document for managers and commissioners and an informational leaflet and poster about the SInQUE.

A few participants suggested substantial modifications to the structure and wording of individual items in the SInQUE that were not implemented by the study team. These decisions were made to preserve the broad scope and logical flow of the tool. We also declined to action some suggestions that were outside the remit of the SInQUE tool, such as adding more or free-text response options to some questions. However, where these suggestions indicated important potential barriers to using the SInQUE, they were noted and integrated into the qualitative analysis and logic model development. A summary of all comments and suggestions that were proposed but not implemented after review by the team can be found in Multimedia Appendix 4.

Interview Thematic Analysis

Overview

The interviews were analyzed using thematic analysis. Primary themes were deductively imposed according to each core element of the ICAMO model: intervention, context, actors, mechanisms, and outcomes [38]. Subthemes were inductively analyzed within each of these primary themes. The resultant thematic framework considering the perceived utility and acceptability of the online SInQUE and addressing aim 2 of the study is presented in Textbox 1. The themes are summarized in the following sections with a selection of illustrative quotes. Multimedia Appendix 5 provides further illustrative quotes for each subtheme.

Textbox 1. Summary of the thematic framework (intervention-context-actor-mechanism-outcome themes and inductive subthemes).

Intervention: combination of program elements or strategies designed to produce behavior changes or improve health status among individuals

- The online Social Inclusion Questionnaire User Experience (SInQUE):

  - Promotion of positive, collaborative discussion

  - Comprehensive and novel questions

  - Ability to repeat over time

  - User-friendly design:

    - Easy-to-navigate website

    - Quick to complete

    - Fixed-response questions

    - Offers options to choose from

    - Web-based format

Context: salient conditions that are likely to enable or constrain the activation of program mechanisms

- Relevance of the SInQUE to staff role

- Inconsistency in current assessments used across services

- Absence of comparably specific assessments

- Emergence from the pandemic

Actors: the individuals, groups, and institutions who play a role in the implementation and outcomes of an intervention

- Staff:

  - Professional knowledge and skills

  - Professional boundaries

- Staff (service user views about staff):

  - Trusting relationship

  - Proactivity in offering guidance and support

- Service users:

  - Familiarity and comfort with the questions

  - Individual language and cultural differences of service users

- Service users (staff views about service users):

  - Engagement in the assessment

  - Existing mental health needs

Mechanisms: any underlying determinants or social behaviors generated in certain contexts

- Using the online SInQUE can accomplish the following:

  - Boost service user proactivity and confidence

  - Identify service users' priorities on social inclusion

  - Prompt novel, personal conversations

  - Monitor changes in social inclusion over time

  - Identify gaps in support available within the organization and local community

Outcomes: behavior changes that follow the immediate knowledge change (intermediate) and changes such as patients' health status and impact on community and health system (long term)

- Intermediate:

- Improve staff relationship with and understanding of the service user
- Help plan more relevant, targeted support for the service user
- Long term:
  - Borough-level improvements and changes in services to support social inclusion
  - Individual-level benefits for service users' recovery and social inclusion

Intervention

In general, staff and service user participants felt that the tool was user-friendly and collaborative. Many noted the ability to repeat the assessment and the web-based format as being particularly useful and felt that the website was easy to navigate. The short length of the assessment was also discussed as an important advantage, with both staff and service users commenting that it felt quick to fill out. Participants noted that, despite the short assessment length, it still offered a range of interesting, positive, and sometimes unfamiliar questions that felt comprehensive and useful to discuss:

> I think that it wasn't too just baseline, it was a little bit more than that and I think that's good. Because it gives the option of, "Okay, you don't want something, how can we improve and what is it that you do want that could help you while you're in our service?" [212; staff member]

Interviewees felt that the user-friendliness was aided by accessible questions that were straightforward for service users to answer and that were cross-culturally appropriate for individuals from different ethnic backgrounds. Although some participants from both groups felt that the fixed-response options for the questions were limited, certain staff members thought that this made the questionnaire more accessible to service users who may otherwise struggle with engagement.

Context

Staff members largely felt that the tool was fitting and relevant to their role in helping support service users, and most did not already use assessments that were highly similar to the SInQUE. Certain staff members highlighted a lack of continuity of support workers within their service and noted that this often made it difficult to build rapport with service users. Some also commented on an inconsistency in assessments used across different services (in the local context, where 6 different provider organizations provided supported accommodation services across the borough). They noted that individual providers currently make their own recommendations on the tools that staff should use:

> If it was a standard central assessment that we do in all supported housing, that's similar, like this for example, it might be beneficial in the long run. But each company has their own policy around it. [205; staff member]

One staff member noted that the tool felt particularly relevant following the COVID-19 pandemic as a means to promote engagement among service users after a period of likely sustained social isolation.

Actors

There were 2 key actors to consider in the application of the assessment: the staff members who asked the questions and the service users who responded to them.

One staff member felt that the assessment was not particularly relevant in the context of their work in a residential care service, where they had an established relationship with service users and already knew much of the queried information about them. However, this was an outlying view. Although most staff members thought that the online tool could be suitable and useful for their work, they emphasized the importance of using their professional knowledge and skills to pick when and for whom the assessment would be appropriate. They suggested that service users acutely struggling with their mental health may find it difficult to maintain concentration and engagement with the questionnaire and others may feel that the assessment is not relevant to them.

Staff members also raised the importance of maintaining professional boundaries with service users, and some expressed a concern that certain questions may feel invasive or uncomfortable for service users to answer:

> I think there was one quite private like about if they're in a relationship or something, and that was the only question that made me feel a bit like I'm asking something very personal about a relationship. Because they might not want to say that. [210; staff member]

However, service user participants did not express any similar concerns about intrusive questions. They generally indicated that they felt comfortable with the assessment and that they were used to answering personal questions. Both staff and service users highlighted trust between those performing the assessment as a key factor in promoting engagement with such questions.

Both respondent groups highlighted the cultural diversity of service users within supported accommodation, and many noted that the tool felt appropriate for those from a variety of religious and ethnic backgrounds. Some service users commented on the importance of the staff members being proactive and taking the time to go through the assessment in detail with them, particularly individuals for whom English was a second language, as further explanation was required for some questions. Various staff members suggested that being provided with information about the assessment and its purpose specifically aimed at service users, for instance, a guidance

leaflet, would be helpful for them to convey the essential information about the assessment.

Mechanisms

Both participant groups discussed how the tool may boost confidence and proactivity for a wide range of service users by highlighting specific, achievable ways in which an individual can improve their social inclusion. They also noted how the assessment encourages service users to open up and enables more profound conversations between them and staff members:

> *Yes I found it really interesting, so like because it's not really topics I would actually talk about. So it gave me a bit of enthusiasm to talk about some of the questions.* [409; service user]

Both groups suggested that it might be particularly useful during key working sessions as a means to get to know an individual better and identify their support preferences soon after moving into supported accommodation. Participants also noted the value of repeating assessments over time, suggesting that this could be a potentially encouraging way to demonstrate service user progress and identify gaps in available support. The most frequently suggested time between assessments was 1 to 3 months, with up to 6 months mentioned as a potential maximum gap.

Outcomes

Interviewees discussed the short- and long-term outcomes that they felt the tool could offer. They discussed how the tool enabled targeted and relevant support that prioritized the service user's interests. Both groups also mentioned the potential for the tool to improve the relationship and understanding between service users and staff members:

> *It asks questions where maybe like for your support worker to get a better understanding of you, like even*

> *though the immediate thing is highlight areas you can work on, it gives a general overview of how you are.* [410; service user]

Some staff members also discussed how prolonged use of the tool could highlight the additional borough-level support that may be needed to improve certain gaps in support and could also promote service user recovery toward the goal of more independent accommodation.

Implementation Strategy

Our implementation strategy was developed to encourage the use of the SInQUE in the supported accommodation services in the borough and was updated through consultation with clinical staff working in the borough's community rehabilitation team and supported accommodation service managers. Our strategy was further informed by feedback from staff and service user participants during both stages of the study.

Each part of the strategy was developed to target an identified potential barrier to staff using the online SInQUE with service users. Subsequently, we mapped each component of the strategy to the 3 broad domains of the Capability, Opportunity, and Motivation–Behavior framework of behavior change [39] to describe whether each element of the strategy was intended to increase the staff's capability, opportunity, or motivation to use the online SInQUE. The complete implementation strategy and the Capability, Opportunity, and Motivation–Behavior domain that each component addressed are outlined in Table 3. Strategies were related to enlisting leadership support to encourage supported accommodation staff to use the SInQUE, providing technical guidance and assistance with using the online tool, and developing bespoke summary output reports to reinforce use and increase the organizational benefits of using the SInQUE.

Table 3. Summary of the implementation strategy to support the use of the online Social Inclusion Questionnaire User Experience (SInQUE).

Activity	Implementation goal being addressed	COM-B[a] domain
Study research assistant (SE) and clinical research staff member (MD) visit all supported accommodation services to introduce the SInQUE tool to staff and offer guidance on its use.	Increase awareness of the SInQUE tool among supported accommodation staff and respond to any of their concerns or other problems.	• Motivation • Opportunity • Capability
NHS[b] community rehabilitation team manager and clinical researcher (MD) review supported accommodation caseloads to identify suitable service users for a SInQUE assessment and ask their key worker to complete an assessment with those service users.	Lack of accountability after initially asking all staff members to use the SInQUE and staff hesitancy over which service users would be suitable for an assessment	• Motivation
NHS community rehabilitation team manager contacts supported accommodation managers to ask them to support and encourage the use of the SInQUE by identified key workers within a given time frame.	Lack of supported accommodation management prioritization for staff to use the SInQUE	• Motivation • Opportunity
Local authority commissioners contact all supported accommodation managers to encourage the use of the SInQUE within services in the borough.	Lack of supported accommodation management prioritization for staff to use the SInQUE	• Motivation
Study lead (BLE) and research assistant (SE) attend local Housing Forum meetings to update on the study and encourage the use of the SInQUE among all managers and staff members present.	Increase visibility and awareness of the SInQUE among supported accommodation managers and respond to any of their concerns or other problems.	• Motivation • Opportunity
Study research assistant (SE) offers supported accommodation staff technological support with SInQUE registration and use.	Uncertainty about how to manage the technical process of using the SInQUE	• Capability
Study team develops and circulates a leaflet about the SInQUE for supported accommodation staff to give to service users to help explain the purpose of an assessment.	Uncertainty among some supported accommodation staff members about how best to explain the purpose of the SInQUE and engage service users	• Capability
Study team sends summary reports to service managers outlining use of the SInQUE and highlighting the areas of social inclusion that are most frequently prioritized and addressed in their service[c].	Increased awareness among supported accommodation managers of the value offered by the SInQUE for service planning to encourage them to prompt staff to use it.	• Motivation
Study team sends summary reports to local authority commissioners outlining which services have used the SInQUE the most and highlighting the areas of social inclusion that are most frequently prioritized and addressed across all services in the borough[c].	Increased awareness of commissioners of the value offered by the SInQUE for service planning and commissioning to encourage them to prompt services to use it.	• Motivation

[a]COM-B: Capability, Opportunity, and Motivation–Behavior.

[b]NHS: National Health Service.

[c]These actions were planned with service managers and commissioners but not carried out during the 5-month implementation period because of the small number of completed SInQUE assessments.

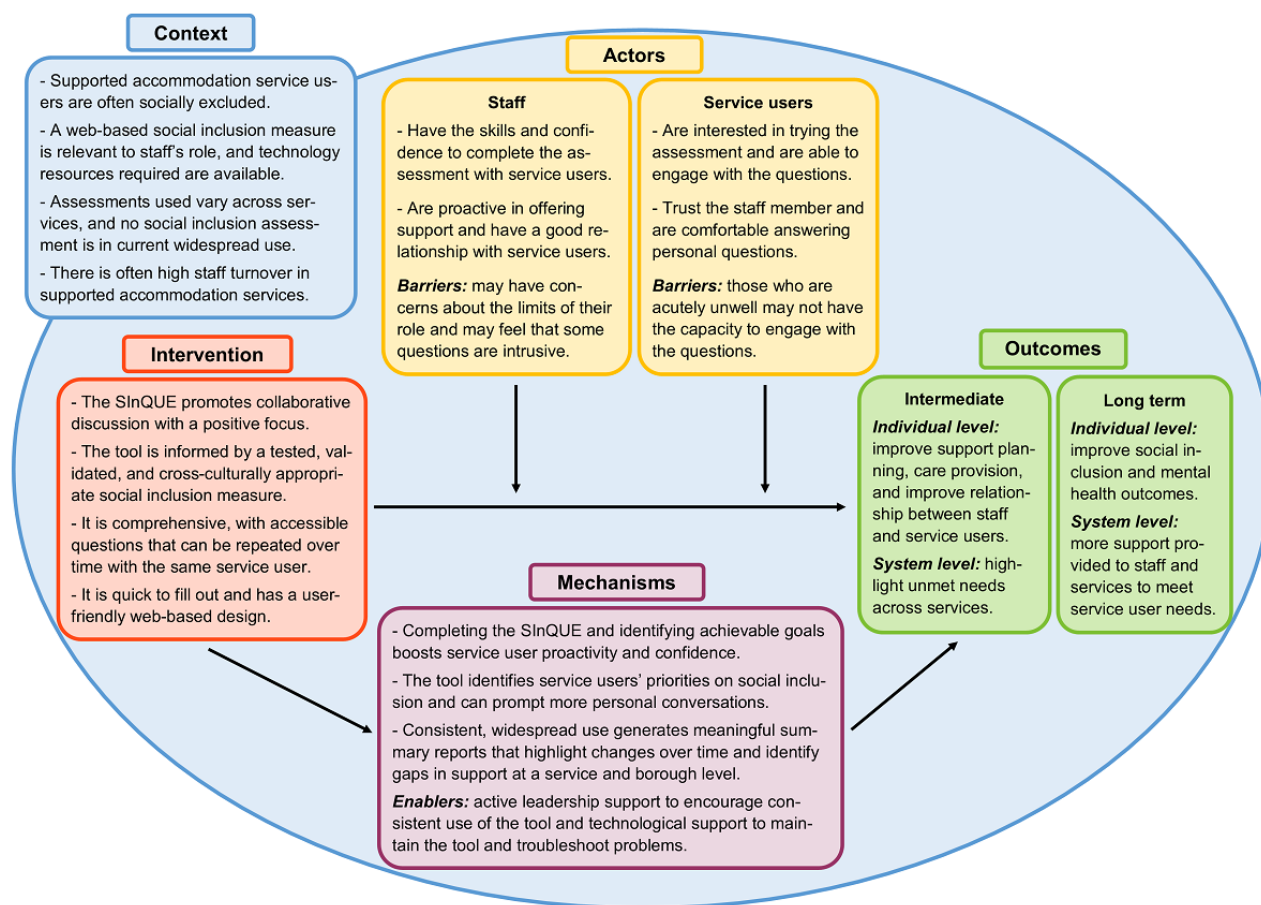
Usage Data

In total, 27 staff members in the inner London borough registered for an account with the online SInQUE. Of the 27 staff members who registered, 17 (63%) from 6 different supported accommodation providers started or completed a SInQUE assessment with at least 1 service user. This resulted in 30 completed SInQUE assessments with 28 service users in the borough. This represented just >10% of the estimated total number of service users living in supported accommodation in the borough. Of the 28 service users, 4 (14%) were from residential care, 19 (68%) were from 24-hour supported housing,

3 (11%) were from 9-to-5 supported housing, 1 (4%) was from floating outreach services, and 1 (4%) was registered as "other" accommodation type. One staff member from 1 of the local authority areas where there was no specific implementation strategy registered for an account with the SInQUE; however, they did not start or complete a SInQUE assessment. This addressed aim 3 of the study.

Intervention Logic Model

On the basis of the collective study findings, we developed a logic model to summarize the processes involved in using the SInQUE and address study aim 4 (Figure 1).

Figure 1. Intervention-context-actor-mechanism-outcome logic model for the online Social Inclusion Questionnaire User Experience (SInQUE).


The logic model was informed by the structure of an "ICAMO map" [38]. The model outlines the key aspects of the intervention (I), including its user-friendliness, its comprehensive nature, and the fact that it was based on a validated measure of social inclusion. It also indicates the potential outcomes (O) from using the SInQUE at both the individual and system levels, including improved support planning, better relationships, and provision of additional support for staff and services, which in turn may improve social inclusion and mental health outcomes as well as care provision more broadly. These operate within the broader societal context (C) of service users often being socially excluded and there being a high turnover of staff within these services and a high degree of variation across services in assessment tools that are recommended and in use, rendering the tool useful and relevant to the staff's role.

The key actors (A) in implementing the SInQUE are the staff and service users, who require the skills and proactivity to administer the assessment and the motivation and trust to engage with the questions, respectively. Staff may encounter barriers such as a concern that some questions are too intrusive, and service users struggling more severely with their mental health may lack the concentration or motivation to engage with the questions. The potential outcomes operate through certain mechanisms (M), which include increased service user confidence and the prompting of more in-depth personal conversations between service users and staff. The tool also identifies more relevant priorities for service users, which may

or may not be chosen as an active priority for support by staff owing to individual or organizational factors. Persistent and wide-ranging use of the tool could, over time, highlight the aspects of social inclusion that are feasible to work on and those that are regularly not being prioritized.

Discussion

Principal Findings

The online SInQUE was generally perceived as acceptable and potentially useful by supported accommodation staff and service users. This is consistent with findings of previous studies that used the SInQUE with other mental health populations [32,34]. Both staff and service users generally found the tool to be user-friendly and relevant and suggested that it could promote more targeted care planning and improve the relationship between staff and service users. Owing to the lower uptake of the SInQUE in residential care and floating outreach services, findings related to the tool's utility in these settings are less conclusive than those for supported housing, where uptake was highest.

Some staff members expressed a concern that certain questions in the SInQUE could be perceived as intrusive by service users, indicating that they did not feel wholly comfortable asking what they perceived to be highly personal questions. However, this sentiment was not echoed by service users, who generally felt that the questions were appropriate and felt comfortable answering them. This finding is interesting given that supported

accommodation service users have highlighted in previous research the importance of feeling personally understood by staff in their service and have endorsed a process of familiarization with staff [25].

We found that implementation support is essential to promote the use of the tool in services, as evidenced by the lack of use of the tool in the 2 regions where the SInQUE was introduced without a concerted implementation strategy. The most effective steps in our implementation strategy were those during which the use of the tool was actively endorsed by individuals in leadership positions, particularly service managers and local service leaders. However, even with our concerted implementation strategy, uptake of the SInQUE was only achieved with approximately 10% of service users living in mental health supported accommodation in the participating borough within the 5-month study period.

