The searches included peer-reviewed original and review papers published from 1997 to 2024. According to the search string applied, the earliest accessible indexed record from WoS dated back to 1997. Therefore, 1997 was used as the initial cutoff point for inclusion. Two independent researchers (AK and EK) carried out the searches, and the retrieved data were evaluated independently on a Microsoft Excel database for relevance to the study scope. Search strategies were based on a literature review, and the search prompt was created with search strategies, such as (TI=("exergame*" OR "gamercising" OR "exergaming" OR "gamercize*" OR "active video game*")). The detailed search strategy appears in Multimedia Appendix 1. The WoS search resulted in 2663 studies. No language restrictions were applied.

As part of the data cleaning process, duplicate records were removed (n=2), and author names, affiliations, and journal titles

XSL•FO
RenderX

were manually reviewed and standardized by 2 researchers to ensure consistency and reduce misclassification. Studies without accessible abstracts or full texts, those published from 2025 onward (n=5), and gray literature (n=1030) were excluded. Gray literature refers to academic work available in journals, books, print, or electronic formats that may be used commercially and are not controlled by publishing entities [32]. Ultimately, 1626 records were included in the analysis.

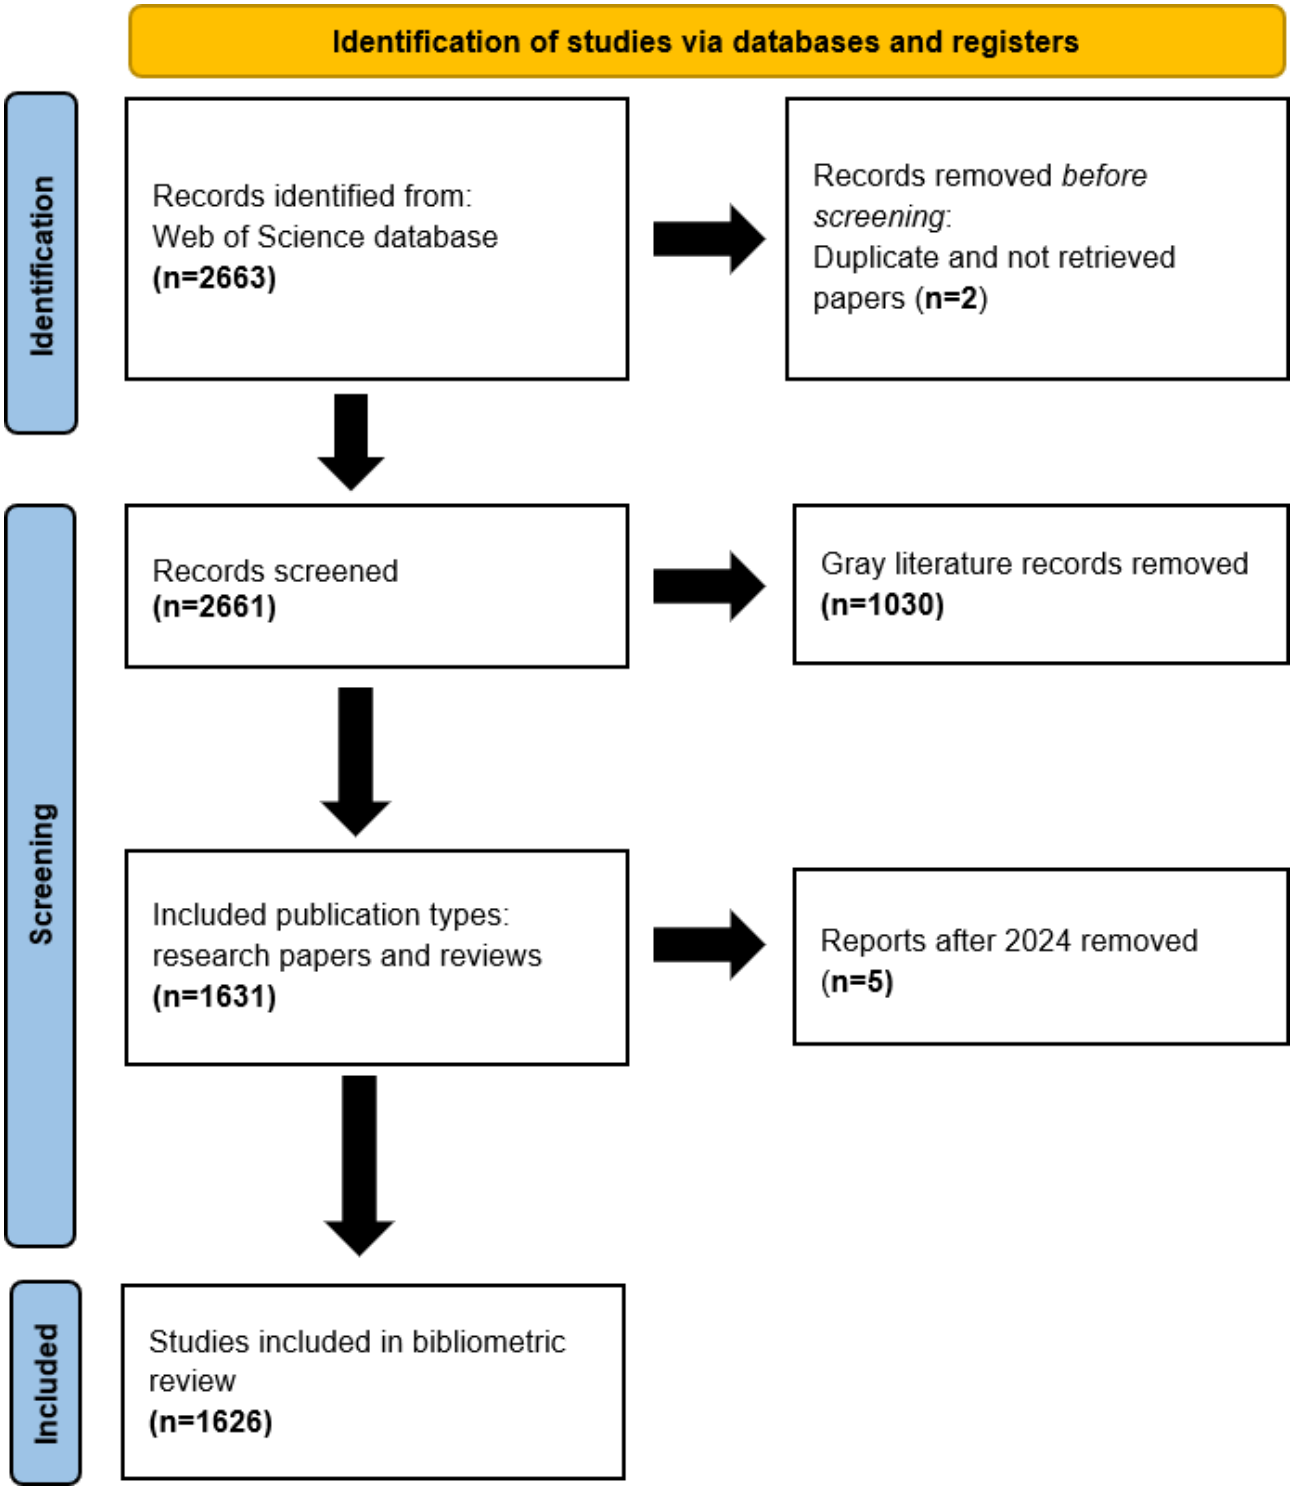
Data Analysis and Visualization

Studies meeting the data processing criteria were imported into the user-friendly Biblioshiny interface via R Studio. The analysis evaluated the impact of sources by examining paper counts, h-indexes, total citation (TC) counts, and citations per publication. The h-index is a key metric for assessing the impact of an author or journal [33]. Citations play a critical role in measuring the influence of sources within a research field. Network metrics, such as modularity (Q) and network density, were also used to evaluate the frequency of relationships and clustering structures. A modularity value between 0.4 and 0.8 indicates a well-structured clustering network [34]. Finally, social network analysis was used to visualize the actors and relationships in exergaming research.

Ethical Considerations

Ethics approval was not required for this study, as human participants were not involved.

Results



Descriptive Statistics in the Field of Exergaming

The data for the 1626 included studies are presented in Multimedia Appendix 2 and are outlined in the data collection flow diagram (Figure 1).

Table 1 provides information on the key descriptive statistics regarding studies conducted in the exergaming field. The research in this area comprises 1626 documents sourced from 553 different outlets between 1997 and 2024. The annual growth rate of publications is 22.07%, with an average document age of 5.7 years. Notably, each study has received an impressive average citation rate of 21.95%. While there are 38 single-authored documents, 6556 authors have contributed to the field, predominantly through papers (n=1402) and reviews (n=224). The rate of international author collaboration is 26.88%, with an average of 5.57 authors per document. Additionally, 2917 keywords provided by the authors enhance the richness of the dataset. Finally, the 1626 documents have been cited 45,050 times in studies indexed on WoS.

Information	Values
Timespan (years)	1997 - 2024
Sources (frequency distribution), n	553
Documents, n	1626
Annual growth rate (%)	22.07
Authors of multiauthored documents, n (%)	6556 (99.4)
Authors of single-authored documents, n (%)	38 (0.6)
International coauthorship (%)	26.88
Coauthors per document (average), n	5.57
Author's keywords, n	2917
References, n	45,050
Document age (average), n	5.7
Citations per document (average), n	21.95

Annual Scientific Production and Average Citations Per Year

Figure 2 shows that studies on exergaming began at very low levels in 1997, experienced significant growth starting in 2015, and peaked in 2021. Although there was a slight decline in 2022, scientific output continued in 2023 and 2024. It has been observed that the studies conducted in the field of exergaming and the average citation counts to these studies are not parallel, and there is a decrease in the average citation counts, unlike the number of publications.

Figure 2. Evaluation of exergaming studies by years and average citations per year.

The Most Effective Journals in the Field of Exergaming and Bradford's Law

An examination of the most relevant journals in the field of exergaming reveals that *Games for Health Journal* ranks first with 139 papers (Tables 2 and 3). This journal is followed by *JMIR Serious Games* with 63 papers. When evaluating the journals with the highest number of citations, *Games for Health Journal* once again tops the list with 1885 citations, followed by *Medicine & Science in Sports & Exercise* with 1241 citations. The local impact and impact factors of the top journals on exergaming are presented in Multimedia Appendix 3. According to the findings of Bradford's law, *Games for Health Journal* occupies a larger share among the core sources compared to other journals and is positioned within the first core group of journals. It is followed by *JMIR Serious Games* and the *International Journal of Environmental Research and Public Health*. The findings for Bradford's law are presented in Multimedia Appendix 4.

Table . Most relevant journals.

Authors' Productivity and the Distribution of Their Productivity Over the Years

Figure 3 shows the publication performance of the most productive authors on exergaming over the years. Gao Zan (n=36) and Eling de Bruin (n=36) are the most productive authors in this field and continue to work on related studies. The analysis of author productivity based on Lotka's law reveals that 79.74% (n=5226) of exergaming researchers have contributed with only 1 publication, 12.85% (n=842) have contributed with 2 publications, and 3.74% (n=245) with 3 publications. These findings do not fully align with Lotka's law. The findings on Lotka's law are presented in Multimedia Appendix 5.

XSL•FO
RenderX

Trending Topics

Figure 4 presents the trending topics in exergaming research over time, showing how these topics have changed over the years. Topics such as “health,” “physical activity,” “exercise,” “virtual reality,” and “obesity” have typically been focal points in this field. In recent years, topics such as “medicine,” “information technology,” and “intention” have emerged.

XSL•FO
RenderX

Figure 4. Popular exergaming topics by year.

Thematic Mapping

Figure 5 illustrates the development and centrality degrees of exergaming research themes. Motor themes represent well-developed and highly relevant core topics in exergaming research. No specific terms were identified in this region.

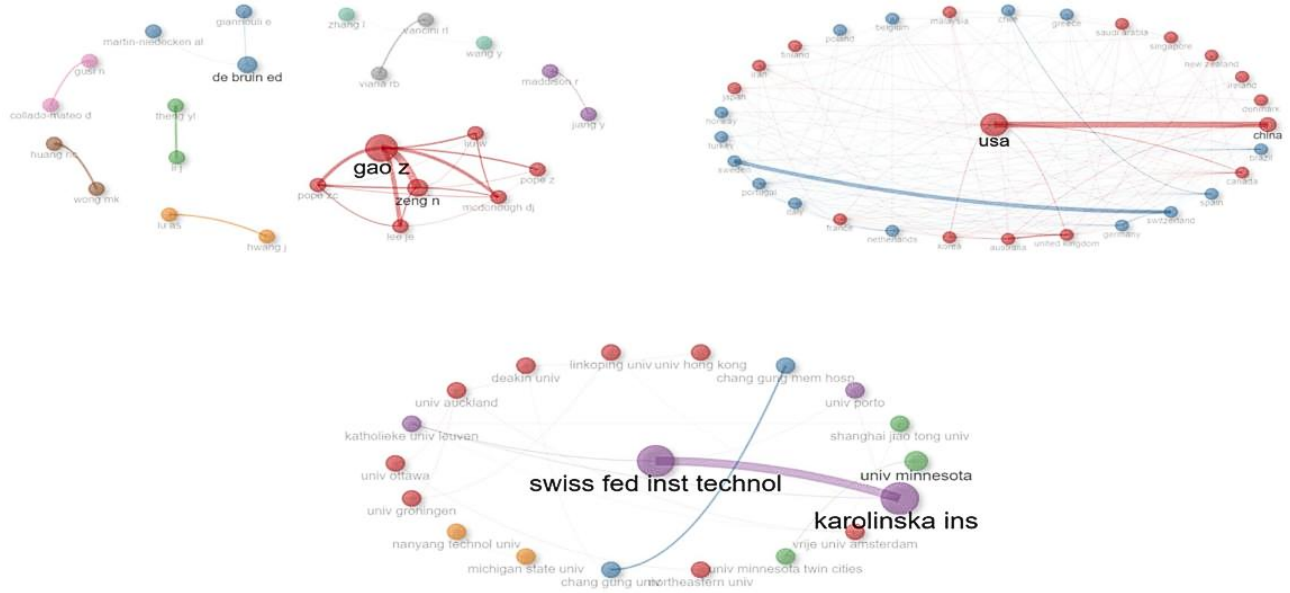
Basic themes encompass topics with high centrality but low density. These themes are foundational to research and represent broadly discussed areas. Notable terms in this region include “randomized controlled trial,” “virtual reality,” “physical activity,” “active video,” and “pilot study.”

Niche themes refer to topics with low centrality but high density. These themes represent specific research topics and specialized subfields within the domain. Terms such as “autism spectrum,” “randomized crossover,” and “neurocognitive disorder” are prominent in this region.

Emerging or declining themes are characterized by low centrality and low density. These themes represent either emerging or diminishing areas of interest in exergaming research. Notable terms in this region include “Wii fit” and “physical education.”

XSL•FO
RenderX

Figure 5. Thematic map findings for exergaming research.



Collaboration

Figure 6 shows the most productive countries, the most productive authors, the most productive institutions, and the connections between them in exergaming research. One of the largest nodes on the graph, Gao Zan, is seen to collaborate closely with Zeng Nan, indicating that they have conducted many studies together. In terms of collaborations between countries, the United States is at the center, showing a strong collaboration with China. Leading institutions include the Swiss Federal Institute of Technology (ETH Zurich) and the Karolinska Institute, which have been very active and show strong relationships between them.

XSL•FO
RenderX

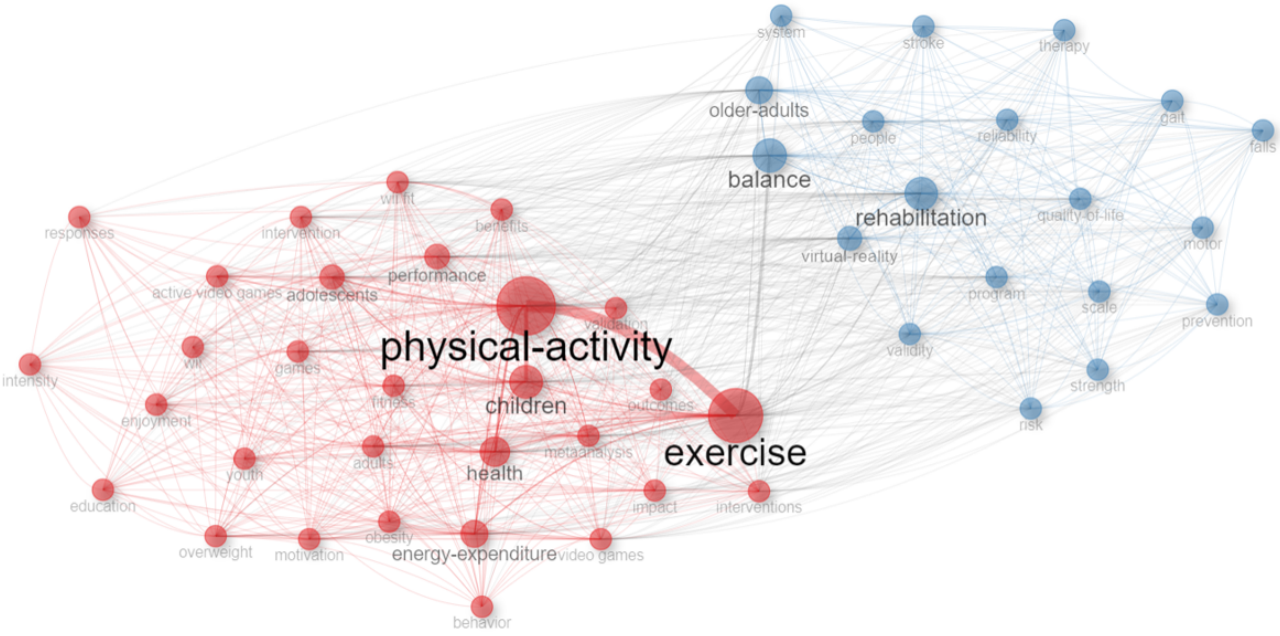


Figure 6. Collaborative network of researchers, countries, and institutions on exergaming.

Coword Network

Figure 7 presents a coword analysis based on the frequency of terms used in the titles, keywords, and abstracts of the 1626 included studies, highlighting the most prominent concepts in the field and the relationships between them. Using word cloud analysis in Bibliometrix, the main themes and concepts driving exergaming studies were identified, with PA (n=436), exercise (n=383), rehabilitation (n=218), and balance (n=213) ranking as the most prominent. The high frequency of these terms indicates their central role in exergaming research. Then coword analysis showed that the studies in the field are divided into 2 main clusters. Cluster 1 focuses on PA, exercise, performance, health, and health-related concepts, with these studies primarily targeting children and adolescents. Cluster 2, on the other hand, provides insights into studies focused predominantly on adults and older people, emphasizing rehabilitation, balance, and strength, highlighting the interconnectedness of these concepts.

Figure 7. Coword analysis of exergaming studies.

Discussion

Principal Findings

This bibliometric analysis has revealed a significant increase in exergaming research since 2010, peaking during the 2020‐2021 period. Thematic analyses demonstrate that exergaming research is inherently interdisciplinary and spans areas such as health, rehabilitation, and behavior change. Collaboration patterns and trend analyses highlight the potential of exergaming to address broader health challenges, providing critical insights to guide future research directions.

Annual Scientific Production in Exergaming Research

The annual production of scientific publications on exergaming has shown significant growth since 1997, following the release

XSL•FO
RenderX

of the Dance Dance Revolution. A prior bibliometric study focusing on VR, AR, and PA observed a similar growth trend, consistent with our findings [26,43]. A significant increase in publication volume has been observed since 2015, with scientific production peaking in 2020 - 2021. This growth reflects advancements in VR and AR technologies as well as increased investments in health-focused gaming applications and the growing role of technology-assisted interventions in health care services [21,44]. Furthermore, this rise can also be attributed to the COVID-19 pandemic, which highlighted the need for home-based solutions to maintain PA, thereby amplifying the significance of exergaming research [45,46]. After 2002, the average citation rate dropped sharply and did not follow a trajectory parallel to the increase in the number of publications. A possible explanation for this is that the growth in the number of studies within the exergaming field led to citations being distributed across a broader range of research. As the field expanded, citations may have been spread among a larger body of work, diminishing the citation impact of earlier studies.

Journals, Authors, and Papers Featured in Exergaming Research

Games for Health Journal, *International Journal of Environmental Research and Public Health*, and *JMIR Serious Games* are leading journals for exergaming research in health and education. These leading journals are essential platforms that facilitate the dissemination of innovative studies, promote interdisciplinary collaboration, and shape the applications of exergaming in improving health and PA outcomes [12,47,48]. According to Bradford's law, this finding indicates that most of the exergaming research is concentrated in a few core journals, while the remaining publications are distributed across a broader range of sources [49].

When examining the publication performance of the most prolific authors in the field of exergaming, a few notable names stand out, such as Gao Zan and Eling de Bruin. The continued production of relevant research by these authors, along with their numerous publications and high citation frequency, highlights their significant roles in the field of exergaming. According to Lotka's law, about 60% of researchers are expected to contribute with a single publication, 15% with 2 publications, and 6.67% with 3 publications [50]. Considering Lotka's law, which reveals the scientific productivity of authors in the field of exergaming, it can be concluded that researchers generally prefer to conduct a single study on this topic, and the number of authors specializing in the field remains limited. This shows that the literature in this field still has room for improvement.

The most cited on exergaming is Biddiss and Irwin's paper [35], which received 386 citations in total. This paper reviews the potential of exergaming to promote PA among children and adolescents and possibly lays the groundwork for further studies by emphasizing the positive effects of exergaming on child health [35]. Another influential paper is the paper by Ijaz et al [5], which received 345 citations and had the highest annual citation rate of 57.5. This study investigates how VR exergaming increases participants' motivation and enjoyment [5]. The high citation counts of these papers demonstrate their important contributions to the field of exergaming and their role as key reference points for other researchers.

Hot Spots in Exergaming Research

In the analysis of trending topics, early studies primarily concentrated on terms such as "obesity," "childhood," and "video games," whereas more specific topics like "virtual reality," "physical activity," and "rehabilitation" have gained prominence over time. This shift reflects the integration of advanced technologies and broader health applications into the field [51]. Furthermore, the rising frequency of terms such as "adolescents" and "adults" indicates a widening demographic focus, extending beyond children to include populations of different age groups. This evolution demonstrates the expanding scope of exergaming research, moving from a niche focus on childhood health to a broader application in preventive health care [52], rehabilitation [15], and lifestyle improvement. Finally, terms such as "intention" and "medicine" have more recently started to receive increasing attention, indicating that exergaming is being increasingly explored for behavior change and clinical interventions. Future studies could further enhance its impact by addressing less-explored topics and demographic groups.

Thematic analysis results reveal that fundamental themes, such as "virtual reality," "randomized controlled trials," and "physical activity," constitute the main research topics in exergaming, particularly focusing on health and rehabilitation applications.

Niche themes, including "crossover trials" and "autism spectrum disorders," delve into specialized research areas, allowing for in-depth studies on specific disease groups and research methods [53]. Themes such as "Wii Fit" and "physical education" efforts for school children represent topics that once gained popularity in exergaming research but have lost attention due to technological advancements and shifting research priorities. Future studies could explore niche themes in greater depth to discover new application areas and diversify basic themes to expand the potential of exergaming to broader audiences.

Author, Country, and Institutional Collaborations in Exergaming Research

Authors such as Gao Zan and Zeng Nan are notable for their extensive collaborations, which may stem from their shared interest in studying the effects of exergaming on health and PA. Furthermore, 26.88% (n=437.07) of the 1626 studies in the field of exergaming had international author collaborations, indicating that more than 1 researcher worked together.

The United States stands out as the most productive country, maintaining strong collaborations with many other nations. China also plays a crucial role, collaborating closely with the United States. These collaborations have facilitated extensive research on exergaming, supported by substantial scientific research funds, robust research infrastructures, and leading technological advancements. Our findings are consistent with bibliometric studies focusing on technologies like VR and AR, commonly used in exergaming applications [26,27].

Leading institutions like the Swiss Federal Institute of Technology (ETH Zurich) and Karolinska Institute are at the

XSL•FO
RenderX

forefront of this field. ETH Zurich, recognized for its expertise in technology and engineering, contributes considerably to the development and application of exergaming devices [54], while Karolinska Institute is prominent in medical research and clinical applications [55]. These institutional collaborations result in extensive and impactful studies investigating various applications of exergaming in fields such as health care and rehabilitation.

Future Research Suggestions

First, previous literature has shown that group-based exergames enhance motivation, promote sustained play, and improve self-efficacy. Family-friendly games like Ring Fit Adventure have the potential to increase PA while strengthening parent-child bonds. Future research should investigate the impact of these games on family dynamics and address critical issues such as "adherence," "sustainability," and "transfer effects." Second, significant increases in energy expenditure as a result of exergaming might be of little importance if one compensates by increasing energy intake. Therefore, promoting exergaming as an obesity prevention tool also requires the quantification of energy intake to adequately assess overall energy balance. Without considering both sides of the equation, energy expenditure and intake, it is difficult to determine the true effectiveness of exergaming in managing or preventing obesity. Future studies should incorporate both metrics to provide a clearer understanding of exergaming's potential health benefits. Third, exergaming has not been widely used in young children such as preschoolers; thus, it needs more research in this population. Fourth, with the advancement of technology and the introduction of new active video games, it is important to explore how these new games can promote PA and other health-related outcomes. Fifth, research could examine how exergaming can be integrated with technological advances and the potential benefits of this integration in health and education. Sixth, more research is needed on the social impacts and community-based applications of exergaming. Finally, further research on the economic issues and financial sustainability of exergaming is critical to assess its cost-effectiveness, economic benefits, and investment opportunities.

Limitations

This study has various limitations. First, only the WoS database was used because the robust analytical capabilities of the Bibliometrix R package with WoS data enhanced the reliability of our results, and WoS's "Keyword Plus" feature identified contextually significant keywords, thereby broadening the scope of the study. However, relying on a single database may exclude relevant sources from other databases, which is considered a limitation. Second, the R-based Bibliometrix tool was used for the analysis and visualization processes in this study, as it provided a sufficient platform aligned with the study's scope without incurring additional software costs. However, the exclusion of additional features offered by alternative software is considered a limitation of this study. Third, the metrics and indicators used, such as citation counts, journal impact factors, and authors' h-indexes, may not fully capture the quality of the research and potentially overestimate the impact of particular studies [56]. Finally, bibliometric methods provide an overview of a research field; however, this study does not offer an in-depth analysis of influential papers and authors. To gain a more comprehensive understanding of research impact and trends, bibliometric analyses should be complemented with other evaluation methods.

Conclusions

This study highlights the growing importance of exergaming research as a key indicator of the increasing integration of technology into the health domain. The COVID-19 pandemic has especially highlighted the value and relevance of home-based solutions in this field. The interdisciplinary nature of exergaming offers significant potential for the development of innovative approaches by bringing together technology and health applications. The thematic evolution of research demonstrates that exergaming has progressed beyond being merely a tool for children's entertainment or PA promotion, expanding into broader health contexts such as rehabilitation, behavior modification, and applications for diverse age groups. This trend suggests that exergaming could play a more active role in public health policies in the future. Future research focusing on underexplored demographic groups, emerging technologies, and niche health applications is likely to further enhance the impact of exergaming.

Abstract

Background: Psychoeducation positively influences the psychological components of chronic low back pain (CLBP) in conventional treatments. The digitalization of health care has led to the discussion of virtual reality (VR) interventions. However, CLBP treatments in VR have some limitations due to full immersion. In comparison, augmented reality (AR) supplements the real world with virtual elements involving one's own body sensory perception and can combine conventional and VR approaches.

Objective: The aim of this study was to review the state of research on the treatment of CLBP through psychoeducation, including immersive technologies, and to formulate suggestions for psychoeducation in AR for CLBP.

Methods: A scoping review following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines was performed in August 2024 by using Livivo ZB MED, PubMed, Web of Science, American Psychological Association PsycINFO (PsycArticle), and PsyArXiv Preprints databases. A qualitative content analysis of the included studies was conducted based on 4 deductively extracted categories.

Results: We included 12 studies published between 2019 and 2024 referring to conventional and VR-based psychoeducation for CLBP treatment, but no study referred to AR. In these studies, educational programs were combined with physiotherapy, encompassing content on pain biology, psychological education, coping strategies, and relaxation techniques. The key outcomes were pain intensity, kinesiophobia, pain catastrophizing, degree of disability, quality of life, well-being, self-efficacy, depression, attrition rate, and user experience. Passive, active, and gamified strategies were used to promote intrinsic motivation from a psychological point of view. Regarding user experience from a software development perspective, user friendliness, operational support, and application challenges were recommended.

Conclusions: For the development of a framework for an AR-based psychoeducational intervention for CLBP, the combination of theories of acceptance and use of technologies with insights from health psychological behavior change theories appears to be of great importance. An example of a theory-based design of a psychoeducation intervention in AR for CLBP is proposed and discussed.

Introduction

Globally, 60%-80% of adults experience low back pain, with 10% developing chronic forms, of which 85% are classified as chronic nonspecific low back pain without a clear etiology [1]. Owing to the limited efficacy and adverse effects of pharmacological approaches, there is a need for nonpharmacological alternatives [2] to improve treatment outcomes [3] and develop effective behavioral interventions [4]. Treatment guidelines recommend behavioral modification, exercise, psychoeducation [5-7], and physiotherapy for trunk muscle strengthening [8-11] to reduce pain and disability.

Educational interventions for chronic low back pain (CLBP) provide knowledge about the condition, coping strategies, and physical activity [3,12], with the objective of enhancing the quality of life and symptom management by mitigating anxiety, kinesiophobia, hyperactive pain behavior, and depression, which are risk factors for pain chronification. Additionally, psychoeducation fosters self-efficacy to break the cycle between anxiety and pain [13,14].

Many traditional interventions to boost physical activity, which is key for CLBP treatment, rely on intention theories for modifying health behavior [15]. A prominent intention theory is the Unified Theory of Acceptance and Use of Technology 2 (UTAUT 2) by Venkatesh et al [16], which examines the acceptance and use of technologies. It has gained recognition in fields such as education, e-commerce, and health research with advancing health technology [17,18]. UTAUT 2 explains the formation of intention for technology use through the constructs of performance expectancy, effort expectancy, social influence, facilitating conditions, hedonic motivation, price value, and habit. These factors may also be useful for predicting the intentions of patients with CLBP toward educational technology adoption. Furthermore, insights from theories focusing on health behavior change may prove fruitful to consider when attempting to change health behavior through the use of a new technology. For instance, Schwarzer's Health Action Process Approach model [19], commonly used in health behavior interventions, highlights self-efficacy and outcome expectation. The Health Action Process Approach distinguishes between intention formation and implementation as well as between nonintenders, intenders, and actors, each requiring tailored interventions to promote self-efficacy, information, and support in implementation [20]. Another example is Michie's Behavior Change Technique (BCT) taxonomy with 93 BCTs outlining strategies for successful behavior change [21].

Immersive technologies can be characterized on the Reality-Virtuality Continuum by Milgram and Kishino [22]. They demonstrate visual display technologies ranging from real to virtual environments, including augmented reality (AR) and virtual reality (VR) [23-25]. AR enables the concurrent presence and interaction of digital and physical elements within real-world environments in real time. VR, in contrast, enables complete immersion in VR and represents the extreme of Milgram's continuum between reality and virtuality [26].

With regard to research in immersive technologies such as VR in the treatment of CLBP, VR-based treatments turned out to be promising in reducing acute, experimental, and chronic pain and can complement conventional CLBP treatments [27].

VR has proven effective in treating acute pain [24] by redirecting attention from unpleasant stimuli such as back pain to more pleasant visual, auditory, and tactile stimuli [27]. VR interventions were found to reduce pain intensity, catastrophizing symptoms, and psychological symptoms in patients with CLBP after one session through distraction, indicating the direct influence of VR on pain perception [26]. Other VR studies demonstrated the feasibility and efficacy of VR for CLBP as an alternative approach, such as VR applications with graded exposure during walking and grasping with integrated game design [28], self-administered VR therapy for CLBP at home [29], and its implementation even during COVID-19 [30]. A recent meta-analysis also showed that kinesiophobia and pain intensity in CLBP can be reduced through VR training [31].

Although there is some evidence for the safety and tolerability of VR treatment for CLBP, most studies lack methodological quality and results were limited to short-term effects. Studies on safety, acceptance, and satisfaction are lacking, including targeted investigations of the risks of spinal pain caused by VR [32]. Thus, while VR is promising in reducing CLBP symptoms, AR might offer additional benefits through the integration of physical and virtual elements, thereby reducing VR-associated discomfort. AR enables the coexistence and interaction of virtual and physical objects in real time in the real world, thus combining the advantages of VR while mitigating its limitations such as cybersickness and visual discomfort [33]. AR can enhance interaction, presence, intuitiveness, and pedagogical flexibility by enriching the real world with digital information, accommodating various learning styles, and facilitating teaching and learning [34]. Despite these presumed advantages of AR, to our knowledge, there are no empirical studies of AR-based treatment for CLBP.

In summary, pain treatment guidelines emphasize the key role of educational CLBP treatment to counteract psychological chronification and promote self-efficacy according to health behavior change models. Furthermore, when health behavior change is addressed using a new technology, a joint consideration of health psychological models with theories of acceptance from a technological perspective, like the UTAUT 2 [35], is considered useful for successful implementation. Existing studies with immersive technology [24,26-31] demonstrated positive effects for CLBP treatment in VR incorporating psychoeducational elements. However, these VR studies have methodological shortcomings and gaps regarding dimensions of user experience such as satisfaction and acceptance. Therefore, by formulating research questions using the PICO (Population, Intervention, Comparison, Outcome) framework, this scoping review aims to first examine research in patients with CLBP (P) receiving psychoeducation through immersive technology (I) compared to conventional psychoeducation (C) to improve pain relief and pain-psychological variables (O) and second on the basis of the results of the literature analysis, to develop an intervention design for AR-based psychoeducation in patients with CLBP that combines conventional methods with immersive technology

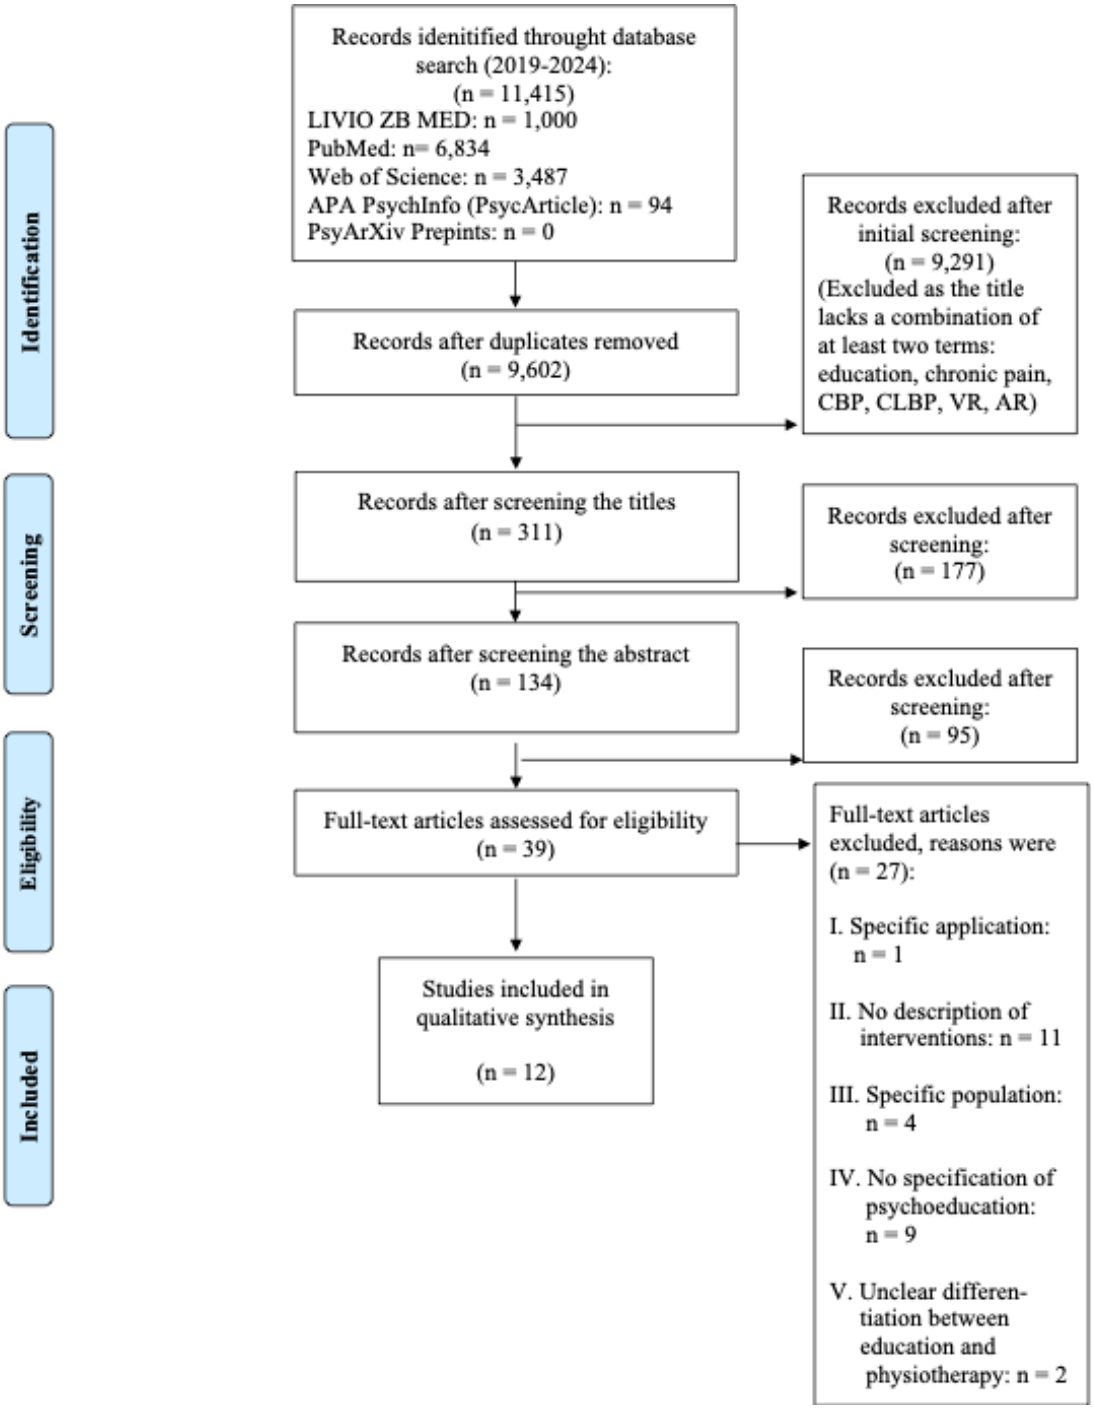
XSL•FO
RenderX

based on a technology acceptance model to promote acceptance and pain management.

Methods

We investigated the research question through a scoping review and followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) extension for scoping reviews [36]. This review includes studies that used psychoeducation for CLBP and chronic pain treatment: (1) conventionally, (2) with immersive technology in VR or AR, or (3) a combination of both, conventional therapy with VR or AR technology use. Only papers published in English or German in 2019-2024 were considered, wherein clinical guidelines were generally updated every 3-5 years with new evidence [37]. The exclusion criteria were as follows: (1) psychiatric patients, (2) acute back pain, (3) back pain after medical procedures, and (4) other specific pain conditions and pharmacological interventions. Scientific investigations or studies in journals or textbooks were included, regardless of the scientific methodology used. An electronic search was performed in August 2024 by using predefined English terms: ("chronic low back pain" OR "CLBP" OR "chronic pain") AND (("virtual reality" OR "augmented reality") OR ("education" OR "multimodal pain therapy" OR "psychological intervention")). Reviewer RC used Citavi to search for in vivo ZB MED and PubMed, and a manual search was conducted in the Web of Science, American Psychological Association PsycINFO, and PsyArXiv Preprints. The search was conducted in line with the Joanna Briggs Institute methodology for scoping reviews, extending the PRISMA statement [38]. In accordance with Arksey and O'Malley's [39] recommendations for scoping reviews, we did not include a formal quality assessment of the incorporated research. The selection process was initially based on a review of titles and abstracts regarding the inclusion and exclusion criteria, followed by an assessment of the full text by a reviewer (RC) and double-checked by another reviewer (ANT). Both reviewers (RC and ANT) extracted the following information from the included studies by using Microsoft Excel, following the Joanna Briggs Institute model: (1) citation, (2) context, (3) participant characteristics, (4) study aim, (5) methodology, (6) results, (7) interventions, (8) limitations, (9) key results related to review questions, and (10) future research areas [40]. Data analysis by the first reviewer (RC) utilized a qualitative content analysis [41]. A deductive approach was used to extract relevant categories for achieving the research objective. Guidelines for the treatment of CLBP [42] as well as recommendations of the World Health Organization for digital health interventions [43] served as the basis for this. Subsequently, 4 categories were extracted to capture all the essential aspects relevant to the design of the envisaged intervention. The categories are as follows: (1) content of CLBP-specific education, (2) factors based on the psychology of learning for the intervention design, (3) technical conditions (framework) for CLBP interventions, and (4) outcome measures of the educational interventions for CLBP.

Results



Study Selection

The study selection process, as shown in Figure 1, began with a database search that yielded 11,415 results. A total of 9602 titles were screened for the following terms: education, chronic pain, chronic back pain, CLBP, VR, and AR. The title should contain a minimum of 2 of the following keywords: education, chronic pain, chronic back pain, CLBP, VR, or AR; 9291 papers were excluded due to the lack of appearance of at least 2 of the defined terms. After applying the inclusion and exclusion criteria to 311 publications, 177 studies were excluded based on the titles and 95 were excluded based on the abstracts. After reviewing the full texts of the remaining 39 publications, 27 were excluded for (1) specific applications (eg, doctor-patient communication), (2) insufficient intervention descriptions, (3) overly specific populations (eg, elite athletes, primary school students, nursing staff), (4) unspecified psychoeducation (eg, cognitive behavioral therapy [CBT], cognitive functional training), and (5) unclear differentiation between education and physiotherapy in intervention design. Finally, the scoping review analyzed 12 publications, displayed in Table 1 [44-55].

The studies originated from Italy, Spain, the Netherlands, France, Chile, India, and Tunisia (8.33% each), Germany (25%), and the United States (16.67%). The review included 9 empirical studies (1 interview study, 8 interventional studies) and 3 reviews (1 systematic, 1 scoping, and 1 narrative review). All studies were peer-reviewed, except the narrative review. The results of the analysis of the 12 publications included are presented below according to the 4 defined categories.

Contents of CLBP-Specific Education

The systematic review evaluated clinical studies from 2011 to 2021 comparing pain education/CBT with conventional physiotherapy for CLBP [45]. Thirteen studies, including 12 randomized controlled trials with 1642 participants, were analyzed. Six studies demonstrated a significant reduction in pain compared with the control group. The review concluded that due to the multimodality and heterogeneity of treatments, no definitive statement can be made regarding the efficacy of pain education or CBT in patients with CLBP [45]. Seven studies included an educational program in conjunction with physiotherapy [45-48,52-54]. Educational content varied considerably, ranging from exclusive focus on pain biology [46-49,52,53,55] to the inclusion of psychological aspects [46,52-55] and multidisciplinary approaches [49]. Most of the programs [48,55] incorporated education on pain physiology, frequently based on the book "Explain Pain" [56] by Butler and Moseley. Psychological education encompassed topics such as physical activity [45,46,49,53], fear of physical activity, emotional management [45-49,51], lifestyle modifications, daily exercises [45,49,52], pain-specific coping strategies [45,52,54], pain sensitization [47,54,55], and relaxation techniques, including stress management and mindfulness [45,49,52-55] in 6 studies, of which 5 included VR interventions. The content, duration, and physiotherapeutic integration of the individual education programs can be found in Multimedia Appendix 1.

Factors Based on Psychology of Learning for Intervention Design

This category encompasses factors of psychology of learning that are pertinent to the design of interactive interventions. Analysis of 3 studies showed that VR-based education employs passive mediation strategies such as informational videos and lectures (provided conventionally and in VR), alongside active and interactive strategies [44,50,54]. Three studies mentioned VR-based gamified approaches [50,52,55] and 2 studies [50,51] mentioned the promotion of intrinsic motivation.

Mediation Strategies

The included systematic review [44] examined the programs, cultural adaptations, and the efficacy of pain neuroscience education for chronic musculoskeletal pain, analyzing 71 studies that met our inclusion criteria and featured pain duration exceeding 3 months in adults. The analyzed studies explored pain neuroscience education in different settings by using

XSL•FO
RenderX

various experimental designs, including secondary analyses of randomized controlled trials, and showed positive effects on pain and psychological variables. Despite cultural influences on pain-relevant factors, only 2 (3%) of the 71 studies culturally adapted the pain neuroscience education material. Passive teaching-learning strategies tended to yield better outcomes for pain and functionality, whereas active methods resulted in significant knowledge improvements, albeit with insufficient description. The outcomes of multimodal therapies for chronic pain depend on the individualized integration of pain-specific education, considering biopsychosocial factors, educational level, culture, and diverse learning methods and materials for conveying pain neuroscience content [44]. Interaction content is passively conveyed through videos or lectures [46-49,53], particularly VR-based 360° nature videos [53].

Gamification and Motivation Enhancement

The Pain-Neuro-Education 2.0 software utilized a VR headset with immersive footage and computer-generated images for visually and emotionally engaging educational and relaxation training for chronic pain. This included interactive emotion regulation exercises such as breathing and mindfulness exercises in natural environments [54]. The VR program Recupt was also used to convey information in an engaging manner by having the user shoot at the pain stimulus with a laser gun, among other things. In the spinal cord phase, participants focus on visual “pain gates” and breathing to metaphorically “close” them and experience relaxation-induced pain relief. The brain component elucidates the reduction in pain response through the visualization and reactivation of illuminated connections. The alarm center gameplay demonstrates how emotions, cognitions, and behaviors influence pain perception. Finally, participants envision the alarm center as a brain region that regulates pain stimuli in an aircraft cockpit [55]. The VR program ViRST provides a therapeutic, interactive user interface with task-based activities in a farm environment [52]. Patients visualize movements and exertion levels by using game-based biofeedback with progress tracking and narrative elements [51]. Exergames incorporate biofeedback such as heart rate variability via photoplethysmography to prevent overexertion in interactive scenarios [52]. Gamification can motivate and enhance therapy adherence by fulfilling the psychological needs of competence, autonomy, and relatedness through interactive knowledge transfer. It also improves user skills through playful activities [50]. In the long term, feedback should be framed positively to maintain intrinsic motivation [52]. Avatars manipulate body perception for therapeutic effects, with the Proteus effect causing users to adopt their avatar’s behavior in real life. Personalized avatars can amplify pain relief [50].

Technical Conditions (Framework) for CLBP Intervention

The technical parameters of 3 enclosed VR studies, comprising 1 needs analysis [52] and 2 feasibility studies [52,53], provide insights into the design of AR-based education and identify potential areas of focus such as user-friendliness [51,53], operational support [51-53], and various application challenges [51,53]. The needs analysis was based on semistructured interviews (n=10) in focus groups to determine the requirements of older patients with chronic back pain, physiotherapists, and psychotherapists regarding VR pain therapy in terms of overall system, hardware, and software [51]. Findings emphasize that the designed system must be user-friendly; provide personalized instructions, demonstration videos, and individual guidance; and be available for rent. Assistants should support this system. Automatic breaks were considered crucial to avoid overexertion and pain aggravation. Activity should be limited to 30 minutes followed by a 15-minute rest. The study also highlighted the importance of balancing active therapy and relaxation. For hardware, it was determined that the VR headset must be independent and removable. Software design should consider user-friendliness by integrating the game environment with the level in-game environment for individual calibration of movement restrictions, particularly in gaming activities. Finally, a spacious room and wireless head-mounted display were considered essential for safety to prevent falls.

One feasibility study also emphasized the importance of safety aspects for the usability of VR headsets. The authors indicate that 93% of the application issues were associated with handling spatial and temporal limitations [53]. The second feasibility study demonstrated that disregarding body height (insufficient arm span) was perceived as disruptive [52]. Operational support software allows therapists to intervene during instances of pain, anxiety, or improper exercise execution by using a help button or emergency assistance [51]. Incorrect exercise execution is considered disruptive [52] and often lacks adequate support personnel for error correction or clinical assistance [53].

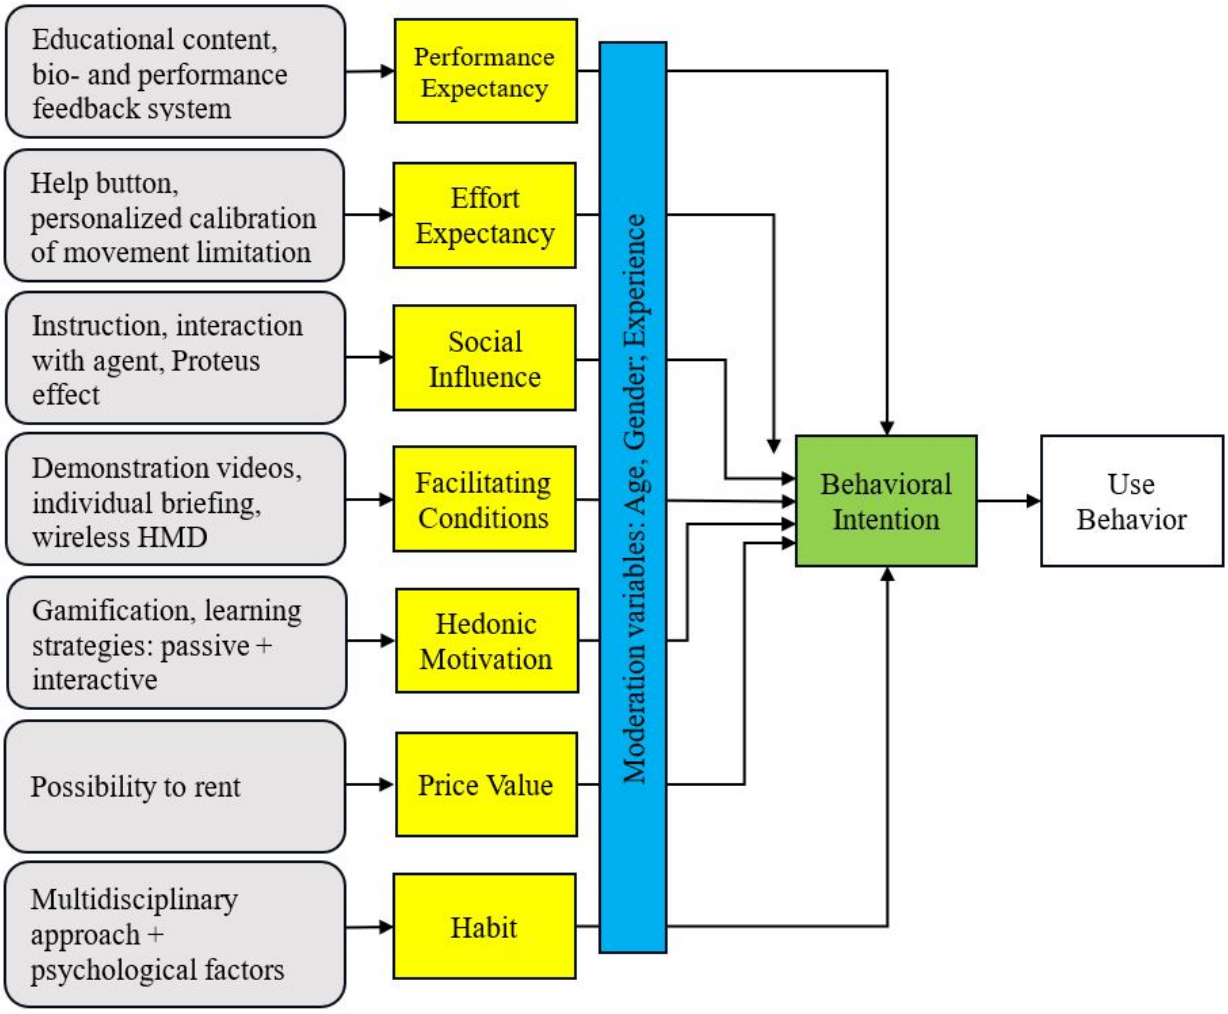
Outcome Measures of Educational Interventions for CLBP

Of the 12 studies [44-55] reviewed, 8 [46-49,54,55] were quantitative interventional studies. Commonly evaluated outcomes in CLBP studies encompassed pain intensity [45-49,51,52,54,55], kinesiophobia [46,48,51-53,55], pain catastrophizing [48,53-55], disability [45-47,51,52,54], health-related quality of life [51,52,54], well-being [47], self-efficacy [47,54], depression [46,53], attrition rate [49,53], and VR intervention user experience [52,53]. A comprehensive table displaying the different methods used, study results, and conclusions for each of the included studies can be found in Multimedia Appendix 2. A list of the pain-specific constructs and their measurement tools assessed in the different studies can be found in Multimedia Appendix 3.

Discussion

Principal Findings

Psychoeducation is a key element for CLBP treatment. Psychoeducation provided in AR could offer more benefits than that in VR or with conventional methods by integrating physical and virtual elements. Additionally, psychoeducation in AR was assumed to be superior to VR due to reported VR-associated discomforts in CLBP treatment, such as cybersickness and visual discomfort. Therefore, we conducted a literature review in the first step to evaluate research on CLBP treatment through psychoeducation using conventional methods and immersive technologies in order to design a psychoeducational intervention



XSL•FO
RenderX

in AR for CLBP. In the second step, we applied the extracted results of the literature review to a theoretical framework, in particular, the UTAUT 2, to provide a design example for AR-based psychoeducation for CLBP.

Our findings indicate that various educational programs were combined with physiotherapy [45-48,52-54]. These studies referred to conventional methods or VR-based interventions. No relevant study with AR for CLBP treatment was found. The varying educational content encompassed pain biology [46-49], psychological education on physical activity [45,46,49,53], anxiety management [45-49,51], lifestyle modifications, daily exercises [45,49,52], coping strategies [45,52,54], pain sensitization [47,54,55], and relaxation techniques [45,49,52-55]. Passive, active [44,50,54], and gamified strategies [50,52,55] were employed alongside the promotion of intrinsic motivation [50,51]. User-friendliness [51,53], operational support [51,52,54], and application challenges [52,53] were considered important for software development. The key variables of educational CLBP interventions included physiological variables such as pain intensity [45-49,51,52,54,55] and disability level [45-47,51,52,54]; psychological variables such as kinesiophobia [46,48,51,52,54,55], pain catastrophizing [48,53-55], quality of life [51,52,55], well-being [47], self-efficacy [47,54], and depression [46,53]; and technical variables such as dropout rates [49,53] and user experience [52,53].

Our results elucidate key aspects of a useful design of a psychoeducational treatment in AR for CLBP, which does not exist to date, to the best of our knowledge. Our findings point out the relevance of the interplay of technical and psychological components, in particular, the health psychological aspects incorporating psychology of learning to foster behavior change. In the next step, the findings were applied to a theoretical framework. For this, we referred to the UTAUT 2 [8,9]. UTAUT 2 encompasses constructs such as (1) performance expectancy, (2) effort expectancy, (3) social influence, (4) facilitating conditions, (5) hedonic motivation, (6) price value, and (7) habit for intention formation as well as the moderating variables age, gender, and experience [8]. Therefore, we recommend the following design suggestions for psychoeducational interventions in AR based on UTAUT 2 for the treatment of CLBP, as exemplified in Figure 2.

Figure 2. Exemplary mapping of the extracted findings from the literature review (grey) applied to the Unified Theory of Acceptance and Use of Technology to design an artificial reality–based psychoeducation for chronic low back pain. HMD: head-mounted display.

RenderX

UTAUT 2 Constructs

Performance Expectancy

It is recommended to convey psychoeducational content that demonstrates how CLBP can be positively influenced through physical activity [45,46,49,53], emotion management in kinesiophobia [45-49,51], pain-specific coping strategies [45,52,54], and stress and mindfulness techniques [45,49,52-55]. This content can be conveyed through a biofeedback system and supportive agent. As many educational measures are combined with physiotherapy [45-48,52-54], the agent can provide movement exercises, educational content, and interactive stress management techniques [54], supplemented by biofeedback. The biofeedback level and multimodal feedback of avatars promote top-down and bottom-up processes and enable associative learning [50]. To avoid discrepancies between instructions and sensory feedback, facilitate rapid corrections, and enhance user-friendliness [52], the avatar should provide immediate visual-acoustic performance feedback [50]. Biofeedback and body feedback are essential interventions for behavioral modification [17]. It is recommended to combine psychoeducation with a mindfulness-based stress reduction body scan and heart rate biofeedback [51], wherein biofeedback demonstrates progress and enables gamification elements [50,52].

Effort Expectancy

Software design should incorporate a gaming environment with in-game level settings to facilitate personalized calibration of movement limitations and body size, particularly for therapeutic activities [51,52]. The system should enable therapists to intervene through a help button or emergency assistance when patients experience pain, anxiety, or perform exercises incorrectly [51]. Frequent feedback for incorrect exercise execution should be avoided, as it may be perceived as disruptive [52].

Social Influence

With regard to social influence, an AR intervention should be accompanied by an agent that conveys pain-specific knowledge through lectures as passive knowledge transfer [44] or through support in psychological interactions, such as stress management exercises [54]. An agent can monitor a patient's body movements to integrate the phenomenon of "virtual body ownership" into the body image or utilize the analgesic effect of the Proteus effect to promote behaviors in the real world [50]. This aligns with BCT's recommendations for behavior change, wherein instruction, repetition, and demonstration of behavior have positive effects on physical activity that persist for up to 6 months [50,51]. Therefore, we propose to increase the intention to use by incorporating an agent in an AR intervention, with both passive and interactive roles.

Facilitating Conditions

A user-friendly system requires personalized instructions, demonstration videos, and individual briefings. For safety considerations, a spacious environment and wireless head-mounted displays are essential to mitigate the risk of falls. An assistant should be present to support the system. Automated breaks are crucial to prevent overexertion and exacerbation of pain, thereby automatically balancing the active therapy and relaxation periods. The VR headset should be designed for independent removal and application [51].

Hedonic Motivation

Passive learning strategies tend to yield superior outcomes in pain and functionality, whereas active methods can elicit significant improvements in knowledge [44]. Gamification demonstrates a motivation-enhancing effect through active and interactive patient engagement [50,52], for instance, through the interactive development of pain-specific knowledge in the Reducept program, where users enter their own brains and shoot with laser guns or connect points [55], or through movement exercises on a simulated farm [52]. A feedback system or biofeedback could be integrated, as outlined in the variable "performance expectancy" of UTAUT 2 and should be phrased positively as praise to increase motivation [51]. Praise as a social reward can occur through interaction with an agent, as described in the variable "social influence" [18]. In CBT, praise serves as positive reinforcement to promote adaptive behaviors and cognitions corresponding to positive CBT, which incorporates positive psychology and solution-focused brief therapy into a cognitive-behavioral context [57]. Gamification in an AR-based intervention enables the implementation of BCTs [17] by creating a material incentive such as within the framework of a game in an AR application [43].

Price Value

The headsets required for the interventions should be provided or loaned rather than purchased [50].

Habit

Educational programs for CLBP should incorporate a multidisciplinary approach that encompasses both physiological and psychological pain while promoting behavioral modifications such as regular physical activity [49]. Conventional recommendations for behavioral change emphasize repetition as crucial for habit formation [50]. For long-term interventions aimed at behavioral modification, theories addressing the intention-behavior gap and behavioral automaticity in physical activity should be considered, such as the Affective Reflective Theory of Physical Inactivity and Exercise [58] or the Physical Activity Adoption and Maintenance model [59].

Strengths and Limitations

This scoping review gives an overview of the most important educational content, elements of psychological training, interactive design forms, and relevant pain psychological variables for developing CLBP interventions in AR. It offers a substantiated basis for a theory-based development of a psychoeducational treatment in AR. Thus, this study provides a framework for the theory-driven extraction of hypotheses for future AR research in CLBP treatment. One limitation of this review encompasses the exclusion of certain sport science and physiotherapy databases (eg, SPORTDiscus) and the restriction to studies published in German and English, potentially omitting relevant publications. Further, the distinction between CLBP and chronic nonspecific low back pain in the included studies

XSL•FO
RenderX

was often imprecise. The distinction might be relevant for the intervention design, which was neglected in our analysis.

Recommendations for Research

First, the theoretically proposed design of AR-based psychoeducation for CLBP should be realized in future research. Second, an evaluation of the feasibility and user experience is needed. Third, the therapeutic efficacy of the psychoeducational content in AR must be demonstrated in a clinical evaluation study with patients with CLBP. As no studies on the psychometric properties of measurements in AR are known, psychometric assessments must be tested for measurement equivalence.

Conclusions

For the development of a framework for an AR-based psychoeducational intervention in CLBP, the combination of theories of acceptance and use of technologies with insights from health psychological behavior change theories appears to be of great importance. An example for a theory-based design of psychoeducation in AR for CLBP is proposed and discussed. Our results offer a substantiated basis for a theory-based development of psychoeducational treatment in AR.

Abstract

Background: Electronic immunization registries (EIRs) are being increasingly used in low- and middle-income countries. In 2022, Indonesia's Ministry of Health introduced its first EIR, named Aplikasi Sehat IndonesiaKu (ASIK), as part of a comprehensive nationwide immunization program. This marked a conversion from traditional paper-based immunization reports to digital routine records encompassing a network of 10,000 primary health centers (*puskesmas*).

Objective: This paper provides an overview of the use of ASIK as the first EIR in Indonesia. It describes the coverage of the nationwide immunization program (Bulan Imunisasi Anak Nasional) using ASIK data and assesses the implementation challenges associated with the adoption of the EIR in the context of Indonesia.

Methods: Data were collected from primary care health workers' submitted reports using ASIK. The data were reported in real time, analyzed, and presented using a structured dashboard. Data on ASIK use were collected from the ASIK website. A quantitative assessment was conducted through a cross-sectional survey between September 2022 and October 2022. A set of questionnaires was used to collect feedback from ASIK users.

Results: A total of 93.5% (9708/10,382) of public health centers, 93.5% (6478/6928) of subdistricts, and 97.5% (501/514) of districts and cities in 34 provinces reported immunization data using ASIK. With >21 million data points recorded, the national coverage for immunization campaigns for measles-rubella; oral polio vaccine; inactivated polio vaccine; and diphtheria, pertussis, tetanus, hepatitis B, and *Haemophilus influenzae* type B vaccine were 50.1% (18,301,057/36,497,694), 36.2% (938,623/2,595,240), 30.7% (1,276,668/4,158,289), and 40.2% (1,371,104/3,407,900), respectively. The quantitative survey showed that, generally, users had a good understanding of ASIK as the EIR (650/809, 80.3%), 61.7% (489/793) of the users expressed that the user interface and user experience were overall good but could still be improved, 54% (422/781) of users expressed that the ASIK variable fit their needs yet could be improved further, and 59.1% (463/784) of users observed sporadic system interference. Challenges faced during the implementation of ASIK included a heavy workload burden for health workers, inadequate access to the internet at some places, system integration and readiness, and dual reporting using the paper-based format.

Conclusions: The EIR is beneficial and helpful for monitoring vaccination coverage. Implementation and adoption of ASIK as Indonesia's first EIR still faces challenges related to human resources and digital infrastructure as the country transitions from

XSL•FO
RenderX

paper-based reports to electronic or digital immunization reports. Continuous improvement, collaboration, and monitoring efforts are crucial to encourage the use of the EIR in Indonesia.

Introduction

Background

Immunization is an important aspect of maintaining the health of individuals and society as a whole. It is a life-saving measure and a highly cost-effective public health intervention, an indispensable element of primary health care that shields children from avoidable mortality, illnesses, and disabilities caused by highly transmissible diseases [1]. Routine immunization plays an important role in reducing the incidence of various infectious diseases such as diphtheria, *Haemophilus influenzae* type B, measles, polio, rubella, and tetanus [2]. Located off the coast of Southeast Asia as the largest archipelagic country with 5 main islands, Indonesia has the fourth largest population in the world at >277 million [3]. This large population potentially poses the risk of rapid disease transmission if they are not protected by immunization. To ensure universal access to immunization services, vaccines must be distributed to geographically isolated regions as well as culturally or socially distinct populations, including hard-to-reach groups such as displaced individuals; migrants; and those impacted by conflict, political instability, and natural disasters [4]. Ensuring comprehensive immunization coverage for the entire population is of utmost importance yet challenging [3].

In recent years, Indonesia has faced challenges in achieving complete basic immunization, with 2020 and 2021 rates reaching 84.2%, falling short of the coverage targets of 92.9% and 93.6%, respectively [5,6]. Catch-up immunization for measles-rubella (MR) in toddlers also had declining coverage, standing at 65.3% (of a target of 76.4%) in 2020 and 58.5% (of a target of 81%) in 2021 [7]. Even with the increase in complete basic immunization coverage in 2022 (94.6%), immunization for preventable diseases remained low in low-coverage areas [5]. The COVID-19 pandemic significantly contributed to this decline as it led to disruptions in community immunization services, hindering the further attainment of herd immunity [5,6,8,9]. To address this issue, the Indonesian Ministry of Health (MoH) introduced the nationwide catch-up immunization campaign, which was called Bulan Imunisasi Anak Nasional (BIAN), in 2022 focusing on improving immunization coverage.

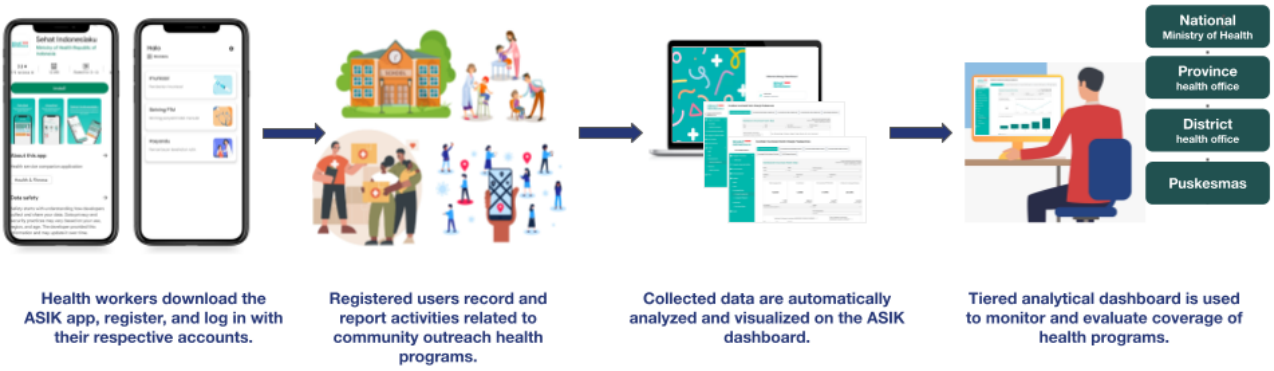
The MoH periodically conducts these nationwide catch-up immunization campaigns [7]. In 2022, Indonesia focused on conducting BIANs for two main activities: (1) supplementary immunization for MR and (2) catch-up immunization for children aged <5 years [7]. This focus was chosen based on several recommendations [7]. First, the National Committee for Measles-Rubella and Congenital Rubella Syndrome Elimination of Indonesia recommended to accelerate the achievement of MR and congenital rubella syndrome elimination targets in Indonesia by strengthening routine MR immunization with doses 1 and 2, aiming for a minimum coverage of 95%. Second, the National Immunization Technical Advisory Group recommended implementing inactivated polio vaccine (IPV) catch-up immunization for infants and children who had missed their scheduled IPV immunization to close immunity gaps and provide protection against the polio virus type 2. Third, the expert committee on diphtheria control recommended catch-up immunization efforts to close immunity gaps, especially among children aged <5 years (toddlers), and outbreak response immunization in areas experiencing outbreaks using appropriate vaccines for the target age group.

The BIAN was held initially for 1 month in May 2022 for the Sumatra, Kalimantan, Sulawesi, Nusa Tenggara, Maluku, and Papua islands and in August 2022 for the Java and Bali islands [7]. A total of 4 vaccines (oral polio vaccine [OPV]; IPV; MR; and diphtheria, pertussis, tetanus, hepatitis B, and *H influenzae* type B [DPT-HB-Hib]) were selected to support Indonesia's commitment to control global diseases, such as polio eradication, elimination of MR and congenital rubella syndrome and hepatitis B, control of diphtheria, reduction of the incidence of tuberculosis, and elimination of maternal and neonatal tetanus [7]. During the implementation of this BIAN, for the first time, Indonesia used an electronic immunization registry (EIR) capturing individual-level records [5] and replacing paper-based records as the latter were shown previously to include inaccuracies due to inexact, incomplete data and late reporting [10-12].

Objectives

EIRs as part of an immunization information system are a tool designed to provide information on immunization programs' target populations. By definition, EIRs include information that facilitates active search to identify individuals' vaccination data and vaccine history and provide support for determining which individuals need to be vaccinated and monitoring of immunization dropouts [13]. The 2 main databases needed for EIRs are demographic data and vaccination event data, which aim to identify the vaccine recipient and the vaccination event itself [13]. EIRs have been widely used in high-income countries as such digital reporting tools can improve reporting timeliness, precision, and overall performance [14]. Indonesia continues to improve its digital health sector and has launched the digital health transformation blueprint, aiming to create an integrated and sustainable health system [15]. As part of this effort, the government embarked on digitizing immunization reporting, shifting from a manual collection of aggregate data to individual digital records using the Aplikasi Sehat IndonesiaKu (ASIK). This paper aims to provide an overview of ASIK and its use and specifically evaluate ASIK implementation during the nationwide immunization campaign (BIAN) period in Indonesia.

XSL•FO
RenderX



Methods

ASIK Overview

ASIK is an integrated application system developed by the MoH of Indonesia for health care workers to capture health care services provided for communities outside public health centers (*puskesmas*) [16,17]. This application is designed to help health care workers in primary care settings record patient data, report health care services provided for each individual, input routine health screening data, and monitor patient conditions [16,17].

The ASIK mobile app is available in an Android version and can be accessed through the Google Play Store. Targeted users of ASIK are health care workers in primary care settings. Health care workers need to register their account, as shown in Figure 1. Once registered and verified, health care workers can report any health care services provided outside the public health centers using ASIK to record individual data. Data reported through the ASIK mobile app are collected and automatically presented in an analytical dashboard provided in a web version of ASIK [17]. This web version of ASIK can only be accessed using a predetermined username and password for public health centers, district health offices, and provincial health offices to monitor and evaluate the coverage of health care services in their respective areas. The data presented in the dashboard are automatically synchronized from the public health centers level up to the national level. A simplified flow for the use of ASIK is shown in Figure 1.

Figure 1. Health service program reporting scheme using Aplikasi Sehat IndonesiaKu (ASIK). Puskesmas: Indonesian for "primary health center.".

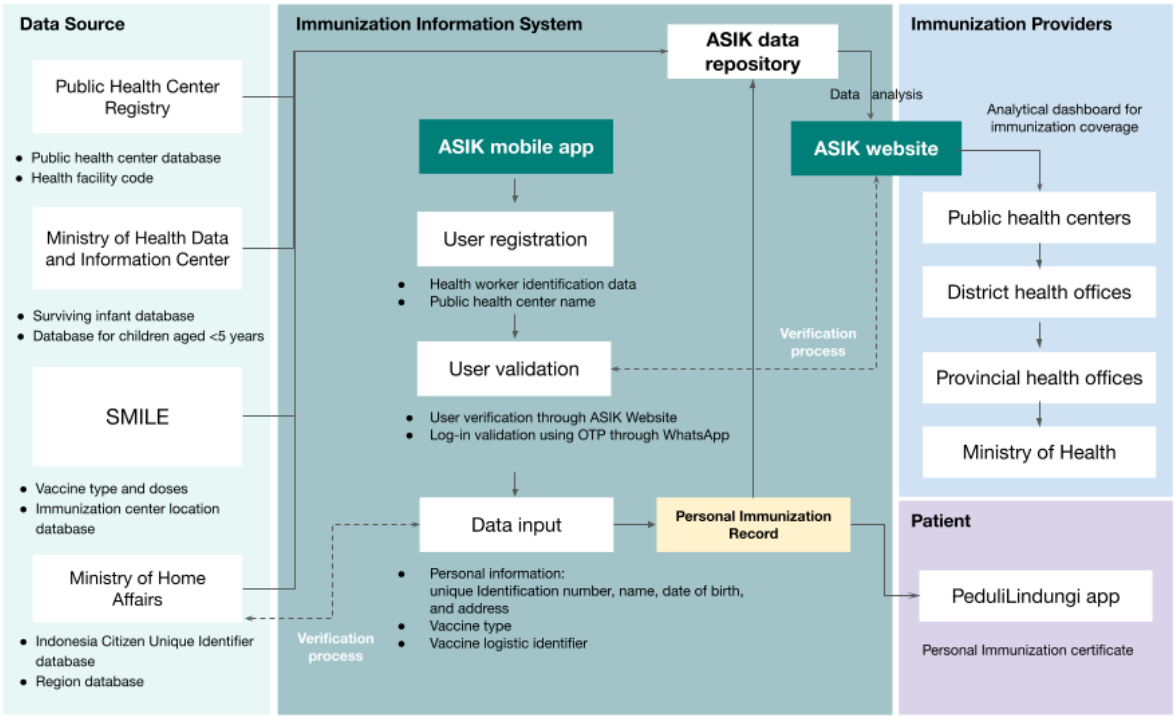
ASIK was designed in line with elements of ideal EIRs according to the Pan American Health Organization's definition [18]. These elements encompass (1) inclusion of all persons at birth or as early as possible; (2) unique ID (national ID; biometrics or birth registration; or a unique combination of variables such as names, date or place of birth, and parental names or IDs); (3) information about each person, including information on geographical area of residence; (4) information about the vaccines administered, dates, and provider; (5) aggregation of data by geographical level as required; (6) timely individualized follow-up of vaccination schedule; (7) data entry as close to vaccination as possible (time and place); and (8) data security and protection of patient confidentiality.

The elements of ideal EIRs in ASIK were incorporated as follows: (1) allowing health workers to record individuals as soon as they are born with no restriction on age; (2) allowing health workers to record unique identification using the Indonesia resident registration number and a combination of name and date of birth as mandatory variables; (3) allowing health workers to record information about each individual using place of birth and current area of residence, which includes province name, city and district name, subdistrict name, village name, and detailed address; (4) allowing individuals to record information about vaccination, which includes vaccine name, vaccine batch number, date of vaccination, and location of vaccination; (5) a tiered dashboard that displays aggregated and structured data in spatial format from the national level to the village level; and (6) protection of patient confidentiality by ensuring a verification process during user registration and a limited access to a dashboard that displays detailed individual vaccination information (this access is designed specifically for the public health centers).

BIAN Immunization Reporting Using ASIK

The MoH launched and tested ASIK during the BIAN in May 2022 [19]. The BIAN 2022 immunization campaign was held in various mass public facilities such as *posyandu* (community-based health care service in Indonesia where local volunteers [cadres], midwives, and health workers provide essential maternal and child health services, including immunization); public health centers; subsidiary public health centers; hospitals; clinics; immunization service posts in schools, Islamic schools (*madrasas*), and Islamic boarding schools (*pesantrens*); and other strategic community-gathering places that could be turned into immunization posts [7]. Through ASIK, health care workers were able to record immunization data individually [16]. All immunization records from ASIK were monitored by the immunization program coordinators in public health centers in near real time.

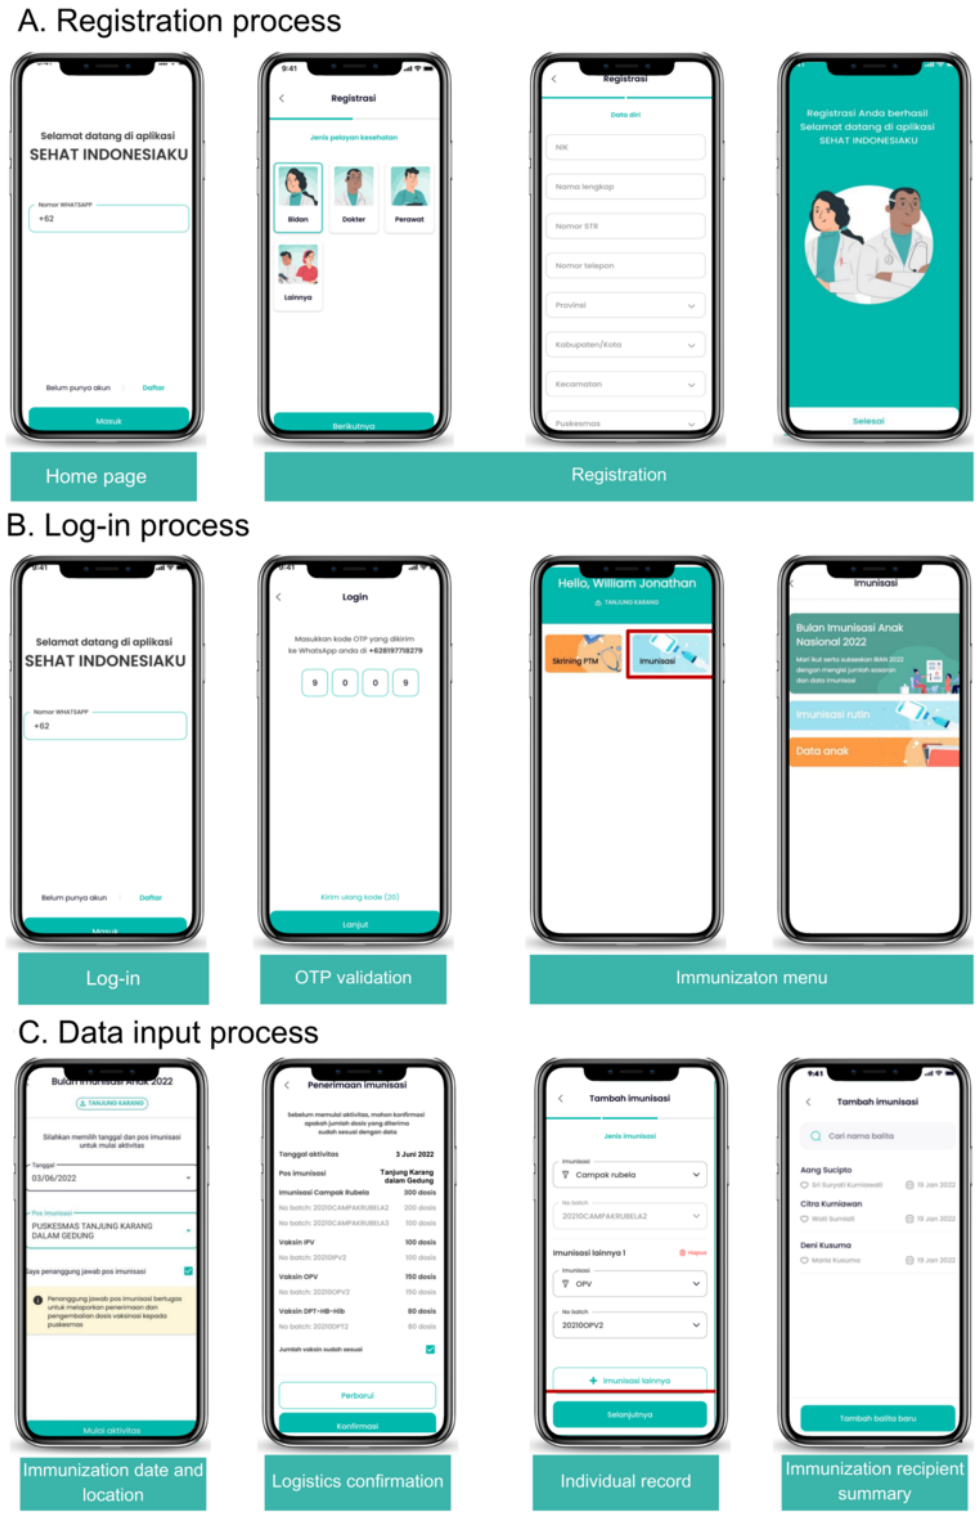
Several databases served as the sources of ASIK data, including the public health center registry (Aplikasi Registrasi Puskesmas), the MoH Data and Information Center database, the Electronic Logistic Management and Information System (SMILE), and the Ministry of Home Affairs database. The Aplikasi Registrasi Puskesmas provides information regarding the location of immunization services, including names and locations of public health centers along with registered codes for each health facility. ASIK used data from the MoH Data and Information Center to acquire information on the number of targeted immunization participants for every district and city. Integration



XSL•FO
RenderX

with the SMILE database allowed ASIK to access data on the types of vaccines available, the quantity of vaccine doses, and the distribution locations. During the process of recording individual data, an interconnected application programming interface with the Ministry of Home Affairs ensured data validation for citizen identification numbers and domicile information.