Limitations

We used an established, iterative process of testing and feedback to develop the online SInQUE and determine its real-world acceptability and utility for use in mental health supported accommodation. However, it is important to acknowledge certain limitations of this study.

As mentioned previously, uptake of the SInQUE tool was highest in supported housing compared with residential care homes and floating outreach support. It is unclear whether this discrepancy reflects a greater reluctance from staff or service users in residential care and floating outreach support to use the online SInQUE. As proposed by one residential care staff member, it is possible that the staff in these services perceived the tool as being less relevant to their role. The discrepancy in part reflects the greater number of 24-hour and 9-to-5 supported housing units in the borough compared with residential care and floating outreach services, with approximately 6 times as many service users living in supported housing compared with residential care and nearly twice as many living in supported housing compared with floating outreach support. Through the local health service community mental health rehabilitation team, we also had a more direct connection with supported housing teams compared with other service types, which may have further contributed to the imbalance in services in which the SInQUE was used.

There were no female service user participants in the qualitative analysis; therefore, the findings may not be applicable to women in supported accommodation. It is unclear why it proved more difficult to recruit female participants, although it may reflect the higher proportion of male service users availing of supported accommodation in England—one review suggests that between 68% and 74% of service users are male across all supported accommodation types [40]. Furthermore, as we only tested the SInQUE in 1 London borough, the findings may not be generalizable to other regions.

As the tool was only used with approximately 10% of service users in the borough, the success of our implementation strategy was limited, and the low uptake may limit the wider generalizability of our findings. Owing to the short period and limited scope of the study, it was also not possible to assess whether use of the SInQUE in practice led to improved outcomes for service users or how useful the repeat assessments were over time. As the staff who participated volunteered to do so and they chose which service users to complete the SInQUE with, the findings may have been affected by selection bias and may not accurately reflect all supported accommodation staff members' and service users' views.

Finally, we removed 1 question from the original SInQUE questionnaire for our online version as asking people whether they lived alone was considered redundant for people living in supported housing. We also made very minor changes to the wording of 2 other questions in response to users' feedback (Table 2). We think it is unlikely that these modest changes substantially affected the SInQUE's psychometric properties. However, revalidation of the SInQUE in its web-based form is desirable in the future to confirm its validity and determine whether the minor wording changes should be retained for all versions of the SInQUE.

Implications for Practice

The SInQUE can be recommended as a potentially useful and acceptable tool for use in mental health supported accommodation settings, particularly supported housing services that offer 24-hour or 9-to-5 support, to provide a thorough assessment of social inclusion and support care planning. The tool may help meet an identified wish from service users for more discussion and support with social inclusion and relationships [41]. It was evident during the study that there is currently no universal tool in widespread use to help with social inclusion in mental health supported accommodation, highlighting the potential gap for an assessment tool such as the SInQUE. If used widely across supported accommodation services, the online SInQUE has the potential to provide benchmarking data and identify service users' most common priorities for greater social inclusion to inform service planning and evaluation.

Our findings also suggest that, for an assessment tool such as the SInQUE to be widely used, it is essential to have active leadership endorsement and support. For example, it may be required for managers or commissioners to direct staff to use the SInQUE with service users who are willing and reinforce this through team meetings, setting of use targets, or implementation of key performance indicators for its use.

Implications for Research

It is important to hear from staff and service users who chose not to use the online SInQUE to understand their reasons for not using the tool and highlight barriers to using the tool that we may have missed in this study. It would be useful to conduct further testing of the tool in residential care and floating outreach supported accommodation settings to better determine the utility of the SInQUE in these service types. It would also be useful to examine the utility of the SInQUE in other population groups within different service types to determine whether the tool may be useful in additional settings.

Future research is necessary to establish the level of uptake of the SInQUE that can be achieved in supported accommodation over a longer period and potentially establish more effective

means of implementation support. A longer-term study is also needed to establish whether the possible benefits from using the SInQUE that were mentioned by staff and service users are achievable through the use of the tool and how any potential outcomes may vary over time. A hybrid implementation-evaluation study would address these queries to determine the effectiveness of the SInQUE tool as an intervention for social inclusion and establish a precise implementation strategy for widespread uptake of the tool in supported accommodation. Further research using the SInQUE is also warranted to examine service user needs related to social inclusion and identify any additional barriers to addressing these needs in supported accommodation services. Such research could be used to inform the development of a future complex intervention to support social inclusion in supported accommodation services.

Although this study chose to examine the utility of the online SInQUE specifically in supported accommodation, the tool may also be useful in other mental health populations. Previous studies have established that the SInQUE can be used with mental health service users with a wide range of diagnoses [13,32,34]. Therefore, it is reasonable to extrapolate that the online SInQUE may be useful to assess social inclusion and inform support and care planning for other mental health service users, not just those living in mental health supported accommodation.

Data Availability

The qualitative data generated and analyzed during this study are not publicly available to preserve participant anonymity. The quantitative data generated during this study are available from the corresponding author (BLE) upon reasonable request.

Authors' Contributions

SE led recruitment, data collection, data analysis, and drafting of the paper. BLE led the study design and project management and supported the data analysis and drafting of the paper. HK, JC, PM, and GM co-designed the study and supervised the project. MD contributed to recruitment and data collection. GT contributed to the development of the study materials. All authors read, critically revised, and approved the final manuscript.

Abstract

Background: Skin picking disorder (SPD) is an understudied mental illness that is classified as a body-focused repetitive behavior disorder. Literature suggests that pathological skin picking is strongly integrated into the daily lives of affected individuals and may involve a high degree of variability in terms of episode characteristics, frequency, and intensity. However, existing data on the phenomenology of SPD are limited and typically involve retrospective assessments, which may fail to accurately capture the behavior's variability.

Objective: This study aimed to investigate skin picking in the daily lives of individuals with SPD by using ecological momentary assessment (EMA). The first aim focused on the description of skin picking patterns (eg, characteristics, intensity, and distribution of episodes and urges), and the second aim explored differences in characteristics and patterns between automatic and focused skin picking.

Methods: Participants were recruited online and underwent a web-based screening, a diagnostic telephone interview, and a comprehensive online self-report questionnaire before participating in an EMA protocol. The latter included 10 consecutive days with 7 pseudorandom, time-contingent assessments per day between 8 AM and 10 PM. The EMA questionnaire assessed the current skin picking urge, the occurrence of the behavior, and a detailed assessment of the episodes' characteristics (eg, length, intensity, and consciousness) if applicable.

Results: The final sample consisted of 57 participants, who completed at least 70% of the scheduled assessments (n=54, 94.7% female: mean age 29.3, SD 6.77 years). They completed 3758 EMAs and reported 1467 skin picking episodes. Skin picking occurred frequently (mean 2.57, SD 1.12 episodes per day and person) in relatively short episodes (10-30 min; 10 min: $n_{episodes}$=642, 43.8%; 20 min: $n_{episodes}$=312, 21.3%; 30 min: $n_{episodes}$=217, 14.8%), and it was distributed quite evenly throughout the day and across different days of the week. Focused and automatic episodes were relatively balanced across all reported episodes (focused: $n_{episodes}$=806, 54.9%) and over the course of the day. The analyses showed statistically significant differences between self-reported triggers for the different styles. Visual or tactile cues and the desire to pick the skin were more important for the focused style (visual or tactile cues: mean focused style [M_f]=4.01, SD 0.69 vs mean automatic style [M_a]=3.47, SD 0.99; $P<.001$; SMD=0.64; desire to pick: M_f=2.61, SD 1.06 vs M_a=1.94, SD 1.03; $P<.001$; SMD=0.82), while boredom and concentration problems were more prominent in automatic skin picking (boredom: M_f=1.69, SD 0.89 vs M_a=1.84, SD 0.89; P=.03; SMD=−0.31; concentration problems: M_f=2.06, SD 0.87 vs M_a=2.31, SD 1.06; P=.006; SMD=−0.41).

Conclusions: These results contribute to an enhanced understanding of the phenomenology of SPD using a more rigorous assessment methodology. Our findings underscore that picking can impact affected persons multiple times throughout their daily lives.

Trial Registration: German Clinical Trials Register DRKS00025168; https://tinyurl.com/mr35pdwh

Introduction

Skin picking disorder (SPD) is a mental disorder, which is characterized by the body-focused repetitive behavior (BFRB) of manipulating one's own skin including, for example, squeezing, scratching, or rubbing—summarized as "skin picking" [1]. With a lifetime prevalence of 1.4% to 3.1% [1,2], SPD is not a rare disorder, even though it received comparatively little attention in research and clinical practice so far.

Until now, there has been little research on the phenomenology of SPD, and the existing research is of questionable validity as it often entails retrospective reporting, so the clinical picture has not been described in sufficient detail to date. This hinders a well-grounded understanding of the disorder as well as the development of specific treatment options.

Few previous studies have described skin picking in terms of the frequency and episode length; for example, one study reported a median of 38 minutes for skin picking per day (range 1-360 min), while another found a mean of 8 (SD 22) episodes per day with an average length of 21 (SD 42) minutes [3,4]. In a more recent study, 78% of participants reported that they typically have 1 to 5 episodes per day and that most episodes are shorter than 30 minutes. Moreover, the majority reported that they picked their skin almost every day [5]. Meanwhile, data on high-risk times throughout the day are very scarce, with only 1 small study reporting such data (n=31) [6]. However, the small number of studies and the large variability among the results suggest a need for additional and more rigorous investigations.

In addition to episode characteristics, different styles of skin picking characterized by the extent of awareness during behavior were examined. "Focused skin picking" is hypothesized to occur more intentionally and in response to urges or difficult emotions, whereas "automatic skin picking" takes place without awareness and is supposed to be associated with certain (routine) situations and passive activities [7]. So far, little is known about the distribution of automatic and focused skin picking within and between individuals, other than that there seems to be high variability. However, a recent study reported a shift from focused skin picking toward more automatic skin picking with increasing age [8].

In terms of episode triggers, previous studies identified certain internal and external states commonly precipitating skin picking behavior. Commonly reported triggers are affective states (eg, tension or boredom), visual and tactile perceptions of skin irregularities, passive activities, and certain situations or places (eg, waiting, reading, or bathroom) [9-12]. Unfortunately, there is currently almost no data available on the distribution of skin picking and skin picking urges over the course of a day and a week.

Moreover, the existing studies on skin picking phenomenology include crucial shortcomings due to their cross-sectional and retrospective designs. It is well known that retrospective assessments imply a high risk of systematic biases, caused by the way memories are stored and retrieved [13]. Moreover, these designs are not able to capture dynamic processes and to identify specific variations, for example, in behavioral patterns throughout the day or week. Both of these issues are relevant to studies on SPD phenomenology. For example, the large range in the number and length of skin picking episodes in former studies indicates that it is critical to examine the distribution and characteristics of the behavior and to explore the role of intraindividual and interindividual variability in the behavior. In the clinical setting, affected individuals often report that the behavior can strongly vary from day to day—depending on a multitude of factors, for example, such as being in company versus alone or at work versus at home. These differences are masked in retrospective studies when the average time spent on skin picking in the last 2 weeks is assessed.

In addition, retrospective studies usually do not allow a reliable assessment and differentiation of characteristics of different styles of skin picking, which are characterized by the extent of awareness during skin picking. Moreover, the distribution of focused versus automatic skin picking as well as the link between specific triggers and different skin picking styles have not been investigated in detail. Of note, as most individuals with skin picking show a mixture of both styles, the retrospective assessment of separate triggers for automatic versus focused episodes would be very likely biased. However, the detailed investigation of skin picking styles and the associated triggers can serve as a solid basis for the specific selection and adaptation of interventions and behavioral strategies for certain risk situations or skin picking styles.

A promising method to comprehensively investigate processes of skin picking behavior is ecological momentary assessment (EMA) [14]. Momentary assessments within the daily life of individuals provide the opportunity to study dynamic processes in real time while minimizing retrospective biases. Since EMA allows a more detailed assessment of behavioral processes and implies a high ecological validity, the method received much attention in psychological research in the last 2 decades and was successfully applied by numerous studies in the

investigation of different psychopathologies (eg, anxiety, substance use, or eating disorders) [15-17].

For skin picking research, EMA is a promising tool for reliably investigating the distribution as well as characteristics of skin picking episodes. The analysis of these data then affords an understanding of the course of skin picking behavior throughout the day and week in detail and identifies high-risk times and related circumstances. To the best of our knowledge, EMA has not yet been applied to investigate these research questions in SPD. Therefore, the main objective of this study was to investigate skin picking in the natural environment of individuals having SPD using EMA. Such data are urgently needed for a more comprehensive description and understanding of the phenomenology and mechanisms of this comparatively new disorder.

The study followed 2 aims: the first aim was to describe skin picking patterns in the daily lives of the participants (eg, number, length, intensity, distribution of skin picking episodes, distribution of skin picking urges, or self-reported triggers).

The second aim of this study was to explore differences between automatic and focused skin picking concerning distributions (eg, daytime), characteristics of the episodes (eg, length or intensity), and self-reported triggers.

Methods

Procedures

Participants were recruited between November 2021 and May 2022 through support groups and online via mailing lists, specific forums, and social media. Inclusion required a minimum age of 18 years; satisfaction of the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) criteria for SPD; and provision of informed consent for study participation. The inclusion of participants involved three stages of assessment: (1) an initial web-based screening, which assessed sociodemographic information and skin picking symptoms; (2) a diagnostic interview via telephone, in which the *DSM-5* criteria for SPD were assessed; and (3) a web-based self-report questionnaire (baseline) for those assessed to be eligible in the interview.

EMA sampling started on the day after completion of the baseline questionnaire. The assessment period comprised 10 consecutive days with 7 pseudorandom, time-contingent assessments per day between 8 AM and 10 PM. In addition, participants were asked to record additional skin picking episodes (event contingent recording). The prompts were sent to the participants' smartphones via text message, which contained a link to the EMA questionnaire. Additional records could be made via the web-based study platform. The time and event contingent EMA records took at most 5 minutes. All assessment procedures were conducted with the software ASMO [18].

Measures

Screening

The screening questionnaire included sociodemographic variables and the German version of the Skin Picking Scale-Revised (SPS-R) [19,20]. The scale assesses skin picking severity over the past week and consists of 8 items that can be split into 2 subscales: symptom severity and impairment. A global score can also be calculated. All items are rated on a 5-point Likert Scale from 0 (eg, "none") to 4 (eg, "extreme"). The internal consistency of the total scale was high in this study (α=0.84; subscales: symptom severity: α=0.77 and impairment: α=0.85).

Diagnostic Interview

To assess the *DSM-5* criteria for SPD, semistructured interviews based on a BFRB module (personal communication with L Mehrmann, February 2021) for the DIPS Open Access Diagnostic Interview for Mental Disorders were conducted via telephone [21]. The interviews were carried out by the first author (CG) and a student worker, who was trained and continuously supervised.

Baseline Measures

Overview

The baseline questionnaire contained the following assessment instruments.

Skin Picking Severity

The current skin picking severity was assessed in the baseline questionnaire with the SPS-R described above [19,20].

Impairment due to Skin Picking

Skin picking–related impairment was assessed with the German translation of the Skin Picking Impact Scale (SPIS) [22,23], which refers to the last week and contains 10 items capturing potential impairments due to skin picking (eg, feeling unattractive, ashamed, or not being able to do certain things due to skin picking) rated on a 5-point Likert scale (0: "not at all"; 4: "severe"). The internal consistency of the SPIS was excellent in this study (α=0.90).

Modes of Skin Picking

Different styles of skin picking (focused vs automatic) were assessed with the German version Milwaukee Inventory for the Dimensions of Adult Skin Picking (MIDAS) [7]. We translated the scale in a former study following generally accepted recommendations including backtranslation and approval by one of the authors of the original scale (DW Woods) [24]. The scale consists of 12 items, which are rated from 1 "not true for any of my skin picking" to 5 "true for all of my skin picking". Both subscales (focused, automatic) contain 6 items and showed an acceptable internal consistency of α=0.62.

Depressive Symptoms

Depressive symptoms were captured using the Patient Health Questionnaire-9 (PHQ-9) [25]. The scale contains 9 items, which are rated on a Likert scale from 0 ("not at all") to 3 ("almost every day") in reference to the last 2 weeks. The scale showed a good internal consistency in our study (α=0.84).

Anxiety

Symptoms of generalized anxiety disorders were assessed with the Generalized Anxiety Disorders-7 (GAD-7) [26]. The Cronbach α was 0.84.

EMA Questionnaire

The EMA assessments included urge intensity (1: "no urge" to 5: "very strong") and skin picking occurrence since the last assessment (yes or no). If skin picking occurred, additional questions assessed the following: intensity of skin picking (1: "very weak" to 5: "very strong"), length of the episode (12 options: about 10, 20, 30, …, 120 min), awareness at episode onset ("Did you notice when you started picking your skin?"; yes or no), and perceived triggers ("What contributed to your skin picking?"). For the last question, seven items had to be rated on a 5-point Likert scale: (1) visual or tactile cues, (2) itching, (3) tension, (4) boredom, (5) difficulties concentrating on a task, (6) desire for skin picking, (7) certain routine (eg, evening routine), and (8) other (text field).

Statistical Analyses

Patterns of skin picking were analyzed using descriptive statistics. Frequencies for the number of episodes with certain characteristics (length, time of occurrence, or consciousness) were analyzed across all individuals and episodes. To control for the unequal number of skin picking episodes reported per person, mean scores within each person were calculated for urge intensity, episode intensity, and the rating of specific triggers. The average scores of the person means are reported. The distribution of skin picking urges as well as the distribution and characteristics of automatic and focused skin picking were also analyzed descriptively. *t* tests (2-tailed) for paired samples were calculated to test differences between focused and automatic episodes. Focused and automatic episodes were classified based on the yes or no question "Did you notice when you started picking your skin?" Differences were quantified using SMD. Analyses were performed in R (version 4.1.2; R Development Core Team, 2021) and with SPSS Statistics (version 29.0; IBM).

Ethical Considerations

All study procedures adhered to the latest version of the Declaration of Helsinki and were approved by the ethics committee of the Medical Faculty of Heidelberg University (S-222/2021). The trial was registered at the German Clinical Trials Register before recruitment started (DRKS00025168).

Participants provided informed consent for this study ahead of the initial screening and were able to discontinue participation at any time. Data are pseudonymized and can be subsequently matched to the respective persons only by authorized personnel. The data are anonymized as soon as possible after completion of the analyses.