Each record generated through ASIK is stored in a separate database and then automatically sent to the ASIK dashboard for data analysis. Processed data are distributed to various beneficiaries, such as health facilities, district and provincial health offices, and citizens, through different platforms. In addition, individuals who have been vaccinated can receive their immunization history data through the PeduliLindungi app, which was rebranded in 2023 as SATUSEHAT Mobile [20]. Figure 2 illustrates the entire data flow within ASIK.



The immunization data collection process in ASIK (Figure 3) comprises the steps outlined in Textbox 1.

XSL•FO
RenderX

Textbox 1. Immunization data collection process in Aplikasi Sehat IndonesiaKu.

User registration

Vaccinators are required to undergo registration to report immunization services using ASIK. The registration process involves providing personal information, specifying the work area, and selecting a specific public health center. Upon completing the registration form, users need to input their phone numbers to receive a one-time password for app log-in. The one-time password is sent through WhatsApp to each registered user to ensure system and user security.

Immunization data input

Vaccinators can record immunization data at designated immunization centers. Before selecting the immunization centers, the pharmaceutical officers must report the vaccine stock distribution to the specific immunization center through the SMILE. Once the logistic stock has been reported, vaccinators can choose a specific immunization center and the date of the immunization service. They can then input immunization data, including the names and addresses of recipients and the type of vaccine administered to each individual.

ASIK analytic dashboard

Immunization records captured by ASIK are integrated into an analytic dashboard. Public health center immunization coordinators can monitor the results of immunization services through this dashboard. The analytic dashboard also provides a spatial representation of the data, organized at provincial, district, and city levels. Thus, immunization data from the public health centers level to the national level can be monitored in near real time, with updates every 2 hours.

Individual immunization record

Parents can access their children's immunization records through the PeduliLindungi mobile app. Originally developed as a mass surveillance tool during the COVID-19 pandemic, PeduliLindungi initially presented COVID-19 vaccine certificates and later extended its functionality to include vaccine certificates from ASIK. Following the revocation of pandemic status, PeduliLindungi was further enhanced to encompass personal medical records. As a result, in 2023, the app was rebranded as a citizen health app named SATUSEHAT Mobile.

Data Collection

Data entry is initiated by selecting the BIAN from the immunization menu within ASIK. In total, 2 distinct roles can be chosen, namely, immunization program coordinator or immunization officer. The immunization program coordinator (ie, the individual in charge of the immunization posts) validates the available vaccine doses for each immunization post to activate the individual data report feature. This involves verifying data related to logistical distribution by reporting the number of vaccine distributions and the return of vaccination doses. On the other hand, immunization officers or vaccinators focus on reporting vaccination data at the individual level.

To record individual data, either the 16 digits of the national identification number or a combination of the full name and date of birth are entered to locate the appropriate personal health record. Consequently, a list of relevant individuals appears, allowing the users to select the relevant data or create a new identification record if the data are not available. Upon completing the identification data, vaccinators proceed to enter information about the administered vaccine type. To minimize error, the system was designed to display only the list of available vaccines suitable for the individual's age. For instance, for children aged 0 to 3 months, the system will not show the IPV in ASIK as the IPV has a minimum age requirement of 4 months. The system automatically records the results of the provided immunization services. It was recommended that vaccinators input the data immediately after services have been provided, although the option for backdating the data input is also available in ASIK, allowing users to submit delayed reports.

A quantitative survey was conducted from September 19, 2022, to October 21, 2022, using cross-sectional methods with a total of 1065 participants. All immunization program coordinators (ASIK users) from all public health centers, district health offices, and provincial health offices from 2 regions were invited to a web-based evaluation meeting. The first region represented a low data input into ASIK (the data gaps between manual and electronic reporting were approximately 30,000 to >100,000 immunization record data), and the second region represented the highest data input into ASIK (data gaps were of <10%). A total of 17.1% (182/1065) of the participants were provincial and district health officers, and 82.9% (883/1065) of the participants were health care workers from the public health centers. A questionnaire was used to collect feedback from the ASIK users (Multimedia Appendix 1). The survey used the Mentimeter platform, which enabled participants to provide direct answers and showed the cumulative, anonymized results directly. The questionnaire consisted of four sections: (1) overall user feedback on the system, (2) data reporting process, (3) supporting infrastructure, and (4) data completeness.

Data Analysis

Three outcomes were assessed in this study: (1) ASIK implementation coverage, (2) BIAN vaccination coverage (MR, OPV, IPV, and DPT-HB-Hib immunization), and (3) ASIK use feedback from users. ASIK implementation coverage and BIAN immunization coverage were calculated from the ASIK database. BIAN vaccination coverage was presented as percentage data; it was calculated by dividing the number of vaccinations (numerator) by the targeted population number for each vaccination (denominator) at the province level.

The results of BIAN immunization services were automatically presented in a structured dashboard that was accessible for public health centers, district health offices, provincial health offices, and the MoH. These data can be queried using predetermined variables. For instance, the analysis includes metrics such as the coverage of children administered the MR vaccine, OPV, IPV, and DPT-HB-Hib vaccine by comparing the service outcome rates (ie, the number of vaccinated children compared to the target numbers). The target estimates were

XSL•FO
RenderX

calculated based on the 2022 Health Development Program Target Population data [7]. Data analysis of the results of immunization services was also presented in a spatial format at the provincial, district, and city levels. Trends in service outcomes were depicted using time-series graphs. Moreover, comparative results of immunization coverage were generated (eg, by sex and age groups).

ASIK implementation coverage was measured by calculating how many public health centers used ASIK for the nationwide immunization program. The coverage was presented as percentage data, calculated by dividing the number of public health centers that reported BIAN immunization services using ASIK (numerator) by the total number of public health centers in Indonesia (denominator). The information was presented in the dashboard using the monitoring and evaluation feature. This feature enables relevant stakeholders to monitor the compliance of public health centers in reporting BIAN immunization services via ASIK. The monitoring and evaluation feature also provides information that represents the coverage of subdistricts, districts, and cities that have submitted their reports through ASIK. In addition, the dashboard generates a list of public health centers that have yet to submit their reports through ASIK. As a result, the provincial, district, and city health offices can effectively plan and implement a tiered monitoring and evaluation process.

ASIK use was assessed using a quantitative survey to obtain users' feedback. The outcome of the quantitative survey was to measure users' feedback on ASIK and how data collection using the digital tool was carried out, including (1) overall user feedback on the system (user understanding, user acceptance based on user interface [UI] and user experience [UX] and the variables presented, and user-friendliness of the system), (2) data reporting implementation (number of staff members for data input, flow of data reporting, and time to input data into ASIK), (3) infrastructure (mobile phone ownership and internet access), and (4) data completeness (availability of data on vaccinated individuals, comprising ID number, full name, date of birth, and gender). Outcomes 2, 3, and 4 were also explored to understand the real-life situations that potentially affected the use of an electronic reporting system in public health centers. The questions in the survey were developed as closed-ended questions, which allowed respondents to choose from a set of predefined answers quickly. The quantitative survey was analyzed using descriptive analysis. The data analysis was conducted using SPSS (version 20; IBM Corp) to describe users' feedback regarding the mobile app use in 2 different regions.

Ethical Considerations

The data collected for this paper do not require ethics approval in accordance with the Indonesian MoH *National Guideline and Standards for Ethical Research and Development in Health* guideline (2017, Chapter IIIB, point 2) [21] as no individual-level data are presented. The immunization analysis data are in anonymized, aggregate format and were handled following the aforementioned guidelines. For the survey, this research was conducted under the ethics approval of the International Agency for Research on Cancer Ethics Committee (22–37). Anonymous participation followed verbal informed consent, which was considered an indication of consent for obtaining and analyzing the data. There was no compensation provided for participants as it is part of the MoH immunization campaign program. No individual data were presented; only aggregated anonymized data were used as per the aforementioned guidelines.

Results

BIAN Immunization Reports by Province and Vaccine Type

The BIAN was held in 2 phases. The first phase began in May 2022 and ran until the end of July 2022, targeting 27 million children across 26 provinces in the Sumatra, Kalimantan, Sulawesi, Nusa Tenggara, Maluku, and Papua islands. The second phase took place in August 2022 in the Java and Bali islands (7 provinces), aiming for roughly 10 million children. The data analysis presented in this paper depicts the BIAN reports between May 2022 and December 2022. Different areas had distinct vaccination targets for each vaccine (Multimedia Appendix 2).

According to the data records in ASIK, there were 21.89 million BIAN immunization services recorded, with details on 18.3 million for the MR vaccine (18,301,057/36,497,694, 50.1%), 938,000 for the OPV (938,623/2,595,240, 36.2%), 1.2 million for the IPV (1,276,668/4,158,289, 30.7%), and 1.37 million for the DPT-HB-Hib vaccine (1,371,104/3,407,900, 40.2%).

The highest coverage of MR immunization was attained by Banten, reaching 96.8% (901,465/931,740), followed by Central Java (1,996,112/2,069,562, 96.5%) and East Java (1,797,337/2,352,409, 76.4%). In contrast, Aceh reported the lowest coverage (93,127/1,444,337, 6.4%), followed by Papua (72,368/792,523, 9.1%) and Central Sulawesi (104,316/708,642, 14.7%).

For OPV immunization, 2 provinces surpassed 100% coverage, namely, Lampung (49,833/37,827, 131.7%) and Banten (111,255/105,771, 105.2%), followed by Central Java (115,771/131,724, 87.9%). A significant contrast emerged in OPV coverage, with Papua (951/118,227, 0.8%), East Kalimantan (658/26,294, 2.5%), and Central Kalimantan (2857/58,389, 4.9%) showing the lowest coverage.

For IPV immunization, Banten reached the highest coverage (163,826/173,701, 94.3%), followed by Bali (1254/1426, 87.9%). In contrast, Papua (1814/167,678, 1.1%), East Kalimantan (747/67,544, 1.1%), and Central Kalimantan (1892/95,243, 2%) recorded the lowest IPV coverage.

For DPT-HB-Hib immunization, 2 provinces surpassed 100% coverage, namely, Banten (188,804/172,619, 109.4%) and Bali (3733/3620, 103.1%), followed by Lampung (64,043/71,504, 89.6%). Conversely, Papua (1294/194,510, 0.7%), Aceh (7282/184,475, 3.9%), and Central Sulawesi (2041/43,691, 4.7%) recorded the lowest coverage (Multimedia Appendix 3).

In summary, significant regional disparities in immunization coverage are apparent based on ASIK data. The Java and Bali islands exhibited the highest coverage across all vaccine types (MR: 7,544,342/9,435,097, 80%; OPV: 637,763/1,102,238,

XSL•FO
RenderX

57.9%; IPV: 927,925/1,747,414, 53.1%; DPT-HB-Hib: 1,087,268/1,759,356, 61.8%), whereas the Sulawesi island had the lowest coverage for 3 vaccine types (MR: 1,480,388/4,270,493, 34.7%; IPV: 25,270/406,208, 6.2%; DPT-HB-Hib: 28,745/315,809, 9.1%). Low coverage was also observed in the Papua, Maluku, and Nusa Tenggara islands for all vaccine types.

Using the specified BIAN 2022 campaign targets as benchmarks [7], we compared the immunization coverage achieved in each province with their predetermined targets. The immunization coverage report (Multimedia Appendix 4) illustrates that only 2 provinces, Banten and Lampung, successfully attained the coverage goal for MR immunization. In parallel, 4 provinces (Bali, Banten, Central Java, and Lampung) exceeded the target for OPV immunization. Similarly, the immunization target for IPV was met only by Bali, Banten, and Central Java. The DPT-HB-Hib immunization target was accomplished only by Bali, Banten, Central Java, and Lampung. These data are in line with past reports in which immunization targets were often unmet in the context of Indonesia, although the current technological implementation allowed for more granular data and for a quicker comparison at a national scale.

Digital Versus Paper-Based Recording of BIAN Implementation

Although the implementation of the BIAN and the release of ASIK happened simultaneously, the technical implementation guideline document for BIAN stated that manual or paper-based reports are still possible using a specified format [7]. Hence, all provinces involved also recorded data using a paper-based format. This manual data collection focuses on reporting aggregate numbers of immunization services, such as the total number of children aged 12 to 59 months receiving DPT-HB-Hib immunization. The data presented in the following paragraphs reflect the paper-based recording of the same campaign used to compare the digital versus paper-based recording of BIAN implementation.

Thus, according to the official letter from the MoH regarding the achievements of the BIAN phase I and phase II in 2022 and using the data from the paper-based records alone, the immunization coverage in Indonesia for MR, OPV, IPV, and DPT-HB-Hib was 72.7% (26,529,596/36,497,639), 54.2% (1,330,928/2,454,340), 45.8% (1,842,869/4,024,564), and 61% (2,011,057/3,294,942), respectively [22] (Multimedia Appendix 3).

The highest coverage of MR immunization was attained by East Java, reaching 100.6% (2,365,820/2,352,401), followed by Jakarta (710,757/715,786, 99.3%) and Banten (918,323/931,739, 98.6%). Conversely, Aceh reported the lowest coverage for MR (280,017/1,444,335, 19.4%), followed by Papua (307,466/792,523, 38.8%) and Riau (880,867/1,913,263, 46%).

In terms of OPV immunization, 3 provinces surpassed 100% coverage, namely, Bali (786/732, 107.4%), Central Java (113,325/106,194, 106.7%), and Banten (107,570/105,085, 102.4%). A significant contrast emerged in OPV coverage, with West Nusa Tenggara (10,224/129,413, 7.9%), West Kalimantan (6556/78,005, 8.4%), and Central Kalimantan (5472/58,389, 9.4%) showing the lowest coverage.

Regarding IPV immunization, Yogyakarta attained the highest coverage at 92.2% (400/434), followed by West Java (611,346/664,213, 92%) and East Java (195,047/212,128, 91.9%). Conversely, Papua (5521/167,678, 3.3%), East Kalimantan (2744/67,544, 4.1%), and Central Kalimantan (4378/95,243, 4.6%) recorded the lowest IPV coverage.

For DPT-HB-Hib immunization, South Sumatra led with the highest coverage (36,117/36,397, 99.2%), followed by Bali (3606/3639, 99.1%) and Central Java (293,073/297,231, 98.6%). In contrast, Papua (9676/194,510, 5%), Aceh (25,323/195,289, 13%), and West Kalimantan (8510/79,635, 10.7%) reported the lowest DPT-HB-Hib coverage (Multimedia Appendix 3).

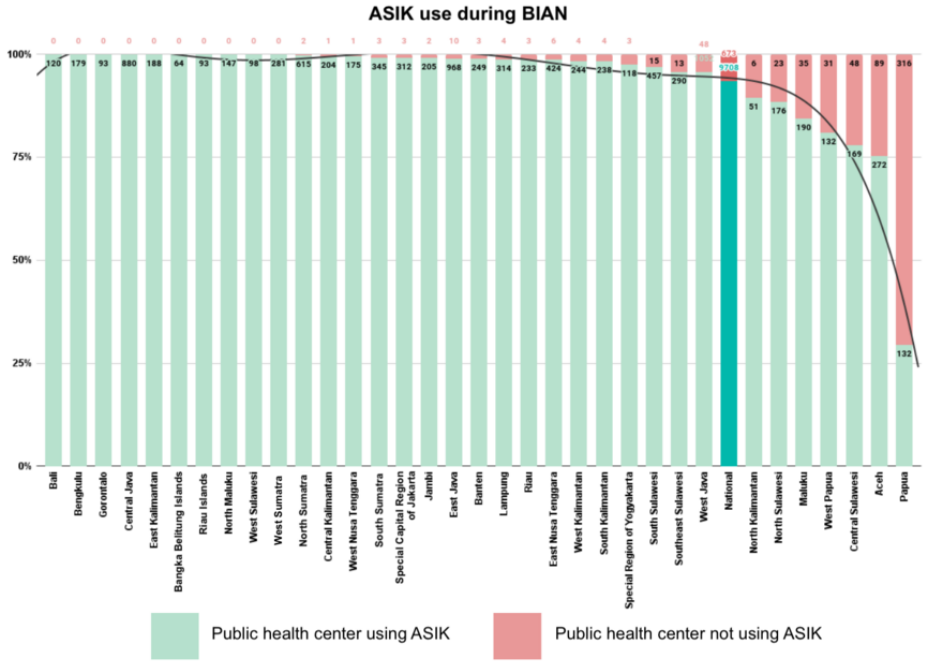
On the basis of the table in the Multimedia Appendix 3, there were gaps between manual reporting data as compared to the digital recording via ASIK.

For MR immunization, the average reporting gap was 24.4% ±3.72% (95% CI: 20.68%-28.12%); the highest gap was observed in Maluku (47.4%), followed by South Sulawesi (47.3%) and Central Sulawesi (47.3%). The greatest reporting alignment was observed in Central Java (1.5%), followed by Banten (1.9%) and South Kalimantan (11.6%).

For OPV immunization, the average gap was 18.3% ±7.26% (95% CI: 11.04%-25.56%); the highest discrepancy was observed in East Java (70.4%), followed by Gorontalo (60.6%) and the Riau islands (53.6%). The greatest alignment was observed in Lampung (−39.7%), followed by Banten (−2.8%) and Jakarta (−1.9%).

For IPV immunization, the average gap was 16.1% ±6.42% (95% CI: 9.68%-22.52%); the highest data discrepancy was observed in the Special Region of Yogyakarta (77.4%), followed by East Java (70.8%) and the Riau islands (56.5%). The closest reporting alignment was observed in Jakarta (−1.8%), followed by West Nusa Tenggara (1.6%) and Papua (2.2%).

For DPT-HB-Hib immunization, the average gap was 20.7% ±7.23% (95% CI: 13.47%-27.93%); the highest data reporting discrepancy was observed in the Riau islands (82.4%), followed by East Java (71.6%) and Maluku (58.2%). The greatest reporting alignment was observed in Banten (−12.2%), followed by Bali (−4%) and Lampung (−0.4%).



ASIK Use and Coverage

To understand the aforementioned discrepancies, 2 further aspects were considered: ASIK use and coverage and user feedback on ASIK use. The results will be presented in the following paragraphs. Regarding ASIK coverage, a total of 93.5% (9708/10,382) of public health centers, 93.5% (6478/6928) of subdistricts, and 97.5% (501/514) of districts and cities in 34 provinces reported BIAN activities using ASIK. On the basis of the coverage as measured at the province level, there were 10 provinces where 100% of their public health centers reported BIAN activities using ASIK, namely, Bali, Bengkulu, Gorontalo, Central Java, East Kalimantan, Bangka Belitung Islands, Riau Islands, North Maluku, West Sulawesi, and West Sumatra, whereas the provinces with the lowest

XSL•FO
RenderX

number of public health centers reporting using ASIK were Papua (132/448, 29.5%), Aceh (272/361, 75.3%), and Central Sulawesi (169/217, 77.9%). Detailed information on other provinces can be found in Figure 4.

Figure 4. Aplikasi Sehat IndonesiaKu (ASIK) use across 34 provinces during the Bulan Imunisasi Anak Nasional (BIAN) implementation.

User Feedback on ASIK Use

In parallel to understanding the coverage and use of ASIK, a quantitative survey was conducted to obtain users' feedback on the system, including explorations of UI and UX, reporting variables, and system interference. A total of 1065 questionnaires were received, although not all respondents answered all questions. The results of the quantitative survey are presented in this section and summarized in Table 1. In general, users exhibited a good understanding of ASIK as the EIR (650/809, 80.3%). For UI and UX, the highest feedback was that it was overall good but could still be improved (489/793, 61.7%), with 35.3% (280/793) of respondents expressing that the UI and UX were very good and 3% (24/793) saying that they were hard to understand. Regarding the required variables for immunization data input in ASIK, 54% (422/781) of the respondents expressed that the variables fit their needs but could still be improved, 39.6% (309/781) expressed that the variables fit their needs, and 6.4% (50/781) of users expressed that there were too many variables. In terms of system interferences, 59.1% (463/784) of users expressed that they sometimes happened, and 24.5% (192/784) expressed that they often happened. The most prevalent system interferences were (1) inability to find individual data in the system (281/779, 36.1%), (2) server errors (217/779, 27.9%), and (3) problems with logistic stock confirmation (135/779, 17.3%).

On the basis of the users' feedback, 44% (382/869) stated that there were 2 to 3 staff members that helped with the data reporting process. However, the number of staff members who helped with data input varied as users in region 2 (high data collection) had >5 staff members for data reporting and users in region 1 (low data collection) only had 2 to 3 staff members to do so. Regarding the flow of data reporting, 33.4% (291/872) of users exhibited a combination of recording the immunization data on paper or on Microsoft Excel first and directly inputting them into ASIK. Furthermore, more users preferred the input of immunization data at public health centers right after the immunization activity was completed (364/1089, 33.4%), followed by inputting the data within 24 hours after the immunization services (203/1089, 18.6%). However, 22.3% (181/813) of users in region 1 input the immunization data 2 weeks after the immunization activity, whereas in region 2, a total of 45.3% (125/276) of their users preferred to input the data right after the activity was completed. Regarding the data reporting process, each region had different characteristics for each variable: number of staff members, data reporting flow, and time to input the data. Region 2 showed a relatively higher number of staff members, more direct flow of data reporting, and timelier input of data into the system. As previously mentioned, region 2 had the highest data collection, comprising 28 cities that did not have any gaps in data collection between ASIK and manual reporting.

No	17/711 (2.4)	12/241 (5)	29/952 (3)[y]
Internet access			
Available at all places	390/710 (54.9)	163/240 (67.9)	553/950 (58.2)
Only available at the public health centers	78/710 (11)	14/240 (5.8)	92/950 (9.7)
Limited availability	242/710 (34.1)	63/240 (26.3)	305/950 (32.1)
Data completeness			
Data availability			
Individual data were complete	157/637 (24.6)	125/219 (57.1)	282/856 (32.9)
Individual data were incomplete	480/637 (75.4)	94/219 (42.9)	574/856 (67.1)

Regarding the existing infrastructure, 97% (923/952) of users had Android mobile phones. A total of 58.2% (553/950) of respondents expressed that internet access was available at all places, 32.1% (305/950) expressed that internet availability was limited in several places, and 9.7% (92/950) expressed that the internet was only available at public health centers (and not available in immunization posts). The data suggested that the internet was more accessible in region 2 compared to region 1.

Another constraint found during data reporting was data completeness of the targeted participants. A total of 67.1% (574/856) of users expressed that the individual data were incomplete, especially on unique identifier (ID number), which was only available for up to 79% of the collected data points; full name, which was available for up to 95% of individual data points; birth date, which was available for up to 95% of the collected data points; and gender, which was available for up to 95% of the collected data points.

Most respondents (618/1065, 58%) indicated several constraints that hindered the use of ASIK and were experienced intermittently or too frequently, including (1) challenges in retrieving individual data, (2) server errors, and (3) logistic stock validation. The first challenge that arose in the early development of the system is the lack of interconnectedness with the civil registration database. During the preliminary development phase of ASIK, the absence of established data sharing agreements between the Indonesian MoH and the Ministry of Home Affairs prevented users from efficiently engaging in data reporting using ASIK.

Interconnection between ASIK and the civil registration database will help health care workers automatically retrieve individual demographic information such as gender, date of birth, and address by inputting the 16 digits of the national ID. During BIAN implementation, ASIK was still not connected to the civil registration database owned by the Ministry of Home Affairs; thus, health care workers needed to input the individual information manually.

The second challenge also stemmed from the early development phase of the system, when the initial server capacity was constrained, leading to suboptimal application performance. System errors that were mentioned by the respondents happened occasionally throughout the recording process. They sometimes happened due to personal data input, vaccine type data input, or the process of saving data. They potentially happened due to limited server performance caused by the high number of users inputting data at the same time.

The third challenge pertains to logistic stock management. In contrast to the first challenge, ASIK was strategically integrated with the logistic system (SMILE) during its development phase, effectively establishing a linkage between immunization and logistic data. However, the compliance and adherence to using the SMILE were variable. Consequently, the comprehensive implementation of the SMILE for monitoring logistic stocks in the context of the BIAN 2022 campaign was not universal across all public health centers. This posed an obstacle in the use of ASIK given that logistic confirmation is a prerequisite for inputting immunization data into ASIK. Respondents were hindered from inputting the immunization data into ASIK if the pharmacy staff had not input the logistic information into the SMILE. This created some delays in the data recording process during BIAN 2022.

These challenges have been addressed, and the system has been enhanced over time, particularly during the latter stage of the BIAN 2022 campaign. The system was integrated with the civil registration database, the server capacity was upgraded, and refinements were implemented in the integration between ASIK and the SMILE. As a result, the efficacy of ASIK had a notable improvement during the latter phase of the BIAN 2022 campaign. Nevertheless, many respondents gave positive responses for the use of ASIK as the Indonesia EIR. The positive response correlated with the convenience of ASIK as an EIR.

Discussion

Principal Findings

The launch of ASIK is a part of the MoH's mission to transform health care services by assisting health care workers in efficiently and comprehensively recording patient data in a single, integrated database [5,15,19]. The use of ASIK as Indonesia's first EIR was broad, covering 34 out of 38 provinces. The rate of adoption reached 93.5% (9708/10,382) of public health centers (ie, the main health care provider for the nationwide immunization campaign). Through 2 phased releases, ASIK managed to record >21 million immunizations. Although most users expressed a good understanding of the

XSL•FO
RenderX

system, several challenges persisted during the implementation phase.

EIRs are instruments proven to be cost-effective in enhancing coverage and timeliness of vaccination [23]. The use of EIRs was considered beneficial in preventing delays in vaccinating children as they help parents keep track of their children's vaccination records and stay informed of their children's vaccination schedule [23,24]. Furthermore, EIRs are helpful to identify high-risk populations; facilitate resource and activity planning, such as monitoring vaccination coverage and vaccine stock availability; and determine the overall performance of the immunization program [23,24]. During ASIK's first launch, Indonesia's MoH emphasized that, in the future, children who have received immunization will have their records digitally stored in ASIK, in which the integrated data aim to facilitate parents' access to their children's immunization data, especially to be used for school-related purposes [19].

In the technical implementation guideline document for the BIAN, recording and reporting of immunization activities are mandated to be conducted electronically through ASIK [7]. Despite electronic data input being mandatory, the data recorded in ASIK did not represent the complete immunization service during the BIAN 2022 campaign. According to the ASIK analytical dashboard, the national coverage recorded in ASIK for MR, OPV, IPV, and DPT-HB-Hib immunization was 50.1% (18,301,057/36,497,694), 36.2% (938,623/2,595,240), 30.7% (1,276,668/4,158,289), and 40.2% (1,371,104/3,407,900), respectively. In addition, there was an average discrepancy of approximately 19% between digital and manual data reporting. When compared to similar supplementary immunization efforts in previous years, the Polio National Immunization Week held in 2016 achieved an impressive coverage rate of 96.5%. MR supplementary immunization activities in 2017 exceeded expectations, reaching >100.9%, whereas in 2018, the coverage stood at approximately 73.4% [7]. Around the same time, between 2017 and 2019, several countries, including Afghanistan, Benin, Ghana, Timor-Leste, Togo, Sierra Leone, Senegal, Rwanda, Pakistan, Niger, Malawi, Lesotho, and Ethiopia, also attained MR supplementary activity coverage rates of >90% [25]. Nonetheless, it is important to consider that these coverage data were obtained from manual or paper-based immunization records and postcampaign surveys [25].

Considering that the immunization data are stored in different files segregated by health center and area, it is nearly impossible to ensure that there is no duplication of data in each record. Studies show that paper-based data reports actually create challenges such as affecting health care workers' ability to make data-driven decisions by analyzing the manual immunization reports and increasing the burden of health workers to input data both in the paper-based and digital reporting systems [26]. Furthermore, the use of paper-based aggregate data for analysis presents gaps, such as limited individual longitudinal data, and omits crucial sociodemographic information [27]. Data stored electronically enable prompt data retrieval, hence facilitating immediate reports related to disease and surveillance, which is in contrast to paper-based reports that rely on manual retrieval [13]. Dual use of EIR and paper-based immunization reports further exacerbates the challenges of data input using ASIK for health care workers. A transition from paper-based reports to paperless reports and dual entry processes are also perceived barriers and challenges to EIR implementation in other countries such as Kenya and Vietnam [26,28]. The immunization program has grown in complexity and leads to an increased need for data, and the immunization information system must be flexible to cater to those needs [13]. Paper-based reports are limited in meeting such needs as they are heavily influenced by population mobility and errors stemming from estimation of population number [13]. Hence, moving forward, it is important for relevant stakeholders to decide whether to solely use paper-based reports or onboard using ASIK for Indonesia immunization programs.

On the other hand, data captured in ASIK represent individual data, which can be linked to personal immunization history records. Individual immunization data recorded in an EIR such as ASIK offer the advantage of providing precise and timely information. This, in turn, facilitates critical activities such as monitoring vaccination compliance, mitigating dosing errors, and identifying unvaccinated individuals [29]. The significance of individual immunization records in clinical decision-making is noteworthy as they provide a comprehensive historical vaccination record and diminish the likelihood of misclassifying vaccination status [30]. Consequently, this aids in reducing instances of both under- and overimmunization in children [31]. Furthermore, integrating individual immunization data from an immunization information system into an electronic medical record or electronic health record can enhance the accuracy of vaccine safety assessments [30,32].

ASIK has achieved significant engagement, involving 93.5% (9708/10,382) of public health centers across Indonesia within a span of 7 months since its launch. This indicates that public health centers were informed about the data input process and user guide updates that come with it, although long-term adherence to data input remains to be seen. The high level of ASIK use might be supported by several aspects, such as the compatibility of the Android app in Indonesia, the user-friendliness of the system interface, and the ease of use. Considering the high level of mobile phone and internet use in Indonesia, the digitization of health service reports is happening apace [33]. In 2021, approximately 90.5% of households in Indonesia owned at least one mobile phone, covering 65.8% of the population, and approximately 62% of the population had access to the internet [34]. Indonesia is estimated to have >200 million mobile phone users and is dominated by Android operating systems (95%) [34,35]. This is in line with our findings, in which 97% (923/952) of respondents stated that they owned Android-based mobile devices. ASIK is built on an Android operating system, which is compatible with various mobile devices, allowing health care workers in Indonesia to benefit from it [33]. Existing EIRs such as ImmunizaCA in Canada, Zindagi Mehfooz in Pakistan, and DHIS2 Android Capture App in Zambia are also built on Android-based platforms [36-40].

A visually appealing or user-friendly UI and UX can prompt users to explore an app, facilitating a comprehensive understanding of its available functions, consequently influencing user acceptability [41,42]. It is essential to acknowledge that ASIK signifies a transition for health care

XSL•FO
RenderX

workers from paper-based to electronic reporting; hence, data and variables should be both useful and recognizable to the health workers as it is important to note that a familiar interface correlates with use frequency [43]. Other than that, a familiarity with workflow and a design that carefully considers health care workers' needs are crucial for effective EIR implementation [26].

Despite the users' acceptability of ASIK as an EIR, the low number of reporting in certain provinces may be due to several factors. First, primary health care workers, often responsible for numerous data collection tasks, are frequently burdened with heavy workloads, lack motivation, and view data recording as undesirable and time-consuming [44,45]. Such excessive workloads can compromise the quality of health care data reported at health facilities, leading to inaccuracies and unreliability when other tasks interfere with data entry [46,47]. Indeed, the lowest compliance was often correlated with the provinces that have the lowest ratios of primary health care staff, and thus, it is presumed that staff time availability is the strongest root cause for the observed variation in ASIK use. The workload also affects workers' opportunities to adequately familiarize themselves (digital familiarization) with any health information system they are about to use, often coupled with inadequate handover and shortage of available staff for this knowledge transfer [48,49]. In the next phase, to ensure that there is an appropriate and sustainable knowledge transfer to all end users, conducting a cascading training-of-trainers approach and establishing a multilevel technical support network is recommended [28].

The sudden explosion in the number of health-related apps in Indonesia, with >400 health-related apps developed and introduced for health care facilities, further exacerbates the burden on health workers regarding digital familiarization and data input [15]. In addition, lack of adequate monitoring by supervisors or managers and provision of technical support affects the effective implementation of data reports through an information system [48,49]. Furthermore, the BIAN implementation coincided with a massive COVID-19 preventive immunization effort, adding more tasks to primary care workers' daily workload [50,51]. The implementation of COVID-19 immunization entailed a collaborative approach involving various sectors, with health personnel sourced from governmental, military, and private practitioner sectors [52]. This stands in stark contrast to the BIAN 2022 campaign, which relied heavily on health workers stationed at public health center facilities [52]. Therefore, there was a double burden for primary care workers to reach both the target for COVID-19 immunization and the target for the BIAN 2022 campaign and report both results using different digital pathways. This further justified the need to simplify, integrate, and ensure the interoperability of the health information system in Indonesia, as mentioned in the digital transformation blueprint, and ensure that the EIR is developed to match users' needs and able to simplify the reporting workflow accordingly [15,26].

In the process of implementing digital technologies in the health care sector, certain challenges are inevitable [53]. These challenges encompass a range of factors, including but not limited to client identification and verification as well as lack of database integration [53,54]. In ASIK, the collection of the national identification number of the service recipient is a prerequisite for generating an immunization service record. Indonesia uses a 16-digit identification number, known as the resident registration number, which serves as a cornerstone of national demographic identification [55]. Current data indicate that 97.2% of Indonesian citizens already possess a unique identification number, but there are also 5.38 million individuals without unique identification numbers [55,56]. During BIAN implementation, there were many instances in which patients did not bring any personal identification tools when immunization services were provided. Consequently, users were burdened to create individual data without unique identifiers while also needing to remember that exact record for identification and retrieval in the future when the same patient visited. Lack of linkage and integration with other databases were also a common challenge, which happened in the development of EIRs in Africa [54]. It is crucial to foster awareness and establish a mutual understanding between the realms of public health and IT to facilitate EIR development [54]. Ensuring that EIRs comprehensively covered all regions across Indonesia, encompassing an estimated target population of 37 million individuals for BIAN immunization, presented a challenge in conveying this requirement effectively, especially in the beginning of the system's development. To build an interoperable EIR system, integration with the national ID database is crucial [28]. Moving forward, the MoH could establish a continuous collaboration with the Ministry of Home Affairs as the primary stakeholders and foster understanding of and commitment to the need for database integration and providing immediate legal identity to the population since birth.

To report immunization data in ASIK, having access to the internet is a prerequisite. Despite statistics indicating that approximately 62% of Indonesia's population use the internet and the country's consistent progress in improving internet connectivity, disparities persist in terms of access across different social classes and regions [34,57]. Notably, significant portions of Indonesia, particularly in the eastern regions, still lack access to the internet [58]. The distribution of infrastructure for signal reception in Indonesia reveals that >3023 villages lack signal reception infrastructure, with >934 of these villages located in Papua [34]. Given the limited internet access, it is unsurprising that the coverage of MR, OPV, IPV, and DPT-HB-Hib immunization reports using ASIK remained low in Papua. Mobile apps that need to constantly rely on internet connectivity reduce effectiveness for users such as health care workers that operate in remote regions [59]. To reduce the digital divide among regions, the government could explore the potential use of satellite-based cellular and internet connectivity for rural areas [60]. This could be done through collaboration with the Ministry of Communication and Information Technology or alongside existing internet provider entities. Other than ensuring internet connectivity, support and assistance to infrastructure and human resources is paramount, particularly in areas with low information and communications technology maturity scores [61].

This is the first study that describes the EIR in Indonesia, which replaces the manual reporting system from the MoH, including

XSL•FO
RenderX

describing its use during the BIAN. Furthermore, the quantitative survey provided an overview of the obstacles in the implementation of ASIK for the BIAN program and provided input on the features that need to be improved for future immunization data collection processes. However, a relative weighing of the factors that require future improvement was not sought and, thus, can become the subject of future research.

This study has several limitations that need to be considered. First, ASIK is only available on Android-based platforms and has not been released for iOS; thus, data reporting is limited to officers who own devices compatible with Android. Second, the quantitative survey that was administered covered a limited number of the actual ASIK users in the field, but it is expected that this number can represent feedback from the field. In addition, using Mentimeter potentially limited the feedback from some of the participants when they did not fill the questionnaire in a timely manner, and considering that the evaluation meeting was conducted on the web, there was a risk of limited control over the participants filling out the questionnaire in a timely manner. Finally, the manual data that were compared to ASIK are the result of a report from the provincial health office, which might not fully capture the recording process that took place. Nevertheless, this study provides a deeper understanding of the use of ASIK in the BIAN program as the first EIR implemented nationally by the MoH.

Conclusions

EIRs have demonstrated their cost-effectiveness in improving vaccination coverage and timeliness, offering numerous advantages in disease prevention and health care management. Adoption and continuous use of EIRs entail numerous challenges, especially in a country such as Indonesia with an enormous number of targeted immunization populations and limited infrastructure settings. Challenges observed from this study included the gap between manually reported data and electronic records due to dual data entry processes; heavy workloads for primary care health workers to carry out immunization campaigns as well as the reporting process; lack of data completeness in ID number, full name, date of birth, or gender; system interferences due to the early development phase of the system; and limited infrastructure settings to support digital connection in remote areas. Addressing these challenges and ensuring adequate support for health care workers are essential steps in enhancing the effectiveness of EIRs in improving public health outcomes.

Although faced with the aforementioned challenges, ASIK as Indonesia's first national EIR managed to reach substantial engagement. More than 93% of its targeted users adopted the system, and this was potentially made possible by ease of system use, continuous system improvement according to users' feedback, and immediate regulation support. Ease of use and user-friendly apps that simplify data input processes are essential to reinforce user acceptability. In the future, ASIK can be developed for a wider immunization program provided that improvement of features is carried out, including the preparation of relevant human resources and supporting digital infrastructure and stronger regulatory support.

Acknowledgments

The authors would like to thank the Digital Transformation Office, Ministry of Health, Republic of Indonesia, for supporting the study implementation and developing the Aplikasi Sehat IndonesiaKu integrated system; the public health centers and district and provincial health offices across Indonesia who participated in the study; and the Directorate of Immunization Management, Ministry of Health of Indonesia, who supported the study implementation. The authors did not receive funding for the creation of this manuscript. This work was supported in part by the International Agency for Research on Cancer (IARC) through training by the Biobanking and Cohort Network (Civilian Research and Development Foundation Global, award 66415). While 2 authors are affiliated with Aceso Global Health Consultants, which is a private company, they declare that this research project did not receive funding from Aceso Global Health Consultants. The company did not have a role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript. Where authors are identified as personnel of the IARC, the authors alone are responsible for the views expressed in this paper, which do not necessarily represent the decisions, policy, or views of the IARC.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

DNA led the study design and developed the paper concept, main structure, and methodology. AU, FMR, and NHA conducted the quantitative survey and accessed and analyzed the data. DNA, AU, FMR, and NHA wrote the first draft of the paper. ZK and LM validated the study and critically revised the manuscript content. DNA and AU had primary responsibility for the final content. All authors contributed to reviewing the study data and the manuscript design and to the approval of the final manuscript.

Conflicts of Interest

LM is the director of Aceso Global Health Consultants, and DNA is a consultant of the company. However, both of them contributed to this paper on a pro bono basis. All other authors declare no conflicts of interest.

Abstract

Background: Family caregivers commonly help manage medications taken by persons living with dementia. Recent work has highlighted the importance of caregiver networks, which are multiple caregivers managing care for a single person, on managing care for persons living with dementia, especially medication management. However, less is known about the composition of caregiver networks.

Objective: The objective of this analysis was to describe the composition of caregiver networks that manage medications, the factors associated with helping with medications within caregiver networks, and whether racial or ethnic differences exist in caregiver network composition.

Methods: This cross-sectional secondary analysis used data from the National Health and Aging Trends Study (NHATS) "other person" files from 2011 to 2022. Descriptive statistics were calculated for caregivers who were identified as helping manage medications for a person with dementia. Mixed-effect logistic regression was used to determine factors associated with helping with medications among caregiver networks, with odds ratios converted to predicted probabilities using marginal standardization. A *P* value of .05 or less was considered statistically significant. Secondary analysis was stratified by race and ethnicity due to identified cultural differences in living situation and overall caregiver network composition.

Results: A total of 15,809 caregivers were analyzed. Of those, 3048 (19.2%) managed medications for persons living with dementia. Caregiver networks that manage medications tend to include a spouse or partner and child, at least one of whom has a college degree. Every person with dementia reported at least 1 person who managed their medications. White persons with dementia had an average of 2.4 (range 1 - 9) people who managed medications, while Black or African American persons with dementia had an average of 2.8 (range 1 - 9) and Hispanic or Latino persons with dementia had an average of 2.9 (range 1 - 8) people who managed medications. Spouses were most likely to manage medications across all racial and ethnic groups. In regression modeling, female gender (predicted probability [PP] 15%, 95% CI 13%-17%; *P*<.001), Black or African American race (PP 7%, 95% CI 4%-10%; *P*<.001), and Hispanic ethnicity (PP 4%, 95% CI 1%-9%; *P*=.04) were associated with an increased probability of helping with medications.

Conclusions: The size and composition of caregiver networks that manage medications for persons living with dementia differ by race and ethnicity but typically includes at least 2 people, one of whom has a college degree. Helping with medications was more likely among non-White family caregivers, while White patients with dementia were more likely to use paid help to manage medications.

Introduction

Persons living with dementia frequently take multiple medications due to comorbid conditions and pharmacologic attempts to manage the behavioral symptoms of dementia [1]. Family caregivers, or spouses, children, and friends who provide care for persons living with dementia, are often responsible for medication management [2]. Approximately 54% of family caregivers manage medications in early-stage dementia, rising to 90% in later dementia stages, as executive functioning declines and persons living with dementia become more reliant on family caregivers [3,4]. There are identified disparities in dementia diagnoses and medication management, dementia being more likely among Black and Hispanic persons [5], with family caregivers from historically minoritized racial and ethnic groups helping with medications at increased rates relative to non-Hispanic White caregivers [6,7].

Medication management of person living with dementia can be challenging and stressful for family caregivers [2,3,8]. Medication management includes components such as filling prescriptions and understanding medication purposes, organizing and administering medications, monitoring for side effects, and sustaining medication regimens, which can be very time-consuming for family caregivers [9].

Most prior studies have focused on medication management by family caregivers in the dementia dyad (eg, one person living with dementia and one family caregiver), but recent literature has highlighted the importance of caregiver networks in managing the care of persons living with dementia [10]. Caregiver networks can be defined as a cohesive network of family and friends who provide support to the persons living with dementia [11]. Caregiver networks can help reduce caregiver burden by sharing stressful tasks over multiple caregivers [12], and caregiver networks can facilitate better patient care through improved caregiver functioning [13]. Caregiver networks can be influenced by cultural factors including race and ethnicity [10]. For instance, Black and Hispanic persons living with dementia are more likely to rely on informal care from family and friends, live in a home with 3 or more household members, and have an adult child in the caregiving network than non-Hispanic White persons living with dementia [14,15]. Despite the importance of caregiver networks, current interventions to support medication management, like providing access to the medical record and using application-based medication trackers, are focused on the person living with dementia–caregiver dyad [8,16]. Networked interventions have the potential to improve adherence and reduce medication administration errors by including the full team of caregivers who help to manage medications [17].

While prior work has highlighted the importance of caregiver networks for providing care, and in communicating between members of caregiver networks when helping with medications [13], the characteristics of the caregiver networks that manage medications for persons living with dementia (the number of people helping with medications, the relationship between the persons living with dementia and the caregivers who help with medications, and the characteristics of those caregivers), and whether there are differences in the characteristics of those who manage medications for persons living with dementia by race and ethnicity, are currently unknown. Hence, the objective of this analysis was to describe the characteristics of caregiver networks that manage medications for persons living with dementia and determine what factors may be associated with helping with medications in caregiver networks.

Methods

Study Design and Setting

This cross-sectional secondary data analysis used data from the 2011 through 2022 National Health and Aging Trends Study (NHATS) “other person” files from rounds 1 through 12. The NHATS is an annual health-related study sampling Medicare beneficiaries in the United States [18]. The NHATS collects detailed information on participants’ physical and cognitive capacity, demographics, and living situations.

Data Source

The NHATS “other person” file is constructed from a roster that is generated from questions in the main NHATS interview and survey, where NHATS respondents were asked about other persons who help with their care. Other persons are cumulative to NHATS participants across rounds, meaning additional other persons are added each round an NHATS participant is interviewed, and each other person is given a unique identifier and resampled with the NHATS participant. While the “other person” file does not specifically identify the demographic features of the NHATS participant, we derived this information by linking the “other person” files with the NHATS participant identifier. NHATS participants and caregivers were analyzed in their most recent year of participation, and data from all waves of NHATS were pooled to increase sample size and estimate the effect of the sampling round on medication management.

Ethical Considerations

This analysis was determined as “not human subjects research” by the Institutional Review Board at the University of Alabama at Birmingham (#300013016). Analytic procedures were determined to be minimal risk to participants and did not require consent or contact with participants, and initial data collection for each NHATS round was approved by the conducting team. Data were deidentified prior to examination and analysis. The reporting of this study adheres to the RECORD (Reporting of Studies Conducted Using Observational Routinely Collected Data) statement (Checklist 1).

Inclusion Criteria

For inclusion as a caregiver in our analysis, caregivers in the NHATS other person file must have been identified as a person who helps with medication management by the NHATS participant or their proxy. The caregiver in the NHATS other person file must also provide care to a patient with dementia, as defined in the NHATS Condition Variable 9, which asks about the presence or absence of a dementia diagnosis.

XSL•FO
RenderX

Assessments

Demographic covariates for caregivers were selected from those collected in the NHATS other person file and included race, ethnicity, gender, relationship to persons living with dementia, education, age, and year of data collection. Race and ethnicity were categorized as White, Black or African American, Hispanic, or other, which included American Indian, Alaska Native, Asian, Native Hawaiian, and Pacific Islander.

Relationship to the persons living with dementia was categorized by self-report as sibling, child, grandchild, spouse or partner, paid helper, or other, which included the sons of step-siblings, boarders and renters, neighbors and nonrelated friends, nonrelated roommates, and ex-spouses or partners. A "paid helper," according to the National Study of Caregiving (NSOC), is someone who was employed to provide care but was not an immediate family member.

We identified caregiver groups who help with medications as those in the other person file who help with the same patient's medications, as determined by an affirmative response to the variable "MEDSHELP," which asks whether the person helps with the patient's medications.

Study Size

We analyzed 15,809 unique caregivers from the "other person" files of NHATS rounds 1 through 12.

Data Analysis

Mixed-effect logistic regression analysis was conducted based on the outcome variable "helping with medications" and independent demographic variables race, relationship to the patient, gender, and education, including a person living with dementia-level random effect to account for multiple caregivers caring for the same person living with dementia. As this was an exploratory rather than confirmatory analysis, variables were not added incrementally. To protect against overfitting and collinearity, we tested for collinearity between independent variables using the variance inflation factor (VIF) and defined problematic collinearity as a VIF greater than 10. We did not impute or otherwise include caregivers who provided missing data. We excluded covariates with problematic missingness, defined as having greater than 20% of missing observations, via listwise deletion to preserve sample size in the regression modeling [19]. Education and age were thus excluded from regression modeling due to missingness, though sensitivity analysis indicated no statistically significant difference between models including and excluding those variables. A predefined α level of .05 was used to determine statistical significance. Odds ratios were converted to predicted probabilities using marginal standardization to aid in interpretability [20]. All analyses were conducted in R version 3.4.1 (The R Foundation for Statistical Computing).

Results

Descriptive Results

Of the caregivers analyzed, 19.3% (3048/15,809) helped manage medications for persons living with dementia. Each person with dementia had at least 1 person who helped manage their medications. Caregivers who helped with medications were 56.9% (1633/2865) non-Hispanic White, 27.8% (799/2865) Black or African American, 9.8% (279/2865) Hispanic, and 4.7% (133/2865) other. Caregivers who helped with medications were 15.0% (445/3033) spouses, 39.1% (1184/3033) children, 4.9% (149/3033) grandchildren, 9.9% (303/3033) other relations, 30.4% (921/3033) paid help, and 1.5% (45/3033) siblings. The mean number of caregivers assisting a person living with dementia with their medications was 2.5, with a range of 1 to 9.

Among non-Hispanic White caregivers who manage medications (n=1633), the mean number of participants assisting with medications was 2.4 (range 1-9). Caregivers who helped with medications were 17.3% (282/1633) spouses, 33.9% (555/1633) children, 2.9% (48/1633) grandchildren, 9.6% (157/1633) others, 35.5% (580/1633) paid helpers, and 0.7% (11/1633) siblings.

Among Black or African American caregivers (n=799), the mean number of caregivers assisting with medications was 2.8 (range 1-9). Caregivers who helped with medications were 8.8% (71/799) spouses, 45.6% (365/799) children, 8.3% (67/799) grandchildren, 12.0% (96/799) others, 22.1% (177/799) paid helpers, and 2.6% (21/799) siblings.

Among Hispanic or Latino caregivers (n=279), the mean number of caregivers assisting with medications was 2.9 (range 1-8). Caregivers who helped with medications were 16.1% (45/279) spouses, 48.7% (136/279) children, 5.3% (15/279) grandchildren, 7.1% (20/279) others, 20.7% (58/279) paid helpers, and 1.7% (5/279) siblings.

Among "other" caregivers (n=133), the mean number of caregivers assisting with medications was 2.4 (range 1-7). Caregivers who helped with medications were 16.5% (22/133) spouses, 31.5% (42/133) children, 5.2% (7/133) grandchildren, 10.5% (14/133) others, 33.1% (44/133) paid help, and 3.0% (4/133) siblings.

Participant demographics can be found in Table 1. See Table 2 for more information on participants by race, ethnicity, and relationship.

Statistical Results

In the univariate statistical model, gender (P<.001) and relationship (P<.001) were associated with helping with medications.

In the fully adjusted regression model, compared to non-Hispanic White race or ethnicity, Black race or ethnicity (predicted probability [PP] 7%, 95% CI 4%-10%; P<.001) and Hispanic race or ethnicity (PP 4%, 95% CI 1%-9%; P=.04) were associated with an increased likelihood of helping with medications among caregivers. Female gender (PP 15%, 95% CI 13%-17%; P<.001) was associated with an increased likelihood of helping with medications. Compared to a spouse or partner, children (PP −51%, 95% CI −56% to −46%; P<.001), grandchildren (PP −60%, 95% CI −66% to −54%; P<.001), paid help (PP −23%, 95% CI −39% to −7%; P=.006), and siblings (PP −63%, 95% CI −69% to −58%; P<.001) were all associated with decreased likelihood of helping with medications. See Table 3 for the fully adjusted regression modeling.

Child	−0.51 (−0.56 to −0.46)	<.001
Grandchild	−0.60 (−0.66 to −0.54)	<.001
Other	−0.62 (−0.67 to −0.57)	<.001
Paid help	−0.23 (−0.39 to −0.07)	.01
Sibling	−0.63 (−0.69 to −0.58)	<.001
Round	0 (0 to 0)	.96

Sensitivity Analysis

We conducted a sensitivity analysis based on reducing the number of distinct relationship categories. In this model, which had relationship categories of spouse or partner, other relative, paid help, and other, we found no improvement from the full regression model when considering Akaike Information Criterion, Bayesian Information Criterion, or overall deviance. See Table 4 for sensitivity analysis.

In subgroup analysis stratified by race and ethnicity, female gender was associated with a higher likelihood of helping with medications, and compared to spouses and partners, children, grandchildren, paid help, and siblings were all associated with a lower likelihood of helping with medications. See Table 5 for subgroup analysis.

Discussion

Principal Results

In our analysis of 15,809 NHATS "other person" data records from 2011 to 2022, we found that the average person with dementia has 2.5 people that help with their medications, and that Black or African American and Hispanic persons with dementia have more people helping with their medications than White persons with dementia. Many children, grandchildren, and siblings of persons with dementia are helping with medications, in addition to spouses. In the regression modeling, we found that Black race, Hispanic ethnicity, and female gender were associated with an increased likelihood of helping with medications, while relationships other than spouses or partners were associated with a lower likelihood of helping with medications. We did not observe differences between helping with medications and the year of data collection.

Limitations

This study was conducted using a large composite sample from a methodologically robust sample of Medicare beneficiaries. While we included participants from all sampled years (2011 - 2022), we analyzed the sample cross-sectionally at the most recent year of data collection to ensure as large of a sample as possible, though our regression modeling is not generalizable to the broader population as we could not appropriately weigh our combined sample. We included sampling year as a covariate to minimize differences in year on our estimates and found that sampled year was not a statistically significant covariate for medication management, but future work should consider longitudinal trends in medication management by family caregiver networks. Additionally, we chose to exclude education level and age from our regression models due to missingness to preserve sample size on our primary covariates of interest. Prior work has not shown that education or age is associated with medication management among individual caregivers [7], and when our analysis included those variables, we found no statistically significant differences between the 2 models, but future work could consider whether those covariates affect helping with medications in caregiving networks. It is possible that the gender composition of our sample, which was 75% female and 25% male, may overestimate female gender being a statistically significant predictor in our regression modeling. Other work has highlighted the importance of including male dementia caregiver perspectives in research [21]; future targeted work to determine the effect of gender on predictors of network composition should consider oversampling male caregivers to limit this potential effect. Finally, we were unable to include the stage or severity of dementia, or what tasks are included in helping with medications, as this is not collected in NHATS. Future work should consider whether there are differences in caregiver networks that manage medications by stage of dementia, and identifying what tasks of helping with medications are being performed by different components of the network.

Comparison With Prior Literature

Prior work with NHATS data from 2011 to 2015 has found that persons living with dementia have caregiver networks that assist with the tasks of care, which includes medication management as well as other medical-related tasks like attending clinic visits and interacting with providers [22]. They found that these networks range in size from 0 to 2+ caregivers but did not specify a total range. Our finding with data from 2011 to 2022 that caregiver networks included at least one person and, on average, 2.5 caregivers that manage medications indicates that medication management could be an activity that is more complex and requires more caregiver involvement than other caregiving tasks. The differences in network size that we found, while small, highlight the shared nature of caregiving. Not one group had an average of below 2.5 caregivers who manage medications, yet current methods of facilitating medication management are focused on an individual caregiver managing medications. Interventions to support medication management should consider supporting caregiver networks as well as the primary caregiver, as the average person living with dementia has at least 2 caregivers who help with medications. Potential interventions could include applications or integrations that allow for proxy access by caregivers or caregiver profiles that allow for the management of patient medications; these interventions have been considered by health systems, though not applied to medication management [23,24].

Other work on cultural differences in the composition of caregiver networks used data from NHATS from 2015 to 2019 and found differences in the size of caregiver networks by race and ethnicity. They found that Hispanic persons living with dementia had the largest care networks with 6.89 members, while non-Hispanic Black persons living with dementia had 6.69 members and non-Hispanic White persons living with dementia had 5.74 members [10]. Our results indicate that the size of the networks that manage medications are smaller than those that help with other tasks like transportation or cooking food, with Hispanic persons living with dementia having 2.9 members, non-Hispanic Black persons living with dementia having 2.8 members, and non-Hispanic White persons living with dementia having 2.4 members. The relative size of the caregiver networks that manage medications could be due to cultural factors: existing literature has shown differences in family size and cohabitation by race and ethnicity which can affect caregiver network size, and larger networks could have more caregivers helping with medications [14]. Network size could be influenced by living situation: Hispanic persons living with dementia and Black or African American persons living with dementia are less likely to live alone and more likely to live in multigenerational homes than non-Hispanic White persons living with dementia [25,26]. Multigenerational living situations could be affecting the size and composition of the networks of caregivers who help with medications.

Addressing cultural factors is critical in providing culturally specific interventions to support caregivers in medication management. Co-designed medication management materials, where interventions and protocol materials are developed collaboratively between persons living with dementia, caregivers, and researchers, have been identified as an informational gap by prior reviews [27]. Our study suggests that including multiple caregivers may be beneficial to co-designing future interventions, especially in Black and Hispanic communities that have more caregivers on average

XSL•FO
RenderX

and different conceptualizations of the role of caregiving [28,29].

Our finding that spousal caregivers of persons living with dementia were more likely to manage medications when controlling for race and ethnicity and within each race and ethnicity extends prior work which found that spouses were more likely to manage medications for their spouses or partners in a sample that controlled for dementia status [30]. Spouses are more likely to live with the person receiving care and be near the person living with dementia around medication times [31]; however, it is notable that our analysis found that children and grandchildren are the plurality of caregivers who help with medications. While spousal caregivers could be most involved in the administration of medications in the home, children or grandchildren could be instrumental in filling or refilling medication prescriptions. Specific roles and aspects of helping with medications should be the target of additional future studies.

Conclusions

Caregiver network size is an important consideration when designing interventions to support medication management by family caregivers, and this study sheds light on the size and composition of family caregiver networks that manage medications for persons living with dementia. Interventions to support medication administration for persons living with dementia should consider caregiver network size and composition to facilitate persons living with dementia adherence to medication prescriptions.

Abstract

Background: Stroke results in both physical disability and psychological distress. The impact can be minimized through rehabilitation, but it is a long-term process, making it difficult for patients to adhere to treatment. Thus, a better understanding of long-term behavior change interventions for patients with stroke is needed as well as how such interventions can support not only rehabilitation of motoric functions but also mental well-being.

Objective: The aim of this study is to understand both the most important behavior change technique (BCT) clusters for long-term stroke rehabilitation in general as well as which are most relevant for each aspect of stroke rehabilitation: behavioral, cognitive, and emotional.

Methods: We applied the 16 BCT clusters. The study used a 2-round Delphi survey, as reliable consensus was obtained among a group of 12 international experts. Experts represented three main backgrounds involved in behavioral intervention in the health context: (1) specialists in behavioral science (n=4), (2) behavioral designers (n=4), and (3) expert health care professionals (n=4). Experts were brought together in this way for the first time. In the first round, web-based questionnaires were used to collect data from the experts. This was followed by a personalized second round. Consensus was determined by statistically aggregating the responses and evaluating IQR and percentage consensus. BCT clusters reaching consensus (IQR ≤1 and percentage ≥50%) were then ranked.

Results: In total, 12 of 16 BCT clusters reached consensus for general importance in stroke rehabilitation, with 11, 9, and 6 BCT clusters achieving consensus for, respectively, the behavioral, cognitive, and emotional aspects of rehabilitation. The overall most relevant BCT clusters were repetition and substitution, social support, feedback and monitoring, and self-belief, with similar outcomes for behavioral and cognitive rehabilitation. For emotional rehabilitation, social support and identity were emphasized. The least relevant BCT clusters were natural consequences, covert learning, and comparison of behavior.

Conclusions: This expert panel study using a 2-round Delphi survey ranked the importance of BCT clusters for long-term stroke rehabilitation. The process yielded a number of novel insights highlighting differences in importance between general rehabilitation and that specifically focused on the behavioral, cognitive, and emotional aspects of stroke recovery. This provides a first but important step toward unlocking the prioritization of BCT clusters for long-term intervention contexts such as stroke rehabilitation and enables effective intervention mapping addressing long-term behavior change and treatment adherence.

Introduction

Background

The World Health Organization defines stroke as "(...) rapidly developed clinical signs of focal or global disturbance of cerebral function, lasting more than 24 hours or until death, with no apparent non-vascular cause" [1]. It is a serious health problem and one of the most common causes of death and acquired disability among adults [2], having "(...) the greatest disabling impact of any chronic disease" [3]. Further, only a small proportion of patients die in the acute stroke phase, leaving the majority with moderate to severe disability that can be mitigated through early and sustained rehabilitation interventions [4]. It is estimated that the number of people living with stroke will increase by 27% in the European Union alone between 2017 and 2047 [5]. As such, stroke has a considerable socioeconomic impact, affecting not only patients themselves

XSL•FO
RenderX

but also their families, caretakers, medical professionals, hospitals, policy makers, and the whole health care system in the long term [6]. This places a critical focus on effective poststroke treatment and rehabilitation [7] not least for making health care interventions usable, safe, and effective.

Patients with stroke experience both physical disability and psychological changes, including emotional, behavioral, and cognitive impairments [3]. Issues, including depression, apathy, anxiety, posttraumatic stress, and anger, among others [3], are prevalent in patients with stroke. These pose significant barriers to rehabilitation by negatively impacting long-term adherence to exercises, hindering treatment processes, and decreasing the chance of patient recovery [8,9]. This places a priority on positively shaping patient behavior change in the long term. Yet, Teasell et al [10] highlight that over two-thirds of interventions in this context focus on improving motor functions, while less than 6% dealt with psychosocial issues. As such, there is a need to highlight the relevance of behavior change techniques (BCTs) in addressing psychosocial issues. However, general discussions of BCTs typically focus on interventions framed in the short term [11]. For example, Liu et al [12] highlight how a single reward can be effective in fostering short-term sign-up behavior, but additional strategies and research are needed to understand how best to maintain engagement. This uncovers a gap between current stroke rehabilitation practice and the potential of BCTs, as it leaves critical questions as to which BCTs should be prioritized when supporting the long-term treatment adherence required. Further, this reinforces the relevance and urgency of addressing long-term behavior change and treatment adherence specifically for stroke rehabilitation.

Together, these challenges reveal a critical disconnect between current stroke rehabilitation interventions and more general guidance on BCT use [13]. Thus, this work focuses on resolving this disconnect by examining how BCTs should be prioritized for stroke rehabilitation with a multifaceted approach that distinguishes between motor rehabilitation ("general rehabilitation" in our terms) and psychosocial rehabilitation (addressed separately as "behavioral," "cognitive," and "emotional" aspects). As such, the aim of this study is to understand both the most important BCT clusters for long-term stroke rehabilitation in general as well as which are most relevant for each aspect of stroke rehabilitation: behavioral, cognitive, and emotional.

Patient Adherence to Treatment

Poor adherence to treatment is a common challenge across health care domains [8]. In physiotherapy, up to 65% (with some sources claiming even 70%) of patients are nonadherent or only partially adherent to home treatment and exercises [8,14]. This high level of nonadherence (noncompliance) has an adverse effect on the cost and effectiveness of rehabilitation [8,15]. Several studies to date have explored the reasons for patient nonadherence to home treatment and exercises [8,14,16,17]. In their review, Jack et al [8] found strong support for the following barriers to treatment adherence: "low levels of physical activity at baseline or in previous weeks, low in-treatment adherence with exercise, low self-efficacy, depression, anxiety, helplessness, poor social support or activity, greater perceived number of barriers to exercise, and increased pain levels during exercise." However, while the importance of identifying and acknowledging the above during patient assessment has been emphasized, few authors offer concrete solutions to address adherence.

Two notable exceptions to this are Campbell et al [15] and Bonnechre et al [16]. Campbell et al [15] note the importance of physiotherapist's presence and contact with the patient as well as including patients as partners in planning therapy; and Bonnechre et al [16] stress the positive effect of patient supervision and suggest that, for example, telerehabilitation or other monitoring systems could be beneficial. However, when compared to the scope of relevant BCTs [18], these examples primarily serve to highlight the untapped potential of behavior changing interventions in support of long-term stroke rehabilitation. First, they are not specific to stroke rehabilitation; hence, they do not address some key issues that patients with stroke deal with compared to other conditions, such as simultaneous impairment of both motoric and cognitive functions. This makes the rehabilitation process more complex and increases the risk of developing other conditions such as depression and anxiety. Second, many approaches to improve patient adherence lack individualization, which is crucial as every patient is "(...) structurally, chemically, and emotionally different" [19]. This is especially true in the case of stroke, which can occur at different ages (despite being more prevalent in older age groups), be located in different regions of the brain with different functional consequences, and yield a range of effects, from mild to very severe [5]. Therefore, potential interventions must be considered in terms of long-term feasibility, as well as suitability for home treatment and rehabilitation, with minimum assistance of third persons. Each of these challenges points to potential mechanisms found in BCTs.

BCTs in Health Care

BCTs used as the basis for health care interventions such as education, training, or facilitating behavior through design, have been successfully applied to drive changes in health care professionals' practice [20,21], patient treatment and rehabilitation [22], disease prevention [23], or self-management [24]. At the same time, while the topic has been studied extensively by both behavioral psychologists [18] and designers [25,26], the differentiation between short- and long-term interventions has been little discussed. This poses a notable issue for rehabilitation, as it is widely acknowledged that sustaining long-term change introduces specific behavioral and design challenges [11,27,28].

A general approach to designing health care interventions suggests the following steps: "(...) identifying barriers, selecting intervention components, using theory, and engaging end-users" [21], linking development to feasibility, evaluation, and implementation [29,30]. In rehabilitation specifically, particular attention is given to the rehabilitation provider, who acts as a facilitator and enabler in driving health behavior change [31]. Nieuwenhuijsen et al [31] also highlight the need to understand a person's context and environmental factors, as these can

XSL•FO
RenderX

become facilitators or barriers to change. While these considerations are essential, guidance on how to approach long-term change or prioritize BCTs in this context is missing. This is particularly relevant in the case of stroke. This is because after the first few months of intense treatment, rehabilitation can take several months or even years in a home setting. Further, due to the complexity and scope of possible BCTs, prioritization efforts are critical to their understanding and application [18,32]. Here, one of the most widely accepted taxonomies of BCTs is provided by Michie et al [18]. Within the taxonomy of Michie et al [18], there are 16 clusters, with 93 individual BCTs, presenting a huge scope for intervention. Therefore, there is an urgent need to better understand which BCT clusters are most relevant to interventions for long-term contexts such as stroke rehabilitation.

Research Question

Bringing the literature together, there is a need to understanding both the most important BCT clusters for long-term stroke rehabilitation in general as well as which are most relevant for each aspect of stroke rehabilitation: behavioral, cognitive, and emotional, that is, supporting not only motoric and cognitive function but also mental well-being. Hence, we address one main research question (RQ): Which BCT clusters are the most relevant for long-term stroke rehabilitation in a home setting in relation to treating its behavioral, cognitive, and emotional aspects?

Methods

Study Design

To address the RQ, we used a Delphi method, which has proven to be essential in ranking importance of BCT clusters in different contexts when large-scale data on intervention outcomes are notably rare [18,32-35].

The Delphi method was administered by email and using a link to a web-based survey tool (Qualtrics) [36]. We followed the procedure set out by Rowe et al [37] and obtained consensus after 2 rounds. The 2-round Delphi survey was used to rank the least and most important BCT clusters across the parameters outlined in the RQ. The 2 rounds were executed in 2021 between June and October. In the first round, the 16 BCT clusters defined in the behavior change technique taxonomy (BCTT; version 1) were used as the basis for the survey structure, and questions were evaluated by 12 international experts [18,33]. BCTT (version 1) was used for two main reasons: (1) it provides a basis for direct comparison with an array of prior ranking studies and hence helps to contextualize the results of this work and (2) it is widely applied in practice, making it accessible to all involved experts. In the second round, the results were iterated by 9 of the original 12 experts to reach a consensus on the ranking of the BCT clusters. The 16 BCT clusters are summarized in Textbox 1 as they were presented to the participants.

Textbox 1. Summary of the 16 behavior change technique (BCT) clusters in behavior change technique taxonomy (version 1) as presented to participants.

1. Goals and planning comprises BCTs that revolve around goal-setting and revision, strengthening commitment to those goals, problem-solving (by analyzing and removing factors influencing certain behavior), and action planning.
2. Feedback and monitoring comprises BCTs that revolve around monitoring (by others) or self-monitoring (yourself) the behaviors or behavior outcomes, which can—but does not have to—be combined with feedback on behavior, its outcomes, or body state (biofeedback).
3. Social support comprises BCTs that revolve around providing different types of social support to assist the person in the process of behavior change.
4. Shaping knowledge comprises BCTs that revolve around providing information on the antecedents of the behavior (including suggesting alternative explanations) and instructions on how to perform the behavior.
5. Natural consequences comprises BCTs that revolve around providing information (and occasionally also monitoring) on the health, social, environmental, and emotional consequences of the person's behavior.
6. Comparison of behavior comprises BCTs that revolve around comparing person's behavior to a correct behavior or others' behavior as well as informing about what other people think about the behavior.
7. Associations comprises BCTs that revolve around providing prompts or cues as a stimulus for the behavior and gradually removing them when the goal is achieved. The cues can also be related to signaling the reward (or lack of thereof) or removing a stimulus that causes adverse effects.
8. Repetition and substitution comprises BCTs that revolve around practicing or rehearsing behaviors (sometimes in an excessive manner—overcorrection) to increase habit and skill, as well as behavior substitution with a wanted or neutral behavior, and habit formation or reversal.
9. Comparison of outcomes comprises BCTs that revolve around providing objective, credible source of information in favor or against the behavior, as well as advising comparison of pros and cons of the behavior or possible outcomes of doing (vs not doing) a given behavior.
10. Reward and threat comprises BCTs that revolve around providing a material or social reward or incentive to encourage the desired behavior. The subtle difference between a reward and incentive refers to the fact that the former is actually performed at a given time (eg, arranging for the person to receive money that would have been spent on cigarettes if and only if the smoker has not smoked for 1 month would be a material reward, while informing that the payment will be made in the future for every month a person did not smoke during pregnancy would be a material incentive). Similarly, a reward or incentive can relate to the behavior itself (eg, sticking to a diet every day for a month) or the outcome of the behavior (eg, losing 5 kg in a month). Finally, the rewards or incentives can be provided externally or by the person themselves (eg, plan to reward yourself with new clothes if you adhered to a healthy diet).
11. Regulation comprises BCTs that revolve around providing different ways to regulate and facilitate one's behavior. That could include encouraging the use of drugs that facilitate behavior change, advising on ways of reducing negative emotions or minimizing mental resources to support behavior change, or giving paradoxical instructions to engage in the unwanted behavior with a point of reducing motivation to do it (eg, asking a smoker to smoke twice as many cigarettes a day than they usually do or tell the person to stay awake as long as possible in order to reduce insomnia).
12. Antecedents comprises BCTs that revolve around changing one's physical or social environment to facilitate the performance of wanted behaviors or create barriers for unwanted behaviors. This can also include adding objects to the environment, advising on how to avoid or reduce exposure to specific social or physical cues that trigger unwanted behavior, or how to distract attention with other activities. It could also mean introducing body changes to facilitate behavior change (eg, strength training).
13. Identity comprises BCTs that revolve around attention to self-image related to the given behavior. It could be informing the person that their behavior may be an example to others, suggesting deliberate change of perspective on behavior (framing or reframing) to change emotions associated with the behavior or drawing attention to differences between the behavior and person's self-image. It could also include asking the person to construct and articulate their new identity (eg, as an "ex-smoker").
14. Scheduled consequences comprises BCTs that revolve around the planned consequences of the behavior, which could be both positive (eg, rewarding completion [or even approximation] of the behavior) or negative (eg, punishing the unwanted behavior or removing the reward).
15. Self-belief comprises BCTs that revolve around the idea of reinforcing one's belief that they can and will successfully perform the wanted behavior and arguing against self-doubt and insecurity.
16. Covert learning comprises BCTs that revolve around imagining performing the given behavior and its consequences or observing the consequences of this behavior for others.

Delphi Panel

For the Delphi panel, we convened 12 international experts on behavioral intervention and stroke rehabilitation based on the scientific, medical, and industrial networks of the authors, following other recent Delphi studies in this area [33,38]. Here, expert was defined as "someone with knowledge and experience on a particular subject matter" [39]. The experts were identified through the academic and professional networks of the authors (focusing on those in the fields of design and clinical practice), with eligibility criteria as follows. All experts had at least a master degree as well as multiple years of experience in practice. Further, they all had expertise in long-term behavioral design, development of interventions in this context, and familiarity with the BCTT, that is, they were able to distinguish the BCTT clusters and their implications. While these criteria led to a relatively small sample, there are several reasons for this. First, the population deeply familiar with both the full BCTT and stroke education and rehabilitation is very limited, with several of our contacts rejecting our invitation on this basis despite

XSL•FO
RenderX

being relevant subject experts. This is a familiar issue for studies of BCT use; thus, our experience and sample align with an array of recent BCT-related Delphi studies [33,34]. Second, we specifically include experts focused on the development of interventions in the emerging area of behavioral design, where there are even less experienced practitioners [26]; thus, in order to maintain a balanced sample, each group was limited based on this smallest population. This subgroup was specifically included due to its growing impact on the development and implementation of health interventions [20,34]. Thus, of the 26 experts approached, we accepted a sample of 12 who agreed to participate in the study.

Overall, 12 completed the first round and 9 (75%) the second round, exceeding the minimum 70% threshold for Delphi round response [40]. Experts represented three main backgrounds involved in behavioral intervention in the health context: (1) specialists in behavioral science, design for behavior change, or psychology, who research BCTs (n=4); (2) behavioral designers working in industry actively developing health-related behavioral interventions (n=4); and (3) expert health care professionals working with patients with stroke daily (n=4). The participants were residents of Denmark (8), Germany (2), and Portugal (2). Given the heterogeneous group, this panel is in line with recommendations for a number of participants [41,42] as well as comparable studies in this area [33,38].

Ethical Considerations

The ethics approval processes at the host research institution and national guidelines were followed. No further ethics approval was needed with reference to the Danish Research Ethics Committees that state on their website that "(...) health science questionnaire surveys and interview studies that do not involve human biological material (section 14(2) of the Danish Act on Committees) are not mandatory to report" [43].

Procedure

Delphi Study First Round

The first round of the Delphi study used a web-based questionnaire distributed via Qualtrics software. The questionnaire consisted of 3 parts. In the first part, the participants were asked to provide demographic information, such as age, gender, education, professional background, type of employment, and country of residence (which in the health care context provides more information than nationality, as clinical practice and rehabilitation process differs depending on location). The second part of the questionnaire consisted of 3 open questions, where the participants could elaborate on the context of their current job or research, their understanding of "behavior change" in the context of their work, as well as what they typically consider a "long-term" change. The third and main part of the questionnaire was divided into sections corresponding to the 16 BCT clusters [18]. Each section started with a description of a given cluster (Textbox 1) as well as the specific BCTs in the cluster and examples of practical interventions using it. The description was followed by 2 questions focused specifically on how the BCTs from this cluster support stroke rehabilitation and treatment of psychological issues after stroke, including emotional, behavioral, and cognitive recovery. The questions used a standard 5-point Likert scale (rated from 1=not at all important to 5=extremely important) and are summarized below:

1. In your opinion, how important is [*BCT cluster*] in the context of rehabilitation of patients with stroke?
2. In your opinion, how important is [*BCT cluster*] for the treatment of the following psychological issues after stroke?
   a. Behavioral (eg social judgment and personality changes)
   b. Cognitive (eg attention, memory, or language impairment)
   c. Emotional (eg, depression, anxiety, posttraumatic stress, and anger)

At the end of the questionnaire, there was an opportunity for the experts to share their impressions on the topic and any comments that arose during the study.

Delphi Study Second Round

After the results from the first round were analyzed, a second questionnaire was designed for each specific participant, delivered via a personalized email. This also provided feedback on the responses to the first round for participants to reconsider their prior answers. The purpose of this round was to determine consensus on only those BCT clusters where no consensus was reached in the first round. This limited the scope of the second round in order to ease participation and followed similar approaches in prior work on BCT ranking [34]. In each case, participants had the opportunity to change their prior answers in light of the first round responses or to provide additional explanations of their reasoning. The explanation of the questions and BCT clusters was the same as in the first round.

Data Analysis: Consensus Evaluation

After both rounds of the Delphi survey were complete, the final level of consensus and ranking of the BCT clusters was determined. While the means for establishing consensus and its level in Delphi studies are debated, we apply two widely acknowledged criteria: (1) percentage consensus [44] and (2) median and IQR [33,45]. In terms of overall percentage consensus, a minimum of ≥50% is considered acceptable and provides context for the IQR evaluation [44]. When using Likert scales in Delphi studies, agreement with respect to a median score is widely evaluated with respect to IQR. Specifically, for a 5-point Likert scale, an IQR of ≤1 is suggested as indicative of a high degree of consensus [44,45]. Thus, in this study, we considered consensus to be reached when both percentage consensus was ≥50% and IQR was ≤1, that is, the majority of answers fell within 1 point on the 5-point Likert scale. The percentage consensus, median, and IQR results are summarized for all BCT clusters in Table 1 (for survey question 1) and Table 2 (for survey question 2a, b, and c).

Table . The percentage consensus and median (IQR) for all behavior change technique (BCT) clusters related to question 1 after round 2.

BCT cluster	Consensus	Median (IQR)
1. Goals and planning	67	4.0 (4.0-4.3)
2. Feedback and monitoring	42	4.0 (4.0-5.0)
3. Social support	50	4.5 (4.0-5.0)
4. Shaping knowledge	58	4.0 (3.8-4.0)
5. Natural consequences	50	3.0 (2.0-3.0)
6. Comparison of behavior	50	2.0 (2.0-3.0)
7. Associations	42	4.0 (3.0-4.0)
8. Repetition and substitution	50	4.5 (4.0-5.0)
9. Comparison of outcomes	67	4.0 (2.8-4.0)
10. Reward and threat	33	3.0 (3.0-4.0)
11. Regulation	50	3.0 (3.0-4.0)
12. Antecedents	50	4.0 (3.0-4.0)
13. Identity	42	3.5 (2.8-4.0)
14. Scheduled consequences	42	2.5 (2.0-4.0)
15. Self-belief	50	4.0 (4.0-5.0)
16. Covert learning	58	3.0 (2.8-3.0)

Table . The percentage consensus and median (IQR) for all behavior change technique (BCT) clusters related to question 2a, 2b, and 2c after round 2 (clusters are numbered for brevity).