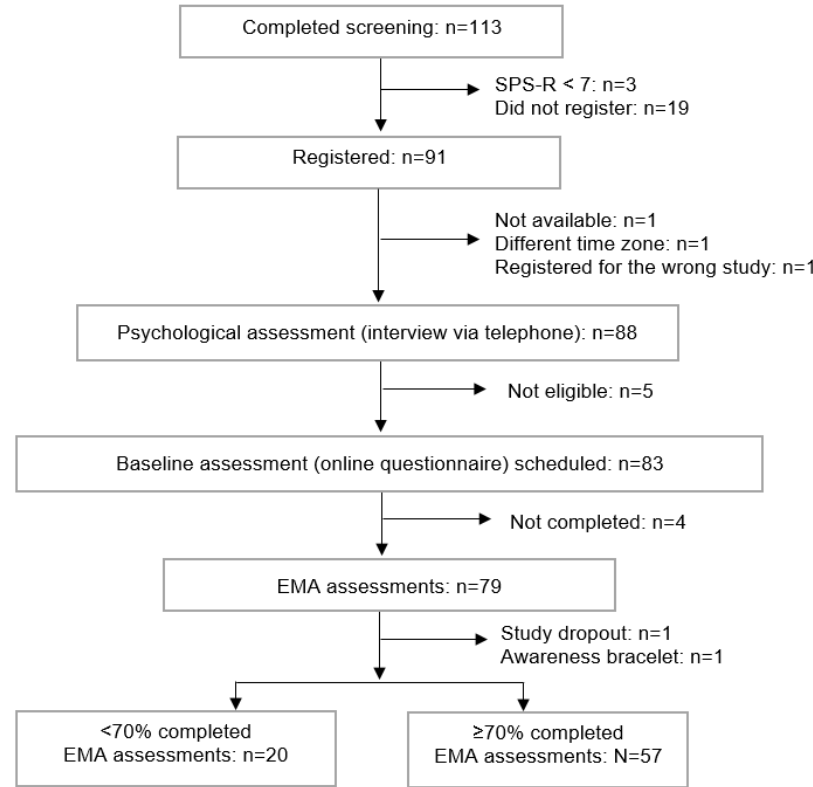
All participants were provided with a €15 (approximately US $16) compensation in the form of a gift voucher for a bookstore. Additionally, if participants achieved an EMA completion rate of at least 70% (49 assessments), the voucher was upgraded to €50 (approximately US $54).

Results

Sample Description

Overall, 113 individuals completed the screening questionnaire. Of these, 79 (69.9%) participants started the EMA assessments. Further, 1 person dropped out during the EMA period and 1 person was excluded from the final analysis due to wearing an awareness bracelet, which vibrates when touching certain body areas for the prevention of skin picking. Overall, 57 (74%) out of 77 answered at least 70% of all scheduled EMA questionnaires (ie, at least 49 assessments). The participant flow is shown in Figure 1.

Participants of the final sample (n=57) completed 65.93 (SD 7.24) EMAs on average, with a range of 51 to 99 per person. Frequencies above the number of scheduled time-contingent assessments (n=70) result from additional entries made by participants on their own initiative (event-contingent records).

Figure 1. Participant flow. EMA: ecological momentary assessment; SPS-R: Skin Picking Scale-Revised.


Participants

The majority of participants were female (54/57, 94.7%) with a mean age of 29.3 (SD 6.77) years. About half (28/57, 49.1%) of the participants were employed and one-third (18/57, 31.6%) were university students. The sample showed a PHQ-9 mean score of 11.63 (SD 5.41), indicating moderate depressive symptoms; a GAD-7 mean score of 9.63 (SD 4.85), indicating mild to moderate anxiety; and a mean SPS-R score of 18.00 (SD 4.00), indicating substantial SPD severity. The participants in the analyzed sample do not differ from the participants who were excluded from the analyses due to the low EMA completion rate (less than 49 assessments, <70%). t tests (2-tailed) for independent samples and χ-quadrat tests did not yield any statistically significant differences in terms of the assessed sociodemographic and clinical variables (all P>.05). A detailed overview of the sample characteristics is given in Table 1.

Table 1. Sample characteristics.

Characteristics	Total EMA[a] sample (n=77)	EMA≥70% (n=57)	EMA<70% (n=20)
Female sex, n (%)	74 (96.1)	54 (94.7)	20 (100)

[a]EMA: ecological momentary assessment.

[b]Not available.

[c]PHQ-9: Patient Health Questionnaire-9, depressive symptoms.

[d]GAD-7: generalized anxiety disorders-7.

[e]SPS-R: Skin Picking Scale-Revised.

[f]SPIS: Skin Picking Impact Scale.

[g]MIDAS focused: Milwaukee Inventory for the Dimensions of Adult Skin Picking, focused skin picking.

[h]MIDAS automatic: Milwaukee Inventory for the Dimensions of Adult Skin Picking, automatic or unconscious skin picking.

Number and Distribution of Episodes

In total, 57 participants completed 3758 EMAs and reported 1467 skin picking episodes during the EMA period of 10 days. Altogether, 1351 (92.1%) episodes were reported in time-based assessments and only 116 (7.9%) in event-based assessments.

On average, participants reported a mean number of 2.57 (SD 1.12; range 0.8-5.4) episodes per day.

Slightly more than half of the sample (32/57, 56.1%) reported episodes on each day of the 10-day EMA phase, while 28.1% (n=16) reported 1 day without skin picking and 15.8% (n=9) had 2, 3, or 4 days without skin picking.

Skin picking episodes were relatively evenly distributed throughout the day. Small peaks in the number of episodes emerged in the first (8-10 AM; $n_{episodes}$=253, 17.3% of all 1467 episodes) and the last (8-10 PM; $n_{episodes}$=211, 14.4% of all 1467 episodes) regular assessment period of each day. The number of episodes over the course of a day is shown in detail in Figure 2 and Table 2. It should be noted that to avoid a biased comparison between time-based and event-based surveys, only the periods covered by the time-based assessment are presented.

Figure 2. Episode distribution throughout the day (event- and time-based EMAs; 8 AM-10 PM). EMA: ecological momentary assessment.
Table 2. Urge and episode parameters over the day[a].

Time	All episodes (N=1467), n (%)	Focused episodes (n=806), n (%)	Automatic episodes (n=661), n (%)	Intensity of episodes (n=1467), mean (SD)	Urge intensity EMA[b] with episodes (n=1467), mean (SD)	Urge intensity EMA without episodes (n=2291), mean (SD)
8-10 AM	253 (17.2)	156 (19.35)	97 (14.67)	2.61 (0.87)	2.53 (0.98)	1.78 (0.79)
10 AM to Noon	202 (13.8)	108 (13.4)	94 (14.22)	2.38 (0.72)	2.54 (0.92)	1.92 (0.73)
Noon to 2 PM	201 (13.7)	103 (12.78)	98 (14.83)	2.19 (0.78)	2.75 (0.86)	1.87 (0.68)
2-4 PM	173 (11.8)	86 (10.67)	87 (13.16)	2.43 (0.86)	2.89 (0.84)	1.83 (0.71)
4-6 PM	163 (11.1)	85 (10.55)	78 (11.8)	2.43 (0.88)	2.90 (0.95)	1.92 (0.76)
6-8 PM	180 (12.3)	99 (12.28)	81 (12.25)	2.43 (0.78)	3 (0.85)	1.92 (0.71)
8-10 PM	211 (14.4)	108 (13.4)	103 (15.58)	2.77 (0.74)	3.02 (0.88)	1.94 (0.76)

[a]Only periods of time-based assessments are listed. The total N refers to all registered episodes ($N_{episodes}$=1467, $N_{persons}$=57). Intensity scores are average scores of person-wise means.

[b]EMA: ecological momentary assessment.

Weekdays

The episodes were quite evenly distributed over the days of the week. Across all participants, the average number of episodes per day ranged between 2.20 for Saturdays and 2.77 for Mondays and Tuesdays (Monday: mean 2.77, SD 1.78; Tuesday: mean 2.77, SD 1.65; Wednesday: mean 2.66, SD 1.50; Thursday: mean 2.54, SD 1.50; Friday: mean 2.53, SD 1.59; Saturday: mean 2.20, SD 1.50; and Sunday: mean 2.57, SD 1.66).

Length and Intensity

Of all 1467 episodes, participants indicated the shortest selectable length (approximately 10 minutes) in 43.8% (n=642), 20 minutes in 21.3% (n=312), and 30 minutes in 14.8% (n=217; Table 3). Only 9 (15.8%) participants reported any episode of 60 minutes or longer and only 6 (10.5%) reported episodes of at least 90 minutes.

Table 2 displays the distribution of focused and automatic episodes as well as episode intensity and urge intensity over the course of the day.

The reported intensity of the episodes across all subjects was on average 2.55 (SD 1.11; 2: "mild", 3: "medium"). Throughout the day, the intensity of the episodes was quite stable. The average person means in the regular EMA phase (8 AM-10 PM) varied between 2.19 (SD 0.78; noon to 2 PM) and 2.77 (SD 0.74; 8-10 PM). Slightly higher average intensities were reported in the evening and the morning (see Table 2).

Overall, in terms of intensity, most episodes were rated as very mild (288/1467, 19.6%), mild (n=448, 30.5%), or medium (n=426, 29%). Participants rated 16.4% (n=240) of the episodes as severe and 4.4% (n=65) as very severe. Further, 10 (17.5%) participants did neither report severe nor very severe episodes.

Table 3. Length of episodes[a].

Approximate length	Episodes), n (%)
10 min	642 (43.8)
20 min	312 (21.3)
30 min	217 (14.8)
40 min	97 (6.6)
50 min	39 (2.7)
60 min	64 (4.4)
70 min	14 (0.9)
80 min	26 (1.8)

120 min	26 (1.8)

[a]All episodes reported in time- and event-based ecological momentary assessments ($N_{episodes}$=1467; $N_{persons}$=57).

Urge Intensity

The mean urge intensity (average scores of person-wise means) in assessments with reported episodes varied between 2.53 (SD 0.98) in the morning (8-10 AM) and increased in small increments throughout the day with the highest mean being 3.02 (SD 0.88) in the evening (8-10 PM). So, the average urge intensity varied between mild ("2") and medium ("3") and was significantly higher in assessments with reported episodes (mean 2.84, SD 0.71) compared to those without episodes (mean 1.89, SD 0.65; t_{56}=12.31; P<.001; SMD=1.63). The average scores for the urge intensity per period are shown in Table 2.

Episode Characteristics

Consciousness

Participants reported a conscious onset of the behavior in 54.9% (n=806; "focused episodes") and an unconscious onset in 45.1% (n=661; "automatic episodes") of all 1467 episodes. Most participants reported both types of episodes (49/57, 86%). One-third of participants (n=19) reported 75% or more focused episodes and 8 (14%) patients of these reported exclusively focused episodes. A proportion of 75% or more automatic episodes was indicated by 8 (14%) participants, and overall, it ranged between 0% and 98.2% (median 39.3, IQR 14.2-63.3).

Across all participants, the ratio between these 2 modes was relatively balanced throughout the day, with focused episodes occurring slightly more often. However, comparatively more focused episodes occurred in the morning (8-10 AM). Details are shown in Table 2.

Focused and automatic episodes did not differ significantly in terms of the intensity of the behavior or urge intensity (intensity: mean focused style [M_f]=2.56, SD 0.62; mean automatic style [M_a]=2.45, SD 0.78; t_{48}=1.52, P=.14; urge intensity: M_f=2.86, SD 0.77; M_a=2.90, SD 0.86; t_{48}=–0.19, P=.85).

Self-Reported Triggers

Across all participants, the highest average values resulted for visual or tactile cues (eg, felt or seen something on the skin; mean 3.64, SD 1.26), tension (mean 2.63, SD 1.29), and habit (mean 2.71, SD 1.45).

Comparisons between focused and automatic episodes showed higher scores in focused episodes for visual or tactile cues as well as for the item "wanted to pick the skin" (SMD=0.64 and 0.82, respectively). In contrast, boredom and problems with concentration achieved higher scores in automatic episodes (SMD=–0.31 and –0.41, respectively).

In the "other" category, additional conditions were mentioned in 97 episodes: working or being at the PC, talking on the phone, smartphone time, reading, watching television, driving, showering, encountering a mirror, physical fatigue or tiredness, hunger, emotional discomfort, and social situations or conflicts. Scores are displayed in Table 4.

Table 4. Self-reported triggers[a].

Trigger	Total (N=57), mean (SD)	Focused (n=49), mean (SD)	Automatic (n=49), mean (SD)	t test[b] (df)	P value	SMD
Visual or tactile cues	3.64 (1.26)	4.01 (0.69)	3.47 (0.99)	4.482 (48)	<.001	0.64
Tension	2.63 (1.29)	2.67 (0.89)	2.84 (0.97)	−1.532 (48)	.13	−0.22
Boredom	1.69 (1.03)	1.69 (0.89)	1.84 (0.89)	−2.187 (48)	.03	−0.31
Problems with concentration	2.17 (1.31)	2.06 (0.87)	2.31(1.06)	−2.847 (48)	.006	−0.41
Wanted to pick the skin	2.14 (1.27)	2.61 (1.06)	1.94 (1.03)	5.753 (48)	<.001	0.82
Habit or routine	2.71 (1.45)	2.82 (1.07)	2.56 (1.10)	1.818 (48)	.08	0.26
Itch	1.67 (1.09)	1.75 (0.94)	1.81 (1)	−0.594 (39)	.556	−0.09

[a]Answers rated on a 5-point Likert scale (1: not at all; 5: extremely). *t* test results refer to comparisons of the average scores of person-means in focused and automatic episodes ($n_{episodes}$=1295, $n_{persons}$=49). Further, 8 persons were excluded from the comparison as they reported no automatic episodes. "Habit/routine" relates to the item "I picked my skin out of a routine (eg, after arriving home or during the evening bath routine)."

[b]2-tailed.

Discussion

Principal Findings

SPD has now been officially recognized as a separate disorder for more than 10 years. However, despite increased research efforts, there is still a lack of studies on the phenomenology of the disorder. To our knowledge, this is the first study to investigate skin picking behavior by using EMA in the daily life of people with SPD.

The results document in several ways how strongly the behavior is interwoven with the everyday life of affected individuals. For example, 56.1% (32/57) reported that they experienced no day without skin picking within the 10-day study phase, but only 15.8% (n=9) reported 2 to 4 days without skin picking. In other words, skin picking occurred almost every day. In addition, participants reported an average of 2.6 episodes per day (range 0.8-5.4), suggesting that the behavior is not limited to 1 daily episode, but occurs several times a day and continuously influences daily life. These results are consistent with the results of 2 retrospective studies reporting also several episodes per day [3,5]. The continuity of the behavior is also reflected by the results over the course of the day and the week. Throughout the day, episodes were more or less evenly distributed, with only small peaks in the morning and evening. Similarly, the average urge intensity varied only slightly over the monitored periods and ranged constantly between weak and medium, with values in the evening being somewhat higher. However, as expected, the urge intensity was considerably higher in assessments with reported episodes compared to those without. Regarding the frequency of the episodes, there were also only a few small differences between the different weekdays. The lowest average number of episodes was reported for Saturdays and the highest for Mondays and Tuesdays, but the differences between other weekdays were quite small. Overall, data regarding the skin picking urges and behavior indicate that both are experienced frequently by affected individuals.

In terms of the episode characteristics, it is important to note that 43.8% ($n_{episodes}$=642/1467) were no more than 10 minutes long and 80% ($n_{episodes}$=1171) of the episodes were no longer than 30 minutes, so the results suggest rather short, but frequent episodes. This is also in line with previous studies reporting that the majority of episodes are under 30 minutes [3,5]. However, short episodes are not necessarily mild since the skin can be severely damaged in just a few minutes.

Regarding consciousness of the episodes, the results show groups of individuals with a quite high preponderance (eg, ≥75% of episodes) of a focused (19/57, 33%) or automatic (8/57, 14%) style. A unilateral skin picking style, where individuals predominantly (>95% of all episodes) show either automatic or focused skin picking, was relatively rare (automatic: 2/57, 4%; focused: 8/57, 14% of the sample).

However, the ratio between focused and automatic episodes was relatively balanced, although there were clear differences between individuals. Overall, more participants showed a tendency toward a focused style. The minor predominance of focused skin picking is also consistent with the results of a recent study that similarly found a slight dominance of focused skin picking for middle adulthood [8].

In recent years, different studies tried to identify different skin picking subtypes between individuals regarding various characteristics (eg, symptom presentation and styles of skin picking, or neurobiology), but nevertheless, this research is still in its beginning [7,27-30]. However, as research shows that most people with SPD show both styles of skin picking, there is an obvious necessity to understand the different types of pathological skin picking to develop prevention and intervention strategies specifically for automatic and focused skin picking. This is especially the case because the onset and course of an automatic episode can strongly differ from focused episodes necessitating different coping strategies matched to the specific picking style.

The results showed statistically significant differences between self-reported triggers for automatic and focused episodes: visual or tactile cues and the desire to pick the skin (item "wanted to pick") played a more important role in focused episodes, while boredom and problems with concentration were more related to automatic episodes. Other triggers (eg, tension or itch) did not differ between the 2 modes of skin picking. The largest

difference was found for the trigger desire ("wanted to pick"; SMD=0.82). Of note, the results do not provide any evidence that 1 of the 2 styles is associated more strongly with tension than the other.

Strengths and Limitations

Overall, the results offer useful insights into the nature, frequency, distribution, and intensity as well as specific triggers of skin picking. They also provide important starting points for future studies that should investigate these aspects in more detail. However, our results should be interpreted in light of the specific strengths and limitations of this study. The latter may include a bias due to the self-selection of the participants. It is likely a rather specific sample of individuals, who are willing to track their skin picking for a period of 10 days several times a day. However, our data suggest a substantial impairment in terms of skin picking severity, depression, anxiety, and skin picking–related impairment.

Another limitation results from the assessment method since self-observation and tracking skin picking can also increase the awareness and therefore the controllability of the behavior. Moreover, is it also discussed that the registration of an episode may serve a punishing function due to the extra effort to record it so that the likelihood of the behavior is reduced. These mechanisms could have produced 2 biases in this study: first, the number of automatic episodes could be underestimated due to the increased awareness during this study. Second, the frequency and intensity of the behavior may have been reduced by the continuous monitoring within this study's period.

Also, the assessment started regularly with the question "Have you picked your skin since the last assessment?" This could have caused a bias toward more reported episodes in the first period of the day as individuals might also report skin picking, which occurred in the night before. Consequently, the total number of the period between 8 and 10 AM should be interpreted cautiously.