BCT	Question 2a		Question 2b		Question 2c	
	Consensus	Median (IQR)	Consensus	Median (IQR)	Consensus	Median (IQR)
1	50	3.5 (3.0-4.0)	33	4.0 (3.0-5.0)	50	4.0 (3.0-4.0)
2	50	4.0 (3.8-4.3)	42	4.0 (3.8-5.0)	50	4.0 (3.0-4.0)
3	58	4.0 (3.5-4.0)	58	4.0 (3.0-4.0)	67	5.0 (4.0-5.0)
4	58	4.0 (3.0-4.0)	42	4.0 (3.0-4.0)	50	4.0 (2.8-4.0)
5	42	3.0 (2.0-3.3)	42	2.0 (2.0-3.0)	67	2.0 (2.0-4.0)
6	42	3.0 (2.0-4.0)	42	3.0 (1.8-3.0)	25	2.5 (1.8-3.3)
7	50	4.0 (3.0-4.0)	50	4.0 (3.0-4.0)	42	3.0 (3.0-4.0)
8	67	4.0 (4.0-4.3)	50	4.0 (4.0-5.0)	33	3.0 (2.8-4.0)
9	67	4.0 (2.0-4.0)	42	3.0 (2.0-3.3)	42	4.0 (2.8-4.0)
10	50	3.0 (2.8-3.3)	50	3.0 (2.0-3.0)	33	3.0 (2.0-4.0)
11	50	3.5 (3.0-4.0)	50	3.0 (3.0-4.0)	50	3.5 (2.8-4.0)
12	58	4.0 (3.0-4.0)	50	4.0 (2.8-4.0)	33	3.0 (2.0-4.0)
13	42	3.5 (2.8-4.0)	42	3.0 (2.8-4.0)	50	4.0 (3.8-4.3)
14	33	3.0 (2.0-4.0)	33	2.5 (1.0-3.3)	33	2.5 (2.0-4.0)
15	50	4.0 (3.8-4.3)	67	4.0 (4.0-4.0)	42	4.0 (3.8-5.0)
16	50	3.0 (2.0-3.0)	50	2.0 (2.0-3.0)	58	3.0 (2.0-3.0)

Ranking

Once the level of consensus was determined, the mean and SD were calculated for all BCT clusters that had reached consensus. The mean was then used to rank the importance of each BCT cluster with respect to the parameters in the RQ. This follows prior work evaluating BCT importance [33].

Results

BCT Clusters for Long-Term Stroke Rehabilitation

In answer to which BCT clusters are the most relevant for long-term stroke rehabilitation in a home setting in general, consensus was reached for 12 of 16 BCT clusters after the second round Delphi survey. No consensus was reached for the comparison of outcomes, reward and threat, identity, and scheduled consequences (IQRs>1). The importance of the remaining 12 clusters is summarized in Table 3 based on their means, and with the 3 most and 3 least relevant highlighted in italics format. The most relevant BCT clusters were repetition and substitution (mean 4.50, SD 0.52), social support (mean 4.42, SD 0.67), feedback and monitoring (mean 4.25, SD 0.75), and self-belief (mean 4.25, SD 0.87), while the least relevant were natural consequences (mean 3.00, SD 1.04), covert learning (mean 2.83, SD 0.83), and comparison of behavior (mean 2.50, SD 0.90).

Table . Consensus importance ranking of behavior change technique (BCT) clusters for overall stroke rehabilitation.

Rank	BCT cluster	Mean (SD)
1	8. Repetition and substitution	4.50 (0.52)[a]
2	3. Social support	4.42 (0.67)[a]
3	2. Feedback and monitoring	4.25 (0.75)[a]
3	15. Self-belief	4.25 (0.87)[a]
5	1. Goals and planning	4.17 (0.58)
6	4. Shaping knowledge	3.92 (0.67)
7	12. Antecedents	3.75 (0.87)
8	7. Associations	3.58 (1.00)
9	11. Regulation	3.42 (0.79)
10	5. Natural consequences	3.00 (1.04)[b]
11	16. Covert learning	2.83 (0.83)[b]
12	6. Comparison of behavior	2.50 (0.90)[b]

[a]The 3 most relevant.

[b]The 3 least relevant.

BCT Clusters for Behavioral, Cognitive, and Emotional Aspects of Stroke Rehabilitation

In answer to our RQ regarding which BCT clusters are the most relevant for treating behavioral, cognitive, and emotional aspects, different levels of consensus were reached across the 3 aspects evaluated. For behavioral rehabilitation, 11 BCT clusters reached consensus, while for cognitive, this number was 9 and for emotional 6. The importance of the remaining clusters in each aspect is summarized in Tables 4-6 (behavioral, cognitive, and emotional, respectively). Again, the 3 most and 3 least relevant for each aspect are highlighted in italics format. For both behavioral and cognitive rehabilitation, repetition and substitution (mean 4.17, SD 0.58 and mean 4.33, SD 0.65, respectively) as well as self-belief (mean 4.00, SD 0.74 and mean 3.83, SD 0.94, respectively) were ranked as most relevant, while covert learning was consistently ranked as one of the least relevant BCT clusters across all 3 aspects. The consensus importance results for the 3 aspects are summarized in Figure 1.

Discussion

Principal Findings

Particularly in the context of the aging population, stroke rehabilitation is a high priority in health care. Yet, while the BCTs in general have received significant attention [18,33], the differences in importance introduced by long-term, multifaceted (behavioral, cognitive, and emotional) rehabilitation have not been widely studied. This study thus takes an important first step by identifying consensus on the importance of 16 BCT clusters for long-term stroke rehabilitation in general and with respect to the behavioral, cognitive, and emotional aspects of stroke rehabilitation, as detailed in the BCTs in Health Care section. Hence, our results directly address our RQ: Which BCT clusters are the most relevant for long-term stroke rehabilitation in a home setting in relation to treating its behavioral, cognitive, and emotional aspects? Specifically, they highlight 3 main insights for the prioritization of BCTs for long-term behavior change outcomes measured by adherence to treatment.

First, our study further confirms the importance of repetition and substitution and feedback and monitoring as key BCT clusters in this context. This aligns with the ranking of Vestjens et al [33], who highlight repetition and substitution as important for complex interventions in general, as well as that of O'Neill et al [46], who highlight feedback and monitoring as important for preventing smoking relapse in the long term. Further, these clusters were also ranked with social support, aligning with wider discussions of the synergy between these BCT clusters [34], as well as practical implementations via, for example, activity monitors [47]. Notably, both our ranking and the long-term focused part of our study differ substantially from the short-term focused rankings reported by O'Neill et al [46]. As such, our results contribute to a growing body of evidence that long-term behavior change emphasizes specific BCTs, which can vary substantially depending on the specific health situation or aspect of care (behavioral, cognitive, and emotional). Further, our results respond to the barriers identified by Jack et al [8] by directly highlighting BCTs that address low levels of self-efficacy, helplessness, and poor social support. In addition, they align with Campbell et al [15] and Bonnechre et al [16], and work in feedback and monitoring can provide a proxy for a physiotherapist's presence, contact, and supervision of the patient. This provides an important insight for practitioners by pointing to potentially valuable long-term BCT clusters as well as emphasizing the need for caution when evaluating BCT rankings derived with respect to short-term interventions.

Second, our results deprioritize both shaping knowledge and natural consequences, including BCTs such as instructions, information about antecedents and health, social, or emotional consequences, and anticipated regret. This also aligns with the work of Vestjens et al [33] and complements the focus of Nieuwenhuijsen et al [31] on the need for contextual sensitivity in effective interventions. This is a notable finding, as such information-focused BCTs form a major, widely used component in many interventions in practice. For example, Guay et al [48] note that 5 of 12 studies included in a systematic review build on some combination of instructions to guide

XSL•FO
RenderX

behavior change. Thus, while information is a critical component in any intervention, especially in this context, practitioners should consider these BCT clusters as supports to more direct, person-focused BCT clusters, such as feedback and monitoring or repetition and substitution.

Finally, linking to focusing on the most relevant BCTs for treating the behavioral, cognitive, and emotional aspects of rehabilitation, we note 2 important differences evident in the emotional rehabilitation results (Table 6). In this aspect, social support and identity become key BCT clusters, in contrast to Tables 3-5, as well as with the long-term ranking of O'Neill et al [46], where identity-related techniques were low ranked and social support was not included. In addition, there were much lower levels of consensus regarding the emotional aspect. This corresponds to the work of Willems et al [34], who also identified a lack of consensus with respect to "stress management or emotional control training," while emotional aspects were also low ranked by both Vestjens et al [33] and O'Neill et al [46]. This suggests the need for further study of how the emotional aspect of stroke rehabilitation might be supported and how it differs from the more traditional focus on behavioral and cognitive aspects. The differences highlight the need for particular attention by practitioners on this aspect, as specific BCTs are required to support emotional rehabilitation, and that due to the lack of consensus in this area, careful monitoring is needed in order to evaluate their impact, and potential interaction with any behavioral or cognitive focused interventions.

Implications and Recommendations

Our work has several implications for patients and clinicians dealing with stroke recovery. The most salient of these is acknowledging the need for dedicated attention to and support for the emotional aspects of stroke rehabilitation, distinct from behavioral and cognitive aspects. Here, there is a need to maintain a positive, progress-oriented approach, where social support and identity-forming interventions are critical. Further, there is also a more general need to ensure adequate social structures around patients during rehabilitation, going beyond the immediate behavioral and cognitive aspects of recovery. One way to support this is through the design of a social-cooperative platform that allows the patient to track their progress, such as improvements in range of motion, enables therapists to monitor and intervene in the patient's home training, and allows relatives and other stakeholders to support the patient's training efforts on a day-to-day basis. An example of such a system has been proposed in the recent work of Lauer-Schmaltz et al [49] on human digital twins in rehabilitation.

These results also point to several issues to consider during intervention design and clinical implementation. First, there is a need for dedicated long-term strategies to be put in place based on consideration of both long-term behavioral results and relevant BCTs but also effective design approaches for maintaining monitoring and support in the long term. Second, while information is an essential component in supporting understanding, it should not be seen as a major intervention in and of itself. Attention should be paid to coordinating multiple targeted interventions addressing each of the behavioral, cognitive, and emotional aspects. Here, care must be taken that each aspect is both individually supported and that the overall set of support is mutually reinforcing and manageable across aspects. Further, there should be provision for monitoring emotional aspects in addition to more typical behavioral and cognitive monitoring. These aspects may be addressed through, for instance, ongoing dialogue with the patients about their intrinsic motivations for rehabilitation, such as resuming previous work or re-engaging in daily activities like cooking, gardening, or sports.

Limitations

The main limitation of this work is the use of an expert panel rather than patient or intervention data to prioritize the BCTs and to solicit patients' perspectives on the potential impact of the results. Here, the Delphi method was used due to the general lack of access to structured data on the efficacy of BCTs in stroke rehabilitation as well as the general challenge in understanding the specific requirements of long-term behavior change. In this context, the Delphi method provides a robust means of establishing expert consensus. Second, 12 experts were involved in the Delphi survey, and while this is an acceptable number for the Delphi method and in line with prior studies, it places a focus on reaching consensus between diverse experts [38,41,42]. As such, we recruited experts from different fields of specialization, professional background, and nationalities. Thus, while further development of the panel might reveal distinctions between subgroups as in the work of Willems et al [34], the current panel provides a basis for the results reported here as well as directions for further study. Finally, while there is debate as to the required level of consensus for Delphi results, we followed prior guidance in considering BCT clusters to have reached consensus when IQR ≤1 and percentage ≥50% [35,44,50]. Notably, this highlighted a distinct lack of consensus with respect to the emotional aspect of stroke rehabilitation. This is despite this aspect being understood as important by all experts. Thus, while the included results build on prior guidance, there is a need for further study of the exact sources and nature of disagreement regarding the emotional aspect of stroke rehabilitation as well as to explore this aspect more concretely in practice via focused feasibility studies [29].

Conclusions

This international expert panel study using a 2-round Delphi survey ranked, for the first time, the importance of 16 BCT clusters for long-term stroke rehabilitation. The process yielded several new insights highlighting differences in BCT importance between general rehabilitation and rehabilitation specifically focused on the behavioral, cognitive, and emotional aspects of stroke recovery. In particular, we identified a low level of consensus with respect to the emotional aspect but also a distinctly different BCT prioritization in comparison to the other aspects, as such, enabling more effective intervention mapping and guiding the design of multilevel rehabilitation and health promotion interventions and implementation strategies [24]. The study results provide decision support for targeted and tailored design of complex interventions for long-term behavior change and treatment adherence. This provides a first but

XSL•FO
RenderX

important step toward unlocking the prioritization of BCTs for long-term intervention contexts such as stroke rehabilitation.

Acknowledgments

The authors thank the study participants for their time and expertise. Each step of the research has solely been conducted by human authors, and no generative artificial intelligence was used. This study was conducted as a part of the ReHyb project: Rehabilitation Based on Hybrid Neuroprosthesis, funded by the Horizon 2020 Framework Program of the European Union (grant agreement ID 871767).

Authors' Contributions

AEW conducted conceptualization, data curation, formal analysis, investigation, methodology, project administration, validation, and visualization and wrote the original draft. PC conducted conceptualization, data curation, formal analysis, funding acquisition, methodology, project administration, supervision, validation, and visualization, wrote the original draft, and reviewed and edited the manuscript. AM conducted conceptualization, data curation, funding acquisition, methodology, project administration, supervision, and validation and reviewed and edited the manuscript. JPH conducted funding acquisition, methodology, and validation and reviewed and edited the manuscript.

Abstract

Background: Little is known regarding patient attitudes toward automatic sharing of race, ethnicity, and language (REL) data in health care settings despite the universal practice of data sharing across health care institutions and providers.

Objective: This study aims to assess public comfort with disclosing and automatically sharing REL data in health care settings and understand the social factors associated with these attitudes.

Methods: Using the 2022 DataHaven Community Wellbeing Survey from 1196 adult Connecticut residents, we examined factors associated with public comfort with disclosing and automatically sharing REL data across health care settings. We generated unadjusted and adjusted logistic models to examine associations between factors and responses to the data-sharing questions.

Results: Most residents surveyed were White (n=873, 73%), followed by African American or Black (n=167, 14%), Asian or Native Hawaiian or other Pacific Islander (n=31, 2.6%), multiracial (n=31, 2.6%), and American Indian or Alaska Native (n=12, 1%). The majority of respondents were not Hispanic or Latino (n=1051, 87.9%). More than half of respondents reported excellent or very good self-rated health (SRH; n=635, 53.1%), and most participants reported almost always trusting their health care provider (n=939, 78.5%). Most participants reported being willing to share race and ethnicity data at a hospital or clinic (n=1008, 84.3%) and REL data automatically (n=947, 79.2%) in health care settings. Hispanic or Latino (adjusted odds ratio [AOR] 0.049, 95% CI 0.25-0.94) and multiracial (AOR 0.32, 95% CI 0.14-0.76) respondents were less likely to be willing to disclose race and ethnicity data compared to those who were not Hispanic or Latino and who were White, respectively. Individuals who sometimes trust health care providers (AOR 0.57, 95% CI 0.35-0.94) or rarely/never (AOR 0.35, 95% CI 0.15-0.85) were less likely to be willing to disclose race and ethnicity data than those who almost always trust health care providers. African American or Black (AOR 0.46, 95% CI 0.29-0.72) and American Indian or Alaska Native (AOR 0.18, 95% CI 0.04-0.75) individuals were less likely to be willing to share REL data automatically than White individuals. Those who sometimes trust health care providers (AOR 0.48, 95% CI 0.31-0.74) or rarely/never trust health care providers (AOR 0.25, 95% CI 0.11-0.56) were less likely to be willing to share REL data automatically than those who almost always trust health care providers. Those with poor/fair SRH versus very good/excellent SRH were less likely to be willing to share REL data automatically (AOR 0.54, 95% CI 0.34-0.85).

Conclusions: Racial and ethnic identity, SRH, and trust in health care providers affect willingness to share REL information with providers and other health systems.

health care disparities; health care justice; data sharing; data autonomy; race; ethnicity; disparity; race, ethnicity, and language; racial identity; ethnic identity; REL

Introduction

Patient data collection pertaining to race, ethnicity, and language (REL) was first mandated in the United States as part of the Civil Rights Act of 1964 as a means to document race-based discrimination in health care settings and drive institutional and social change [1]. This groundbreaking legislative change was one of the first steps to improve health care disparities among

XSL•FO
RenderX

racially and ethnically minoritized people who face marginalization because of systemic oppression. In recent years, REL data collection has become digitized following the passing of the Health Information and Technology for Economic and Clinical Health Act (HITECH) in 2009, which used monetary incentives to encourage the use of electronic health record (EHR) systems [2]. Despite being codified as a federal mandate, REL data collection for patients is not always implemented systematically in health care settings, nor is it always accurate [3]. For example, during the initial height of the COVID-19 pandemic, race and ethnicity data were missing from as many as 56% of reported cases at certain points in time for various public health surveillance data [4]. As a result, health care and public health systems and state government agencies have invested in ensuring improved REL data collection in health [5].

Though race and ethnicity data collection in health care systems is the main mechanism to examine quality of care across diverse populations based on racialized identities, there have been long-standing challenges to consistent data collection despite various improvement efforts [6]. These challenges include concern among clinical staff about asking patients about their information and a lack of training for clinical staff on the importance of data collection. Furthermore, if patients do not have a clear understanding of why these data are being collected and whether the data will be used outside of a clinical setting for research purposes, they may feel less comfortable disclosing information. Efforts to overcome these obstacles to data collection have included reassuring patients about the confidentiality of their data, as well as introducing scripts and training for clinical staff. Beyond individual system-level quality improvement efforts, health systems have been using and sharing this information with other systems across health care settings, which can help standardize data collection practices [7]. While data sharing across health systems and organizations serves as both a mechanism to support public health and streamline care for patients, it may occur without patients' knowledge or explicit consent [1,8-10]. Several prior studies have specifically examined patients' preferences regarding sharing of health data with other clinical providers, finding that patients prefer to be asked permission before having their data shared electronically outside of emergency contexts and that patients who are unwilling to share their data automatically with other health care providers cited concerns about potential breaches in security [11-13]. Although these studies focused on the automatic sharing of general health data, little is known about how patients in the United States feel about sharing specific aspects of their medical records, such as REL data, that are embedded in their EHR [14,15]. One study found no significant difference in patients' willingness to share general health data automatically based on their race and ethnicity; however, this study did not specifically investigate attitudes toward automatic sharing of REL data [16].

This study aims to understand how adults aged 18 and up in Connecticut feel about having their REL data collected and automatically shared with health care systems and whether there are differences in their preferences associated with their racial and ethnic identities, as well as other sociodemographic factors.

Methods

Study Design

This cross-sectional study involved analysis of data from the 2022 DataHaven Community Wellbeing Survey [17]. The DataHaven Community Wellbeing Survey is conducted on an ongoing basis in Connecticut and is designed to measure well-being and quality of life at the statewide, town, and zip code level. The cost of fielding the survey is shared across more than 100 public and private agencies, including all of the state's acute care hospitals, large community foundations, and major cities, as well as many agencies representing rural and suburban communities.

Setting

Survey data were collected by the Siena College Research Institute between August 1 and August 28, 2022. Respondents to the 2022 DataHaven Community Wellbeing Survey were contacted via cell phone and landline or were part of an online exchange. The landline sample included both listed and unlisted telephone numbers, using random digit dialing. The cell phone sample was drawn from dedicated wireless telephone exchanges within Connecticut. Dynata's Wireless LITe database was utilized, which enabled targeting of cell phone samples by region or zip code. The online sample was provided by Lucid, a market research platform that runs an online exchange for survey respondents. The samples drawn from this exchange matched a set of demographic quotas on age, gender, and region. Respondents were sent from Lucid directly to the survey software operated by the Siena College Research Institute. All respondents taking the survey online completed an attention check before and during the survey to ensure proper attention was being paid throughout. The cell phone and landline interviews were conducted in English or Spanish, while online surveys were conducted in English. All respondents were screened for residence in the state of Connecticut.

Participants

The survey sample included 1196 respondents randomly selected from Connecticut residents, aged 18 years or older, to inform state-level estimations of resident well-being, equity, and quality of life, as previously described [17]. The only inclusion criterion for the survey was being a Connecticut resident aged 18 years or older. Among the respondents, 727 (60.8%) completed the survey on a cell phone, 321 (26.8%) completed it on a landline, and 148 (12.4%) completed it online. Respondents represented all 169 Connecticut towns. We followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for a cross-sectional study for reporting [18].

Assessments and Data Sources

The outcome variables for this study were delevoped from 2 questions that were added to the 2022 DataHaven Community Wellbeing Survey. The first question was "Patients are often asked their race and ethnicity at a hospital or clinic. Are you OK sharing this information at a hospital or clinic?" Response options were "Yes" or "No." The second question was "If you were offered the choice to have your race/ethnicity/language

XSL•FO
RenderX

information automatically shared electronically with the different places where you receive medical care, how likely would you be to agree to it?" This question was adapted from a prior study [11]. Response options fell along a 4-point Likert scale from "Very likely" to "Very unlikely." "Very likely" and "Somewhat likely" were collapsed into one category, while "Somewhat unlikely" and "Very unlikely" were collapsed into one category.

The covariates for this study were race and ethnicity, gender, age, primary language, reporting of chronic disease, self-rated health (SRH), trust in health care provider, and prior experience with discrimination in health care settings. We selected these covariates as prior research suggests they may influence the relationship between a person and their comfort with sharing personal data for either research or health care use [12,19-21]. Race categories were "African American or Black," "American Indian or Alaska Native," "Asian," "Native Hawaiian or Other Pacific Islander," "White," and "other/something else." Ethnicity categories were "Hispanic or Latino" and "not Hispanic or Latino." Asian and Native Hawaiian or other Pacific Islander were collapsed into one category because of small sample size. Respondents who selected more than one race category were placed in the "Multiracial" category. Chronic disease information was collected by asking respondents about the following conditions: high blood pressure or hypertension; diabetes; heart attack, also called myocardial infarction; angina or coronary heart disease; stroke; and asthma. Respondents who indicated they had any of the conditions were grouped into one category. Respondents with "Excellent" or "Very good" SRH were grouped into one category, while those with "Fair" or "Poor" SRH were grouped into one category. Trust in health care providers was collected by asking how often the following statement was true: "I trust that my health care provider is trying to do what is best for me." Response options were "Almost always," "Sometimes," "Rarely," and "Never." "Rarely" and "Never" were collapsed into one category. Prior experience of discrimination in health care settings was collected by asking, "When seeking health care, have you ever been treated with less respect or received services that were not as good as what other people get?"

Study Size

For our analytic approach, we first conducted univariate analysis to describe survey participants who had any data available for analysis (n=1196). We then removed participants who were missing outcome data (n=69) or covariate data (n=134), leaving a final analytic sample of 993.

Data Analysis

We conducted unadjusted and adjusted parsimonious logistic models to compare demographic characteristics and responses to the data-sharing questions and to determine the independent predictors of our outcomes. We entered covariates with a *P* value <.20 from the unadjusted models into the multivariable regression models using backward elimination, retaining covariates with a *P* value <.05. For the multivariate adjusted model analyzing comfort with REL disclosure, the following variables remained in the parsimonious model: race, ethnicity, gender, and trust in health care provider. For the multivariate adjusted model analyzing comfort with REL sharing, the following variables remained in the parsimonious model: race, age, trust in health care provider, self-rated overall health, and any chronic diseases. Correlations between covariates were examined, and no significant collinearity was observed. All analyses were conducted using SAS Version 9.4 (SAS Institute).

Ethical Considerations

This study did not meet the regulatory criteria for human subjects research because the data from the 2022 DataHaven Community Wellbeing Survey comprise a publicly accessible deidentified database, and as such, institutional review board review and approval were not required [22]. During data collection, informed consent was obtained by DataHaven, and identifiable data was removed before the data were made publicly accessible.

Results

Among the sample of 1196 adult Connecticut residents aged 18 years or older who were randomly selected to participate in the 2022 DataHaven Community Wellbeing Survey, half of the respondents identified as female (Table 1). The majority of residents surveyed were White (n=873, 73%), followed by African American or Black (n=167, 14%), Asian or Native Hawaiian or other Pacific Islander (n=31, 2.6%), multiracial (n=31, 2.6%), and American Indian or Alaska Native (n=12, 1%). Most respondents were not Hispanic or Latino (n=1051, 87.9%). This population slightly overrepresented African American or Black, Native Hawaiian or other Pacific Islander, and American Indian or Alaska Native groups while underrepresenting White, Asian, and Hispanic or Latino groups relative to the Connecticut population reported in the most recent census [23]. In the cohort, 22.1% (n=264) of individuals were between the ages of 18 and 39 years. Only a small percentage of the participants did not speak English as their primary language (n=64, 5.4%). The majority of respondents reported excellent or very good SRH (n=635, 53.1%), and more than half reported a chronic disease condition (n=668, 55.9%). Most participants reported almost always trusting their health care provider (n=939, 78.5%), and the majority did not have a prior experience of discrimination in a health care setting (n=990, 82.8%). Most participants were willing to share race and ethnicity data at a hospital or clinic (n=1008, 84.3%) and were willing to share REL data automatically (n=947, 79.2%; Table 1).

Unadjusted models suggested that the likelihood of being willing to share race and ethnicity data at a hospital or clinic was associated with a respondent’s race, ethnicity, gender, and primary language and how much they trust their health care provider (Table 2). In the multivariate logistic regression model, multiracial participants were significantly less likely to be willing to share their race/ethnicity data compared to White participants (adjusted odds ratio [AOR] 0.32, 95% CI 0.14-0.76; Table 2). Similarly, Hispanic or Latino participants were significantly less likely to be willing to share their race/ethnicity data compared to those who were not Hispanic or Latino (AOR 0.49, 95% CI 0.25-0.94). Female respondents were more likely to be willing to share their race/ethnicity data compared to male respondents (AOR 1.59, 95% CI 1.07-2.41). Individuals who reported they only sometimes (AOR 0.57, 95% CI 0.35-0.94) or rarely/never (AOR 0.35, 95% CI 0.15-0.85) trust that their health care provider has their best interest in mind were less likely to be willing to share race/ethnicity data compared to those who almost always trust their health care provider.

In unadjusted models, an individual's likelihood of being willing to share REL data automatically with various health care locations was associated with their race, SRH, and how much they trust their health care provider (Table 3). In the multivariate logistic regression model, African American or Black (AOR 0.46, 95% CI 0.29-0.72) and American Indian or Alaska Native

XSL•FO
RenderX

respondents (AOR 0.18, 95% CI 0.04-0.75) were significantly less likely to be willing to share REL data automatically compared to White respondents (Table 3). Respondents who were aged 40 - 64 years (AOR 0.56, 95% CI 0.34-0.92) and 65+ years (AOR 0.51, 95% CI 0.30-0.87) were significantly less likely to be willing to share REL data than those aged 18 - 39 years. Individuals who reported they only sometimes (AOR 0.48, 95% CI 0.31-0.74) or rarely/never (AOR 0.25, 95% CI 0.11-0.56) trust that their health care provider has their best interest in mind were also significantly less likely to be willing to share REL data automatically than those who almost always trust their health care provider. Respondents with fair/poor SRH were also significantly less likely to be willing to share REL data automatically compared to those with very good/excellent SRH (AOR 0.54, 95% CI 0.34-0.85). In contrast, respondents who reported having any chronic disease were significantly more likely to be willing to share REL data than those who reported not having any chronic disease (AOR 1.58, 95% CI 1.10-2.31).

Sensitivity analyses showed consistent adjusted results using 2 additional race/ethnicity categorization methods: the common method of grouping race/ethnicity prior to the new 2024 United States Office of Management and Budget race/ethnicity collection guidelines (Tables S1 and S2 in Multimedia Appendix 1) and the rarest classification method to enumerate small populations (Tables S3 and S4 in Multimedia Appendix 1) [24].

Discussion

Principal Results

In general, the majority of Connecticut respondents are comfortable disclosing their race and ethnicity and having their REL data shared automatically. However, racially and ethnically minoritized individuals are less comfortable disclosing race and ethnicity information at hospitals and clinics and having their REL data automatically shared with health institutions where they receive care. As compared to respondents who were White and were not Hispanic or Latino, multiracial and Hispanic or Latino respondents were the least likely to be willing to disclose their race and ethnicity data, respectively, while Black or African American and American Indian or Alaska Native respondents were less likely to be willing to have their REL data automatically shared between medical providers.

Comparison With Prior Work

While previous studies showed no significant difference in respondents' willingness to automatically share general health data between race and ethnicity identity groups [11,16], the results of this study add a more nuanced view of specific data elements within the EHR that certain minoritized individuals feel less inclined to share automatically. It is possible that prior studies saw no significant difference in willingness to automatically share general health data because respondents were not explicitly informed about all the sensitive data that comprised their EHR, such as REL data. Additionally, the previous studies were conducted in California, which has a substantially different representation of race and ethnicity both in the survey samples and the state population than in the current study in Connecticut, with higher representation of Hispanic or Latino and Asian or Native Hawaiian or other Pacific Islander respondents and lower representation of Black or African American respondents. In the United States, Black, Indigenous, and Latino communities have faced discrimination when accessing health care systems, leading to poorer health outcomes and health care delivery than their White counterparts [25,26]. These discriminatory experiences may contribute broadly to diminished comfort with REL data collection and automatic sharing [27].

The finding that lower SRH was independently associated with a decreased likelihood of being willing to share REL data automatically warrants further examination. Past studies have demonstrated a relationship between race and ethnicity and SRH [28-30]. Furthermore, studies investigating the relationship between SRH and likelihood to share data with physicians have shown that those with lower SRH are more likely to share information with their physician, which is consistent with our finding that individuals with chronic disease were more likely to be willing to share REL data [31,32]. However, among our study population, no correlation was found between SRH and chronic disease, suggesting that Connecticut residents may use other metrics to determine their SRH beyond chronic disease. Given the findings of this study, it may be possible that individuals with lower SRH are more comfortable with sharing general health data specifically for treatment purposes but draw the line at sharing REL data, whereas those with chronic disease are comfortable sharing all elements of their data. Follow-up studies could further explore relationships between one's social identities, health status, and sharing of information.

Our finding that trust in health care providers is highly associated with comfort with sharing is consistent with past studies that have established a link between patient trust in their provider and willingness to disclose or share health information [19,33]. Additionally, a previous study found differences in health information seeking behavior of individuals by race and ethnicity, with Black and Hispanic individuals, compared to White individuals, more trusting of health information from media, charitable organizations, and religious organizations and Hispanic individuals, compared to White individuals, less trusting of and willing to seek information from doctors [34]. The results of our study further highlight the importance of trust between patient and provider and reveal that individuals with decreased levels of trust in their health care providers may be hesitant to disclose and share any data, whether health-specific or demographic. Our initial work in this area suggests that trust in health care providers may mediate these relationships between the correlates of interest and outcomes (data not shown). Future studies can explore these relationships.

Limitations

This study had several limitations. Namely, the number of individuals identifying as American Indian or Alaska Native or Native Hawaiian or other Pacific Islander was very low, which affected the statistical analyses. Given that individuals who identify as American Indian or Alaska Native or Native Hawaiian or other Pacific Islander tend to be minoritized in most areas of the United States, a larger cohort would be needed to better understand the nuances of comfort with REL data disclosure and sharing among these communities. Additionally, the 2022 DataHaven Community Wellbeing Survey was only conducted in English or Spanish, which limits representation of communities in Connecticut that do not speak either of these two languages. Further, the population of Connecticut is not representative of that of the United States, and therefore, generalizations made while using these results should be done with caution.

Conclusion

The results of this study have implications for how we operationalize health information exchange across clinical and public health settings in the current discussion of how to most effectively enhance the nationwide health data ecosystem and standardize social and structural drivers of health data [35]. This study suggests that nuances exist in how people think about race and ethnicity data and the sharing of specific information within their health record. People's individual backgrounds likely influence their comfort with sharing sensitive data and their comfort with that data being shared automatically with

XSL•FO
RenderX

other health settings. More work is needed to gauge whether patients have an understanding of what components comprise their health record, which of these components may be shared, and with whom the data are being shared.

Acknowledgments

We thank the team at DataHaven for collecting the data and making it available to us. Generative artificial intelligence was not used in any portion of this manuscript. We acknowledge Dr Daniel Sarpong for assistance with statistical analysis.

This publication was made possible in part by the Genentech Health Equity Innovation Fund and National Institutes of Health/National Library of Medicine (G08LM013801). Funders did not contribute to this work.

Abstract

Background: Obesity is rising among Saudi adolescents, with rural females particularly underserved due to limited health education and sociocultural barriers. Global guidelines promote non–weight-centric approaches to reduce stigma. The Green Apple program delivers school-based, weight-neutral education, with an added metabolic noncommunicable disease (MNCD) prevention unit. Although previously tested in urban settings, it has not yet been evaluated among rural female students.

Objective: This study aimed to examine the effectiveness of the Green Apple intervention in improving MNCD knowledge and its safety, defined as no adverse psychological (body image discrepancy and disordered eating) or behavioral (sedentary behavior) outcomes.

Methods: This quasi-experimental study included 105 participants from urban and rural schools in Saudi Arabia, with 4 classes assigned to either the intervention group (Green Apple) or the enhanced intervention group (Green Apple+MNCD). Both programs were implemented in female-only classrooms by trained facilitators during regular school hours. The intervention was delivered once per week over 2 consecutive weeks (2 sessions), while the enhanced intervention included an additional third session. Linear mixed-effects models assessed intervention effects across three time points: baseline, postintervention, and 1-month follow-up.

Results: The mean age across participants was 16.42 (SD 0.66) years, with a significant difference between groups: 15.97 (SD 0.41) years in the enhanced intervention group and 17.00 (SD 0.42) years in the intervention group (P<.001). Both interventions significantly improved knowledge across schools. The enhanced intervention (Green Apple+MNCD) group demonstrated an increase of 1.65 (95% CI 0.61-2.70; P<.001) from baseline to follow-up, while the intervention (Green Apple) group showed an increase of 1.26 (95% CI 0.10-2.43; P=.02). However, no significant between-group differences were observed at baseline (mean difference 0.20, SE 0.46; P=.65), postintervention (mean difference 0.79, SE 0.45; P=.08), or follow-up (mean difference 0.73, SE 0.49; P=.13). Although sedentary behavior did not significantly decrease across all schools, a significant reduction was observed in rural schools receiving the Green Apple intervention (–3.12, 95% CI –5.67 to −0.56; P=.02). Regarding safety outcomes, no adverse effects on body image or disordered eating were observed. A significant reduction in disordered eating symptoms was found only in urban schools receiving the enhanced intervention (–0.94, 95% CI –1.61 to –0.26; P=.007).

Conclusions: The Green Apple program is a culturally tailored, weight-neutral intervention that improves metabolic health literacy and reduces sedentary behavior among Saudi female adolescents without harming body image or eating behaviors. By focusing on an underserved subgroup, it addresses a key gap in health promotion and aligns with global calls for stigma-free approaches. Broader regional studies are needed to assess its long-term impact.

Introduction

As of 2020, over 100 organizations have endorsed the Joint International Consensus Statement or pledged their commitment to eliminating weight stigma [1]. These endorsements come from a diverse range of entities, including scientific societies (eg, American Society for Nutrition, UK Association for the Study of Obesity, and Obesity Australia), academic institutions, professional organizations, medical journals (eg, *Obesity*, *Obesity Reviews*, *Obesity Science and Practice*), and parliamentary groups across the globe [1]. Weight stigma has been linked to anxiety, suicidality, disordered eating, sedentary behavior, and even weight gain [2-4]. Among adolescents, weight stigma is strongly linked to disordered eating, body dissatisfaction, and psychological distress [4]. A comprehensive systematic review by Levinson et al [5] identified consistent associations between experienced, anticipated, and internalized weight stigma and harmful eating behaviors. However, most studies were cross-sectional and based on predominantly White, female samples, limiting generalizability [5]. In addition, school-based obesity prevention programs that emphasize weight loss, BMI reporting, or calorie restriction have been associated with increased body dissatisfaction and disordered eating behaviors among adolescents [5,6]. Physiologically, stigma can activate stress responses, while psychologically, it damages self-esteem and fosters body shame, leading to disordered behaviors [7,8]. These effects underscore the need for weight-neutral interventions that avoid reinforcing weight-based shame [7,8].

In response to the growing awareness of weight stigma, non–weight-centric approaches, which focus on overall health and well-being rather than weight loss, are increasingly being adopted in adolescent school-based obesity interventions [9]. These programs emphasize holistic well-being, body acceptance, intuitive eating, and joyful movement, while tracking outcomes such as blood pressure and psychological health instead of BMI [9]. Evidence suggests that non–weight-centric interventions are associated with improved metabolic health, reduced disordered eating, and greater sustainability of healthy behaviors, while also significantly decreasing internalized weight bias and body dissatisfaction [6,9].

Dugmore et al [6] conducted a meta-analysis comparing weight-neutral and traditional weight loss interventions. Weight-neutral approaches, often guided by Health at Every Size (HAES) principles, showed comparable or superior outcomes for bulimia nervosa, self-esteem, and eating behaviors, without adverse effects on physical health. They also had lower dropout rates and better adherence [6]. However, the studies were few, small, and methodologically inconsistent. Overall, the evidence supports adopting culturally sensitive, weight-neutral interventions that focus on health behaviors rather than weight loss, particularly for vulnerable adolescent populations [6].

However, balancing obesity prevention with avoiding weight-based stigma remains a global challenge, prompting calls for research beyond Western cultural contexts [1,10]. Since perceptions of obesity and weight stigma differ across languages and cultures, it is essential to explore non–weight-centric prevention strategies in non–English-speaking regions [1,10]. Increasing awareness of these cultural and linguistic differences is vital to building inclusive public health narratives that reduce stigma globally [1,10].

In Saudi Arabia, an Arabic-speaking country, adolescent obesity rates are rapidly increasing [11,12]. Recent studies report an obesity and overweight prevalence of 31.6% (2504/7931) among Saudi adolescents [13]. In response, the Saudi government has launched initiatives like the “Strategy to Combat Obesity and Promote Physical Activity in the Arab Countries” and the “RASHAKA Program,” a school-based initiative focused on increasing physical activity and reducing body weight [14,15]. Although no studies have directly measured the psychosocial consequences of these programs in Saudi Arabia, global guidance from the World Obesity Federation cautions that language used in such campaigns — such as “eliminate obesity” or “combat obesity” — can reinforce stigma by portraying individuals with higher weight as problems to be solved [1,10]. To counter this, school-based obesity prevention programs should shift focus from weight reduction to overall well-being, moving away from the “eat less, move more” narrative [10].

A recent review of obesity prevention studies in Saudi Arabia identified only 8 interventions, despite the nation’s high prevalence of adolescent obesity [16-18]. Most studies prioritized weight reduction, emphasizing obesity prevalence and associated health risks and promoting reduced portion sizes, caloric intake reduction, and increased physical activity [16,17]. Even when interventions included components aimed at fostering positive body image and reducing stigma, the primary focus remained on weight reduction and highlighting obesity prevalence and related health risks [19]. Such framing contradicts current guidance, which discourages language that may perpetuate weight stigma or promote disordered weight-control behaviors [10,20]. A 2024 cross-sectional study conducted in Saudi Arabia found that 63% of adolescents (1023/1624) were dissatisfied with their body weight [21]. The results demonstrated significant positive correlations between weight stigma, mental health issues, and BMI, with a statistically significant regional variation.

Despite increasing attention to adolescent health in Saudi Arabia, current initiatives mostly adopt a one-size-fits-all approach that overlooks the distinct needs of rural adolescents. These populations face structural and sociocultural barriers, including limited access to health education, physical activity resources, trained personnel, and specialized health care services, placing them at a disadvantage compared with urban peers [22-24]. Rapid urbanization may also be reshaping rural communities in ways that existing public health strategies have yet to address, underscoring the need for contextually adapted, weight-neutral interventions that promote health without reinforcing stigma or excluding vulnerable subgroups.

Focusing on rural female adolescents is especially important, as this subgroup encounters intersecting barriers related to geography, gender norms, and socioeconomic status [22-24]. Compared with urban girls, they experience limited mobility due to cultural expectations, as well as fewer educational and

XSL•FO
RenderX

recreational opportunities, particularly in relation to structured physical activity [22-24]. These challenges are further intensified by higher poverty rates and lower levels of parental education, which can limit access to health information and preventive care [22,23]. By targeting this underserved population, this study addresses a critical gap in the literature and responds to the urgent need for culturally tailored, equitable health interventions for those most at risk of poor health outcomes. This study is the first to implement and evaluate a culturally adapted, weight-neutral school-based intervention specifically designed for and delivered to Saudi rural female adolescents.

The Green Apple program was intentionally designed as a universal school health initiative aimed at addressing the specific challenges faced by rural and urban female adolescents in Saudi Arabia. By adopting a non–weight-centric, health-focused approach, the program avoids stigmatizing language and instead promotes positive, practical health behaviors relevant to daily life. It delivers culturally sensitive, age-appropriate content in Arabic, ensuring accessibility for students in underresourced rural areas. Importantly, the program emphasizes macronutrient education, metabolic disease prevention, and strength-building exercises that do not require special facilities, making it feasible for rural schools with limited infrastructure. Accordingly, this study was conducted to evaluate the effectiveness of the Green Apple program in enhancing knowledge about MNCDs and sedentary behavior, while also monitoring safety outcomes related to body image and disordered eating symptoms.

Methods

Study Design and Participants

This study employed a quasi-experimental design with 4 parallel arms, incorporating blinding and nonequivalent groups. Of the total, 2 arms received the intervention (1 urban school and 1 rural school), while the other 2 arms received the enhanced intervention (1 urban school and 1 rural school). The study was conducted in 2023 at 1 urban public female high school and 1 rural public female high school in the Medina region of Saudi Arabia. Refer to Checklist 1 for the checklist used to report this study, as recommended by the TREND Group for reporting nonrandomized evaluations of behavioral and public health interventions [25].

The schools were purposefully selected by the Ministry of Education's School Health Department to represent urban and rural populations and ensure administrative feasibility and support. The urban school was in a city center with greater access to health care services and extracurricular health programs, while the rural school served a geographically isolated population with fewer health education resources. In addition, both schools were chosen for their history of successful collaboration with the Ministry of Education, ensuring administrative support and feasibility for program implementation.

Classes within each school were assigned to one of two program versions: (1) enhanced intervention (Green Apple+MNCD): a 3-unit, non–weight-centric program that included content on the prevention of MNCDs and (2) intervention (Green Apple): a 2-unit, non–weight-centric program without MNCD content. A randomized controlled trial (RCT) design was considered during the planning phase; however, logistical, ethical, and administrative constraints necessitated the use of a quasi-experimental design instead. RCT was not feasible due to real-world constraints, including the limited number of schools and classes, especially in rural areas. For example, in the selected rural region, only 1 secondary school for female students was available, and each grade level contained only 1 class. Randomization at the individual or class level would have introduced risk of contamination and was not permissible under school policy. Therefore, a quasi-experimental design was used.

To reduce potential selection bias, first-grade students in both urban and rural schools were assigned to the enhanced intervention condition, while second-grade students were assigned to the intervention condition. This decision was guided by the understanding that second-grade students had completed a Ministry-mandated "Healthy Lifestyles" course and would likely demonstrate higher baseline knowledge. To minimize bias from this difference, the enhanced intervention was deliberately limited to first-grade students to ensure outcome comparability. In addition, a baseline assessment of knowledge revealed no significant differences between the intervention versions. To further strengthen internal validity, linear mixed-effects models were used to adjust for potential confounding factors. These models included time, school type, and intervention type as fixed effects. Although propensity score matching is a common method for reducing selection bias in quasi-experimental studies, it was not implemented due to the limited sample size and the clustered structure of the school-based data [26,27]. Instead, baseline equivalence between groups was assessed, and no significant differences were found in preintervention knowledge scores. While quasi-experimental designs limit the ability to make causal inferences compared with randomized trials, several strategies were used to enhance internal validity. These included grade-level assignment, baseline equivalence testing, and statistical covariate control. Blinding was maintained at the classroom level between intervention groups, as well as during data collection, to reduce performance and detection bias. Nonetheless, potential limitations such as residual confounding or contextual differences across classrooms cannot be fully ruled out. All participants completed self-reported measures at 3 time points: before the intervention (baseline), immediately after the program was delivered (postprogram), and 1 month after the program was delivered (follow-up). Only students who were enrolled in the participating schools, attended the classroom sessions where the intervention was delivered, and provided both informed consent (from guardians) and assent (from students) were included in the analysis. Students who did not provide consent or assent were excluded from data collection and subsequent analysis.

Green Apple Program

Green Apple is an innovative, educational, and universal program aimed at shifting the focus from weight and obesity to the role of liver fatty acids and vascular fat in MNCDs and how lifestyle management can address conditions like diabetes and high blood cholesterol. Unlike traditional programs, Green

XSL•FO
RenderX

Apple deliberately avoids terms like “obesity,” “weight reduction,” “eat less,” and “move more.” Instead, it encourages critical thinking about macronutrients and their relationship to body energy, cardiometabolic disease prevention, and lifestyle management of MNCDs.

The Green Apple program is grounded in 3 complementary theories of behavior change: the health belief model (HBM), social cognitive theory (SCT), and the transtheoretical model (TTM) [28-30]. These models collectively inform the program’s structure and messaging. According to HBM, adolescents are more likely to change their behaviors when they perceive themselves at risk for serious health conditions — such as diabetes, fatty liver, or stroke — and believe that actionable steps can mitigate those risks. SCT emphasizes the importance of self-efficacy and skill-building, which Green Apple fosters through experiential learning, practical lifestyle tips, and positive reinforcement. The TTM supports the idea that behavior change is a staged process, and the Green Apple program is designed to guide students from awareness to long-term action by progressively reinforcing key health concepts across sessions.

Rather than focusing on obesity or weight reduction, the program reframes the discussion around visceral fat and liver fat, highlighting their roles in MNCDs. This framing provides a more neutral, stigma-free way to promote healthy behaviors such as balanced macronutrient intake, strength-building activities, and adherence to MyPlate dietary guidelines [31,32]. The aim is to enhance students’ understanding of metabolic health while improving self-efficacy and motivation for lifelong health habits. In addition, it empowers students with knowledge and practical lifestyle tips to support family members or friends with cardiometabolic diseases without contributing to stigma for those affected by these conditions. To ensure cultural and developmental appropriateness, all materials were delivered in Arabic and tailored to the gender-specific school environment. Sessions were delivered in female-only classrooms by 2 female researchers — one with a PhD in Nursing and the other in Clinical Nutrition — both of whom have experience in teaching school-aged students. The program was delivered once per week over a 2-week period, with each session taking 1 class period (approximately 45 min). Teaching methods included active discussion, visual aids such as culturally adapted Microsoft PowerPoint slides, and non–weight-stigmatizing illustrations.

The Green Apple program was recently evaluated in a pilot study involving 69 urban students (46 boys and 23 girls; mean age 16.18, SD 0.53 y) [33]. The intervention significantly improved MNCD knowledge ($F_{1,64}$=23.45; P<.001), with a large effect size (partial η^2=0.27). Notably, no significant change in students’ body image discrepancy was observed from pre- to postintervention (P=.70), reinforcing the safety of this weight-neutral approach. The program also demonstrated strong feasibility, achieving a recruitment rate of 82% (95/115) and a retention rate of 72% (69/95).

Accordingly, the current program consists of 3 structured sessions (outlined in Table 1). For this pilot study, a lower-intensity version of the program was implemented to assess its effectiveness and safety.

XSL•FO
RenderX

Table . Overview of the Green Apple program curriculum. The Green Apple program is a school-based, non–weight-centric educational intervention designed to promote metabolic health literacy among adolescents. The table outlines the content structure across 3 instructional units, including core topics and the rationale for each unit. All students received units 1 and 2; however, those in the enhanced intervention also received an additional unit 3 focused on the prevention of metabolic noncommunicable diseases.

Unit	Unit title	Topics	Rationale
Unit 1 (Green Apple)	Basics of nutrition	1. Carbohydrates 2. Proteins 3. Fats	To understand the relationship between macro and micronutrients, hunger and appetite, and convenience foods and whole foods.
Unit 2 (Green Apple)	Calories and energy	1. Energy in the body: how is energy produced, and why do we need it? 2. The relationship between food and energy 3. Where is energy stored in the body, and how is it released? 4. The relationship between physical activity and energy storage	To understand the relationship between macronutrients and energy sources, diet and exercise, and aerobic and weight-resistance exercises
Unit 3 (Enhanced Green Apple)	Metabolic chronic diseases management	1. Cholesterol: understanding its types and sources (beneficial and harmful), treatment with modern medicine, and lifestyle. 2. Diabetes: understanding types of diabetes and how modern medications and lifestyle influence blood sugar control. 3. How to help someone with MNCD[a].	To understand the mechanisms of stroke and diabetes and possible medical and lifestyle management plans.

[a]MNCD: metabolic noncommunicable disease.

Ethical Considerations

This study is part of a larger pilot initiative and was conducted in accordance with ethical standards approved by the Shaqra University Ethics Committee (approval ERC_SU_20230005). To ensure ethical treatment of participants, multiple procedures were implemented to safeguard their rights.

Before the intervention, written informed consent was obtained from the parents of all participating students. Consent was secured approximately 3 weeks before the program began and specifically covered both participation in the educational sessions and completion of the study surveys. The study's purpose, procedures, and voluntary nature were explained to students in an age-appropriate manner through both verbal presentations made by teachers and simple written materials provided to students and parents.

Participation was entirely voluntary. Students were clearly informed that choosing not to participate or choosing to skip any survey questions would not affect their academic grades. The intervention was delivered to all students within the classroom setting as part of the school health program; however, only students who provided informed consent and assent were included in the study analyses. Confidentiality and privacy were maintained by deidentifying all data before analysis. As a gesture of appreciation, all students received a small nonmonetary token (a keychain medley) upon completing the program surveys.

Measurements

Demographics

Baseline demographics included age, self-reported weight and height (if known), parents' education level, and monthly family income. Education level was categorized for both parents as either high (college degree and above) or low (high school degree and below). However, aside from age, rural students had limited knowledge of these details and could not complete this information, so it was excluded from the analysis.

Physical Activity

The Arab Teens Lifestyle Study (ATLS) includes a 22-item self-reported questionnaire designed to measure weekly physical activity by reporting the types and frequency of 11 specific physical activities (eg, walking, running, weight lifting, and housework) [34]. Then, the total energy expenditure in metabolic equivalent minutes per week (METs-min/wk) is calculated for high-vigorous physical activity of 6 METs and moderate-vigorous activity of 4 METs [34]. The ATLS also contains a 10-item self-reported eating habits questionnaire designed to measure 4 positive eating habits (eg, fruit and vegetable intake) and 6 negative eating habits (eg, sugary drink and fast food consumption) [34]. Scores are calculated based on the frequency of each habit per week. Total scores for positive eating habits (0 - 28) and negative eating habits (0 - 35) are generated based on frequency responses (eg, the number of days per wk). The ATLS has been specifically developed for

XSL•FO
RenderX

and validated among Arab adolescents, including those from Saudi Arabia [35].

Sedentary Behavior

The weekdays subscale of the self-reported Sedentary Behavior Questionnaire weekdays contains 9 items designed to measure sitting time during various sedentary activities (eg, watching television, playing computer or video games, listening to music, and reading books) during weekdays [36]. The average total sitting time is calculated based on 5 weekdays. Sitting ≥7 hours/day during weekdays is considered a highly sedentary behavior [37]. In our study, weekday sedentary behavior was measured at baseline and during follow-up. The Sedentary Behavior Questionnaire was originally developed for Western populations; however, its items have been culturally adapted and translated into Arabic, and it has been used among Saudi college students and adolescents with acceptable levels of reliability [33,36,38].

Exposure to Noncommunicable Diseases Health Education

Students' exposure to MNCD health education topics (eg, stroke and diabetes) was measured using a 4-item self-reported (yes or no) questionnaire developed by the researchers. A total score (0 - 4) was generated.

MNCD Knowledge

An 18-item true or false quiz was developed to assess students' knowledge of macronutrients and their role in MNCDs (eg, liver fat, vascular fat, diabetes, and hyperlipidemia). The items were aligned with the educational objectives of the Green Apple program. To ensure content validity and cultural relevance, the quiz underwent expert review by 2 nutrition professionals and a health education specialist. Items were reviewed for accuracy, relevance, and clarity in Arabic. The quiz was also piloted with a small group of students (n=12) to confirm age-appropriateness and understanding. Revisions were made to improve wording and comprehension. The quiz was intended to measure factual knowledge across multiple distinct subtopics (eg, liver fat, sugar, insulin, and vascular fat), rather than a single unidimensional construct. A total score ranging from 0 to 18 was calculated for each participant. The need for educational intervention was then evaluated using cutoff levels recommended in the guidelines of the Food and Agriculture Organization of the United Nations [39]. Using these guidelines, an urgent need for intervention was identified if 70% or fewer participants answered correctly. A considered need was indicated when 71% - 89% of participants answered correctly. No need for intervention was noted if 90% or more participants answered correctly. This scoring method enabled a targeted assessment of the gaps in students' knowledge of macronutrients and their role in MNCD prevention. MNCD knowledge was measured at baseline, postintervention, and during follow-up.

Body Image Discrepancy

Body image discrepancy was assessed using silhouettes representing 4 different body sizes [40] and a silhouette rating scale, which is a widely validated and reliable tool for assessing perceived and ideal body size among adolescents [41,42]. Silhouette scales are designed to be ethnically and culturally neutral, minimizing potential bias and ensuring applicability across diverse populations, including Saudi adolescents [43,44]. Students were asked to select the silhouette that best represented their ideal body size and the one they felt most closely resembled their current body size. The difference between the 2 selections (ideal vs current) was used to determine the degree of body image discrepancy. A negative score indicated a drive for thinness (desire for a smaller body size), while a positive score reflected a drive for fullness (desire for a larger body size) [43]. Body image discrepancy was measured at baseline, postintervention, and during follow-up.

Disordered Eating Symptoms

The Arabic version of the Sick-Control-One Stone-Fat-Food was used to assess disordered eating symptoms through a 5-item self-reported questionnaire with "yes or no" response options [45]. An answer of "yes"=1 and "no"=0, with a total score range from 0 - 5. Disordered eating symptoms were measured both at baseline and during follow-up. The Sick-Control-One stone-Fat-Food screening tool has been translated and validated in Arabic and used successfully with adolescents [45,46].

Statistical Approach

Descriptive statistics were first calculated for all study variables, including means and SDs for continuous variables and frequencies and percentages for categorical variables. Group differences at baseline were examined using independent samples *t* tests for continuous variables and chi-square tests for categorical variables. A series of linear mixed-effects models was used to examine the effects of time, intervention type, and school type on various outcome variables, while accounting for repeated measures across time points. The analyses were conducted using IBM SPSS Statistics (version 29) with restricted maximum likelihood, allowing for robust handling of the repeated measures design. For each model, estimated marginal means were calculated to explore pairwise comparisons between time points, intervention types, and school types. The Bonferroni correction was applied to adjust for multiple comparisons. The goodness-of-fit for each model was evaluated using the Akaike information criterion and Schwarz's Bayesian criterion. In total, 4 outcome variables were examined: knowledge, body image discrepancy, disordered eating symptoms, and sedentary behavior. Each model included time (baseline, postintervention, or follow-up), intervention type (Green Apple-MNCD or Green Apple), and school type (urban or rural) as categorical fixed effect variables. Repeated measurements were modeled with time as the repeated factor and student ID as the subject variable to account for the correlation between repeated measurements from the same individual. An unstructured covariance matrix was used to account for variability at different time points. Pairwise comparisons were conducted for both the 2-way interaction (time×intervention type) and the 3-way interaction (time×intervention type×school type). In addition, for the knowledge model, exposure to MNCD health education was included as a continuous covariate to control baseline health literacy. However, for the body image model, knowledge was included as a continuous predictor to assess its effect on body image. For the disordered eating symptoms and sedentary

XSL•FO
RenderX

behavior models, there were no additional covariates. Statistical significance was determined at $P<.05$.

Sample Size

The sample size for this study was calculated using G*Power 3.1.9.7 software (Heinrich-Heine-Universität Düsseldorf), assuming a repeated measures ANOVA design to approximate the linear mixed model framework. A medium effect size (f=0.25), a significance level (α=.05), and a power ($1-\beta$=.80) were used. Although our previous pilot evaluation of the same program demonstrated a large effect size (partial η^2=0.27, equivalent to f≈0.61), we selected a more conservative medium effect size (f=0.25) for the current sample size estimation [33]. This decision was based on both methodological caution and practical considerations, as we anticipated a relatively small sample due to school and class availability constraints in rural areas. The design included 2 groups and 3 time points (pre, post, and follow-up), with an assumed correlation of 0.5 among repeated measures. The analysis indicated that a total sample size of 86 participants was required to achieve sufficient power. However, when adjusted for an expected attrition rate of 20%, the required sample size increased to 108 participants.

Missing Data

An intention-to-treat approach was applied to ensure that all participants were analyzed in their original groups, even if they had missing data at later stages. Missing data were handled using restricted maximum likelihood, which is appropriate for data assumed to be missing at random in linear mixed models [47]. This method enables the use of all available data without requiring imputation or exclusion of cases with missing values, resulting in robust parameter estimation. No imputation techniques were applied, as linear mixed models inherently accommodate incomplete data in repeated measures by using the available observations for each participant [47]. Model fit was evaluated using the Akaike information criterion, and likelihood ratio tests were performed to compare nested models. The normality of residuals and homoscedasticity was checked graphically using residual plots, and no major violations of assumptions were observed.

Data Collection

Surveys were administered in paper-based format and completed during regular class periods under the supervision of research assistants (registered nurses), who provided clarification when necessary. Baseline surveys required approximately 45 minutes to complete, while postintervention and follow-up surveys required 15 - 20 minutes. Upon collection, all surveys were collected immediately and reviewed for completeness and then entered manually into a secure electronic database (Microsoft Office Forms) by the research assistants. To minimize entry errors, data were double-checked, and any discrepancies were resolved through cross-checking.

Results

Sample Baseline Characteristics

Demographics by School Type

A total of 107 students agreed to participate in the study. Furthermore, 2 cases from the urban school were excluded due to missing identification, resulting in 105 students included in the final analysis (refer to Multimedia Appendix 1 for details on data completeness). Overall, 7% of data were missing, with the majority occurring at the follow-up stage (9%). Little's Missing Completely at Random test indicated that the data were missing completely at random (χ^2_{111}=124.7; P=.18), suggesting that the missingness was unlikely to introduce systematic bias. All students contributed data at a minimum of two time points.

The mean age across all participants was 16.42 (SD 0.66) years (Table 2). A significant difference in age between the intervention groups was found ($P<.001$). Combining both urban and rural schools, the overall mean age for the enhanced intervention (Green Apple+MNCD) group was 15.97 (SD 0.41) years; for the intervention (Green Apple) group, the mean age was 17.00 (SD 0.42) years. For additional baseline characteristics by intervention type, refer to Multimedia Appendix 2.

Green Apple	46	17.10 (0.42)
Total	105	16.42 (0.66)

[a]MNCD: metabolic noncommunicable disease.

Physical Activity and Sedentary Behavior

Table 3 presents a comparison of urban and rural schools regarding various physical activity behaviors, exposure to MNCD health education, and the need for educational interventions. Urban students reported a higher mean sedentary time than rural students; however, this difference was not statistically significant (*P*=.09). Urban students exhibited significantly higher total energy expenditure in METs-minutes/week than rural students (*P*=.03). This was primarily due to a significantly higher energy expenditure from vigorous physical activity (*P*=.009). Although urban students reported higher energy expenditure from moderate-vigorous physical activity, this difference was not statistically significant (*P*=.17).

XSL•FO
RenderX

Table . Baseline descriptive statistics by school type (urban vs rural): physical activity, exposure to metabolic noncommunicable diseases, health education, knowledge, body image, eating disorder symptoms, and perceived need for intervention. *P* values reflect between-group comparisons using independent sample *t* tests or chi-square tests where appropriate.

Variable	Urban school	Rural school	*P* value
Physical activity behaviors, mean (SD)			
Sedentary behavior (h/d)	7.85 (3.17)	6.96 (3.68)	.09
Total-intensity physical activity (METs[a]-min/wk)	3092.62 (3025.67)	2127.11 (2217.04)	.03[b]
Vigorous-intensity physical activity (METs-min/wk)	1370.75 (2042.03)	667.11 (961.12)	.009[b]
Moderate-intensity physical activity (METs-min/wk)	1592.33 (1433.34)	1353.43 (1166.18)	.17
Exposure to MNCDs[c] health education	3.68 (0.53)	3.38 (0.93)	.02[b]
MNCDs knowledge, mean (SD)	11.78 (2.51)	10.14 (2.34)	<.001[b]
Body image discrepancy, mean (SD)	−0.769 (0.8)	−0.23 (0.98)	.002[b]
Eating disorder symptoms, mean (SD)	1.93 (1.16)	1.37 (1.04)	.006[b]
Need of intervention assessment, n (%)			
Urgent need	21 (52.5)	57 (87.7)	<.001[b]
Considered need	19 (47.5)	8 (12.3)	—[d]
No need	0 (0)	0 (0)	—

[a]MET: metabolic equivalent.

[b]Indicates statistically significant differences (*P*<.05).

[c]MNCD: metabolic noncommunicable disease.

[d]No measurement.

Exposure to MNCD Health Education

Urban students reported significantly higher exposure to MNCD health education than rural participants, with a significant *P* value (*P*=.02). Furthermore, urban students reported significantly higher MNCD knowledge than rural participants (*P*<.001) (Table 3).

Need for Intervention Assessment

A notable disparity was observed between urban and rural schools regarding the perceived need for an intervention (Table 3). In urban schools, 53% (21/40) of participants reported an urgent need for intervention, while 48% (19/40) considered the need but did not find it urgent. In rural schools, 88% (57/65) of participants reported an urgent need, with only 12% (8/65) considering the need but not finding it urgent. This difference was significant (*P*<.001).

Body Image Discrepancy and Disordered Eating Symptoms

Urban students demonstrated a significantly greater drive for thinness (*P*=.002) and more disordered eating symptoms (*P*=.006) than rural students (Table 3). This suggests that urban students may be more vulnerable to body image dissatisfaction and disordered eating symptoms, highlighting a potential need for targeted interventions.

Green Apple Intervention

Program Effectiveness on Knowledge Level

At all 3 time points (baseline, postintervention, and follow-up), there were no statistically significant differences between the enhanced intervention (Green Apple+MNCD) group and the original intervention (Green Apple) group in knowledge about MNCDs (all *P* values >.05; Table 4). This lack of significance may reflect the substantial overlap in core educational content between the 2 interventions, particularly regarding macronutrient understanding and behavior change strategies.

[a]NCD: noncommunicable disease.

[b]MNCD: metabolic noncommunicable disease.

[c]Indicates statistically significant differences (*P*<.05).

[d]DE: disordered eating.

[e]No measurement.

Although the enhanced intervention (Green Apple+MNCD) group received additional disease-specific content, the intervention intensity (1 extra session) may not have been sufficient to produce a measurable advantage, especially given the short follow-up period and modest sample size (refer to Multimedia Appendix 3 for details on types of units included within each intervention).

The direction of the difference at follow-up favored the enhanced intervention (Green Apple+MNCD) group (mean difference 0.73, SE 0.49, 95% CI –0.24 to 1.71), suggesting a possible trend that may warrant further investigation in larger or longer-duration trials. The enhanced intervention (Green Apple+MNCD) led to significant improvements in knowledge about MNCDs across all schools, with an adjusted mean difference from baseline to postintervention of 1.85 (95% CI 0.89 - 2.81; *P*<.001) and from baseline to follow-up of 1.66 (95% CI 0.61 - 2.70; *P*<.001) (refer to Table 4 for within-group school differences in knowledge scores). In addition, when effectiveness was examined based on school type, it was found that the enhanced intervention (Green Apple+MNCD) led to significant improvements in urban schools from baseline to both postintervention with an adjusted mean difference of 2.70 (95% CI 1.21 - 4.19; *P*<.001) and remained significantly higher at follow-up with an adjusted mean difference of 1.83 (95% CI 0.27 - 3.39; *P*=.02). In rural schools, the enhanced intervention (Green Apple+MNCD) showed no significant improvement at postintervention with an adjusted mean difference of 1.00 (95% CI –0.20 to 2.20; *P*=.13), but a delayed significant improvement was observed at follow-up with an adjusted mean difference of 1.48 (95% CI 0.09 to 2.88; *P*=.03).

On the other hand, the intervention (Green Apple) group showed a modest overall improvement from baseline to postintervention across all schools, with an adjusted mean difference of 1.27 (95% CI 0.10 - 2.43; *P*=.02). However, this was not maintained at follow-up, where the improvement was not statistically significant, with an adjusted mean difference of 1.13 (95% CI –0.10 to 2.35; *P*=.08). Furthermore, when this effectiveness was examined based on school type, it was found that in urban schools, the intervention (Green Apple) group showed marginally nonsignificant improvement at postintervention, with an adjusted mean difference of 1.86 (95% CI –0.08 to 3.81; *P*=.06), and nonsignificant improvement at follow-up, with an adjusted mean difference of 1.22 (95% CI –0.82 to 3.25; *P*=.44). Similarly, in rural schools, the intervention (Green Apple) group showed no significant improvement at postintervention (adjusted mean difference 0.67, 95% CI –0.61 to 1.96; *P*=.61) or follow-up (adjusted mean difference 1.03, 95% CI –0.204 to 2.39; *P*=.20), further supporting the conclusion of limited effectiveness.

Program Safety for Body Image Discrepancy and Disordered Eating Symptoms

A key aim of this study was to determine whether the program, including both the intervention (Green Apple) and the enhanced intervention (Green Apple+MNCD), maintained a neutral effect on body image discrepancy and disordered eating symptoms, as indicated by a lack of significant changes. Results across various school settings, both urban and rural, provide insight into whether these interventions unintentionally influence drive for thinness or disordered eating behaviors, which would indicate a safety concern. First, at baseline, there was no significant difference in body image discrepancy between the enhanced intervention (Green Apple+MNCD) group and the intervention (Green Apple) group (mean difference –0.05, SE 0.19, 95% CI –0.42 to 0.33; *P*=.80). This similarity at baseline confirms that the groups were comparable in this outcome before the intervention. Postintervention, the difference remained nonsignificant (mean difference –0.04, 95% CI –0.41 to 0.32; *P*=.81). However, at follow-up, a statistically significant difference was observed in favor of the enhanced intervention (Green Apple+MNCD) group (mean difference –0.37, SE 0.19, 95% CI –0.73 to –0.001; *P*=.05), indicating a greater reduction in body image discrepancy compared with the intervention (Green Apple) group.

Although the effect size was small, this finding suggests a potential delayed benefit of integrating MNCD-focused content within a weight-neutral framework. Across both intervention types and school settings, there was a general trend toward a reduction in body image discrepancy; however, none of the observed changes from baseline to follow-up reached statistical significance. For instance, in the intervention (Green Apple) group, the overall mean difference from baseline to follow-up across all schools was –0.26 (95% CI –0.67 to 0.14; *P*=.35), suggesting a modest improvement in body image perception that did not reach statistical significance. Similarly, the enhanced intervention (Green Apple+MNCD) group showed a slight increase in body image discrepancy across all schools, with a mean difference of 0.06 (95% CI –0.29 to 0.41; *P*>.99). When the data were disaggregated by school type, urban and rural schools in both interventions reflected similar nonsignificant trends. For example, in urban schools, the intervention (Green Apple) group showed a mean change of 0.42 (95% CI –0.24 to 1.08; *P*=.36), while the enhanced intervention (Green Apple+MNCD) group showed a mean change of 0.09 (95% CI

XSL•FO
RenderX

–0.43 to 0.60; *P*>.99). These results suggest a generally neutral effect on body image discrepancy across both interventions, although the trends, particularly the reduction observed in the intervention (Green Apple) group, indicate potential in reducing the drive for thinness without causing psychological harm (refer to Table 5 for between-group differences and Table 4 for within-group differences in body image discrepancy).

Table . Adjusted between-group mean differences (enhanced intervention: Green Apple+MNCD vs intervention: Green Apple) at baseline, postintervention, and follow-up for key outcomes. Estimates are derived from linear mixed-effects models controlling for time and school type. Values represent adjusted mean differences with SEs and 95% CIs.

Variables	Baseline			Postintervention			Follow-up		
	Mean (SE)	95% CI	*P* value	Mean (SE)	95% CI	*P* value	Mean (SE)	95% CI	*P* value
Knowledge about MNCDs[a]	0.20 (0.46)	−0.71 to 1.12	.65	0.79 (0.45)	−0.10 to 1.7	.83	0.73 (0.49)	−0.24 to 1.71	.13
Body image discrepancy	−0.05 (0.19)	−0.42 to 0.33	.80	−0.04 (0.19)	−0.41 to 0.32	.81	−0.37 (0.19)	−0.73 to 0.001[b]	.05[b]
DE[c] symptoms	0.30 (0.23)	−0.15 to 0.75	.18	—[d]	—	—	−0.38 (0.27)	−0.92 to 0.16	.16
Sedentary behavior	−0.07 (0.99)	−2.04 to 1.90	.94	—	—	—	0.80 (1.09)	−1.36 to 2.96	.46

[a]MNCDs: metabolic noncommunicable diseases.

[b]Indicate statistically significant differences (*P*<.05).

[c]DE: disordered eating.

[d]No measurement.

Despite the absence of statistically significant change, the observed decrease in discrepancy scores may still hold clinical relevance, as even modest reductions in the drive for thinness could reflect a shift toward healthier body image perceptions. The lack of significance may be attributed to the relatively short intervention and follow-up duration, the complexity of modifying entrenched body image attitudes, or limited statistical power to detect small effects. Second, both the enhanced intervention (Green Apple+MNCD) and the intervention (Green Apple) demonstrated no significant increases in disordered eating symptoms across various settings, supporting the safety of these weight-neutral programs (refer to Table 5 for between-group differences and Table 4 for within-group differences in disordered eating symptoms). At baseline, disordered eating symptoms were slightly higher in the enhanced intervention (Green Apple+MNCD) group than in the intervention (Green Apple) group across all schools, with a nonsignificant mean difference of 0.30 (95% CI −0.15 to 0.75; *P*=.18), suggesting comparable starting levels between the groups (Table 5). At follow-up, the enhanced intervention (Green Apple+MNCD) group showed a slight reduction in mean disordered eating symptoms, while the intervention (Green Apple) group showed a slight increase. However, neither of these changes reached statistical significance (*P*=.17 for between-group comparison at follow-up), supporting the safety of the interventions in not exacerbating disordered eating symptoms.

Across all schools, the enhanced intervention (Green Apple+MNCD) group showed a slight, nonsignificant reduction in disordered eating symptoms from baseline to follow-up (mean difference −0.43, 95% CI −0.88 to 0.03; *P*=.06). In urban schools, the enhanced intervention (Green Apple+MNCD) group demonstrated a significant reduction in disordered eating symptoms (mean difference −0.94, 95% CI −1.61 to −0.26; *P*=.007), suggesting a positive safety profile. In rural schools, the enhanced intervention (Green Apple+MNCD) group showed a nonsignificant change in symptoms from baseline to follow-up (mean difference 0.09, 95% CI −0.53 to 0.69; *P*=.78), possibly reflecting contextual differences in program delivery or participant characteristics. Similarly, the intervention (Green Apple) group in both urban and rural schools showed no statistically significant changes in symptoms, reinforcing the safety of the program's weight-neutral design concerning disordered eating symptoms. However, it is important to note that both programs were weight-neutral; therefore, a significant difference between the 2 intervention arms was not necessarily expected. The significant reduction observed in urban schools within the enhanced intervention (Green Apple+MNCD) group may be partially explained by the higher baseline mean of disordered eating symptoms in this subgroup compared with others. This suggests that the intervention may have been particularly beneficial for students with elevated symptoms at baseline, while producing few or no significant changes in groups with lower levels of disordered eating symptoms.

Program Safety on Sedentary Behavior

This study aimed to assess the impact of the intervention (Green Apple) and enhanced intervention (Green Apple+MNCD) on sedentary behavior, defined as hours spent sitting per day during weekdays, with 7 or more hours defined as sedentary. A decrease in hours would suggest a positive effect on reducing sedentary behavior, supporting the interventions' safety to not exacerbate sedentary tendencies. Overall, there was a trend toward decreased sedentary behavior across all schools in both intervention groups, with the enhanced intervention (Green Apple+MNCD) and intervention (Green Apple) groups showing

XSL•FO
RenderX

reductions in mean sedentary hours from baseline to follow-up (refer to Table 5 for between-group differences and Table 4 for within-group differences in sedentary behavior). Across all schools, the enhanced intervention (Green Apple+MNCD*)* group showed a decrease in sedentary behavior from baseline (mean 10.22 h) to follow-up (mean 8.69 h), though this change was not statistically significant (mean difference −1.53, 95% CI −3.50 to 0.45; *P*=.12). In the intervention (Green Apple) group, sedentary behavior declined significantly across all schools (mean difference −2.39, 95% CI −4.73 to −0.06; *P*=.04), suggesting a positive impact.

When the data were examined by school type, both the enhanced intervention (Green Apple+MNCD) and intervention (Green Apple) groups in urban schools showed reductions in sedentary behavior from baseline to follow-up, although these changes were not statistically significant (*P*=.49 and *P*=.39, respectively). In rural schools, the intervention (Green Apple) group exhibited a statistically significant reduction in sedentary behavior (mean difference −3.12, 95% CI −5.67 to −0.57; *P*=.02). Meanwhile, the enhanced intervention (Green Apple+MNCD) group showed a nonsignificant decrease in sedentary behavior in rural schools (mean difference −1.05, 95% CI −4.69 to 2.59; *P*=.12), which supports the program's safety. The nonsignificant difference between the 2 intervention groups regarding sedentary behavior may be attributed to the overlap in content related to calories and energy. Both interventions included the same unit discussing how energy is produced, where it is stored in the body, how it is released, and how physical activity and energy balance are related. The only distinction is that the enhanced intervention (Green Apple+MNCD) additionally linked this unit to the management of MNCDs.

Discussion

Principal Findings

This study found that the Green Apple program, a non–weight-centric school-based intervention, significantly improved students' knowledge of MNCDs, reduced sedentary behavior — especially among rural students — and showed promising trends in improving body image discrepancy and disordered eating symptoms without causing harm. These findings support the effectiveness and safety of implementing culturally tailored, weight-neutral interventions in adolescent populations.

To our knowledge, this implementation trial is one of the first Arabic-language, school-based programs to evaluate a weight-neutral approach for improving understanding of MNCDs — particularly metabolic conditions like diabetes, stroke, and hyperlipidemia — while focusing on visceral fat and lifestyle changes rather than weight loss among rural and urban female adolescents. Developed using a theoretically guided process and formative research, the intervention prioritized health-promoting behaviors without reinforcing weight stigma.

Comparison With Previous Work

The Green Apple program's effectiveness in improving MNCD-related knowledge without exacerbating sedentary behavior tendencies can be attributed to several targeted components. First, the curriculum emphasized interactive and culturally tailored lessons that linked macronutrient intake with specific metabolic health outcomes, such as liver health and vascular fat accumulation — making abstract biomedical concepts more relevant and accessible to adolescents. Second, rather than prescribing dietary changes or promoting physical activity directly, the program employed a health literacy approach that fostered critical thinking and informed decision-making. For example, students were taught to distinguish between aerobic and resistance exercises and to identify how each affects energy metabolism. This empowered students to re-evaluate their daily habits, which may explain the observed decrease in sedentary behavior without an explicit call to increase activity. The use of relatable examples, age-appropriate language, and visual aids (eg, infographics and simplified diagrams) also played an important role in reinforcing key messages and supporting knowledge retention. The Green Apple program engaged students not only as passive recipients of information but as active participants in understanding their own health behaviors, which may have been instrumental in achieving both cognitive (knowledge) and behavioral (sedentary time) changes.

The Green Apple program was developed with a foundation in the HBM, SCT, and the TTM, aiming to enhance metabolic health literacy, self-efficacy, and staged behavior change among adolescents. Beyond these, Green Apple shares theoretical intersections with frameworks frequently used in international weight-neutral interventions. For instance, elements of self-determination theory are reflected in the program's emphasis on autonomy (students are encouraged to make informed health decisions rather than passively follow directives), building competence (through skill-based, practical lessons), and fostering relatedness (via collaborative classroom activities) [48]. Similarly, social learning theory is embodied through its use of observational and peer-supported learning, including interactive discussions and role-modeling by program facilitators [49]. While acceptance and commitment therapy was not an explicit design framework, the program's avoidance of weight-centric language and focus on values-driven, health-promoting behaviors may support the psychological flexibility and acceptance central to acceptance and commitment therapy–based interventions [50]. By integrating these diverse theoretical perspectives, Green Apple addresses multiple drivers of adolescent health behavior in a culturally sensitive manner.

The Green Apple program's effectiveness in enhancing students' understanding of MNCDs aligns with previous research highlighting the importance of health education in obesity prevention [16,51]. By focusing on the role of liver fatty acids and vascular fat in metabolic conditions rather than on weight loss, the program shifts the conversation away from potentially stigmatizing weight-centric approaches. This approach supports recent calls to reshape the global obesity narrative to recognize and reduce weight stigma [1,10,52]. The program's success in increasing knowledge about MNCDs suggests that high school students can comprehend topics like metabolic diseases and their connection to macronutrients and body energy. This

XSL•FO
RenderX

education-focused intervention demonstrates the potential of such strategies in promoting health literacy among adolescents.

Recent years have seen a global shift toward school-based health interventions that adopt weight-neutral approaches, emphasizing overall well-being, health behaviors, and body acceptance rather than weight loss or BMI reduction [53,54]. Innovative programs like Good Food for All (Australia) and Imagine HEALTH (United States) incorporate experiential activities, intuitive eating, and guided imagery to foster positive relationships with food and movement, improving psychosocial health and lifestyle behaviors without targeting weight loss [54,55]. Mindful eating curricula, such as "Eat My ABCs," further extend these principles by teaching self-regulation and satiety awareness, leading to healthier eating behaviors in children [54]. While these programs and other international interventions share key characteristics with the weight-neutral, stigma-reducing strategies now associated with the mind-body modalities of the HAES paradigm [53,54], they are not always formally aligned with or derived from HAES.

The Green Apple program shares similarities with the HAES movement [54] in that both emphasize promoting health without focusing solely on weight, avoiding calorie counting and restrictive dieting, and encouraging a healthy relationship with food. However, there are important distinctions between the 2. The Green Apple program was specifically designed for school settings and is driven by the goal to increase metabolic health literacy among adolescents, particularly in relation to macronutrients, energy metabolism, and lifestyle-related noncommunicable diseases (eg, diabetes and hypertension). In contrast, HAES is a broader, philosophically driven approach that promotes body inclusivity, intuitive eating, and joyful movement across all populations, regardless of age, gender, or health status [53,54]. While HAES has been praised for reducing weight stigma and supporting psychological well-being, some critics argue that its generalizability to targeted disease prevention (eg, metabolic syndrome) may be limited [56,57]. On the other hand, Green Apple's structured and curriculum-based model offers clear educational content aligned with disease prevention but may require more rigorous implementation and contextual adaptation.

Furthermore, the Green Apple program may be more culturally adaptable in non-Western contexts, such as Saudi Arabia, where public health messages around metabolic disease are often aligned with national health priorities [14,15]. In contrast, HAES's strong focus on body autonomy and its rejection of medical weight loss may face cultural or institutional resistance in certain settings. In summary, both programs focus on health promotion beyond weight loss, but the Green Apple program — specifically, the enhanced intervention (Green Apple+MNCD) used in our study— uniquely targets metabolic health literacy and prevention, making it more tailored for specific outcomes related to metabolic disease management in adolescent females. In a previous pilot study, the Green Apple+MCND combination showed greater pre-post effectiveness on knowledge than the Green Apple program alone among male and female urban adolescents [33]. Thus, the findings from this study contribute to the literature by highlighting the effectiveness of this program among rural students and its sustainability at follow-up.