Another limitation refers to the assessment of the episode length, which was assessed by multiple choice with options in steps of 10 minutes. The shortest selectable option was "about 10 minutes," but during this study, we received feedback from participants that their episodes were much shorter. However, this also leads us to the open question of what constitutes a skin picking episode and if micro episodes might play an important role. In addition, we know from clinical work that some people report that the behavior occurs almost constantly throughout the day. In this context, the question arises, whether and for whom it makes sense to divide the behavior into episodes. In this study, participants were forced to report behavioral episodes, but it remains unclear what participants have defined as an episode for themselves and if they tracked microepisodes. Future research needs to address these issues by applying an even tighter, more precise measurement of behavior, but this will also need to take the abovementioned difficulty of measurement reactivity into account.

Despite these limitations and the need for further research, this study also has some important strengths. To the best of our knowledge, this is the first study using EMA to assess skin picking, and it is also the first EMA study in the field of pathological BFRBs in general. It provides new insights into the phenomenology of the SPD allowing for a more reliable and accurate description of skin picking in the everyday life of affected individuals, which is essential for a comprehensive understanding of SPD of this relatively newly defined disorder. The study clearly demonstrates the advantages of measurement via EMA, since behavioral parameters could be assessed that cannot be measured at all—or only with considerable distortions—in retrospective assessments. Furthermore, this study was conducted with a sample of individuals fulfilling the diagnostic criteria for SPD, who showed good adherence overall, so this study provides high-quality data allowing for a detailed analysis of the phenomenology of SPD.

Our experience with the assessment of skin picking using EMA and the resulting data serve as a firm basis for further EMA studies on SPD and other disorders in the field of BFRBs and contribute to an enhanced understanding of an understudied but highly impairing mental disorder.

Data Availability

The data sets analyzed during this study are not publicly available to protect participant privacy.

Authors' Contributions

CG handled the conceptualization, methodology, data curation, formal analysis, writing of the original draft, project administration, and funding acquisition. MM acted on the conceptualization, methodology, supervision, and review and editing of the writing. MW worked on the conceptualization, methodology, visualization, and review and editing of the writing. NK did the supervision, and review and editing of the writing. Abstract

Background: To sustain performance during a task that requires attention may be a challenge for children with attention deficit/hyperactivity disorder (ADHD), which strongly influences motivation for tasks and has been connected to the level of arousal.

Objective: This study aimed to analyze the effect of musical stimulus on attentional performance in children with ADHD and typically developing children.

Methods: A total of 76 boys (34 with ADHD and 42 typically developing) performed the Attention Network Test (ANT) for children under 2 experimental conditions (with and without music). Four attentional measures were extracted from the ANT. We tested the effect of the experimental condition and its interaction with the group using repeated measures ANOVA.

Results: We found no significant main effects or interactions for the reaction times of the alerting, orienting, and conflict attentional networks of the ANT (all P>.05). Regarding ANT errors, we found a significant main effect for music, with a moderate effect size ($F_{1,72}$=9.83; P=.03; ηp^2=0.06) but the condition×group interaction was not significant ($F_{1,72}$=1.79; P=.18). Participants made fewer errors when listening to music compared to the control condition.

Conclusions: Music seems not to interfere in the attentional network in children and adolescents. Perhaps background music affects motivation. Future studies will be needed to validate this.

Introduction

Attention deficit/hyperactivity disorder (ADHD) is a common neurodevelopmental disorder characterized by harmful levels of inattention, impulsivity, and hyperactivity [1]. ADHD exhibits considerable heterogeneity, with individuals' symptoms reflecting impairments in different cognitive aspects [2], causing distress or problems at home, at school, and with peers [3].

Impaired cognitive aspects in ADHD include frequent compromises in executive functions (ie, working memory, inhibitory control, cognitive flexibility, planning, and problem-solving), self-regulation states (ie, the purposeful or automatic mechanisms that enable behavior to be adapted appropriately to a changing context), motivation (ie, temporal reward discounting), and time perception (ie, the ability to discriminate and compare time intervals) [4-6]. The

XSL•FO
RenderX

hyperactivity and inattention levels of children with ADHD are noticeably higher than expected.

The attentional modeling of Berger and Posner [7] provides an appropriate theoretical framework to account for ADHD dysfunction because it conceptualizes most of the abilities mentioned above as part of attentional networks, such as alerting (ie, arousal of the cognitive system), orienting (ie, allocating attentional focus in the visual field), and executive control (ie, ability to control our own behavior, resolve conflict, and inhibit impulsive responses). A task that requires extra effort for children to sustain performance may be a challenge for children with ADHD, especially in suboptimal conditions [8]. On the other hand, effort is determined by the motivation to perform the task and has been connected to the level of arousal and activation [8,9]. This explains why children with ADHD, who are easily distracted by external stimuli, may benefit from stimuli that promote increased alertness and consequently improve performance in the task [10,11].

A recent systematic review showed listening to music without lyrics that was chosen by the listener seemed to improve performance in tasks requiring attention [12]. Music enhances arousal, can affect mood, and increases motivation, especially when it is preferred by the listener, potentially benefiting the learning process through emotional processes [13-15]. This heightened state of alertness and pleasant mood can enhance attentional resources, allowing the listener to concentrate better and sustain focus on cognitive tasks [16,17]. Music holds the potential to augment the emotion regulation abilities and mood of young individuals in their daily experiences [18].

Knowledge of the effect of music on the cognitive function of individuals with ADHD is still limited due to inconsistent results [19]. Among studies that evaluated music as a form of stimulation in ADHD, 2 reported improvements in mathematical problem-solving [20,21], while another study assessing schoolwork completion (including math, reading, reading comprehension, and language arts) showed no significant difference in cognitive function. The heterogeneity in the methodology of these studies makes it difficult to draw conclusions on the true effect of music on task performance.

Nevertheless, a recent review indicated that listening to music can reduce symptoms of ADHD and improve timing perception and regulation [22], which are important for the functionality and well-being of this population.

At present, there is a lack of data assessing the impact of music listening on the attention networks of children with ADHD. Therefore, the aim of this study was to investigate the effects of music listening on the attention networks—namely, alerting, orienting, and conflict—in children with ADHD and typically developing children, while also exploring the relationship with the attentional profile of these children. Given that previous studies involving ADHD [23,24] incorporated measures of error types alongside conventional assessments of the 3 attention networks, we will also examine whether music influences error rates during task performance. Our hypothesis is that music may enhance attentional performance in children with ADHD differently from their typically developing peers.

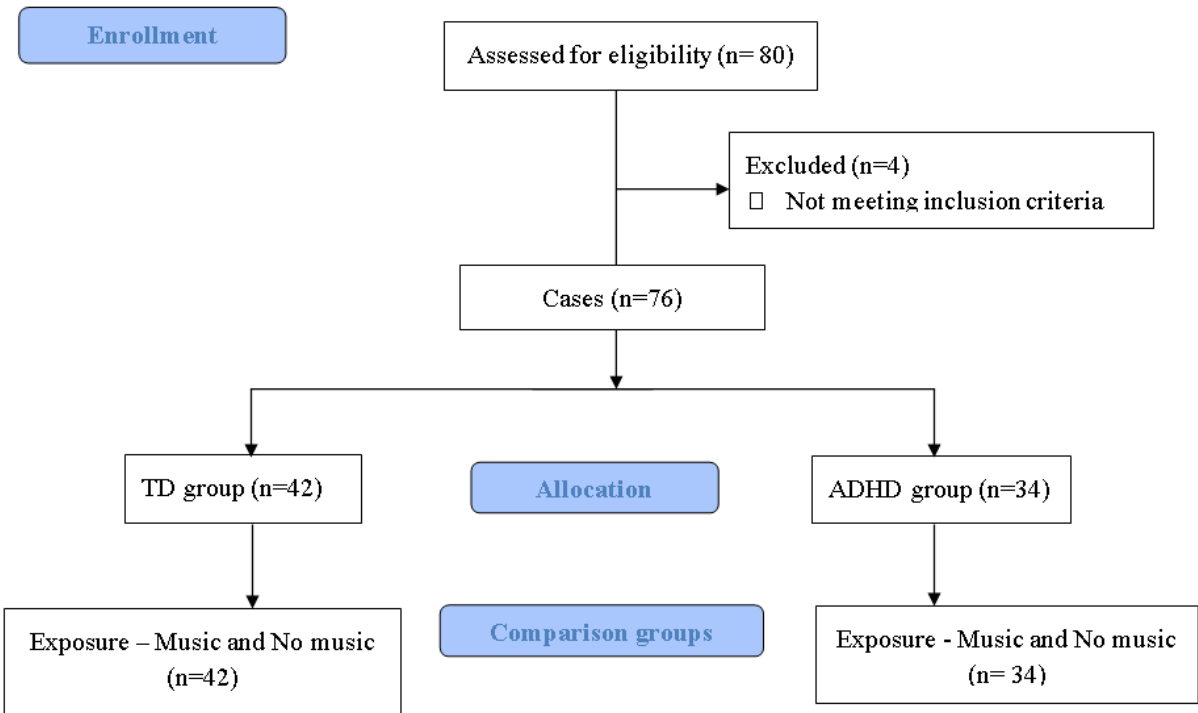
Methods

Study Design

This preliminary, experimental, repeated-measures study was conducted from 2019 to 2022 to explore the impact of music listening compared to no music listening on attention performance. We enrolled boys aged 10 to 12 years, both with and without ADHD, who completed the Attention Network Test (ANT) for children twice under randomized conditions.

Recruitment

A total of 76 boys aged 10 to 12 years participated, comprising 34 with ADHD and 42 without ADHD (Figure 1). This age range was selected based on evidence indicating that children younger than 10 years are still developing their musical preferences, while adolescents tend to be more receptive to unfamiliar music styles [25]. Given that the musical stimulus in our study needed to be familiar and preferred by the listener, we focused on the age range of 10 to 12 years. Also, only boys were included, because the majority of children treated at the university hospital were male.

Figure 1. Flow diagram of the research process. ADHD: attention deficit/hyperactivity disorder; TD: typically developing.


Participants were recruited from a university hospital that provides psychiatric care for children and adolescents with ADHD, as well as pediatric follow-up for healthy individuals. Children with ADHD met the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, criteria [1] and underwent assessment using the semistructured Schedule for Affective Disorders and Schizophrenia for School-Age Children–Present and Lifetime (K-SADS-PL) [26]. Moreover, they achieved scores at or above the 10th percentile on the Brazilian version of Raven's Colored Progressive Matrices intelligence test [27].

The control group was selected from the local community between 2021 and 2022. This group was matched with the ADHD group in terms of age and socioeconomic status, and they met the inclusion criteria by not having a diagnosis of ADHD or by not scoring above the cutoff points on screening questionnaires for ADHD. These cutoff points included having more than 5 ADHD symptoms identified by the Swanson, Noland, and Pelham Scale IV (SNAP IV) or having a *t* score greater than 70 on the ADHD scale of the Child Behavior Checklist for Ages 6-18 (CBCL/6-18) [28,29].

Intervention

The intervention required participants to perform an attention task in 2 different conditions: with music and without music. The music selection comprised 5 songs chosen through

interviews with children aged 10 to 12 years, who shared their favorite and most frequently listened-to songs. These songs were played during the test. It is important to note that the children interviewed about their favorite music were not necessarily participants in the study.

To gauge the emotional connection between listeners and songs (including familiarity, preference, mood, and arousal), a questionnaire was administered. Participants listened to song excerpts and answered questions such as "Do you know this song?" (answers were yes, maybe, or no), "Do you like this song?" (answers were yes, neutral, or no), and "How do you feel listening to these songs?" using the adapted Self-Assessment Manikin Scale [30]. A 5-point Likert scale was used to rate subjective mood (1=very sad, 2=sad, 3=neutral, 4=happy, and 5=very happy) and arousal (1=nonarousal, 2=low arousal, 3=neutral, 4=arousal, and 5=high arousal) based on images pointed to by the children. This questionnaire was administered before the ANT to ensure that the results were not influenced by the child's performance. It can be found in Multimedia Appendix 1.

To prevent experimenter bias, the order of play of the songs was determined through a random drawing using Microsoft Excel (Table 1). The music was played using a Samsung Galaxy J5 and Shure 440 Hz headphones, with the volume standardized to the same level for all participants.

Table 1. List of selected songs and their order of play.

Order	Title	Duration (min:s)
1	Fortnite OST–Battle Royale Menu Music (Rock Version) [31][a]	3:50
2	Alone (Mashmallo) – Modified [32][b]	3:19
3	Free Fire New EPIC Theme Song [33][c]	3:56
4	Herobrine's Life (Instrumental) [34][d]	4:00
5	Olha a explosão (Mc Kevinho) – Modified [35][b]	3:07

[a]This song is part of the game Fortnite and was formerly played in the Battle Royale menu and when a player wins the Battle Royale mode. It was composed by Rom Di Prisco; all content belongs to Epic Games.

[b]The original song was modified with Audacity (version 2.3.2; Audacity Team), an audio editor, to remove the voices.

[c]This song is the theme song of Free Fire 2019.

[d]This song is a Minecraft parody of the song "Something Just Like This" by The Chainsmokers and Coldplay.

Procedure

The attention task involved the child version of the ANT [36] under 2 conditions (with and without music). The child ANT was run using E-prime (version 2.0 professional; Psychology Software Tools) downloaded on a Samsung notebook from the webpage of Jin Fan [37]. All participants faced the laptop on the table in a comfortable, seated position (Figure 2). Prior to the ANT, the experimenter administered Conner's Continuous Performance Test (CCPT) to the children. The entire procedure lasted approximately 1 hour and 30 minutes.

Figure 2. Experimental setup.

The first author (CGM) contacted parents or caregivers via telephone to arrange the experiment day. For the ADHD group, the experiment was scheduled on the same day as the participant's psychiatrist appointment at the university hospital, or another agreed-upon day, to enhance adherence to the intervention. Children were individually escorted to a quiet office while their parents completed behavior scales and a sociodemographic questionnaire in the waiting room. It is crucial to highlight that this was a clinical sample. All children were under psychiatric monitoring and had a confirmed diagnosis of ADHD prior to participation.

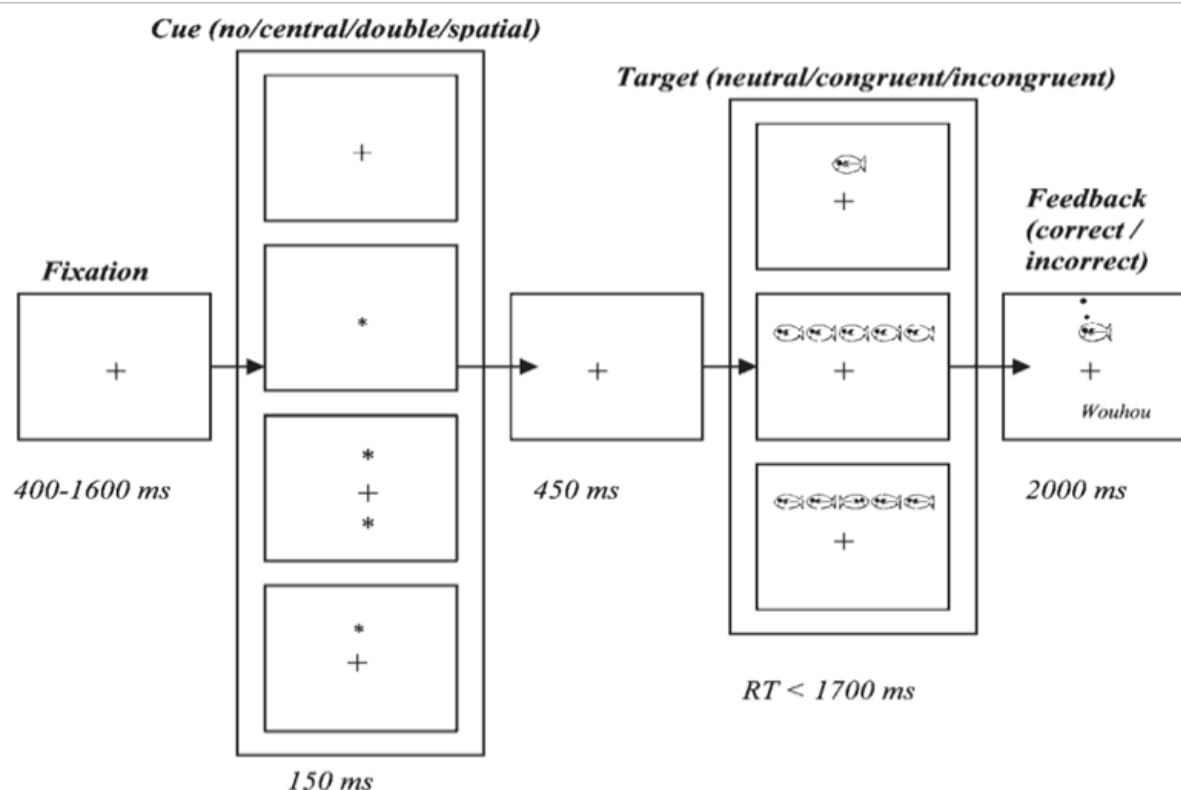
For the control group, the experiment was scheduled on the most convenient day and location for caregivers, provided the child met all eligibility criteria. Screening for ADHD was conducted using the SNAP-IV and CBCL/6-18 scales, which were completed by the parents as a web form. When the experiment was held at a participant's home, the child performed the task on a table in the quietest area of the house.

Additionally, all children and caregivers were asked to complete a semistructured questionnaire, which can be found in Multimedia Appendix 2, before starting the task.

Measures

Primary Outcome Measure

The ANT (child version) was designed to assess 3 attention networks (alerting, orienting, and conflict) within a single task framework based on the model described by Posner and Petersen [38]. In this version, participants are instructed to feed a central colorful fish by pressing a joystick button corresponding to the direction (left or right) in which it swims. The fish may appear alone or accompanied by other fish moving in the same or opposite direction (neutral, congruent, or incongruent stimuli) combined with various cuing conditions (no cue, central cue, double cue, and spatial cue) [38] (Figure 3).

Figure 3. Schematic of the child version of the ANT. In the actual task, the background color for every display is blue and the fish appear in yellow; the auditory feedback was used only in practice trials. RT: reaction time.


Originally, the task comprised 24 practice trials followed by 3 experimental blocks of 48 trials each. Since children completed the task twice (with and without music), practice rounds were administered separately. This procedure typically lasted approximately 45 minutes, including 5 minutes of practice and 15-minute rounds of 48 trials each, with 1-2 minute rest intervals. Psychometric properties of the ANT were assessed with a sample size of 40, yielding test-retest reliabilities of 0.52, 0.61, and 0.77 for the alerting, orienting, and conflict measures, respectively [39]. Additionally, with a sample size of 104, test-retest reliabilities of 0.36, 0.41, and 0.81 were reported for the alerting, orienting, and conflict measures [40].