Future studies should explore the program's effectiveness among rural male adolescents and its sustainability among urban male adolescents. Notably, rural students in this study demonstrated a delayed improvement in nutrition knowledge, with no significant gains immediately following the intervention but a marked increase at follow-up. This pattern may indicate a need for more time to absorb and consolidate new information, particularly among populations with lower baseline health literacy [22,58]. Overall, the Green Apple program demonstrated its universal acceptability among rural female adolescents and its long-term effectiveness during follow-up among both rural and urban students.

The trend reduction in sedentary behavior observed among participants is particularly noteworthy, given the high prevalence of sedentary lifestyles among Saudi youth [59]. At baseline, all schools exhibited sedentary behavior (over 7 h of sitting daily). By follow-up, sedentary time decreased by 1 - 3 hours per weekday, despite the program not explicitly instructing students to reduce sitting time or increase physical activity. Several mechanisms may explain this outcome. First, the program emphasized the physiological relationship between macronutrients and energy usage, highlighting how different types of physical activity (eg, aerobic vs resistance training) impact health. This knowledge-based approach may have fostered greater internal motivation and self-efficacy to engage in movement, leading students to make conscious efforts to reduce sedentary time. Second, increased awareness of energy balance and muscle health could have encouraged students to re-evaluate their daily habits, choosing more active routines in response to improved health literacy. Similar findings have been observed in other weight-neutral interventions [54]. For example, a pilot RCT involving Latino adolescents with BMIs >95th percentile found that those who attended 12 weekly sessions of a non–weight-centric lifestyle education program called H.E.A.L.T.H. that incorporated guided imagery experienced significant reductions in leisure sedentary behavior (P<.05) compared with adolescents (n=14) who attended the same program with digital storytelling sessions [55]. Future studies should further explore these mechanisms by assessing not only the types and duration of physical activity adopted but also changes in students' beliefs, confidence, and motivations regarding movement. To sum up, these findings support the potential of non–weight-centric school-based interventions to meaningfully reduce sedentary time through education and empowerment, rather than prescriptive behavioral mandates.

Finally, the promising trends in decreasing body image discrepancy and disordered eating symptoms in this study are particularly noteworthy, given the potential negative consequences of weight stigma and body dissatisfaction on adolescent mental health [2,60]. Although these changes were not statistically significant, they may still be clinically meaningful and suggest that weight-neutral approaches like the Green Apple program can support the development of positive body image and healthy eating behaviors without exacerbating weight concerns. These findings highlight the potential of such interventions to contribute to the prevention of disordered eating

XSL•FO
RenderX

symptoms, even in the absence of immediate measurable effects. This aligns with recent research supporting the efficacy of weight-inclusive interventions in enhancing psychological well-being and reducing disordered eating behaviors [6,54,60]. For example, a meta-analysis found nonsignificant trends toward improvements in drive for thinness and body dissatisfaction with weight-neutral interventions [6]. However, consistent with our study, a statistically significant improvement in disordered eating symptoms was observed within one of the weight-neutral intervention groups [6].

This study's results also highlight the importance of tailoring interventions to specific cultural contexts. The observed differences between urban and rural schools highlight the need for tailored interventions based on regional disparities. Urban students reported higher levels of knowledge and exposure to health education, along with higher body image discrepancy and disordered eating symptoms, while rural students exhibited a greater need to increase their knowledge about MNCDs. Body image is strongly shaped by social and cultural influences, and this program offers a valuable starting point for future interventions that aim to include more tailored strategies for addressing body image concerns, particularly in rural settings. This study observed an average discrepancy of less than 1 body size among students, which is consistent with previous findings suggesting that body image discrepancy tends to be low among rural adolescents [61,62]. As such, future iterations of the Green Apple program may benefit from further customization to address the specific needs of rural populations, ensuring that interventions are both accessible and effective across diverse settings. Furthermore, the use of silhouette scales, while widely accepted for body image assessment, may be limited by participants' memory effects. Damasceno et al [63] found that participants often selected the same or very similar silhouettes within a 15-day interval, suggesting that repeated exposure to the same silhouettes over short periods can artificially inflate reliability and reduce sensitivity to actual change. This may have contributed to the lack of observed changes in body image over time.

Overall, the results in both settings demonstrate the potential for adapting weight-neutral approaches to non-Western cultures. This is particularly relevant given the limited research on obesity prevention in Saudi Arabia and the need for culturally appropriate interventions. The program's effectiveness in both urban and rural schools further underscores its adaptability and potential for widespread implementation.

However, the observed differences between urban and rural schools warrant further exploration. Urban students generally had higher baseline levels of health literacy, greater previous exposure to health education, and better access to digital and extracurricular resources, which may have facilitated quicker knowledge gains and behavioral changes [58,64]. In contrast, rural students demonstrated a delayed improvement in nutrition knowledge, with gains becoming evident only at the follow-up stage. This delay may reflect disparities in educational resources, differences in school infrastructure, or cultural variations in how health information is received and processed [58,64]. These findings emphasize the need to tailor the program's delivery with reinforcement strategies to better support students in underresourced rural settings and reduce health literacy gaps between regions [58,64].

Public Health Policy Recommendations

The findings of this study suggest a significant need for policy reform in school-based health interventions, particularly in how obesity prevention is addressed in Saudi Arabia.

First, adopt non–weight-centric frameworks in school health programs. Current school health initiatives should transition from weight-focused models to non–weight-centric approaches that emphasize metabolic health. Rather than using BMI as the primary indicator of health, schools can implement annual wellness screenings that assess cardiovascular fitness, physical activity habits, and dietary quality [1,65-67]. For instance, in collaboration with schools, community health nurses, physical education staff, and local primary health care centers can adopt metrics such as heart rate recovery, physical endurance, and nutrition intake to provide a more holistic and less stigmatizing view of adolescent health.

Second, revise educational content to use stigma-free, health-promoting language. Health education policies should be revised to eliminate language that links health behaviors explicitly to weight loss. Instead, curricula should emphasize building healthy habits, such as engaging in enjoyable physical activity, eating diverse whole foods, and understanding how nutrition supports organ health [1,3]. For example, Ministry of Education health textbooks should be updated, and teacher development workshops on inclusive language should be delivered. These workshops can include scenario-based training and feedback sessions to help educators identify and eliminate implicit weight bias in their teaching [66,68].

Third, tailor health interventions to address regional disparities. As this study indicates, rural areas often lack access to tailored health education programs. To bridge this gap, mobile regional health directorates can deploy school health units to deliver interactive workshops and preventive screenings in underserved schools. In addition, rural teachers can be trained as "health ambassadors" in collaboration with local universities, ensuring consistent delivery of health messages that are culturally and contextually appropriate. Pilot programs in targeted rural regions can serve as models for broader scale-up [10,69,70].

Fourth, support long-term sustainability through policy and resource allocation. Health policies should ensure that resources are allocated for ongoing support, including teacher training and curriculum development, to maintain the positive outcomes seen in short-term interventions [10,66,68].

Fifth, encourage research and innovation in weight-neutral health promotion. Government agencies and research institutions should allocate additional resources to support studies that explore weight-neutral approaches to health promotion and obesity prevention [10,66]. National grants can prioritize school-based interventions that focus on improving metabolic indicators without relying on weight loss as an outcome. In addition, research institutions can be encouraged to collaborate with school systems to cocreate evidence-based, student-centered health programs. Finally, evaluating the Green Apple program's adaptability to other adolescent health issues,

XSL•FO
RenderX

such as iron deficiency anemia, malnutrition, or diabetes management, could broaden its impact and support more comprehensive school-based health education efforts, especially given the limited availability of evidence-based interventions targeting metabolic health in the current Saudi literature [71].

Limitations and Recommendations

While this study presents promising results, several limitations must be acknowledged. First, the relatively short follow-up period limits our ability to assess the long-term impact and sustainability of the intervention. Some of the nonsignificant findings — particularly in outcomes such as body image discrepancy and disordered eating symptoms — may be attributed to the brief duration of the intervention, which may not have been sufficient to elicit measurable changes in complex psychosocial constructs. Future research should incorporate longer follow-up periods to better capture delayed or long-term effects. Second, the modest sample size may have reduced the statistical power to detect small but meaningful effects, especially in subgroup analyses and interaction terms. Finally, the similarity in content between the 2 intervention arms — both of which adhered to a non–weight-centric framework — may have reduced the likelihood of observing substantial between-group differences, as both emphasized promoting healthy behaviors without explicitly targeting weight loss or body image modification. In addition, since this study focused only on female students in Saudi Arabia, its findings may not be generalizable to other populations. Further research is needed to test similar interventions across diverse cultural settings and among different gender groups.

Despite these limitations, the study provides a significant contribution to adolescent obesity prevention literature, particularly in non-Western contexts. The Green Apple program's success suggests that weight-neutral, culturally adapted interventions can effectively promote health and well-being among Saudi female adolescents. Its impact on increasing MNCD-related knowledge and its promising trends in reducing sedentary behavior, body image discrepancy, and eating disordered symptoms reinforce the value of moving away from weight-centric approaches to obesity prevention.

Overall, these findings add to the growing evidence in support of weight-inclusive health promotion strategies and underscore the need for culturally appropriate interventions in addressing global health challenges.

Conclusions

This study demonstrated that the Green Apple program, a school-based intervention grounded in a non–weight-centric approach, effectively enhanced adolescents' health behaviors and psychosocial outcomes. Specifically, the enhanced intervention (Green Apple+MNCD) led to significant improvements in knowledge about MNCDs across all schools. In addition, the Green Apple program without the MNCD session resulted in a notable reduction in sedentary behavior by −3.12 hours per day among rural students and a significant overall reduction of −2.39 hours per day across rural and urban schools. Both versions of the program showed promising trends in improving body image discrepancy and disordered eating symptoms without causing harm. At follow-up, a statistically significant difference was observed in favor of the enhanced intervention (Green Apple + MNCD) group, indicating a greater reduction in body image discrepancy compared with the Green Apple group. Furthermore, in urban schools, only the enhanced intervention (Green Apple+MNCD) group demonstrated a significant reduction in disordered eating symptoms. These findings support the effectiveness and safety of implementing culturally tailored, weight-neutral interventions in adolescent populations.

Future research should pursue longitudinal studies to assess the sustainability of knowledge gains and behavioral changes over extended periods. RCTs are recommended to confirm the program's effectiveness in broader and more diverse populations, including male adolescents and students in other regions of Saudi Arabia. In addition, implementation research is needed to evaluate the program's scalability, feasibility, and cost-effectiveness in real-world school settings. Specific priority areas include adapting the intervention to different cultural or socioeconomic contexts, integrating digital tools to enhance reach and engagement, and examining the role of school infrastructure and policy in supporting long-term behavior change. For instance, a mobile app could track daily activity and provide visual feedback on sedentary behavior, while an online platform could host culturally tailored modules on nutrition and chronic disease prevention, accessible to both students and parents. These digital enhancements would not only broaden the program's reach but also increase engagement and retention of health messages across diverse student populations. Addressing these areas will help inform national strategies aimed at preventing metabolic chronic diseases through inclusive, sustainable, and culturally sensitive school-based interventions.

Acknowledgments

The authors would like to express sincere gratitude to the Ministry of Education School Health Department in Medina and all the participating schools for their invaluable support.

Abstract

Background: Adherence to antiretroviral therapy is a critical component in achieving viral suppression in people living with HIV in addition to increasing overall quality of life. Several indirect methods have been used to measure adherence including the Simplified Medication Adherence Questionnaire (SMAQ).

Objective: The objective of this study is to evaluate the reliability and validity of the SMAQ in men living with HIV/AIDS attending a Mexican national hospital.

Methods: A cross-sectional analytical design study was carried out in a Mexican National Hospital in Jalisco, including men aged >18 years with at least 3 months of antiretroviral treatment, excluding those with cognitive difficulties in answering the survey. A minimum sample size was calculated to detect the contribution of the variables within the model. The analysis included descriptive tests, confirmatory factor analysis, reliability and validity assessment, correlation between adherence and viral load, and association between viral load and adherence.

Results: The final analysis included a total of 260 patients with a mean age of 43 (SD 12) years and an average of 8.97 (SD 6.33) years on antiretroviral treatment. The SMAQ showed sufficient structural validity (comparative fit index=1, root-mean-square error of approximation=0, 90% CI 0-0.085) with satisfactory factor loadings on most questions except item 2 (Do you always take your medication at the prescribed time?). The reliability of the scale is acceptable (Cronbach α=0.702, ω=0.718). Adherence correlated with viral load significantly but not with recent TCD4 lymphocyte levels. Patients classified as adherent were three times more likely to be undetectable than nonadherent patients (odds ratio 3.31, 95% CI 1.13-9.64, *P*=.04).

Conclusions: The SMAQ represents an adequate tool to assess adherence in men living with HIV in the Mexican context, this will contribute to this study and compression of adherence to establish future intervention programs.

Introduction

According to the Joint United Nations Program on HIV/AIDS, 39 million people were living with HIV by 2022, of which only 76.4% were receiving antiretroviral treatment (ART). In Mexico, by 2022, there were 270,000 cases registered with the Ministry of Health, 80% (n=270,000) of which were men; in addition, Jalisco ranks 4th in prevalence of people living with HIV with a record of 7134 patients on ART and 78% of this population has achieved viral suppression through such treatment [1,2].

The World Health Organization defines adherence to treatment as an individual's behavior regarding medications, diet, and lifestyle changes that correspond to the recommendations provided by a health professional [3].

Therapeutic adherence is a complex process that is made up of a personal component represented by the patient, where their attitudes toward their disease and the positions they take on it are concentrated, as well as a relational component involving the health professional and the health structure that surrounds them. All these components work synergistically toward a common goal to benefit the patient's health [4].

Adherence to ART is a critical component to achieve viral suppression in people living with HIV as well as to increase the overall quality of life [5]. Its study is important because in Mexico there has been a sustained prevalence in recent years, and it is necessary to improve the tools available to optimize treatment success [6].

There are various methods for measuring adherence in a patient; however, there is no gold standard for this purpose. Due to this, its measurement will depend on the characteristics of the population studied; in addition, the method should have basic psychometric standards of acceptable validity and reliability [7]. These methods are classified as direct, those that directly quantify the drug and its metabolites in blood or any other fluid or tissue, but they are costly and impractical for routine implementation, and indirect, that is they base their measurement on pill counts and self-reports, among others [8].

An indirect tool that has been used by several authors is the Simplified Medication Adherence Questionnaire (SMAQ). This questionnaire has been used in studies to evaluate adherence to ART in people living with HIV, and its six-question structure makes it practical in clinical contexts where a rapid evaluation is required [9,10]. This scale was introduced in 2002 by Knobel et al [9]. They designed the scale intending to create a questionnaire to identify nonadherent patients and found that this instrument had a sensitivity of 72%, a specificity of 91%, and a likelihood ratio of 7.94, as well as a Cronbach α of 0.75 [9].

The SMAQ questionnaire has also been validated in different pathologies, medical conditions, and chronic diseases, such as hypertension, diabetes, and tuberculosis. These validations have shown consistent results, supporting the usefulness and validity of the questionnaire in different health care settings [9,11]. The instrument was originally developed for the Spanish population in 1999, but the current social and pharmacological context differs for the population we are now studying. It is important to evaluate the validity and reliability of the instrument when used in contexts different from its original development, to ensure the quality of the collected information. This is because the metric quality of a self-report questionnaire must be explored in the context where it will be applied. Otherwise, the psychometric properties would be compromised, leading to negative consequences for the evaluation [12,13].

This questionnaire is not yet validated in Latin people, thus, its utility in our population is unknown. There is only a pilot study with 10 participants that used the SMAQ in Peruvian people living with HIV; where item comprehension was evaluated, as cultural applicability and social acceptance [14]. To our knowledge, no studies have been conducted to validate this instrument in the Mexican population. This study aimed to evaluate the reliability and validity of the SMAQ in people living with HIV/AIDS attending a Mexican national hospital.

Methods

Study Design

This study is a cross-sectional analytical design study concerning people living with HIV/AIDS receiving ART at the Civil Hospital of Guadalajara "Fray Antonio Alcalde."

Selection of Participants

Men older than 18 years of age receiving ART for at least three months before their inclusion in this study were included. Every participant gave his informed consent before participating in the research. On the other hand, those persons diagnosed with serious mental illnesses that may affect their ability to understand or answer the questionnaire were excluded, as well as those with cognitive or communication difficulties that may hinder their participation in the evaluation. Additionally considered as an exclusion criterion is not having performed the test to detect viral load within the period established for this study.

Sample Size Calculation

To determine the sample size, we used a calculator that used a structural equation model approach, in which we anticipated an effect size (factor loading) of 0.5, which would reflect a significant contribution of the latent construct to the observed variables (items), ensuring sufficient construct reliability, a power of 80%, one latent variable, five observable variables, and a probability level of 0.05, resulting in a minimum sample of 100 participants, to detect the specified effect given the structural complexity of this model [15,16].

Variables

The variables considered for this study were age in years, schooling (considered as the last completed grade of studies); municipality of residence (with the category "other" for those participants who indicated not being from a nearby municipality); marital status; employment (was considered positive when they would indicate having an economically remunerated activity); the use of tobacco, alcohol, and illicit drugs (it was considered positive when patients indicated to use in the last 30 days on more than two occasions); the number of pills (including those belonging to a treatment other than ART);

XSL•FO
RenderX

time living with HIV and time on ART (which were calculated considering from the date of HIV diagnosis and the start of ART until the date of enrollment in this study); and finally, clinical stage was classified according to the Center of Disease Control classification [17].

Instrument

The questionnaire consists of 6 questions: the first 4 can be answered with "yes" or "no," while the last 2 require numerical responses: "1. Do you ever forget to take your medication?" "2. Do you always take your medication at the prescribed time?" "3. Do you ever stop taking the drugs if you feel unwell?" "4. Did you forget to take the medication over the weekend?" "5. In the last week, how many times did you miss a dose?" and "6. In the last 3 months, how many full days did you miss taking the medication?" The six questions assess three components of ART adherence: (1) the intentional (question 3), (2) the unintentional (questions 1 and 2), and (3) frequency or quantity (questions 4, 5, and 6). The patient is classified as nonadherent if they answer any in a "nonadherence sense" and if they report missing more than two doses in the last week or reports not having taken more than 2 full days of medication in the last three months [10].

Statistical Analysis

For descriptive analysis, normality tests were performed as necessary. Quantitative variables were described with means or medians, and qualitative variables with frequencies and percentages.

The evidence of validity based on internal structure. was assessed by confirmatory factor analysis using the weighted least squares method with adjusted mean and variance [18]. Model fit was assessed using recognized indices, such as comparative fit index (CFI>0.90) [19], root-mean-square error of approximation (RMSEA<0.08) [20], and weight root-mean-square residual (WRMR<1) [21].

To determine reliability, we estimated the internal consistency coefficients according to Ponterotto and Charter [22]. Scores Cronbach α>0.70 were considered as reliable scores [22]. In addition, we investigated validity by examining the relationship between adherence and undetectable plasmatic viral load using the Pearson correlation coefficient [23].

Finally, Fisher exact tests were used to calculate the odds ratios (OR) to evaluate the association between having an undetectable (patient in control) versus detectable (patient not in control) plasmatic viral load and the scale classification of adherent versus nonadherent (based on the concept that a patient with an undetectable viral load was an adherent patient) [5].

The descriptive and correlational analyses were carried out in SPSS (version 24; IBM Corp) software, while the factor analysis was performed with Mplus (version 7; Muthén & Muthén) software [19]. Finally, the analysis of ORs was performed in Epi Info (Centers for Disease Control and Prevention) software in the Stat Cal module [24].

Ethical Considerations

This research was approved by the Bioethics Committee of the Civil Hospital of Guadalajara (169/23), and it was carried out under the ethical standards for research on human participants. All participants signed an informed consent form that outlined the objectives of the research, the procedures to be followed, and the contact information for the research team. Any questions or concerns were addressed verbally prior to signing the consent form. The information collected was handled exclusively by the research team, and to protect participants' identities an alphanumeric code was assigned to each. Additionally, identifying data were excluded from the database used for analysis. Finally, no direct financial compensation was provided to participants for their involvement in the study.

Results

Characteristics of the Participants

A total of 299 patients were evaluated, 259 men and 40 women, and due to the ratio between groups, we decided to exclude the group of women from the analysis, to maintain the homogeneity and representativeness of the sample [25].

Of the 259 participants included, the mean age was 43 (SD 12) years with an average of 8.97 (SD 6.33) years in ART treatment. Considering schooling, the majority had high school (n=87, 34.6%) or middle school (n=57, 22%) education. The most common municipality of residence was Guadalajara (n=110, 42.5%) and the vast majority were single (n=214, 82.6%). Regarding substance use, 89.6% (n=232) had not consumed illicit substances in the last 30 days while 33.6% (n=87) had consumed alcohol and tobacco in the same period. The mean number of pills per day was 2 (SD 2) and the mean number of years living with HIV was 10 (SD 7.17) with an average CD4+ T lymphocyte count of 686.5 cells/µL (SD 353.88; Table 1).

Responses From the Participants

Regarding the responses to the questionnaire, 66.6% (n=172) of the respondents reported not forgetting their medication, while 33.4% (n=87) admitted to having forgotten it at least once. On the second question, 80.3% (n=198) stated that they took their medication at the indicated time and 19.7% (n=61) admitted not following this pattern. Regarding whether they stopped taking the drugs if they felt unwell, the great majority (n=242, 92.2%) stated that they did not do so but 7.8% (n=17) admitted having done so at some time.

The majority reported not having forgotten to take their medication over the weekend (n=250, 96.6%). In the last week, the majority (n=242, 93.8%) reported missing only one dose, while 6.2% admitted missing a dose once or twice.

On the other hand, of the responses to question 6, a total of 66.5% (n=174) indicated not having missed taking medication on any full day, while 30.6% (n=174) acknowledged having experienced some degree of medication interruption.

Finally, according to the scores of the questionnaire, 66.6% (n=174) of participants reported being adherent while 33.4% (n=88) reported being nonadherent (Table 2).

Table 2. Distribution of responses to the Simplified Medication Adherence Questionnaire (N=259).

Questions	Participants, n (%)
1. Do you ever forget to take your medication?	
No	172 (66.6)
Yes	87 (33.4)
2. Do you always take your medication at the prescribed time?	
No	61 (19.7)
Yes	198 (80.3)
3. Do you ever stop taking the drugs if you feel unwell?	
No	242 (92.2)
Yes	17 (7.8)
4. Did you forget to take your medication over the weekend?	
No	250 (96.6)
Yes	9 (3.4)
5. In the last week, how many times did you not take a dose?	
1	242 (93.8)
2	16 (5.9)
3	1 (0.3)
6. In the last 3 months, how many full days did you not take your medication?	
0	174 (66.5)
1	51 (20.6)
2	17 (5.9)
3	7 (3.1)
>4	10 (1)
Outcome on adherence	
Adherent	174 (66.6)
Nonadherent	88 (33.4)

Evidence of Validity Based on Internal Structure

The unidimensional model obtained favorable fit indices (CFI=1; RMSEA=0, 90% CI 0-0.085; WRMR=0.072), as well as factor loadings around what was expected, except for item 2 (Do you always take your medication at the prescribed time? Table 3). After performing a second analysis without item 2, the results are adequate both at the level of fit indices (CFI=1; RMSEA=0, 90% CI 0-0.103; WRMR=0.047) and factor loadings (>0.50; Table 3).

Regarding reliability, the magnitudes were acceptable for both scores (Cronbach α=0.702) and construct (ω=0.718).

Finally, the correlation of adherence with viral load was statistically significant (r=0.128; P=.04), but not with recent CD4 T lymphocyte counts (r=0.015; P=.81).

On the relationship between undetectable viral load and adherence, those patients classified as adherent by the scale were 3 times more likely to be undetectable compared to those classified as nonadherent (OR 3.31, 95% CI 1.13-9.64, P=.04; Table 4).

Discussion

Principal Findings

Adherence is vital to achieve viral suppression and increase the quality of life of people living with HIV; however, its measurement represents a major challenge [26]. Although direct methods exist to measure adherence (eg, plasma drug concentration), they are costly and impractical for routine implementation in clinical settings with limited resources such as ours [8], thus, indirect measurement methods based on self-reporting may have a good performance and could be used routinely.

This study aimed to evaluate the reliability and validity of the SMAQ in people living with HIV/AIDS attending a public hospital in the western region of Mexico.

As for the factorial structure, 4 of the 5 original items were retained, and the one that was eliminated obtained the lowest factorial loading, and its response was oriented in the opposite direction to the other items, which reinforces the argument that this type of item usually presents methodological problems. This new four-item version obtained adequate fit and reliability indices (CFI=1; RMSEA=0, 90% CI 0-0.103; WRMR=0.047) [27].

The validity of its relationship with other variables was analyzed using an association with viral suppression (or undetectable viral load), finding a threefold greater probability of achieving viral suppression when classified as adherent (OR 3.31, 95% CI 1.13-9.64, *P*=.04).

The use of the SMAQ in the framework of explanatory studies could provide greater insight into the factors associated with adherence, providing evidence for the design of appropriate interventions to improve adherence in this patient population [28]. This, in turn, would strengthen the capacity of health services to enhance and promote quality care, ultimately yielding a positive long-term impact on people living with HIV.

Concerning previous studies, the study by Agala et al [10] also found adequate factor loadings, except for one item, like this work. However, there is no agreement on the eliminated item, which could be attributed to differences in the populations studied because the analysis of our study was only in men and theirs in women. This highlights the existing differences in adherence behaviors between these groups [10].

This situation underscores the need to consider sociodemographic and cultural characteristics when analyzing the evidence and validity of self-report tools such as the SMAQ.

Limitations

Regarding its limitations, it is important to recognize that, despite its simplicity, it may be subject to self-report bias [11]. Similarly, only men were considered due to the proportion that was recruited from both groups and to maintain statistical homogeneity [29]. This limitation does not allow for the opportunity to explore differences that could influence adherence between the two groups.

It is concluded that the SMAQ presents favorable evidence of validity per internal structure and association with viral suppression, as well as acceptable levels of reliability.

In future studies, we recommend that the SMAQ be analyzed at a psychometric level in the group of women to explore possible differences by gender. In addition, this tool will allow studies focused on adherence and its determinants to be carried out with a greater degree of precision.

Conclusions

The use of the SMAQ provides a valuable tool for assessing adherence among the Mexican population living with HIV. This evaluation is critical for enhancing health outcomes and

XSL•FO
RenderX

optimizing therapeutic interventions. Additionally, the SMAQ helps to strengthen public health programs by furnishing reliable data on treatment adherence, which can inform the development of targeted strategies to support patient engagement and medication management.

Abstract

Background: Interstep variations in step riser height and tread depth within a stairway could negatively impact safe stair negotiation by decreasing step riser height predictability and, consequently, increasing stair users' fall risk. Unfortunately, interstep variations in riser height and depth are common, particularly in older stairways, but its impact may be lessened by highlighting steps' edges using a high-contrast stripe on the top front edge of each step.

Objective: This study aimed to determine (1) if fall-related events are associated with greater interstep riser height and depth variations and (2) if such fall-related events are reduced in the presence of contrast-enhanced step edges compared with a control stairway.

Methods: Stair users were video recorded on 2 public stairways in a university building. One stairway had black vinyl stripes applied to the step's edges and black-and-white vertical stripes on the last and top steps' faces. The stairway with striping was counterbalanced, with the striped stairway than a control, and the control with stripes. Each stair user recorded was coded for whether they experienced a fall-related event. A total of 10,000 samples (observations) of 20 fall-related events were drawn with 0.25 probability from each condition to determine the probability of observing a distribution with the constraints outlined by the hypotheses by a computerized Monte Carlo simulation.

Results: In total, 11,137 individual stair user observations had 20 fall-related events. The flights that had 14 mm in interstep riser height variation and 38 mm in interstep depth variation were associated with 80% (16/20) of the fall-related events observed. Furthermore, 2 fall-related events were observed for low interstep variation with no striping, and 2 fall-related events were observed during low interstep variation with striping. A total of 20 fall-related events were observed, with 4 occurring on flights of stairs with low interstep variation. For stairs with high variability in step dimensions, 13 of 16 (81%) fall-related events occurred on the control stairway (no striping) compared with 3 of 16 (19%) on the high-contrast striping stairway. The distribution of fall-related events we observed between conditions likely did not occur by chance, with a probability of 0.04.

Conclusions: These data support the premise that a vision-based strategy (ie, striping) may counteract fall risk associated with interstep riser height and tread depth variation. Possibly, perception and action elicited through the horizontal-vertical illusion (striping) may have a positive impact on the incidence of fall-related events in the presence of high interstep riser height and depth variation. The findings of this study suggest that contrast enhancement (ie, striping) may be a simple and effective way to reduce the risk of falls associated with interstep variation, highlighting the potential for this approach to make a significant impact on fall prevention efforts.

Introduction

When approaching a stairway, stair users seemingly anticipate uniformity in the step riser height and tread depth [1,2]. However, this assumption may lead to fewer attentional resources being allocated to estimating these metrics, potentially compromising the safe negotiation of the stairway. Unfortunately, interstep riser height and tread depth variations are common. Often described as dimensional uniformity in building code, stair riser heights and tread depths shall be of uniform size and shape. The tolerance between the largest and smallest riser height, or tread depth, shall not exceed 3/8 inch in any flight of stairs. In our investigation, the range of dimension uniformity is referred to as interstep variation. Interstep variations, as small as 6 mm, between adjacent stair risers or treads can disrupt step cadence and increase the risk of accidents or falls [3]. One strategy to mitigate this risk involves applying a horizontal-vertical illusion and black stripes to the top front edge of each step, which could potentially decrease the frequency of slips, trips, and falls [4-6]. Recent research has demonstrated that adding a high-contrast stripe along the top front edge of each step [4,7-11] can lead to increases in heel clearance above the step. Similarly, adding vertical monochrome striping to the faces of the bottom and top steps can also enhance vertical foot clearance [4,5,12,13].

Although the exact mechanism behind these interventions is not fully understood, it is possible that they increase step height by drawing more attention to each step's edge [7] or by creating a horizontal-vertical illusion, which makes the steps appear taller than they actually are [14,15]. Ultimately, either mechanism may decrease the likelihood of a slip, trip, or fall on stairs with high interstep variation. We, therefore, hypothesized that when comparing 2 flights of stairs with similar interstep variability, the stairs with vertical monochrome striping and tread edge highlighters would record fewer fall-related events than stairs without this intervention. In addition, stairs with greater interstep variation in riser heights and tread depths would generally record more fall-related events than stairs with less interstep riser height and tread depth variability, but this effect would be lessened with the addition of monochrome striping and tread edge highlighters.

To test our hypotheses, we estimated the probability of observing a range of fall-related event distributions that could plausibly occur by chance, given our hypotheses [high or low interstep riser height and tread depth variations and control or striping intervention conditions]. We codified our hypotheses in a Monte Carlo simulation using 4 constraints based on our hypotheses. First, there would be more fall-related events on control flights of stairs (without the contrast intervention) with greater interstep variation than those with lower interstep variation. Second, both control and intervention (with the contrast enhancement) flights of stairs with low interstep variation should observe a comparable frequency of fall-related events (ie, a difference of less than 2 fall-related events between conditions). Third, fewer (less than or equal to half the number of) fall-related events should be observed with high interstep variation intervention stairs compared with the high interstep variation control stairs. Finally, the relative difference in fall-related events between high and low interstep variation stair flights in the control condition should be greater than on the intervention flights.

Methods

Participants

This cross-sectional study took place on 2 public stairways on the Utah State University campus. Video capture occurred on public stairways, and most stair users appeared to be young adults.

As previously discussed, 11,137 individual stair user observations were coded and balanced across the stairway conditions (control and intervention) and stairways (East and West) [16]. There were 7458 (66.97%) feminine observations and 3679 (33.03%) masculine observations, where most observations (n=10,970, 98.5%) were in the age group of 18-40 years. Additional participant details were described previously [6]. Given the observational nature of this study in a public space, no screening was performed in advance. Eligibility criteria were as follows: (1) inclusion—visually appearing 18 years of age and older, captured within local time (eg, 7 AM-5 PM) and (2) exclusion—use of assistive walking devices (eg, crutches and walking boots), individuals that did not transverse the stairs, or involved unusual stairway behavior, as described by Harper et al [6] were documented and removed during the data cleaning phase.

Protocol

High-resolution security cameras (8 megapixels, 4K Ultra HD, 3840×2160 resolution at 7 frames per second, Lorex cameras [Lorex Technology Inc]) were placed in the stairways to record stair users' behavior.

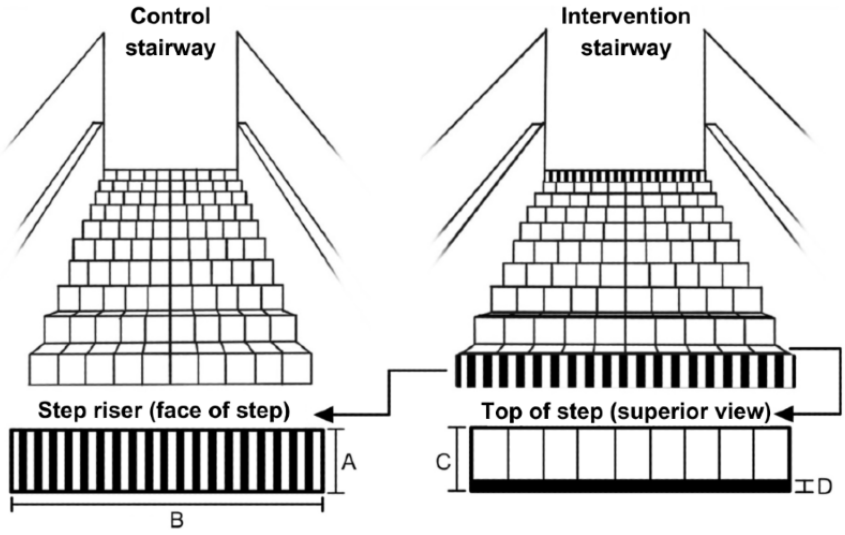
Intervention

High-contrast black vinyl film (Gerber High-Performance Series 220 vinyl film [Gerber Technology]) stripes (5.5 cm wide, 0.063-0.09 mm thick) were applied flush to the top front edge of each stair [4,9,12]. A total of 19 black-and-white vertical vinyl stripes (12 cycles/1 meter) were placed on the very bottom and top steps' faces [4,9,12].

Figure 1 [6] depicts the combined striping intervention. Stairway interstep riser height and depth variations were measured across every step, from the middle part of the step (Figure 2) [6].

XSL•FO
RenderX

Figure 1. Control and interventional stairway conditions. Intervention conditions are further illustrated to show step riser (face of step) and top of step (superior view) vinyl stripes. Step riser height=step height. Stairway width=step tread depth. Vinyl striping depth. Adapted from Harper et al [6], which is published under Creative Commons Attribution 4.0 International License [17].



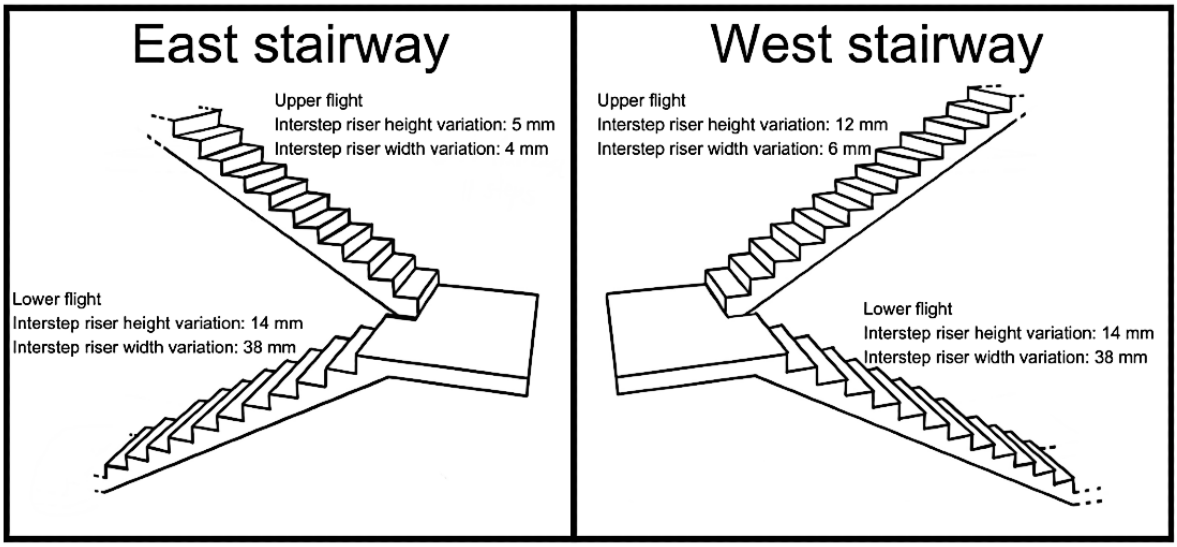


Figure 2. Real-world stairway design. East upper and lower stairway flights interstep riser height variation ranged between 5 mm and 14 mm, and interstep depth between 4 mm and 38 mm, respectively [6]. West upper and lower stairway flights' interstep riser height variation ranged between 12 mm and 14 mm, as well as interstep tread depth variation of 6 mm and 38 mm respectively, are shown [6]. Adapted from Harper et al [6], which is published under Creative Commons Attribution 4.0 International License [17].

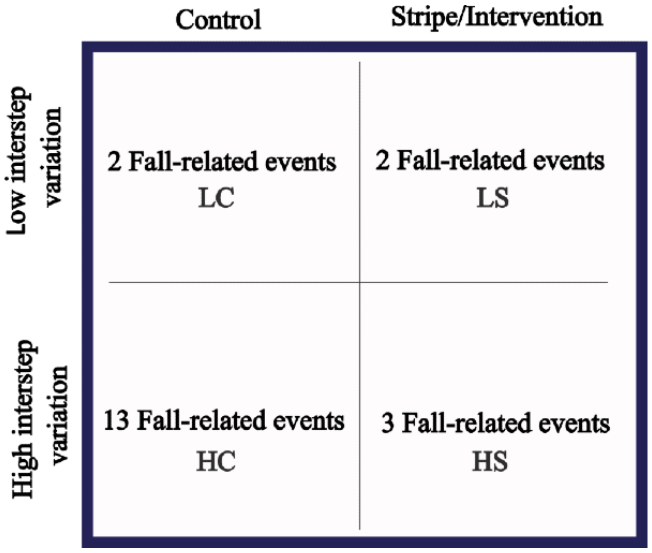
In total, 48 steps were observed across 4 flights of stairs. The control stairway was unaltered and used to compare with the intervention stairway. Halfway through data collection, the intervention (striped) and control stairways were counterbalanced.



Measures

Each outcome variable was assessed by stairway location (East and West) and condition (intervention and control), as well as by stairway flight (lower and upper; Figure 3).

In total, 4 assumptions were used to code our hypotheses based on our a priori knowledge of the total number of fall-related events recorded (n=20): (1) the number of fall-related events high interstep variations, control condition>low interstep variations, control condition; (2) the difference between low interstep variations, stripe intervention and low interstep variations, control condition ≤2 fall-related events; (3) the number of falls in high interstep variations, control condition will be ≥2 times of high interstep variations stripe intervention; and (4) the difference between low interstep variations, control condition and high interstep variations, control condition > the difference between low interstep variations, stripe intervention and high interstep variations stripe intervention. The probability of a distribution meeting these assumptions occurring by chance is approximately 0.04 with a sample size of 20.

XSL•FO
RenderX

Figure 3. The probability of observing a range of distributions of fall-related events. The following assumptions evaluated the observed fall-related event distribution. HC: high interstep variations, control condition; HS: high interstep variations stripe intervention; LC: low interstep variations, control condition; LS: low interstep variations, stripe intervention.

Data Sources

We coded stair users' navigation direction (ascent and descent) and the presence of a fall-related event. As described previously, a fall-related event was coded if an observed stair user experienced a relatively subtle trip or slip, with minimal recovery action, through a complete loss in balance, resulting in a fall [6]. If a fall-related event occurred, the stairway and step number (starting from the bottom to the top) were recorded. To assess research bias or intercoder reliability, each week, one of the researchers would randomly select and evaluate 10% of the data collected for that week. If an error was present, a second coder reviewed all data recorded by the first coder for the week in question, and the second coder made a determination on the final coding record [6]. Data were encoded using Microsoft Excel.