Secondary Outcomes

The SNAP IV is a screening scale for ADHD and oppositional defiant disorder (ODD) based on the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* criteria [29]. It consists of 26 items divided into subsets of symptoms (inattention, hyperactivity/impulsivity, and ODD) rated on a 4-point Likert scale ranging from 0 (not at all) to 3 (very much). Scores can be computed using 3 methods: averaging scores for each dimension, summing total scores, or counting the number of symptoms [29]. We used the symptom count to screen for ADHD, while the second and third methods were used for sample characterization. In a Brazilian sample, parental assessment of the SNAP IV demonstrated robust psychometric properties, with Cronbach α values of 0.94 and 0.92 for the inattention and hyperactivity scales, respectively [29].

The CBCL/6-18 is a self-report questionnaire assessing behaviors with 118 items scored as 0 (not true), 1 (somewhat or sometimes true), or 2 (very true or often true). Scores yield raw scores for 8 narrowband scales and 3 broadband scales, which are then transformed into *t* scores based on normative data [28]. The CBCL/6-18 aids in ruling out other pathologies potentially confounding ADHD diagnosis and establishing inclusion criteria for typically developing children. Internal consistencies as measured by Cronbach α for the problem scales range from 0.72 to 0.97 [28].

The CCPT is a computerized test measuring sustained attention and vigilance in individuals aged 6 years and older [41,42]. Performance metrics include measures of reaction times, errors, and response variability. Participants respond to letters displayed on a screen by pressing the spacebar, except when the letter *X* appears. The CCPT-2, chosen as a baseline attention measure, demonstrates good internal consistency (Cronbach α ranges from 0.64 to 0.96) and adequate test-retest reliability (coefficients range from 0.48 to 0.79) [42].

The Brazilian Economic Classification Criterion (CCEB) assesses the socioeconomic status of families based on household properties, educational attainment of the family head, and access to infrastructure [43]. Scores categorize families into socioeconomic levels from A to E. Considering that economically vulnerable children may exhibit more ADHD symptoms and externalizing disorders, this assessment ensures the appropriate pairing of groups to mitigate bias [44].

In addition to standardized instruments, a questionnaire gathered information on the children's musical experience, preferences, and listening habits at home. Details can be found in Multimedia Appendix 3. At the study's conclusion, the children were asked about their preferred testing condition.

Statistical Analysis

The sample size of 46 was determined using G*Power (version 3.010; Universität Düsseldorf), considering α=.05, a medium effect size of 0.25, and a power of 90%. Statistical analyses were conducted using SPSS (version 22.0; IBM Corp) for personal computers. Descriptive statistics were used to calculate the mean and SD for sample characterization. Attention network scores (alerting, orienting, and conflict) for each participant were derived by subtracting error rates, including omissions, perseveration, and outliers, as outlined by Fan et al [40].

To compute orienting and alerting scores per participant, the mean reaction time (RT) per cue condition across flanker conditions was calculated (orienting = RT for spatial cue – RT for central cue; alerting = RT for double cue – RT for no cue condition). Conflict scores were obtained by computing the participant's mean RT for each flanker condition across cue conditions (RT for incongruent – RT for congruent). Mean scores across participants were calculated for each network using an Excel macro obtained from Jin Fan [37]. Error rates were determined by averaging errors across all conditions (cue and flanker). Detailed calculations are illustrated in Figures 4 and 5, based on the Excel macro downloaded from Jin Fan [37].

Figure 4. Example of calculations of attentional networks for participant 1, session 2, using an Excel (Microsoft Corp) macro.

Average of PracSlideTarget.RT				cue				
outiler	practice	PracSli	FlankerType	center	double	no	orienting	Total Geral

Conflict (724 - 641) = 82								

Figure 5. Example of calculations of overall errors of participant 1, session 2, using an Excel (Microsoft Corp) macro. The outlined squares indicate the values used for the calculations in the example.

We used an ANOVA with a repeated measures design to test if the experimental conditions (music×no music), groups (control×ADHD), and their interactions were related to changes in ANT scores. We used 1 model for each attention network measure and error rate. To reduce potential biases arising from individual differences in attention on ANT scores, we included fine-grained age-corrected measures of attention errors from the CCPT. Errors of commission (ie, responding to a stimulus when one should not) and omission (not responding to a stimulus when one should) were entered as covariates in each model.

Ethical Approval

Ethical approval for this study was obtained from the University's Ethics Review Committee (97425218.4.0000.5149). Written informed consent was provided by all parents or guardians, while minors provided written informed assent before participation in the trial. The study protocol was initially registered at ReBEC.gov (U1111-12589039). The study adhered to the Transparent Reporting of Evaluations with Non-randomized Designs (TREND) statement [45].

Results

Descriptive behavioral characteristics of the eligible participants are presented in Table 2. Additional information regarding the participants' previous musical experiences and emotional connections with the music selections can be found in Multimedia Appendices 1-3. Nearly half of the children reported both familiarity with and enjoyment of the songs used in this study. Moreover, 57 of 76 children (75%) expressed a preference for taking the test while listening to music compared to the no-music condition.

Independent sample *t* tests (2-tailed) revealed no significant age differences between the control and ADHD groups (t_{74}=0.47; *P*=.63). Similarly, no significant disparities in socioeconomic status were observed between the groups (t_{71}=−1.158; *P*=.25).

Table 2. Demographic characteristics of participants (N=76).

Characteristics	TD group (n=42), mean (SD)	ADHD group (n=34), mean (SD)
Age (years)	11.0 (0.85)	10.9 (0.75)
Brazilian Criteria of Economic Classification[a]	28.5 (11.32)	31.5 (11.15)
SNAP-IV[b] symptoms (_t_ score[c])		
Inattention	1 (1.97)	6 (2.35))
Hyperactivity/impulsivity	0.5 (0.84)	5 (1.85)
CBCL-ADHD[d] (_t_ score[c])	44.7 (5.90)	61.6 (11.47)
CCPT[e] score		
Omissions	11.7 (9.5)	11.9 (8.6)
Commissions	25.0 (6.0)	25.4 (7.3)

[a]For the Brazilian Criteria of Economic Classification, 0-16=class D and E, 17-22=class C2, 23-28=class C1, 29-37=class B2, 38-44=class B1, and 44-100=class A.

[b]SNAP-IV: Swanson, Noland, and Pelham Scale IV. Each item is categorized as present (1 point, which means all answers are equivalent to 2, "quite a bit," or 3, "very much") or absent (0 points, which means all answers equivalent to 0, "not at all," or 1, "just a little"). The cutoff point for screening ADHD is >5.

[c]Mean _t_ scores calculated with reference to Brazilian normative data [25].

[e]CCPT: Conner's Continuous Performance Test.

Effect of Music on ANT and Error Rate

Table 3 presents the means and SDs for each ANT measure across different conditions and groups. Repeated measures ANOVA models are shown in Table 4. We did not find significant main effects for music or the interaction between group and music for the alerting, orienting, and conflict attentional networks (all were nonsignificant, with _P_ values ranging from .28 to .74). Regarding ANT errors, we found a significant main effect for music with a moderate effect size ($F_{1,72}$=9.83; _P_=.03; ηp^2=0.06) but not for the group×music interaction ($F_{1,72}$=1.79; _P_=.18). Both the typically developing participants (mean 0.041, SD 0.036 vs mean 0.039, SD 0.049) and ADHD participants (mean 0.066, SD 0.058 vs mean 0.052, SD 0.042) made fewer errors in the ANT while listening to music.

Table 3. Mean reaction time and SDs for correct responses in each condition (music and no music) and in both groups (attention deficit/hyperactivity disorder and typically developing).

Group and flanker condition	Reaction time with music (ms), mean (SD)				Reaction time without music (ms), mean (SD)			
	Central cue	Double cue	No cue	Orienting	Central cue	Double cue	No cue	Orienting
Typically developing group								
Congruent	639 (120)	626 (266)	692 (130)	619 (192)	635 (135)	614 (177)	675 (229)	612 (296)
Incongruent	702 (106)	689 (343)	736 (201)	680 (62)	674 (75)	680 (177)	723 (109)	660 (203)
Neutral	621 (167)	597 (115)	664 (227)	590 (182)	634 (205)	612 (255)	657 (63)	598 (246)

Discussion

Principal Findings

The results across both ADHD and control groups revealed neither a significant main effect of music in attention networks, as indexed by the ANT, nor a significant interaction between music and group. However, a significant main effect was found in the overall number of errors during the ANT, suggesting listening to music decreases the error rate.

This study hypothesized that listening to music during testing may improve the attention performance of children with ADHD. However, our findings did not fully support this hypothesis. We found listening to music can improve performance accuracy by decreasing the number of errors, and this happened in both groups. The deficits in the attentional networks of children with ADHD assessed through the ANT are still controversial, and there are previous studies that also did not find differences in the efficiency of their networks when compared to children without ADHD [24,46]. Also, higher alertness seems to be associated with increased error rates [45,47,48], so music helped promote an optimal condition, that is, one that would not affect the accuracy of the attentional network, or it generated a weak effect size for the detection of differences.

The effects of music on cognitive performance are affected by motivation, especially if it is a favorite song [48]. In this study, most of the participants reported positive feelings (ie, liking the song and feelings of happiness) about the pieces of music used, and they preferred to perform the ANT listening to music. This may have increased the motivation to complete the task, consequently contributing to making fewer mistakes while listening to music, but this is only speculative. In the case of the children with ADHD, they may have lower levels of motivation and self-regulation problems, which lead to the devaluing of rewards that are not immediate in comparison to typically developing children [49,50]. Although we did not find a significant difference between the groups, our results suggest a tendency for the effect of music to be more significant in the group with ADHD, which corroborates studies on the role of motivation in achieving school tasks [51-53]. Children with

ADHD, when motivated, are more likely to try harder when faced with difficulties or not to give up when something is difficult to finish or is not interesting to them [54]. So, it is important to understand that strategies that motivate these children can directly affect their performance of a task, and this does not necessarily have to be through an attentional route.

Also, previous studies demonstrated that when music has lyrics, it might impair performance attention [55,56], which could have been another important factor that contributed to the reduction of errors during the performance of the task in our study. Still, our musical stimulus was composed of songs that could have created an atmosphere to captivate the children, as 3 of the songs were from games that these children routinely played. This may have generated a feeling of reward and motivated the children more during the test.

The concept of affect-matching music refers to the idea that individuals tend to seek out and prefer music that aligns with their current emotional state or desired emotional state. Improvements in cognitive performance are facilitated by listening to affect-matching music [57]. On the other hand, music is also capable of inducing emotions [12,15]. In this study, we chose to use music that was familiar and preferred by most participants, so it is possible that the combination of these factors, music that induces emotions, plus the listener's perception (emotion and arousal), led to our results.

Since it was developed, the ANT has been widely used by the scientific community in diverse cultures and investigations (for, eg, anxiety, ADHD, bilingualism, borderline personality disorder, deafness, mindfulness training, schizophrenia, and time of day) [46,58], and the child variant [36] is the gold standard in this population, being engaging and visually stimulating. Thus, it was the best tool to assess the effect of music on performance attention.

This study has some limitations. First, the results are only generalizable to the specific music used in this study and potentially to other music in the same genre and with a specific visual task in a laboratory setting. It will be necessary to carry out the same study with the same type of music while performing school tasks or in the classroom.

XSL•FO

RenderX

Second, the sample of children with ADHD was recruited from only one clinical care setting, and this may have generated biases. Also, because it is a single clinical sample, the findings may not generalize to the broader population, limiting the external validity of the study.

Conclusion

Our findings, while preliminary, suggest that music does not appear to interfere with attentional networks. However, they do indicate that listening to music reduces the number of errors during directed attention tasks such as the ANT. Can similar results be observed during academic tasks? Could listening to music serve as a means to motivate children, thereby enhancing their engagement and accuracy in completing tasks? These questions warrant further investigation.

The motivational significance of a task plays a crucial role in channeling the additional effort required to sustain attention, potentially contributing to the reduction in errors observed. However, the effects of music on attention may vary among individuals with ADHD. While some children may find certain types of music beneficial for enhancing attention, others may find it disruptive. Therefore, it is essential to consider personal preferences and sensitivities when assessing the impact of music on attention in children with ADHD.

Ultimately, our research underscores the importance of exploring alternative and complementary treatments for ADHD that incorporate music, as it possesses intrinsic motivating potential and is readily accessible in people's daily lives. Further studies are needed to deepen our understanding of how music can be effectively used to support attention and cognitive function in individuals with ADHD.

Abstract

Background: Numerous studies have been conducted to predict depressive symptoms using passive smartphone data, mostly integrating the GPS signal as a measure of mobility. Environmental factors have been identified as correlated with depressive symptoms in specialized studies both before and during the pandemic.

Objective: This study combined a data-based approach using passive smartphone data to predict self-reported depressive symptoms with a wide range of GPS-based environmental factors as predictors.

Methods: The CORONA HEALTH app was developed for the purpose of data collection, and this app enabled the collection of both survey and passive data via smartphone. After obtaining informed consent, we gathered GPS signals at the time of study participation and evaluated depressive symptoms in 249 Android users with the Patient Health Questionnaire-9. The only GPS-based data collected were the participants' location at the time of the questionnaire, which was used to assign participants to the nearest district for linking regional sociodemographic data. Data collection took place from July 2020 to February 2021, coinciding with the COVID-19 pandemic. Using GPS data, each dataset was linked to a wide variety of data on regional sociodemographic, geographic, and economic characteristics describing the respondent's environment, which were derived from a publicly accessible database from official German statistical offices. Moreover, pandemic-specific predictors such as the current pandemic phase or the number of new regional infections were matched via GPS. For the prediction of individual depressive symptoms, we compared 3 models (ie, ridge, lasso, and elastic net regression) and evaluated the models using 10-fold cross-validation.

Results: The final elastic net regression model showed the highest explained variance (R^2=0.06) and reduced the dataset from 121 to 9 variables, the 3 main predictors being current COVID-19 infections in the respective district, the number of places in nursing homes, and the proportion of fathers receiving parental benefits. The number of places in nursing homes refers to the availability of care facilities for the elderly, which may indicate regional population characteristics that influence mental health. The proportion of fathers receiving parental benefits reflects family structure and work-life balance, which could impact stress and mental well-being during the pandemic.

Conclusions: Passive data describing the environment contributed to the prediction of individual depressive symptoms and revealed regional risk and protective factors that may be of interest without their inclusion in routine assessments being costly.

Introduction

Background

Depression is a serious and widespread disease accompanied by a high individual burden [1]. Early detection of depressive symptoms facilitates care through early intervention and can thus prevent the development of severe symptoms such as suicidal ideation [2]. Therefore, knowledge of the current incidence and rapid recognition of trends in the prevalence of depressive symptoms is of great social relevance [3], for instance, for planning treatment strategies and identifying capacities.

To identify such trends in a timely manner, population-wide (broad) data collection in real time is pivotal. Collecting survey data requires the commitment of the participants, and they have to take the time and effort to answer questions. With the proliferation of smartphones, an alternative data source is available that does not require the effort of participants. Smartphone data have been used in research on mental health [4,5] and explicitly for depressive symptoms [6,7]. Analyses based on these smartphone data often aim to predict, for instance, depressive symptoms by including all available data [4,6,8,9]. A distinction is made between active and passive data collected via smartphones. Active smartphone data involve data that require the active involvement of the smartphone user (eg, survey data collected via the smartphone), and passive smartphone data include data that can be collected without the user's involvement [4]. Passive smartphone data can be divided into activity data, social media data, and sensor data [10]. A whole body of evidence investigates the predictive power of activity data (eg, text messages sent, calls made, and screen activity), which are understood as objective measures of behavior [11]. It has been shown that some of these activity data are clearly related to depressive symptoms [12-15]. Social media data include information about posts on social networks, and these aspects of social interaction are also associated with depressive symptoms [16]. Smartphone sensor data involve the data measured with the sensors integrated in smartphones, such as GPS [10]. Studies often use GPS to analyze mobility behavior and have been able to identify correlations with depressive symptoms as well [4,7,10,14,17-20]. However, by including GPS sensor data in research on depressive symptoms, it is further possible to describe the participants' environment in detail. Environmental factors include, for example, the sociodemographics of the population living in the surrounding area, economic conditions, social affairs, or living conditions (Table S1 in Multimedia Appendix 1). These environmental factors are external factors that affect people's living conditions. For example, urbanization and population density are controversially discussed as risk factors for depressive symptoms [21]. In addition, different types of noise and air pollution were predominantly identified as positively related to depressive symptoms [21]. A poor home or building environment has been repeatedly identified as positively correlated with depressive symptoms, and the same applies to a lack of green areas [21].

This study was conducted during the COVID-19 pandemic. This was a time when people spent more time at home due to contact restrictions and lockdowns [22]. Researchers argue that environmental factors may have been particularly important for mental health during the pandemic, as more time was spent in those same environments [23-25]. This is also indicated by the results showing an association between housing conditions (eg, available space) and depressive symptoms during the COVID-19 pandemic [23,26]. For this reason, environmental factors should be included in studies on depressive symptoms (especially during the COVID-19 pandemic). In addition, integrating environmental factors allows for a better understanding of depressive symptoms, namely, to what extent environmental factors are risk and protective factors for depressive symptoms [27]. Furthermore, as some environmental factors such as sociodemographics (eg, employment rate and age distribution), economic conditions (eg, investments per employee), social affairs (eg, percentage of households with children), and living conditions (eg, percentage of 1-person households) can be passively measured via GPS data, the prediction and identification of depressive symptoms can be achieved with much lower costs, effort, and in a faster manner. However, it is unclear how accurately self-reported individual depressive symptoms can be predicted purely on the basis of GPS signals.

Study Design

The aim of this study was to clarify to what extent environmental factors that can be passively measured via an individual's location tracked by GPS explained the statistical variance in individual depressive symptoms. In contrast to many studies that have focused on single predictors only [13], this study used a comprehensive approach and integrated a wide range of data available through GPS smartphone data (eg, sociodemographics, economic conditions, social affairs, and living conditions). Since this study was conducted during the COVID-19 pandemic, GPS-based COVID-19–specific variables such as the pandemic phase and the regional COVID-19 infection count were integrated as well.

The analyses were based on a data-driven statistical approach that allowed us to analyze a large number of predictor variables for individual depressive symptoms in an exploratory fashion without overfitting the data. Hence, there was no a priori selection of included variables based on any assumed connection to depressive symptoms, but all available variables of the data source were included.

Methods

Sample and Procedure

Data collection took place by means of the developed CORONA HEALTH app, a cooperative project between the German

universities of Würzburg, Ulm, and Regensburg, and the German Robert Koch Institute. The CORONA HEALTH app was specifically designed to explore factors during the COVID-19 pandemic and allows for both cross-sectional and longitudinal data analyses [28]; in this paper, we exclusively used cross-sectional data. Participants were recruited by means of public relation measures (eg, press releases and social networks). Participation in this study was voluntary, and participants did not receive incentives for participation. The inclusion criterion (for the analyzed study) was a minimum age of 18 years. In this study, only those data from smartphones with Android operating systems were analyzed. To participate, participants had to download the app and were then requested to provide informed consent (including use of GPS data). The study information provided was based on the quality standards set out by Beierle et al [29].

Based on the recorded GPS signal during survey participation, we assigned each participant to the nearest district, which was the smallest possible regional unit. The only GPS-based passive data collected were the participants' location at the time of the questionnaire. This location was used to link participants to district-level sociodemographic and environmental data from official German statistical sources. For data protection reasons, the resolution of the location was reduced to an accuracy of 11.1 km. In Germany, the statistical offices of the counties and the federal government provide current average values for 160 indicators at the regional level in the so-called Regional Atlas [30]. All these available average values for population structure, housing conditions, and so forth, were assigned to each participant according to his or her respective district. Data were gathered from July 2020 to February 2021, coinciding with the COVID-19 pandemic. This period in Germany was marked by several waves of infections and accompanying contact-restricting measures and correspondingly restricted public life [22]. Based on the date of the first questionnaire completion, the COVID-19 incidence rate in the respective district and information on the pandemic phase [22] were determined and assigned to the individual dataset.

The conception and implementation of the app followed medical device regulations and were certified accordingly (see the study by Holfelder et al [31]). This study was approved by the ethics committee of the University of Würzburg (130/20-me).

Due to the inclusion of exclusively passive data, the dataset did not contain any individual sociodemographic information but rather the sociodemographic averages in the respective district. The following sociodemographic averages describe the sample: those aged 0-17 years accounted for 15% of the population (averaged across all districts), those aged 18-24 years accounted for 8.3%, those aged 25-44 years accounted for 29.7%, those aged 45-64 years accounted for 25.6%, and those older than 65 years accounted for 27.5%. It is important to note that while those aged 0-17 years were mentioned as comprising 15% of the population, this figure provides general context about the population, as individuals younger than 18 years were not included in the study sample. On average, 39.6% of the population in the districts graduated from school with a general matriculation standard, and an average of 6% did not have a school-leaving certificate.

The original sample had 1760 participants. Eighteen individuals were dropped in a plausibility check based on correspondence between similar items, straightlining, intraindividual response variability, and extreme outliers. Of the remaining sample of participants, 60.4% (1052/1741) had an Android operating system, and 28.1% (490/1741) consented to the collection of passive data. Of the remaining sample, only those districts with more than 20 participants were included to meet the condition of normally distributed data in the clusters. This resulted in a final sample of 249 participants. Details on the sample can be found in Table S1 in Multimedia Appendix 1.

Measures

The primary outcome of this study was depressive symptoms, measured using the German version of the Patient Health Questionnaire-9 (PHQ-9) [32]. The PHQ-9 is a validated self-report instrument consisting of 9 items (eg, "Over the last week how often have you experienced little interest or pleasure in doing things?"), with responses on a 4-point scale (0="Not at all" to 3="Almost every day"). The total PHQ-9 score ranges from 0 to 27, with higher scores indicating more severe depressive symptoms. A score of 0-4 suggests minimal depressive symptoms; 5-9, mild symptoms; 10-14, moderate symptoms; 15-19, moderately severe symptoms; and 20-27, severe symptoms. The internal consistency of the PHQ-9 in this sample was excellent, with a Cronbach α=0.85.

The PHQ-9 is widely used in both clinical and general populations and was chosen as the outcome measure because it allows for the assessment of the severity of depressive symptoms in a continuous format, which aligns with the study's objective to explore predictors of individual depressive symptoms. As a COVID-19 pandemic–specific variable, the number of infections per 100,000 inhabitants in the respective district at the time of assessment was included. These data were derived from official statistics reported by the Robert Koch Institute based on all laboratory-confirmed officially reported SARS-CoV-2 cases within the framework of the German Infection Protection Act [33]. In addition, the pandemic phase at the time of assessment was included in each case according to the classification by Schilling and colleagues [22] ranging from 1 (calendar weeks 10-20 in 2020) to 3 (calendar week 40 in 2020).

The respective regional environmental factors were determined using the district-level statistics of the Regional Atlas of the Federal Statistical Offices [30]. All variables available on the website on April 30, 2022, at the district level were included, with each construct included once. These included data on sociodemographics (eg, age group percentages in 2019, youth ratio in the regional population in 2021, percentage of the population without school-leaving qualifications in 2019, employment rate in 2020, disposable income per inhabitant in euros in 2020, and percentage of unemployed people in 2020), economy (eg, percentage of employed individuals by sector in 2019, investments per employee in thousand euros in 2019, and average length of stay of tourists in 2019), social affairs (percentage of households with children in 2011, percentage of children in care by age on March 1, 2021, proportion of fathers receiving parental benefits in 2014, and places in nursing homes

per 1000 inhabitants aged 65 years and older in 2020), and living environment (eg, percentage of 1-person households in 2011, population density of inhabitants per square kilometer in 2020, percentage of area by use in 2015, and consumption-based charge for drinking water supply per cubic meter in 2019). A complete list of variables is shown in Table S1 in Multimedia Appendix 2. Due to the district clusters, the respective districts were included in the analyses as dummy variables. In addition, the pandemic phases were included as dummy variables. In total, the dataset included 121 variables.

Data Analyses

Using GPS coordinates, each participant was assigned to a district. To control for the nested data, the respective districts were included in the analysis as dummy variables. Two participants who had a GPS location outside Germany were excluded. The data contained only 3 missing values (in the depressive symptoms variable); these were replaced using a single imputation with 500 iterations using classification and regression trees (cart method) with the R package "mice" (ie, the mice package for multivariate imputation by chained

equations was developed by Stef van Buuren and is supported by Utrecht University) [34]. Metric variables were z standardized.

For the prediction of individual depressive symptoms, we chose to compare ridge, lasso, and elastic net regression models [35]. The predictive performance, signaling the best fit, relied on the root-mean-square error, mean absolute error, and explained variance (R^2). Using a grid search, we implemented hyperparameter optimization. The analyses included automated variable selection. This allowed for a statistical check of which variables remained in the model with the best predictive performance, that is, the lowest degree of prediction errors [36]. To avoid overfitting, we split the dataset into a training (70%) and a test dataset (30%). In the training dataset, the final model was calculated using 10-fold cross-validation with 5-fold repetition [35]. In the test dataset, the model was evaluated for its predictive performance in a sample that had not been part of the model training. The result was a ranking by variable importance (Figures 1 and 2). Variables were ranked based on their contribution to the prediction of individual depressive symptoms.

Figure 1. Total variable importance as an indicator of the contribution to reduce the estimation error in the prediction of depressive symptoms in the lasso regression model.
Figure 2. Total variable importance as an indicator of the contribution to reduce the estimation error in the prediction of depressive symptoms in the elastic net regression model.
Ethical Considerations

The conception and implementation of the app followed medical device regulations and were certified accordingly [31]. The original data collection for this study was approved by the ethics committee of the University of Würzburg (130/20-me). This approval explicitly covered both initial data collection and any potential future secondary analyses using the collected data. As such, no additional institutional review board approval or exemption was necessary for the present secondary analysis. In accordance with local regulations and institutional guidelines, the secondary use of existing, anonymized data does not require a separate review or approval. Specifically, the main institutional review board votum issued during the original data collection already included provisions for future secondary analyses. This is in line with German medical research standards, which state that when data are collected with informed consent that includes provisions for future use, and the data are anonymized, additional ethical approval is not required for secondary analyses (see Article 89 of the German Data Protection Regulation). All procedures adhered to institutional ethical standards for research involving human subjects, and all participant data were fully anonymized to protect privacy. Participation was voluntary, and no financial compensation was provided.

Results

The comparison of the individual models (ridge, lasso, and elastic net regression) showed the following differences: in the prediction of individual depressive symptoms, lasso regression had the smallest average root-mean-square error (5.59). The explained variance was second to highest (R^2=0.05). The elastic net regression produced the highest explained variance (R^2=0.06; Table 1). The listed characteristic values showed lasso and elastic net regression as the analyses with the best fit. Lasso regression reduced the dataset from 121 variables to 7 variables, and elastic net regression reduced it from 121 to 9 variables.

The lasso and elastic net regression models shared the first 3 predictors. The most important predictor was the number of current COVID-19 infections in the respective district. The second was the number of places in nursing homes, and the third was the proportion of fathers receiving parental benefits. Both models also included the 3 variables population share of the 0-17 years age group, average length of stay of tourists, and the consumption-based charge for drinking water.

Lasso regression showed the second pandemic phase as a relevant predictor (Figure 1). Elastic net regression further listed (in descending variable importance) the third pandemic phase, investment per employee and the youth ratio as relevant predictors (Figure 2).

Table 1. Model fit indices for predicting depressive symptoms resulting from stepwise, ridge, lasso, and elastic net regression based on 50 replicate samples[a].

	Minimum	1st quantile	Median	Mean	3rd quantile	Maximum
MAE[b]						
Ridge	3.628	4.127	4.515	4.448	4.746	5.524
Lasso	3.606	4.231	4.440	4.464	4.643	5.717
Elastic net	3.605	4.162	4.506	4.483	4.741	5.764
RMSE[c]						
Ridge	4.165	5.071	5.626	5.594	6.080	7.373
Lasso	4.216	5.244	5.630	5.585	5.942	7.104
Elastic net	4.169	5.219	5.677	5.618	5.912	7.162
R^2						
Ridge	0.000	0.003	0.019	0.048	0.079	0.228
Lasso	0.000	0.003	0.019	0.053	0.052	0.366
Elastic net	0.000	0.009	0.034	0.063	0.083	0.415

[a]Overall, elastic net regression had the best model fit due to the largest variance explained (R^2), and lasso regression had the best model fit when including the smallest mean absolute error and root-mean-square error.

[b]MAE: mean absolute error.

[c]RMSE: root-mean-square error.

Discussion

Principal Findings

This study aimed to identify correlates of depressive symptoms based on regional factors allocated via GPS (passive data). It should be noted that the only GPS-based passive data collected were the participants' location at the time of the questionnaire, which was then used to assign participants to regional sociodemographic and environmental data based on their district. For this purpose, we used a passive data collection method. This had the advantage of integrating a wide range of data without any effort on the part of the participants.

The results helped identify regional and freely available variables as risk and protective factors for individual depressive symptoms. The identified risk and protective factors are presented as follows, starting with the 3 aspects that had the greatest relevance in both models.

The weekly number of cases of COVID-19 infections in the respective district was positively associated with higher individual depressive symptoms. In many cases, high COVID-19 case numbers were associated with contact restrictions in everyday life imposed by law or by the population itself [37]. A connection between these contact restrictions and individual depressive symptoms has been discussed repeatedly [38-41]. Different arguments were used to explain this connection. The reduction in social contact promoted loneliness, which has been identified as a risk factor for individual depressive symptoms [42,43]. In addition, an increase in misconduct and home violence has been reported [44]. Moreover, the high number of cases might have been associated with increased fear of infection, which increased substantially during the pandemic [41], a lack of care capacities, or a severe course of the disease

[45]. This could be related to individual depressive symptoms as an additional burden [46].

The proportion of fathers receiving a parental allowance was a risk factor for higher individual depressive symptoms. Parental allowance is a financial state benefit to mothers or fathers in Germany that is granted for a certain period during which the parent is not or only partially employed and devotes himself or herself to the care of their child. For methodological reasons, it was not possible to derive any causal associations from the results of our analysis. However, one possible explanation could be that paternal receipt of parental allowance might be an indicator for those families in which both parents are employed. These families were thus dependent on the functioning of the childcare infrastructure and therefore particularly challenged by the double burden of working from home and homeschooling for the duration of the pandemic. In a different study, increased individual depressive symptoms were also observed in parents of underage children during the COVID-19 pandemic, which also indicates the special burden on families [47].

In addition, the pandemic phase was a relevant factor for individual depressive symptoms. Phase 2 of the pandemic was positively related to individual depressive symptoms. The second phase of the pandemic, from the end of May to the end of September 2020, was accompanied by the opening of restaurants, gradual school openings, and the lifting of travel restrictions [22]. It is possible that with this return to regular daily life, depressive symptoms became more noticeable. In other words, it could be that it was only at the moment when a person was no longer able to cope with demands that he or she became aware of his or her own mental health condition. This could have been the case for those affected by depressive symptoms after the contact restrictions were removed and they

returned to everyday demands. The same reasoning could apply to the negative correlation between phase 3 of the pandemic and individual depressive symptoms. The third pandemic phase was characterized by a nationwide partial lockdown at the beginning of November 2021 with tightened contact restrictions and a nationwide lockdown with moderately strict regulations from mid-December and the Christmas holidays [22]. Due to contact restrictions and holidays, there were fewer day-to-day demands to attend to during the period, such as homeschooling, daily logistics due to travel, and social obligations. In the case of individual depressive symptoms associated with reduced drive and anhedonia [48], these individual depressive symptoms would have been less noticeable during the lockdown, as there were fewer events to manage anyway.

In contrast to previous findings, a high proportion of the 0-17 years age group and a high youth ratio were associated with lower levels of individual depressive symptoms. In contrast, numerous studies have shown that stress and individual depressive symptoms in families increased during the pandemic [47,49,50]. Since only proportions of the population and not the absolute numbers were collected, a large share of the 0-17 years age group can also mean that the proportion of families was correspondingly large and thus the proportion of people living alone correspondingly smaller. Research showed that 1-person households correlated with lower well-being compared with households with 2-4 people during the pandemic [51]. Furthermore, correlations between loneliness and individual depressive symptoms were also found [52].

In contrast to the present results, previous studies showed a correlation between nearby green spaces [25] or the quality of housing conditions (>60 m^2, view from the windows, and poor indoor quality) [23] and lower depressive mood. A systematic review confirmed this and identified poor housing, lack of green spaces, and both noise and air pollution as environmental factors that were associated with depressive mood across studies [21]. The reason for the deviation of the present results could be that availability alone was not the decisive predictor for the association with depressive symptoms. Using the example of green spaces, research conducted during the COVID-19 pandemic, for example, showed that although natural areas were visited more often, visits to parks decreased [25]. The authors further discussed to what extent it was the time spent in green spaces that was related to low depressive symptoms or whether the green space was explicitly visited to participate in sports or to maintain social contacts and whether these were actually relevant predictors [25]. Sonnentag et al [53] found that the psychological mechanisms underlying recovery seem to be enhanced in natural environments.

Strengths and Limitations

A central strength of this study is the application of a data-driven statistical approach that allowed us to analyze a large number of predictor variables in an exploratory fashion without overfitting the data. By these means, the approach allowed us to investigate which environmental factors had predictive power. The collection of passive data via smartphone made it possible to reach participants despite pandemic-related contact restrictions and to make a corresponding statement about the included predictors for the COVID-19 pandemic period.

The cross-sectional study design of this study was limiting; statements about causal relationships were therefore not possible. In addition, the final dataset was very small, which might have weakened the significance of the analyses. A limitation that other studies have also observed [12] is the limited predictive power of individual depressive symptoms based on the passive data used. The use of GPS data was also a limitation, as it included only the location at the time of questionnaire processing. This was not the same as the place of residence of the respective person. How long the respective person was exposed to the general conditions could therefore not be inferred from the data. In addition, the informative value of the GPS data regarding individual environmental conditions was limited due to the regional resolution: since large variances in the average values were possible, it was of course not possible to draw conclusions about individual cases. Moreover, the image of the environment was only very roughly described. However, it represented the smallest possible regional size at which data from statistical offices could be collected nationwide. In addition, a higher spatial resolution, for example, per block of houses, would make it impossible to anonymize the data, as too few people would remain in the respective cluster. The validity of this study is further limited by the nonrepresentative dataset. As this analysis was limited to data from Android smartphones and required agreement to the collection of passive data, selection bias could not be ruled out. This must be taken into account when evaluating the results of this study. In addition, neither changes in predictors over time nor long-term data collection was considered to depict cause and effect more validly. This study can therefore make statements only about correlations and not about cause and effect.

Conclusions

This study showed that regional average data on socioeconomics and living environment seemed to be limited predictors of individual depressive symptoms; for the pandemic period, individual depressive symptoms were predicted, although the predictors had a rather low explanatory value and are not transferable to postpandemic periods. This suggests that the spatial resolution would need to be modified or that the dataset would need to be supplemented with additional data sources. Nevertheless, the results help classify freely available average data as risk or protective factors for individual depressive symptoms.

Authors' Contributions

JSE and MW developed the research questions and methodology in consultation with CC. MW and HS advised the planning of the statistical analyses. RP developed the app and data collection processes. JSE and MW performed the data analyses and wrote the manuscript in consultation with HS, RP, HB, and CC. All authors critically revised the paper and approved the final revision to be published.

Abstract

Spontaneous pneumothorax is one of the most common conditions encountered in thoracic surgery. This condition can be treated conservatively or surgically based on indications and guidelines. Traditional surgical management includes pleurodesis (mechanical or chemical) in addition to bullectomy if the bullae can be identified. Mechanical pleurodesis is usually performed by surgical pleurectomy or pleural abrasion. In this case report, we present a case of a young patient with spontaneous pneumothorax who needed a surgical intervention. We performed a new, innovative surgical technique for surgical pleurectomy where we used carbon dioxide for dissection of the parietal pleura (capnodissection). This technique may provide similar efficiency to the traditional procedure but with less risk of bleeding and complications.

Introduction

Spontaneous pneumothorax (SP) is a condition in which pneumothorax occurs without trauma or iatrogenic cause. It can be classified as a primary SP if there is no obvious underlying lung disease. The most common cause is usually a small bulla or bleb in the lung [1,2]. Comparatively, secondary SP happens due to underlying lung diseases such as chronic obstructive pulmonary disease [3]. The new British Thoracic Society (BTS) guidelines advise surgical treatment for SP at initial presentation if recurrence prevention is deemed important (eg, patients presenting with tension pneumothorax or those in high-risk occupations). Elective surgery should be considered for patients with a second ipsilateral or first contralateral pneumothorax [4].

The surgical treatment that is recommended by the BTS guidelines for SP is surgical pleurodesis with or without bullectomy [4]. There are 2 common ways to perform surgical pleurodesis: the first one is surgical pleurectomy and the second one is pleural abrasion. Surgical pleurectomy is considered more efficient, but it can be associated with an increased risk of bleeding and infection [5]. The novel surgical technique that we provide here can give a similar success rate but with less risk of complications such as bleeding or infection.

Case Presentation

Our patient was a young male individual who was previously healthy. He presented with a recurrence of an SP for the first time (2 SPs in total). The previous episode was treated conservatively 7 months prior, and his computed tomography

scan for this episode showed that he had small apical bullae. The decision was made to list the patient for elective surgical treatment, and after discussion with the patient, he was listed for a pleurectomy and bullectomy.

A standard anterior video-assisted thorascopic surgery (VATS) approach was taken. A small incision was made at the sixth intercostal space, and another small port site was created for the camera, which was later converted into the drain site (Figure 1). Carbon dioxide (CO_2) insufflation at 6-8 mm Hg on high flow was used to achieve capnothorax. A small anterior VATS incision was made at the sixth intercostal space, and the dissection of the parietal pleura was performed extrapleurally using Roberts forceps with a traditional technique. The forceps were exchanged for a curved metal sucker, and the CO_2

insufflation was attached at high flow and used to mobilize the whole parietal pleura, first from apex to inferior and then from posterior to anterior (Multimedia Appendix 1). The posterior parietal pleura was then excised off the ribs using thorascopic scissors 4 cm from the sympathetic chain posteriorly, 2 cm lateral to the internal mammary vein anteriorly, and 2 cm cranially to the diaphragm. Lastly, a bullectomy was performed using a manual stapler to excise the presumed culprit apical bullae seen on the computed tomography scan. Blood loss was minimal, approximately 50 mL, predominantly from VATS entry. Operative time was approximately 40 minutes. The postoperative care was routine, and the drain was removed after 48 hours. The patient was discharged on the third postoperative day.

Figure 1. Video-assisted thorascopic surgery (VATS) ports setup and surgical instruments.

Ethical Considerations

On the day of the operation, the patient completed a written consent form. The patient kindly agreed to the recording of the procedure and the utilization of his nonidentifiable data for this case report and publication, which was further discussed between the patient and GQ. Consent was sought by GQ and given by those in the operating theater for recording of the technique and publication as a case report.

Discussion

The use of CO_2 in thoracic surgery has increased significantly with the growing use of a minimally invasive approach. Capnothorax leads to better visualization by collapsing the lung and reduces the rate of complications [6,7]. In our department, we usually use CO_2 with robot-assisted thorascopic surgery and VATS for these reasons.

Surgical pleurodesis of SP is the recommended treatment in the BTS guidelines because it gives better long-term outcomes with less risk of recurrence in the future [4]. Surgical pleurectomy, in spite of it is efficiency, carries a risk of bleeding, infection, and reoperation [8]. Surgical pleural abrasion is another method that can be used for surgical pleurodesis. Chang et al [9]

published the first systematic review and meta-analysis that compared surgical abrasion against surgical apical pleurectomy. They found that there is no difference in the recurrence, but pleural abrasion has a shorter length of stay in hospital, postoperative chest tube duration, and operative time and less surgical blood loss [9]. This may cause clinicians to consider a change of practice from surgical pleurectomy to abrasion. A systematic review of randomized controlled trials found that SPs managed with a chest drain alone had recurrence rates that ranged from 26.1% to 50.1%, whereas after VATS talc pleurodesis, these ranged from 0% to 3.2%. Alternative chemical pleurodesis can be achieved with tetracycline rather than talc, although recurrence rates were reported as ranging from 13% to 33.3% [10].

Our literature search did not find any studies in which capnodissection was used for pleurectomy as a treatment of SP. However, Dai, et al [11] recently published their findings for using CO_2 for visceral pleurectomy and decortication in patients with malignant mesothelioma. They found that the positive pressure of CO_2 can facilitate dissection of the visceral pleura, making the procedure easier while achieving an acceptable postoperative air leak and chest drain output. They concluded that capnodissection can be used in pleurectomy and decortication for patients with mesothelioma [11]. It should be

taken into consideration that although the effect of capnodissection on gas exchange has not been rigorously studied, there is evidence to show that hypercarbia can result from CO_2 insufflation for capnothorax during VATS or robot-assisted thorascopic surgery procedures [12]. This must be taken into account by surgeons and anesthetists when considering compensatory ventilator strategies, especially in patients with compromised gas exchange.

Our experience with the use of capnodissection for surgical pleurectomy was successful, and after 17 months from the procedure, the patient did not have any recurrence or complications. Moreover, this technique was not time-consuming (40-minute operative time), and the patient was discharged after 48 hours, with the surgeons noticing less pain in comparison to the traditional surgical pleurectomy,

although pain is subjective. After VATS talc pleurodesis, the chest drain is typically removed no sooner than the second postoperative day, with discharge later that day. There is a theoretical risk of increased recurrence, as while the relatively atraumatic nature of this technique may reduce patient pain, it may also reduce the proinflammatory process required for pleurodesis and hence recurrence prevention [13]. More cases and longer follow-up are required to investigate the noninferiority of our technique to the traditional procedure.

Conclusions

In this case, capnodissection of the parietal pleura was a novel, safe, and successful technique that may decrease the risk of bleeding and postoperative pain.

Abstract

Degenerative cervical myelopathy (DCM) is a common neurological condition, with disease progression that is both variable and difficult to predict. Here, we present a case of DCM in a gentleman in his late 60s with significant radiological disease progression without consequent change in clinical symptoms. The case serves as a reminder of an enduring medical aphorism that clinical history and examination should be prioritized above more complex data, such as imaging investigations. In addition, the case also highlights that guidelines should be contextualized within individual clinical circumstances.

Introduction

Degenerative cervical myelopathy (DCM) is the most common cause of adult spinal cord dysfunction worldwide and is estimated to affect up to 2% of adults [1,2]. It arises secondary to degenerative pathology in the cervical spine, which leads to spinal cord compression. Cord compression may precipitate progressive neurological deficits including motor, sensory, and sphincter dysfunction [3].

The radiological progression of DCM does not always correlate well with its clinical progression [4-6]. Imaging findings such as the level and severity of spinal cord compression may not match the patient's experience of their symptoms over time, thereby adding complexity to the clinician's role of interpreting and reconciling clinical and radiological features of the disease [1,7].

Guidelines are clear in the event of symptom progression and advocate for surgery [8]. In contrast, the management of radiological progression without worsening symptoms is less defined and remains controversial. This report describes a case of the latter scenario, with the discussion focused on management.

Case Presentation

A retired man in his late 60s presented reporting a 2-year history of lower limb weakness, impaired balance, and calf aches. He associated this with a preceding episode of influenza.

He had a background of long-standing lower back pain secondary to lumbar stenosis, for which he had previously undergone 3 surgical decompressions and atrial fibrillation, for which he took aspirin daily. His father had undergone a cervical laminectomy many years previously. The patient was otherwise fit and well, regularly cycled for exercise, and was a nonsmoker.

His symptoms resulted in a referral to neurology and investigations including magnetic resonance imaging (MRI) of his cervical spine. The MRI revealed multilevel degenerative changes from C3 to C7 in the cervical spine, on a background of a congenitally narrow spinal canal (Figure 1). He was

therefore referred to the neurosurgery department. Consent was obtained from the patient.

On assessment in the neurosurgery clinic, the patient was diagnosed with DCM. His modified Japanese Orthopaedic Association (mJOA) score was 14 (4+6+2+2); a score of 12 to 14 indicates moderate myelopathy. Further exploration of his symptoms revealed dysesthesia in the region of the left shoulder, hypoesthesia of the third and fourth digits of the left hand, difficulties with tandem walking, and bladder issues with minor episodes of urinary incontinence. He was reluctant to undergo surgery, and hence, it was agreed to monitor his symptoms with reassessment in the clinic, with a strong recommendation to consider surgery if there was further progression.

The appointment 5 months later demonstrated no further progression of his symptoms, with an unchanged mJOA score. A further 6 months later, at a third neurosurgical clinic appointment, the patient reported some deterioration in his condition; he had been finding cycling more difficult, felt lower back stiffness, had worsened pain, and reported a mild electric shock sensation on the right upper limb. His mJOA score remained unchanged. He underwent a repeat MRI of his cervical spine, with a view to considering surgical decompression. The MRI showed progression of the degenerative changes at C3 to C7 (Figure 2).

Nonetheless, at his subsequent follow-up appointment, the patient reported improvement in the symptoms and the mJOA score remained 14. He had, however, developed left L4 sciatica, which had become his main concern. Three months later at his fifth appointment, his mJOA score was 13 (4+5+2+2). He reported increasing work and concentration required to walk and climb stairs. Compared to the third appointment, there had been a slow, gradual clinical progression. At this stage, the patient was put on the waiting list for surgery, just before the national lockdown in the United Kingdom during the COVID-19 pandemic.

At 3 subsequent follow-up appointments over the succeeding 8 months, there was no further clinical progression of the patient's DCM. Therefore, it was agreed to remove him from the waiting list for surgery and continue with an expectant approach. At the ninth appointment 6 months later, symptoms were again stable. At the 10th appointment, the patient reported some worsening back and lower limb pain, as well as some deterioration in his general mobility. A further MRI was therefore requested, which demonstrated significant radiological progression of his DCM compared to his MRI 5 years earlier (Figure 3).

At the 11th appointment, 5 months later, the symptoms had improved to the patient's previous baseline, including balance, dexterity, numbness, and urinary urgency. His mJOA remained 13. The radiological progression was in stark contrast with the fact that the patient remained clinically stable. Therefore, it was agreed to continue with expectant management and continue close clinical follow-up.

Figure 1. T2-weighted sagittal magnetic resonance imaging demonstrating multilevel degenerative cervical spondylosis and disc degeneration.
Figure 2. T2-weighted sagittal MRI demonstrating the progression of multilevel degenerative changes in the cervical spine, including disc degeneration at C3-C7.

Figure 3. T2-weighted sagittal magnetic resonance imaging showing significant radiological worsening of cervical cord compression at C3-C7 levels despite unchanged symptoms and modified Japanese Orthopaedic Association clinical severity score.

Ethical Considerations

According to the National Health Service Health Research Authority, research ethics committee approval was not required for this work. Informed patient consent was obtained for publication.

Investigations

The first MRI showed multilevel degenerative changes of the neck on the background of a congenitally narrow spinal canal: C3/4—disc osteophyte complex causing central compression of the spinal cord; C4/5—moderate stenosis; C5/6—moderate stenosis; C6/7—severe compression, with associated T2 signal changes.

The second MRI showed disc and facet joint degenerative changes between C3 and C7: C3/4—central disc protrusion causing moderate spinal canal stenosis and compression of the spinal cord, which had progressed compared to the first MRI; C4/5—broad-based disc bulge causing mild spinal canal narrowing and indenting the undersurface of the cord; C5/6—broad-based disc bulge causing moderate spinal canal narrowing and mildly compressing the spinal cord, which had progressed compared to the first MRI; C6/7—broad-based disc bulge causing mild to moderate spinal canal narrowing, indenting the anterior surface of the spinal cord.

The third MRI scan showed multilevel degenerative changes from C3 to C7, with scoliotic deformity: C3/4—severe circumferential stenosis with cord compression; C4/5—significant circumferential stenosis with cord compression; C5/6—circumferential stenosis with cord compression; C6/7—circumferential stenosis with cord compression.

Differential Diagnosis

The differential diagnosis for a presentation of lower limb weakness, imbalance, and calf ache can be divided into upper and lower motor neuron patterns of weakness. Causes for the upper motor neuron pattern include pathologies in the brain and spinal cord. In the brain, this includes demyelinating disorders such as multiple sclerosis, vascular disorders such as stroke, space-occupying lesions such as a parasagittal meningioma or abscess, and motor neuron diseases such as amyotrophic lateral sclerosis. In the spinal cord, this includes demyelinating disorders such as transverse myelitis, myelopathies such as DCM, space-occupying lesions, for example, tumor or abscess, trauma, syringomyelia, and spinal stenosis (spinal claudication).

Causes for the lower motor neuron pattern include drugs such as alcohol, metabolic disorders such as vitamin B_{12} deficiency, diabetes mellitus, inherited disorders such as Charcot-Marie-Tooth, infections such as HIV or syphilis, and autoimmune disorders such as vasculitis and chronic inflammatory demyelinating polyneuropathy. The causes of calf aches include trauma, vascular disorders such as peripheral vascular disease (intermittent claudication), and inflammatory disorders such as myositis.

Treatment

Since being diagnosed 5 years ago, an expectant approach has been taken in the management of this patient. International DCM management guidelines recommend surgical management for moderate, severe, or progressive DCM; however, for mild DCM, the optimal treatment strategy remains undefined, with a recommendation of either surgery or supervised nonsurgical management [8]. In this patient's case, there is moderate DCM, with an mJOA score of 13, with significant radiological progression but clinical and symptomatic stability across serial assessments.

Outcome and Follow-Up

The patient continues close neurosurgical follow-up, currently at 12 monthly intervals, alongside careful safety netting advice.

Discussion

Principal Findings

Degenerative changes in the cervical spine include disc herniation, osteophytosis, ligament hypertrophy, and ossification [9]. DCM is a clinical syndrome that arises when these changes result in spinal cord compression that is associated with symptoms, which may include neck pain or stiffness, limb pain or weakness, urinary incontinence, decreased manual dexterity, imbalance, or falls [1]. In this patient's case, there was also a risk factor for congenital stenosis of the cervical canal.

A challenging aspect of the management of DCM is how to deal with symptoms changing over time and correlating this with evolving imaging findings. Another challenging aspect is the important decision on the timing of any surgical management.

The guidelines advise clinicians to take a structured, consistent approach to management. Each person with DCM requires consideration of individual factors, which may mean that clinical judgment or patient preferences result in deviation from guidelines in some circumstances. The patient was diagnosed with moderate DCM; the mJOA score for the patient was initially 14 and then decreased and remained stable at 13.

Strict application of the guidelines would lead to a recommendation for surgical intervention. However, while the mJOA includes consideration of upper and lower limb motor function, upper limb sensory function, and sphincter function, it does not capture all symptoms and clinical features. For example, in this case, limb pain was not captured. Nonetheless, it is a validated scoring tool for the assessment of functional status and is responsive to changes in the severity of DCM [10].

The complexity of this case requires a nuanced approach to management. Surgical intervention within DCM is primarily aimed at halting symptom progression; however, without symptom worsening, the decision of when to operate becomes more complicated. This patient's symptoms were managed expectantly with nonsurgical interventions such as physical therapy as tolerated, oral analgesics, and neuropathic agents for any acute pain flares. Urinary symptoms were stable and were not actively managed. Waiting to operate at an older age may increase the risk of further complications, and this possibility

should be explained to the patient. This should be part of a shared decision-making approach, where patients are empowered to make decisions through collaboration with their clinicians with the understanding that, in the context of a chronic disease like DCM, this decision will likely be revisited [11].

The factors driving the disconnect between clinical and radiological severity are unknown. Nonetheless, a model proposed by Davies et al [12] postulates that DCM is a function of (1) mechanical stress, (2) duration of injury, and (3) individual vulnerability. Using this model, a scenario of limited clinical progression and significant radiological progression over time could be explained by decreased vulnerability to injury.

An individual's vulnerability to DCM comprises primary protective mechanisms such as genetics and age, in addition to adaptive protective mechanisms, such as autoregulation of spinal cord perfusion, functional reserve capacity, and nutritional status [12]. For example, certain genotypes are associated with increased regenerative capacity, such as the *HIF-1A* polymorphism rs11549467 [13]. This polymorphism is associated with susceptibility to DCM and its clinical features, including severity measured by mJOA.

Furthermore, adaptive protective mechanisms such as autoregulation of spinal cord perfusion may minimize ischemic injury. Decreased blood flow can result in blood-spinal cord barrier dysfunction, leading to microglia activation, neuroinflammation, and neuronal apoptosis [14]. In addition to the ischemia precipitating apoptosis [14], dysregulation of the autoregulatory system can occur from mechanical cord compression in DCM [15-17]. It is possible that dysregulation occurs to a lesser degree in some individuals, such as this patient. Furthermore, reserve capacity within the central nervous system [17-19] refers to resilience in the neurological system to account for the disconnect between the clinical phenotype and underlying histological pathology. In the context of DCM, cervical spinal cord compression and injury are initially asymptomatic, and the radiological changes affecting the spinal cord represent, at best, a proxy for the clinical presentation of the condition [12].

Conclusions

In summary, individuals may have different vulnerabilities and protective mechanisms that may account for the disconnect between clinical and radiological features of DCM. The message is therefore to treat the patient rather than treating the findings from the imaging. This is especially important, given that asymptomatic cervical spinal cord compression is common in the general population [2,7].

Introduction

Selfies are a modern, yet preventable cause of injury and death [1]. Medical responses and retrieval of persons, often in challenging terrain, burdens emergency medicine practitioners. To help prevent this issue, this study aimed to visualize selfie-related incidents globally by initially creating a scrollable visual story overlayed on a satellite map of the incidents in Australia. This type of visual storytelling technique using a world map helps illustrate the spatial context of this public health issue.

Methods

Overview

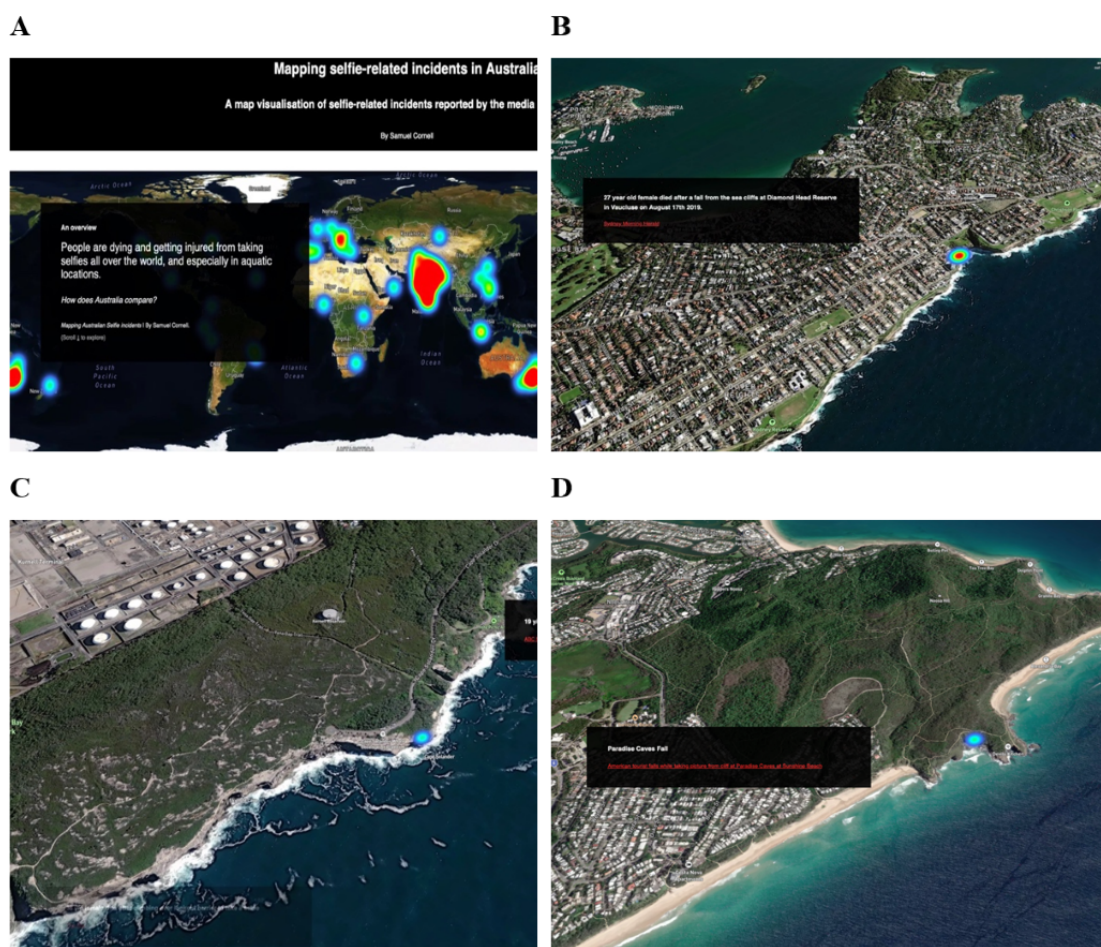
Incident data were acquired via publicly accessible news reports and a Wikipedia repository [2] and cleaned and prepared in Excel (Microsoft Corp). Incidents in aquatic areas (eg, coastal locations and inland waterfalls) were included; those in other settings (eg, falls from artificial structures and incidents involving trains) were excluded. Entries for each incident were created using associated media reports, incident types bring falls or drowns. Map coordinates were obtained by locating the incident using Google Maps and inputted into a coordinate finder using the Mapbox Location Helper [3]. Mapbox Studio [4] was used to create a custom map. A satellite template was chosen to best display the geographic context surrounding each selfie incident. The data set was imported into the Mapbox Studio custom map, which populated the data layer onto the map. A heat map setting was chosen for the data. To create the "scrollytelling" map story, the Mapbox storytelling template available from GitHub was used [5]. The primary input is a story comprising sections (chapters), each associated with a particular view of a map, enabling the user to "scroll" down the web page, and the resulting output is a zoomed-in view of a specific case layered on the map. The data and corresponding map visualization are hosted on GitHub and are published with GitHub pages.

Ethical Considerations

Ethics approval was not required due to the use of publicly available media reports and a Wikipedia repository to create the map.

Results

The publicly accessible map and data can be viewed on the web [6]. The heat map displays a worldwide overview of 104 cases from June 2014 through August 2023 (Figure 1 [7-9]). Once the user scrolls, the map displays 11 chapters, each showing an individual selfie-related incident in Australia including 9 deaths and 2 serious injuries. All cases reportedly involved emergency services, 3 of which occurred in the same location: Diamond Bay, Vaucluse, a suburb of Sydney, New South Wales. Two cases occurred at Gibraltar Falls, Australian Capital Territory. Further cases in Australia that are included in the map story are detailed in Multimedia Appendix 1.

Figure 1. (A) Image taken from the web-based site heat map of worldwide selfie-related incidents. The image provides a worldwide overview of incidents based on the obtained media data used in this study. (B), (C), and (D) Example images acquired from the web-based site. These images illustrate the scrolling story of the heat map focusing on a location that has seen selfie-related incidents. Each incident is indicated in a "chapter," which provides a description of the incident in that location and a link to the corresponding news report. Images were acquired from Mapbox [7] and OpenStreetMap [8]. OpenStreetMap is licensed under the Open Data Commons Open Database License [9].


Discussion

Our heat map of media-based incident data provides a globally applicable visual representation of the selfie-incident phenomenon in Australia. Using a scrolling story template, overlayed on top of a map, selfie incidents can be illustrated in a geographic context. It is clear from the heat map that certain locations worldwide (nations such as India) and in Australia (cities such as Sydney) require specific and targeted prevention strategies to attenuate the incidence of selfie incidents, which is in line with their specific topographical realities.

Future research in this space should seek to further ascertain the burden on emergency and retrieval services by evaluating response times, resource allocation, retrieval or rescue methods, and health care costs associated with treating selfie-related injuries. Geographic disparities in service usage and response times, terrain, and retrieval or rescue methods should be identified and added to the visual map.

Understanding the geographic distribution and burden of selfie-related incidents is essential for designing targeted public awareness campaigns, improving safety regulations, and optimizing the allocation of resources for emergency and retrieval services.

The main limitation results from the use of media cases as the basis of these incident reports. It is not possible to acquire precise latitude and longitude coordinates. The coordinates provide the best approximation using details provided in media reports and analyzing the geography described in the report. Nevertheless, this map provides a good overview of the geographic nature of selfie-related incidents. Given the ethical limitations regarding the use of coronial data and identification of individual incidents, publicly available information of this nature remains the most appropriate data source.

In conclusion, selfie-related incidents present a significant geographic challenge for emergency services and retrievalists due to the inherent geographic context surrounding this type of event. Mapping selfie events may be a useful method of analyzing and tracking these phenomena and may be of benefit to emergency managers and land managers in collaborating to attenuate this issue.

Data Availability

All data are publicly available and can be found in a GitHub repository [10].

Introduction

It is well known that health care spending in the United States is much higher than similar countries but that this does not result in better health outcomes [1]. Research has shown that this higher spending is driven by high prices rather than greater utilization of care [2]. Until recently, publicly available information on health care prices has been scarce [3,4]. This began to change when the hospital price transparency (HPT) went into effect on January 1, 2021 [5].

HPT requires hospitals to post prices or negotiated rates of common, "shoppable," services, as defined by the Centers for Medicare and Medicaid (CMS), in a machine-readable format. Examples of these shoppable services include common blood tests and radiology services such as X-rays and mammograms. In July 2022, the CMS also mandated that payers post the prices for a more expansive set of services, under the Transparency in Coverage (TIC) regulation [6]. Thanks to HPT and TIC, health care prices are no longer hidden from the public.

CMS's stated goal [5,7] for these transparency initiatives is to help inform consumers about the cost of medical services prior to receiving them, as this information can help people make informed decisions about where they receive services. Additionally, transparency about prices could lead to greater competition and potentially lower prices and health care spending.

These transparency initiatives can be impactful if people are aware that they can access information on health care prices for decision-making, especially for shoppable services with comparable quality across providers. This impact is only actualized if hospitals comply with CMS requirements to provide complete and accurate data on prices in a timely manner.

This paper aims to examine whether people are aware that they can look up prices of health care services prior to receiving care, and whether this newly available information is being used.

Methods

Overview

The data for this study come from a nationally representative survey conducted by Gallup in partnership with West Health Institute from November 2023 through January 2024 that included 5149 randomly selected adults aged 18 years and older from across all 50 states and the District of Columbia from the Gallup Panel [8].

Ethical Considerations

The survey received ethical approval from Gallup's internal institutional review board for all human subject and external reporting considerations (2023-10-04). Participation in the survey was voluntary. All the responses were deidentified and no personal health information or other sensitive personal information was shared with the authors. Web respondents were offered an incentive of $5 while mail respondents were offered an incentive of $2.

Survey

The survey response rate was 38%. Further details on the sampling strategy are in Multimedia Appendix 1. The survey consisted of questions on people's experiences and perceptions of health care in America. For this study, we focus on four questions: respondents' (1) awareness of, (2) use of, and (3) and (4) opinions about compliance with price transparency laws. Percentages were estimated as the count of responses divided by the number of respondents, multiplied by 100. Probability

sampling weights provided by Gallup were used to weight the estimated percentages and to calculate the population estimates.

Results

Low Awareness of Price Transparency

Almost three-quarters of respondents (73%) were not aware that they could look up prices for common health care services provided by hospitals. Men were less likely (77%) than women (70%) to be aware of HPT. Lack of awareness was similar across all ages (Table 1).

Table 1. Awareness of price transparency.

Characteristics	Responses, %		Population size, N
	Yes	No	
Are you aware that hospitals are required to post prices on their website?			
Full sample (n=4946)	27	73	248,092,303
Gender			
Male (n=2513)	23	77	124,047,066
Female (n=2371)	30	70	118,640,004
Race			
White (n=3091)	28	72	194,419,832
Non-White[a] (n=1827)	23	77	51,826,750
Age (years)			
18-29 (n=345)	27	73	43,876,733
30-39 (n=619)	27	73	44,685,260
40-49 (n=576)	25	75	41,625,267
50-64 (n=1551)	25	75	60,433,949
65 years and older (n=1855)	29	71	57,471,094
Have you ever looked up the price of a healthcare service before going to a hospital ?			
Full sample (n=4954)	19	81	248,212,278
Gender			
Male (n=2523)	21	79	123,971,168
Female (n=2369)	16	84	118,835,877
Race			
White (n=3096)	23	77	194,756,253
Non-White (n=1830)	18	82	51,610,304
Age (years)			
18-29 (n=346)	29	71	43,614,198
30-39 (n=620)	23	77	44,980,477
40-49 (n=575)	20	80	41,553,530
50-64 (n=1554)	16	84	60,512,956
65 and older (n=1859)	11	89	57,551,117

[a]The category "non-White" is used because there was 1 race/ethnicity variable instead of 2 separate variables for race and ethnicity. The non-White group included a mix of races and ethnicities.

Limited Use of Price Transparency Data

Less than 20% of respondents said they had looked up the price of a medical service prior to their visit. Younger respondents (age 18-29 years; 29%) were more likely than older respondents (aged ≥65 years; 11%) to have ever looked up a price prior to going to a hospital.

Opinions About Enforcing Compliance

Overall, 78% of respondents preferred stricter penalties for hospitals that have not yet released their prices, and only 26% were in favor of CMS allowing hospitals more time to comply with the HPT requirements (Table 2).

Table 2. Opinions on enforcement of price transparency rules.

Characteristics	Responses, %			Population size, N
	Disagree or strongly disagree	Neutral	Agree or strongly agree	
The federal government should impose and enforce stronger penalties on the hospitals that have not made their negotiated prices public.				
Full sample (n=5004)	5	17	78	249,963,323
Gender				
Male (n=2534)	7	19	75	124,394,088

Race				
White (n=3122)	6	16	78	195,617,984
Non-White[a] (n=1854)	5	18	78	52,499,618
Age (years)				
18-29 (n=348)	3	18	79	44,314,231
30-39 (n=617)	5	13	81	44,620,889
40-49 (n=575)	5	15	79	41,571,949
50-64 (n=1571)	6	17	77	61,030,674
65 and older (n=1893)	6	18	75	58,425,579
The federal government should allow more time for hospitals to comply before strictly enforcing the law.				
Full sample (n=4958)	51	23	26	248,828,600
Gender				
Male (n=2510)	46	26	28	123,838,600
Female (n=2386)	56	20	23	119,584,767
Race				
White (n=3102)	54	23	23	195,228,742
Non-White (n=1828)	40	24	36	51,754,137
Age (years)				
18-29 (n=347)	45	24	31	44,180,940
30-39 (n=618)	56	20	23	44,916,392
40-49 (n=576)	57	23	20	41,625,267
50-64 (n=1557)	55	20	24	60,693,140
65 and older (n=1860)	45	27	28	57,412,860

[a]The category "non-White" is used because there was 1 race/ethnicity variable instead of 2 separate variables for race and ethnicity. The non-White group included a mix of races and ethnicities.

Discussion

Increased price transparency has the potential to increase competition and decrease health care spending in the United States [3,4,9]. It can also help consumers of health care make informed decisions [5]. We found limited awareness and use of HPT data among the public, but there is a strong desire for transparency in health care prices. It should be noted that these findings are based on self-reported data and might differ from actual awareness and use of HPT. The CMS should improve compliance among hospitals by aggressively enforcing the existing penalties [10]. Public awareness efforts could also lead to increased use by consumers.

Conflicts of Interest

YP is an employee of Gary and Mary West Health Institute. DM is the founder and CEO of Simple Healthcare. Both organizations have a goal of lowering health care costs in the United States.

Abstract

The psychological well-being of astronauts is becoming just as vital as their physical and technical readiness as space missions extend into deep space. Long-duration missions pose unique challenges, such as isolation, confinement, communication delays, and microgravity, which can significantly affect mental health and cognitive performance. This commentary discusses the need for innovative mental health support systems, including automated psychotherapy, as well as Earth-based training methods like mindfulness and relaxation techniques, to address the psychological demands of space travel. By integrating these approaches into pre-mission preparation and in-flight routines, astronauts can develop self-regulation strategies to manage stress, improve focus, and enhance emotional resilience. Automated psychotherapy available 24-7 provides real-time confidential support when communication with Earth is delayed. As space exploration moves forward, the success of missions will depend not only on technological advancements but also on the development of psychological countermeasures that prioritize mental health alongside physical well-being. This paper emphasizes the importance of continued research and collaboration to refine and test these tools in analog environments, ensuring astronauts are mentally and emotionally prepared for the challenges of space.

Introduction

The manuscript "Automated Psychotherapy in a Spaceflight Environment: Advantages, Drawbacks, and Unknowns," written by Smith [1], explores the potential of automated psychotherapy to address the mental health challenges faced by astronauts during space missions. This technique could be highly relevant for human space exploration, particularly in overcoming delayed communication issues in long-distance missions. However, further research is needed in this field, which represents a new frontier in both space exploration and mental health care.

Psychological Aspects of Space Exploration

As humanity pushes further into space, the psychological well-being of astronauts becomes as critical as the technical aspects of a mission [1]. Long-duration missions, including those on future Mars and lunar habitats, present unique challenges beyond just the physical demands [2]. Astronauts face months, even years, of isolation, confinement, communication delays, and microgravity in an extreme environment that is, from multiple perspectives, "hostile" to human life. These factors can impact mental health; cognitive performance; and, ultimately, mission success [3].

Astronauts are highly trained individuals, but they are still human. Prolonged isolation and distance from Earth, coupled with the stress of living and working in space, can lead to undesirable psychological reactions and reduced cognitive function [4,5]. As missions become longer and more distant, space agencies need to consider not only the physical but also the psychological needs of astronauts to ensure that they can function at their best.

Psychological Support in Space

Providing psychological support during space missions is not a new concept [6], but as missions extend into deep space, the challenges become more complex. Traditionally, astronauts have had access to Earth-based psychologists via private communications. Private consultations and ongoing support can help manage interpersonal tensions, alleviate feelings of isolation, and address stress in real time. While this has worked well for missions in low earth orbit, such as those aboard the International Space Station, long communication delays in deep space are expected to make this system less effective [2]. For example, a Mars mission could experience a communication delay of up to 30 minutes each way. In such cases, astronauts need tools that allow for real-time mental health support, including the possibility of an automated psychotherapy system. This is also where pre-mission psychological training and on-demand support systems come into play. These include resilience training, team dynamics workshops, and tailored psychological tools that astronauts can access during the mission.

Mindfulness and Relaxation: Key Tools for Managing Stress

One promising approach to managing stress during long missions is through mindfulness and relaxation techniques [7]. These practices have been shown to substantially reduce stress, enhance focus, and improve emotional regulation, making them valuable tools for astronauts facing long-term isolation and confinement. Mindfulness encourages individuals to stay present and manage stress without judgment, which can be particularly helpful in an environment where stressors are constant and inevitable. Astronauts trained in mindfulness techniques are expected, according to subject matter experts, to handle stress more effectively, maintaining mental clarity and decision-making abilities even in high-pressure situations [8]. Recently, mindfulness disposition has been demonstrated as a protective factor against stress in an analog environment, the Concordia base in Antarctica [9].

Relaxation training, such as diaphragmatic breathing and progressive muscle relaxation, can also play an important role. These techniques can reduce physiological stress, promote better sleep, and help astronauts manage their emotional responses to challenging situations. Given the stressful and sometimes monotonous environment of space, these practices offer simple yet powerful ways to maintain both mental and physical well-being [7].

By integrating mindfulness and relaxation into astronauts' training, space agencies can equip them with effective self-regulation tools to help manage the ongoing psychological demands of space missions. These methods are not only noninvasive but also easy to practice, making them ideal for space, where time and resources are limited.

The Role of Automated Psychotherapy in Space

With communication delays limiting real-time support from Earth, automated psychotherapy offers a crucial solution for mental health care during space missions. These systems can provide astronauts with immediate access to cognitive behavioral therapy and other interventions tailored to their specific needs and the unique stresses of space travel. One of the most compelling aspects of Smith's [1] manuscript is the focus on how automated psychotherapy could overcome the challenges of delayed communication in deep space missions. This is particularly relevant as human space exploration moves toward Mars and beyond, where real-time communication with Earth will no longer be possible. Smith's [1] work provides a strong foundation for understanding the psychological complexities of long-duration missions, particularly the potential for automated systems to fill gaps in mental health support when traditional Earth-based therapy is not feasible.

Automated psychotherapy tools also offer additional advantages. They are available 24-7, offering astronauts confidential on-demand support. This is particularly useful for addressing sensitive issues that astronauts might not feel comfortable discussing with crewmates or mission control. These systems can guide astronauts through therapeutic exercises, helping them manage anxiety, stress, or feelings of isolation as they arise. Furthermore, automated systems can be integrated with other mental health tools, such as mindfulness and relaxation practices, creating a comprehensive mental health support network. This combination of tools ensures that astronauts can address both immediate psychological needs and long-term mental health maintenance without relying on Earth-based professionals. As these systems are refined, they have the potential to become a critical component of mental health care for long-duration missions.

Conclusion

As space exploration advances into longer, more isolated missions, the psychological and human aspects of space travel become increasingly critical. The challenges of isolation, stress, and confinement in space demand innovative solutions that go beyond traditional mental health support [2].

The integration of automated psychotherapy, as well as newly developed training techniques (eg, mindfulness and relaxation training), offer a proactive and effective approach to safeguarding astronaut mental health. By providing astronauts with these essential tools, space agencies can ensure that crews are not only physically prepared but also mentally resilient, capable of adapting to the extreme demands of long-duration missions. The success of future space exploration, however,

will depend on our collective commitment to supporting the psychological well-being of astronauts. The development, testing, and refinement of these psychological tools in analog environments are imperative. As we advance into the next phase of space exploration, space agencies, researchers, and innovators need to work together to ensure that mental health receives the same attention as physical and technical preparation, helping astronauts thrive on their journeys into the unknown.