Statistical Analysis

Data are presented as mean (SD) as well as count (percentage) of observed results. The distribution of fall-related events was assessed across stairway flights (interstep variations) and conditions (control and intervention) using a 0.5-inch threshold (approximately 13 mm), given that 75% (80/101) of stair accidents occurred in stairways with interstep riser height variations of ≥0.5 inch [18]. A Monte Carlo simulation in Julia [19] was used to estimate the probability of observing the distribution of fall-related events defined by our hypotheses by chance. Specifically, 10,000 samples (observations) of 20 fall-related events (refer to the Results section) were drawn with 0.25 probability from each condition to determine the probability of observing a distribution with the constraints outlined by the hypotheses through a computerized Monte Carlo simulation [20,21].

Ethical Considerations

Ethical approval was obtained from the institutional review board of Utah State University (10773). As an observational study, participants did not give written consent. Given the observational nature, participants were not compensated to participate. The video recordings were taken in a public setting, and only the approved research team had access to the identifiable data. Therefore, our video data are not available as supplementary material.

Results

Individuals who had any visible health-related conditions (eg, crutches and walking boots) were documented and removed before analysis. In addition, those who visually appeared under the age of 18 years were documented and removed before analysis. All steps were measured at the center of the steps. The average of the East and West stairways combined was 168 (SD 4) mm, with the average riser height of the West stairway steps being 171 (SD 3) mm, and the East stairway being 166 (SD 3) mm, independently. The average step tread depth for the East and West stairways was 328 (SD 8) mm, the average depth of the West stairway steps was 327 (SD 8) mm and the Easy stairway was 329 (SD 8) mm.

Of 20 observed fall-related events, 80% (n=16) of events were observed on the flights where interstep variations were the greatest (riser height ranged 14 mm and tread depth ranged 38 mm). In comparison, 4 of 20 fall-related events were observed on flights with lower interstep variation. Between East and West stairways, 7 of 20 (35%) fall-related events occurred on steps that had step riser heights greater than 1 SD from their mean including 2 fall-related events that occurred on the first step while ascending (step riser height=170 mm; flight mean 166, SD 3 mm), 3 events on the last step while descending the East, lower stairway (height=155 mm; mean 166, SD 3 mm), 1 event on the last step while ascending the East, upper stairway (height=170 mm; mean 166, SD 3 mm), and 1 event on the second-to-last step while ascending the West, lower stairway (height=173 mm; mean 171, SD 4 mm).

A total of 20 fall-related events were recorded. On flights where interstep riser height variation ranged 14 mm and step depth variation ranged 38 mm, 13 of 16 (81%) fall-related events occurred on the control stairway condition (no striping),

compared with 3 of 16 (19%) on the striped intervention stairway. Finally, 2 fall-related events were observed for low interstep variation with no striping, and 2 fall-related events were observed during low interstep variation with striping.

The estimated probability of observing data that fit the range of distributions constrained by our hypotheses and using a sample size of 20 fall-related events, was approximately 0.04 (Figure 3). This result suggests that (1) interstep variations may be contributing to falls and (2) adding a striping intervention to the stairs may reduce the impact of interstep variations on fall-related events.

Discussion

Principal Results

We sought to assess the impact of interstep riser height and tread depth variations on fall-related events (eg, slips, trips, or falls) occurring on stairways to determine if fall risk increases with greater interstep variations but is reduced by adding high-contrast striping. The lower flights of stairs, which had interstep riser height variations that ranged 14 mm and interstep depth variations that ranged 38 mm, accounted for 80% (16/20) of the observed fall-related events, supporting the notion that stairways with greater interstep variations may be associated with a greater risk of fall-related events. Furthermore, 35% (7/20) of fall-related events were observed on steps where interstep riser height variation was greater than 1 SD from the flight mean. Together, these results suggest that flights of stairs with greater interstep riser height variation exhibit more fall-related events than flights with lower interstep variation. When high-contrast striping was added to flights of stairs with high interstep variation, there were fewer fall-related events observed over a similar time period (3/20 fall-related events in the intervention vs 13/20 fall-related events in the control condition). This result suggests the addition of high-contrast striping to stair flights with high interstep variation may reduce the number of fall-related events resulting from interstep variation.

Comparison With Previous Work

Interstep Variations Increase Fall Risk

Interstep variations on stairways can have a profound negative impact on fall risk. Even minor interstep variations, such as a 6 mm variance in riser height [3], can disrupt step cadence and increase the likelihood of a fall, as can interstep variation in tread depth. Furthermore, a review of 80 stairway falls from 1992 to 2007 found that 60% (48/80) of riser height and 34% (27/80) of interstep depth variation were greater than 3/8 inch in a study by Cohen et al [7], and greater (3/8 inch compared with 0.5 inch) interstep variation that can disrupt cadence [3]. Francksen et al [22] found that adults could adjust their stepping behavior for increases in depth, but they could not adjust for interstep riser height variation over 10 mm. Stair-related fall injuries are also more commonly associated with interstep riser height variation than interstep tread depth variation [7]. Alternatively, the greater association of falls with interstep riser height variation could be due to the increased frequency of observing interstep riser heights compared with tread depth variations (eg, > 3/8 inch is observed more often in riser heights [48/80, 60%] than tread depths [27/80, 34%]) [7]. Nevertheless, additional research is needed to explore the extent and impact of interstep variation on stair-related falls. In this study, we observed that 80% (16/20) of fall-related events on stairs occurred when the interstep riser height variation was 14 mm and depth was 38 mm. Since interstep riser height and depth variations were both present in our observational design, we are unable to distinguish which of these factors may have had a greater role.

The Intervention Was Associated With Reduced Fall-Related Events With Interstep Variation

Broadly, our findings indicate that greater interstep variations are associated with an increased frequency of fall-related events. Importantly, the frequency of these fall-related events decreased when the intervention was present. Our data suggest that adding high-contrast stripes may reduce fall-related events on stairs when large interstep variations are present. Of the 20 fall-related events observed, 16 were on the flights of stairs with larger interstep variation, but only 19% (3/16) occurred when the intervention was present, whereas 81% (13/16) occurred when the intervention was absent.

Mechanisms Contributing to the Reduction in Fall-Related Events

The intervention may induce a horizontal-vertical illusion by the intervention. This occurs when horizontal and vertical lines of similar length are presented together (like the letter “T”), which results in an illusory sense that the vertical line is longer than the horizontal one. The intervention used in this study included black vinyl stripes applied to each step’s top front edge and black-and-white vertical stripes on the face of the first and last steps. Together, the abutting edges of the combined striping that formed “T”-like configurations could have contributed to an increased perceived step riser height [14], resulting in greater step heights. Indeed, previous research suggests that under similar experimental conditions, perceived step height is increased and is associated with an increase in the height of the step taken [12,13,15]. In further support for this mechanism, the horizontal-vertical illusion effect is reduced when only edge highlighters are present [13], suggesting that the vertical lines contribute to the increased step height and, perhaps, that the horizontal-vertical illusion is a primary mechanism contributing to the reduction in fall-related events we observed with the intervention. It is also possible that other intervention formats, such as those that could induce the Müller-Lyer illusion [23], could reduce fall-related events. The Müller-Lyer illusion occurs when the perceived length of a line is influenced by the orientation of arrow-like segments attached to its ends. Lines of the same length appear shorter or longer depending on whether the arrowheads at the ends point inward or outward. By manipulating the direction of the fins at the end of the lines, perhaps step height could be increased or decreased depending on the particular interstep variation. Recent outdoor observational research suggests that greater vertical foot clearance occurs when a “fins out” configuration is applied to a 2-step stairway [24], which is the illusion’s expected effect.

XSL•FO
RenderX

Future research could examine whether a "fins in" configuration reduces step height.

By accentuating the steps' edges, the intervention may draw attention to them, thereby enhancing the accuracy with which stair users can estimate the dimensions of each step and then compensate for irregularities. Future research could investigate whether the presence of striping increases awareness of interstep variation, thereby evaluating this potential mechanism. In addition, the novelty of the intervention itself may have drawn attention to the stairs. Schomaker and Meeter [25] suggest that novel visual stimuli, such as a change in contrast, may increase attention to the stairs [26]. It is worth noting that the striping intervention was installed several days before data collection began. It is likely that some stair users had exposure to the striping before the start of video recording and this early exposure could have reduced the novelty of the striping effect before data collection, thus reducing the drawing effect. We also expect that this effect would have worn off over time as many of the observed stair users traverse the stairs frequently due to regular classes in the building.

What Should Be Done About Excessive Interstep Variations

Maybe the most important challenge associated with observing increased fall-related events with greater interstep variations is what to do about it. Is the risk of falls sufficient to warrant widespread evaluation and enforcement of building codes? Although we do not provide recommendations here, conducting assessments, enforcing regulations during construction, and evaluating older stairways (likely to exhibit the greatest interstep variation) may reduce fall-related events, especially when considering cost-effectiveness. For older stairways, as used in this study (built in 1971, and at the time of construction, the 1967 Uniform Building Code [Sec 3305 (d)] that was in place in the United States required the maximum interstep variation in riser height and tread depth to be no more than 3/16 inch), adding an intervention like painting stripes might be the most cost-effective way (an estimated US $288 for the high-contrast striping used here) to reduce the impact of interstep variations (assuming the application or materials used to apply the striping do not themselves increase fall risk through reduced or increased friction, or materials peeling). While increased interstep variation is associated with a greater risk of fall-related events, there are cost-effective interventions that can help reduce this risk. By enforcing building codes and evaluating stairways for interstep variation, we can work toward creating safer environments for everyone.

Limitations

While these results are promising, we acknowledge several limitations of this study. Even with over 10,000 observations, we only observed 20 fall-related events. A larger sample of falls would provide a more precise estimate of the differences between flights of stairs and strengthen the inferences that could be drawn from these data. Since most of the observations in this study were younger adults, future work should consider targeting older or clinical populations (eg, those with visual impairment and mobility-related limitations) to determine if such an intervention could reduce fall-related events. However, future designs will need to consider comparing historical fall frequency records to future intervention fall frequencies rather than using a control condition if it could pose a fall risk to these populations. Furthermore, we did not include Cohen κ, as a measure of interrater reliability. In addition, the lack of a validated questionnaire, such as Yang et al [27], are methodical limitations and should be included in future studies. In addition, given the emphasis on younger adults in this study, it is unknown whether the striping intervention's impact is greater in younger versus older adults. Finally, since the steps used here had interstep variations in both riser heights and tread depths, future observational designs could assess these 2 factors independently to determine the impact of each on fall risk.

Future Directions

Given the considerable negative impact of falls on public health, continued research is necessary to improve safety on stairways. In addition, programs, such as educational campaigns, could be used to raise awareness of factors that contribute to falls [28] and perhaps to help motivate small actions, such as painting stripes on problematic stairways that could have a big impact on public health and provides support for scaling up effective public health interventions for long-term population health benefits.

Conclusions

This study highlights the importance of addressing interstep variations in stairways to reduce the risk of fall-related events. By understanding the factors that contribute to fall risk and implementing cost-effective interventions, we can work toward creating safer environments for everyone. The findings of this study suggest that contrast enhancement (ie, striping) may be a simple and effective way to reduce the risk of falls associated with interstep variations, highlighting the potential for this approach to make a significant impact on fall prevention efforts.

Acknowledgments

We would like to thank Christopher Long, Samantha Corbridge, Alex Braeger, Brevin J. Zollinger, Kenneth Harrison, Travis Boman, Amy Hale, Emmalee Rolfe, McKay Wilding, Erika Larson for their assistance in data coding.

Abstract

Background: Loneliness is a global public health issue contributing to a variety of mental and physical health issues. It increases the risk of life-threatening conditions and contributes to the burden on the economy in terms of the number of productive days lost. Loneliness is a highly varied concept, which is associated with multiple factors.

Objective: This study aimed to understand loneliness through a comparative analysis of loneliness data on Twitter and Reddit, which are popular social media platforms. These platforms differ in terms of their use, as Twitter allows only short posts, while Reddit allows long posts in a forum setting.

Methods: We collected global data on loneliness in October 2022. Twitter posts containing the words “lonely,” “loneliness,” “alone,” “solitude,” and “isolation” were collected. Reddit posts were extracted in March 2023. Using natural language processing techniques (valence aware dictionary for sentiment reasoning [VADER] tool from the natural language toolkit [NLTK]), the study identified and extracted relevant keywords and phrases related to loneliness from user-generated content on both platforms. The study used both sentiment analysis and the number of occurrences of a topic. Quantitative analysis was performed to determine the number of occurrences of a topic in tweets and posts, and overall meaningful topics were reported under a category.

Results: The extracted data were subjected to comparative analysis to identify common themes and trends related to loneliness across Twitter and Reddit. A total of 100,000 collected tweets and 10,000 unique Reddit posts, including comments, were analyzed. The results of the study revealed the relationships of various social, political, and personal-emotional themes with the expression of loneliness on social media. Both platforms showed similar patterns in terms of themes and categories of discussion in conjunction with loneliness-related content. Both Reddit and Twitter addressed loneliness, but they differed in terms of focus. Reddit discussions were predominantly centered on personal-emotional themes, with a higher occurrence of these topics. Twitter, while still emphasizing personal-emotional themes, included a broader range of categories. Both platforms aligned with psychological linguistic features related to the self-expression of mental health issues. The key difference was in the range of topics, with Twitter having a wider variety of topics and Reddit having more focus on personal-emotional aspects.

Conclusions: Reddit posts provide detailed insights into data about the expression of loneliness, although at the cost of the diversity of themes and categories, which can be inferred from the data. These insights can guide future research using social media data to understand loneliness. The findings provide the basis for further comparative investigation of the expression of loneliness on different social media platforms and online platforms.

Introduction

Loneliness not only affects quality of life but also leads to other mental health issues, thus burdening the public health service system. The monetary loss as a result of loneliness is estimated to be between US $8074.80 and US $12,077.70 per person per year in the United Kingdom [1]. The monetary cost of lost days and loss in productivity is estimated to be US $3.14 billion per year for employees in the United Kingdom. Loneliness is shown to be associated with a high risk for multiple health conditions such as physical and mental health issues, dementia, and early mortality [2].

Loneliness is formally defined as, "the unpleasant experience that occurs when a person's network of social relationships is deficient in some important way, quantitatively or qualitatively" [3]. Loneliness, thus, is the perceived and subjective dissonance between one's desired and actual social contacts and relationships. It is difficult to know whether a person is lonely when there is no direct reporting by the person, as loneliness is a very subjective phenomenon. As opposed to social isolation, which is objective and points to a lack of any social connection, loneliness is hard to identify. Loneliness also follows a U-shaped curve demographically, that is, young and old people are the loneliest [4]. Because social media and technology are more frequently used by the younger generation, they are helpful for analyzing loneliness. A previous report provided a theoretical explication of loneliness, loneliness informatics, and the gaps in research on the topic of loneliness informatics, that is, the application of informatics tools to study loneliness [5].

The causes of mental health issues can vary from genetic factors to social and economic factors, and might involve immediate family or finding meaning in life. The result can be withdrawal from human bonds and touch. Loneliness can be addressed through different interventions. However, there is a need to understand the prevalence of loneliness to devise technology-based and community-oriented strategies. Technology may have resulted in fragmented and individualized existence, but it can also be a great healer. The rise of social media has transformed the way we interact with others, offering new opportunities for social connection and communication. Loneliness is a common experience that can have negative effects on mental and physical health, and social media use has been implicated as a potential contributor to loneliness.

To better understand loneliness, this study performed a comparative analysis of Twitter and Reddit data. The aim of this study was to analyze data from these 2 different social media platforms to identify the topics and themes highly associated with the mention of loneliness. We aimed to identify the associations of socioeconomic, political, and personal-psychological factors with the feeling and expression of loneliness. We were not interested in finding out how many people are lonely. We wanted to assess what kind of expression is associated with loneliness. Both platforms are popular social media sites that allow users to post and interact with others, but they differ in terms of their user base and content focus. Twitter is a micro-blogging site with a broad user base that covers a wide range of topics, while Reddit is a forum-based site with niche communities focused on specific topics.

Loneliness is a subjective experience. Social media has become one of the best sources to study loneliness because loneliness must be studied by self-reporting of this subjective feeling. Understanding the nature of social media platforms viz-a-viz the kind of expression about loneliness is important. This study is a step toward understanding the difference in how loneliness is expressed via different social media platforms. The aim is not to conceptualize loneliness per se as this is beyond the scope of this study, but our analysis will provide insights into what terms, topics, and categories occur more frequently in the mention of loneliness.

The aim of the study is not to discuss the qualitative difference between Reddit and Twitter. The difference between both platforms will stand for all topics of analysis. We do not claim to present the differences between the 2 platforms, which is beyond the scope of this paper. Moreover, discussing the differences between different social media platforms may not be of research interest. The research interest is to assess whether the expression of loneliness varies on different social media platforms. We found that there was some variance. The actual reasons may not be known as we are not aware of any research that mentions why people prefer one social media platform over another. Using natural language processing techniques, we analyzed user-generated content on both platforms to identify and extract keywords and phrases related to loneliness. We then compared the prevalence and nature of loneliness-related content on Twitter and Reddit to identify common themes and trends related to loneliness across the 2 platforms. We wanted to understand the topics mostly associated with loneliness and their frequency of occurrence with the mention of loneliness. Before carrying out this analysis, sentiment analysis of tweets was performed through the valence aware dictionary for sentiment reasoning (VADER) tool from the natural language toolkit (NLTK) [6]. The research questions were as follows:

1. What topics and themes can be identified from the data collected on the expression of loneliness from social media? It is important to understand what the data covers and then to carry out an objective comparison.
2. Are there differences in the expression of loneliness on different social media platforms?
3. How the topics and themes associated with loneliness across social media platforms can be divided into various categories?

Social media data with public access are available for Twitter and Reddit. Facebook, a popular social media platform, does not provide access to information based on key terms. As of October 2023, Facebook provides access to an Ad Targeting dataset. Quora, which is a blog-based social media platform, does not have any public application programming interface (API) to provide access to its information. Reddit and Twitter were selected as their data were publicly available when we started collecting data.

Reddit and Twitter as well as other social media platforms can have their own audience, and it cannot be said with any certainty why people use or prefer one platform over the other. This paper

XSL•FO
RenderX

does not provide an answer to this question. The characteristics of each social media platform are broadly true for any kind of data extracted from them. In this study, we wanted to investigate whether the expression of loneliness varies on different social media platforms. The objective reasons or causal reasons for the differences are beyond the scope of this study.

Several systematic and scoping reviews have been performed to better understand loneliness. Understanding loneliness theoretically and evaluating its relation to mental health have been the topics of several studies [7]. Theoretical studies on loneliness have established the negative effects of loneliness. Similarly, from the health informatics perspective, there have been multiple systematic reviews of the connection between loneliness and mental health [8]. Moreover, there have been studies dealing with the application of technology-based interventions to cope with loneliness [5].

A comparative methodology has been used to compare countries in terms of the parameters of public health [9,10]. Although this study does not involve a country-wise comparative analysis, it is pertinent to note that a comparative analysis of different topics is an established practice. Foufi et al [11] used Reddit as a source to mine textual information about chronic diseases, the entities for the expression of diseases and conditions, and their relations. Similarly, Reddit was used by Schrading et al [12] for an analysis of domestic abuse. They developed a classifier based on the data available on Reddit to classify whether a post is about domestic abuse. Twitter data were analyzed by Tsai and Wang [13] to evaluate people's attitudes toward public health policies. The use of Twitter to analyze mental health or other public health conditions during COVID-19 is a prevalent approach, with studies focusing on a range of issues from insights into the pandemic [14] to analyzing social network data [15] and discerning emotions about COVID-19 [16].

Comparison of social media data for different purposes has been carried out in the literature because each social media platform is associated with a particular kind of user and a particular mode of expression. Cinelli et al [17] used Gab, Facebook, Reddit, and Twitter to assess the difference of opinion across different platforms. Curiskis et al [18] focused specifically on Twitter and Reddit for document clustering and topic modeling, while Gozzi et al [19] performed a comparative analysis of media coverage on Reddit and Wikipedia. Similarly, both Twitter and Reddit were used to monitor the spread of hateful content in the wake of COVID-19 [20].

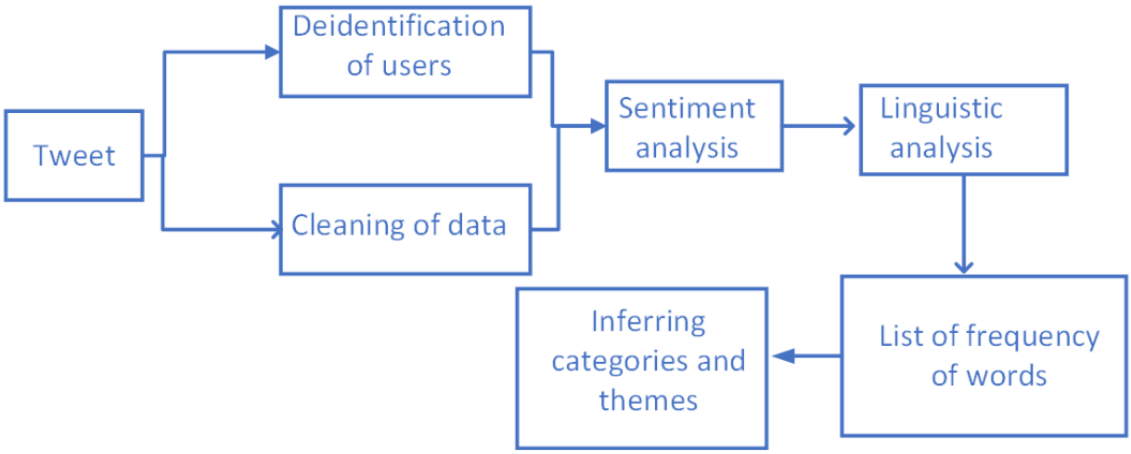
This study builds on literature reviews involving a comparative analysis of social media and other such comparative techniques to better understand loneliness. This study attempts to assess how loneliness is expressed on Reddit and Twitter. The reason for this analysis is to clarify the roles of these platforms in research on loneliness. As social media can provide an intimate perspective on the experience and expression of the feeling of loneliness, understanding how different social media can contribute to research on loneliness is important. Loneliness is a subjective experience, and analysis of social media data can play a fundamental role in informing strategies to counter loneliness and understand its dynamics. This study attempts to clarify how different social media platforms can be used to understand loneliness. The findings of this study will be helpful in devising a large framework using social media for understanding loneliness.

Methods

Ethical Considerations

This study was exempt from seeking ethical approval as it analyzed publicly available online content. The study did not use the identity of the people from the data but provided an overall picture based on opinions expressed publicly. Data were collected from the public domain, and the data analysis involved aggregate terms, which were not concerned with individual statements. There were no relevant guidelines from the institutional review boards of the authors' institutions regarding the use of publicly available social media data. In the literature, no ethical approval has been taken for using social media data to perform different assessments.

Methodology



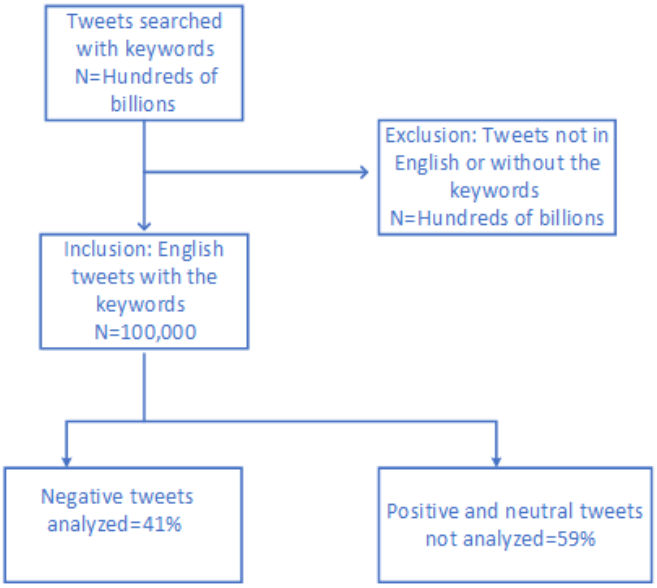
We used social intelligence analysis (SIA) to identify the themes associated with the expression of loneliness. SIA is a broad theme that incorporates multiple social media sources such as Facebook, Reddit, and Quora. SIA is important to gain insights into users' data and, in our case, understand the dynamics of loneliness. While SIA can be used for a variety of purposes, such as mining content to create stories and finding trends, we used SIA for sentiment analysis of collected data on loneliness. This is a comparative study to assess the themes associated with loneliness across different social media platforms. Therefore, we used Twitter and Reddit to collect data. The following subsections describe in detail the processes of data collection and analysis for Twitter and Reddit data.

Twitter

We performed an analysis of publicly available data of users posting about loneliness. Figure 1 presents our pipeline of the analysis of data collected from Twitter. Twitter is a social media platform that is used for connectivity and opinion sharing, and allows users to post via short messages consisting of 280 characters. Twitter provides access to user data through its publicly available Twitter API for developers. Relevant tweets about loneliness were gathered and stored in a database. Twitter data analysis involved the following 3 stages: (1) data collection (tweet collection); (2) division of the collected data into negative and other tweets through preliminary analysis (sentiment analysis of tweets); and (3) further analysis of tweets with negative sentiments through manual coding to find relevant themes and categories (manual coding and analysis of tweets).

XSL•FO
RenderX

Figure 1. Pipeline for processing Twitter data.



Tweet Collection

Tweets containing the keywords "lonely," "loneliness," "alone," "isolated," and "isolation" were collected. In theoretical literature, the words "loneliness" and "lonely" are used to describe the feeling under consideration in this study. The authors of a previous report [21] collected Twitter data based on the keywords "lonely" and "alone." We went further and included the synonyms and related words of loneliness for collecting our Twitter data.

We did not want to exhaustively search for data from a specific country because we wanted the collected data to be a proof of concept. We focused exhaustively on cities or countries and collected more data. The majority of tweets were from the United States (38%) and India (24%). The rest were from various countries across the globe. Tweets were extracted from these 2 countries to make a subdataset. This was meant to reflect the majority composition of the dataset. The subdataset contained 100,000 tweets. The collected data were merged based on location, user ID, and tweet ID to identify tweets belonging to the United States and India. We did not have control over the countries from which the data were collected. However, after data collection, we found that most tweets were from the United States and India. From the data collected, we made another dataset that contained 60% data from the United States and 40% from India. No city-wise allocation of data or analysis was carried out. Figure 2 presents the process of collecting data from Twitter and the process of tweet analysis.

Figure 2. STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) diagram for Twitter data.

Sentiment Analysis of Tweets

The next step was to perform a preliminary analysis of the collected tweets through sentiment analysis. This step is required because loneliness is a negative feeling. To determine how it is expressed in its meaning for mental health analysis, we filtered out tweets where the expression of loneliness was negative. If we decided to report all tweets that contained feelings of loneliness, we would not have required a further step. In our case, the problem becomes determining the association of themes (which may represent loneliness) with the keywords depicting loneliness. For instance, we had to assess the relationship of "hurt," "sick," "tired," "sleep," etc with the expression of loneliness. This task is usually carried out through the association of lexicon categories with tweets including the word "lonely" or "alone." The collected tweets also contained

XSL•FO
RenderX

metaphorical use of lonely or loneliness, which does not pertain to our use of loneliness. Such mentions of loneliness are represented by positive and neutral sentiment tweets. The definition of loneliness in this paper connotates a negative feeling. While loneliness can also be a positive or neutral feeling for some people or some situations, when it comes to its association with mental health issues, the negative consequences of loneliness must be considered.

Therefore, to perform the task of separating tweets with negative connotations for loneliness, we used sentiment analysis. Sentiment analysis was carried out after cleaning the data, such as removing redundant characters, numbers, special characters, user profile IDs, and information like "retweets." For finding tweets with negative sentiment, we used VADER based on Python's NLTK. VADER is suited for microblog content, such as that of Twitter. VADER combines the lexicon, that is, dictionary-based analysis, and rule-based approach to characterize the sentiment. VADER uses gold-standard quality like Linguistic Inquiry and Word Count (LIWC) [22], which has been validated by humans. It distinguishes itself from other efficient tools, such as LIWC, in that it is more sensitive to sentiment expression in social media contexts. VADER also provides valence of the sentiment on a range from 1 to 9. Owing to the sentiment score, we can know through VADER the extent to which the sentiment is negative or positive.

This valence is based on generalizable rules that represent grammatical and syntactical conventions that humans use in contexts meant for emphasizing sentiment intensity. For our purpose, another important feature of VADER is the inclusion of sentiment-bearing lexical nonverbal items, such as emoticons, and verbal items, such as slang, acronyms, and initialisms, which are prevalent in social media contexts. The combination of valence polarity through both the lexicon and rule-based approaches is valuable for fine-grained sentiment analysis. The shortcomings of the lexicon-based approach include coverage, general sentiment intensity, and acquiring a new set of human lexical features.

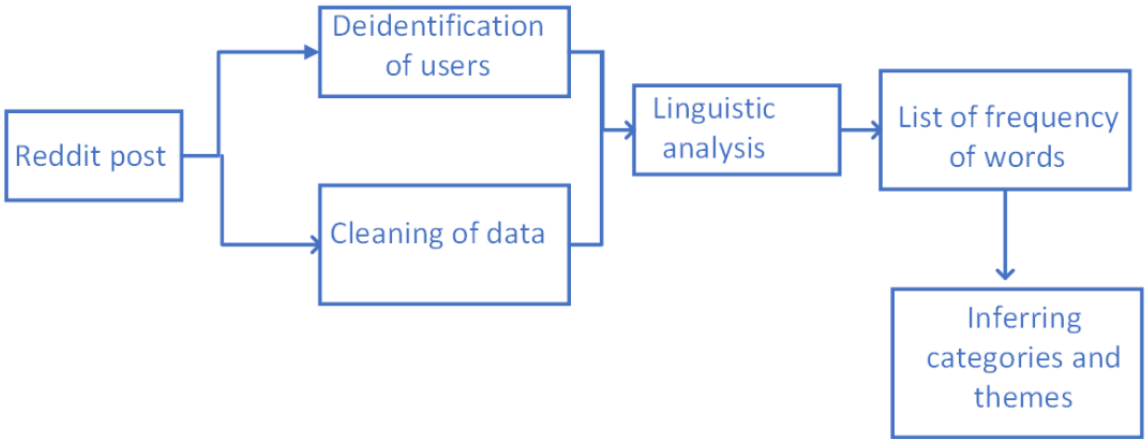
Manual Coding and Analysis of Tweets

We stored tweets with negative sentiments separately to carry out further analysis. We assessed the themes and categories that most prominently featured in the tweets with negative sentiment. This we performed through manual coding and analysis. We composed a list where the number of occurrences of each word was presented. Before creating the list, we removed stop words and carried out lemmatization to find out the root words. Lemmatization reduces the number of words, and hence, the list was compact.

Manual analysis of the list of occurrences helped in devising larger socioeconomic or emotional-personal categories. The lists were thoroughly searched to identify meaningful words. There were words used for grammatical construction and others not mentioned significantly. This step was subjective and depended on the number of occurrences in the list. The words to include as topics under different categories were guided by the literature [21,23]. The creation of categories and the assignment of topics were subjective. This part of the classification can be considered qualitative as it was guided by the authors' judgments and opinions based on the literature.

Reddit

The Reddit assessment involved only 2 steps: data collection and manual coding. The intermediary step was not required because the Reddit data were forum-based, with a focus on coping with the negative effects of loneliness.



Reddit Data Collection

The Reddit data collection methodology was relatively straightforward. Reddit is a forum-based social media platform where people post about a topic on a subforum dedicated to the topic. These subforums are called subreddits. The Reddit API provides access to individual subreddits to download posts along with comments. The API provides access to download the top posts on a topic determined by the number of up-votes and other parameters of engagement. Figure 3 presents our pipeline for processing posts from Reddit. The difference between Figure 1 and Figure 3 is that there is no additional step of sentiment analysis for Reddit posts. After glossing over the subreddit "loneliness," we found that the posts were about the emotional expression of loneliness and did not involve metaphorical or off-topic use of loneliness. The nature of Reddit and subreddits designed for each topic encourages serious engagement on the topics. Because of this fact, sentiment analysis of Reddit data was not deemed important, and posts were analyzed through the frequency of the occurrence of words to identify the themes and topics most highly associated with loneliness.

Reddit posts from the "loneliness" subreddit were collected through the Reddit API. The "loneliness" subreddit had 13,000 members, and people could post and comment in the subforum. Reddit has its own algorithm for providing a score (ie, higher visibility for posts), which also considers inputs from other users in the form of up-voting. We collected the top 2000 Reddit posts from the "loneliness" subforum with all comments. The comments varied for each post in terms of both number and size. It is worth noting that some of the comments were of the same or even larger size than the original post. Thus, comments can be considered to include data on loneliness. The total number of individual texts analyzed was more than 2000 (posts multiplied by the average number of comments). Some posts did not have any comments, and the maximum number of comments for a post in the data we collected was 55. The average number of comments was 4.51, while the total number of comments was 8570. Combining the comments with the posts provided more than 10,000 unique texts or personal expressions on loneliness from Reddit.

XSL•FO
RenderX

Figure 3. Pipeline for processing Reddit data.

Reddit Data Manual Coding and Analysis

We analyzed both the posts and comments to identify the frequency of the occurrence of words to locate the associations of topics and themes with loneliness. The Reddit posts and comments were analyzed without performing any sentiment analysis.

The Reddit posts and comments were collected in a database, and stop words were removed. We performed lemmatization to find out the root words. Then, a list of occurrences of each word was created and analyzed similarly to the method presented in the subsection Manual Coding and Analysis of Tweets.

Reason for Using Manual Coding and Analysis

As the aim of this study was to identify differences between expressions of loneliness on Twitter and Reddit, assessment of important topics was an objective way to achieve this. A qualitative comparison of different tweets and different Reddit posts could be performed, but this would be biased and limited. When the comparison involves thousands of tweets and Reddit posts, it might not be possible to achieve a meaningful subjective comparison. Breaking down the tweets and Reddit posts into topics and categories allows for objective assessments of similarities and differences.

This method of searching for relevant categories of sociopolitical and personal-emotional content and topics was used because it has more flexibility. Usually, the n-gram method indicates the association of words that co-occur, which cannot be perceived to have happened by chance. However, this method does not indicate the occurrence of individual topics and words, and thus, the impact of a topic will not be known. The use of a keyword-based method (ie, using the collected data for some keywords and then reporting their occurrences) is a deductive approach, and it can help in searching the data for predefined keywords. In this study, we used more of an inductive approach, where we let all the important themes and topics in the data emerge. This allowed us to perform a more thorough analysis of data rather than being limited by keywords to look for in the data. This method to analyze the data is a quantitative approach. We did not qualitatively analyze the tweets and Reddit posts (ie, we did not provide our observations on what is contained in them). We reported the number of occurrences of meaningful words and then divided them into relevant categories. This quantitative stating of sentiment analysis and the words contained in negative sentiment tweets under categories was achieved by reading the literature and following the literature.

Results

Comparison of Reddit and Twitter Data

The number of tweets and Reddit posts for analysis was not determined by a specific rule. In the literature, different numbers of tweets and Reddit posts have been used for analysis. For example, Zubaiga [24] carried out an analysis of collected tweets to show the diversity of subjects and dataset sizes. The size of the datasets ranged from over a hundred thousand to more than 10 million. The aim of the study was to reflect in indicative terms the difference in the use of social media according to the expression of loneliness, and therefore, the numbers identified were considered reasonable.

Tables 1 and 2 provide basic details of Twitter and Reddit data, respectively. As discussed earlier, the dataset for Twitter analysis was obtained by combining tweets from the United States and India. The proportions of tweets with negative sentiment for the dataset of each country and for the combined dataset are presented in Table 1. Tweets with negative sentiment were then further analyzed to identify the frequency of the occurrence of topics. For Reddit data, the breakup of the data into words provided a total of more than 25,000 words. For the sake of the meaningful mention of topics and brevity, we only included topics that were mentioned at least 50 times, resulting in 411 words for analysis. Among these 411 words, there were many words related to language construction, such as propositions, and sentence structure. Words that were meaningful in terms of emotions or other expressive qualities were finally included in the analysis.

Table 3 presents the topics highly associated with negative mentions of loneliness in the Twitter dataset. Tweets with negative sentiment were first tokenized and stemmed to obtain a concise list of words and topics associated with loneliness. The list was then analyzed, and meaningful words representing topics of interest, such as emotional, social, and health identifiers, were found. Words like “oh,” “yeah,” and “ur” were ignored when composing the list. For the overall dataset, intimate relationships and interpersonal relationships showed

XSL•FO
RenderX

the highest associations with loneliness (Table 3). “Death” as a topic representing matters of health occurred the most in mentions related to loneliness, along with mentions related to COVID. In terms of socioeconomic factors and political expressions, a wide range of topics were identified.

Table 4 provides a list of themes mentioned with loneliness in the loneliness subreddit. The numbers given represent the total number of occurrences of the word or topic in the Reddit posts. The focus was mostly on relations and emotional expression. As longer posts are allowed, people have more space to express their feelings and open up. Social media platforms provide spaces to own one’s vulnerabilities without facing the backlash that can come in the form of social ostracization. In Table 4, the topics and their relevant thematic categories provide deeper insights into the personal-emotional associations of loneliness.

Similarities and Differences in Reddit and Twitter Data

There are similarities in the categories and themes that can be found in conjunction with mentions of loneliness, but differences in the use of both social media platforms can be crucial in devising strategies to use social media data to understand loneliness. Reddit data are more focused on themes around personal-emotional categories and have a larger number of occurrences of topics around these categories. For Twitter, a range of categories were identified, and personal-emotional categories were the dominant ones, but other topics also occurred. Moreover, the associations of themes and topics with expressions of loneliness were in line with broader psychological linguistic features focused on the self-expression of mental health issues. The difference again was in the range. Twitter can have a wider range of topics that are associated with expressions of loneliness, while Reddit is more focused on psychological personal-emotional categories. These findings will help in providing a guideline for further research into deploying social media data to understand loneliness.

The differences that can be observed in Tables 3 and 4 involve diversity and extensiveness. In Twitter data, the range or diversity of topics and themes can be seen. Because of the limited-character expression on Twitter, people can express their thoughts or opinions, and from these, we can find the association with loneliness. There can be a range of such themes involving direct mentions of loneliness with mentions of a topic in a negative way. On the other hand, Reddit data indicate the extensiveness or depth of a theme or group of topics associated with loneliness.

Some categories, such as “political” and “insomnia,” are missing from Reddit data. The reason for this might be a conjuncture, as direct evidence for the lack of data on Reddit needs to be obtained after following a proper study protocol. However, it can be assumed that because Reddit is more personal (ie, anonymous with the culture being encouraged to reveal personal problems), the general associations of loneliness, such as political and extensive social themes, are not present. For “insomnia,” the easy nature of Twitter (ie, the requirement of short posts) might be seen as a better alternative to discuss sleep problems later at night. Again, these can be conjectural inferences, but the wider social and cultural context can inform the interpretation of these results.

Another reason for Twitter data containing socioeconomic and political categories, which are lacking in Reddit data, is the geographical composition of the data. However, further investigation is needed to determine the geographical composition of the data. According to these findings, Reddit data could be useful for finding the depth of a theme associated with loneliness (ie, what subthemes or topics under a broader category are related to loneliness). Twitter, on the other hand, showed the range and diversity of themes and categories associated with loneliness. This is important to investigate the possible causes of loneliness. The fact that Twitter provides a range of topics and themes and Reddit shows the depth of a theme can be used in a complimentary way.

Discussion

Principal Findings

The study performed a comparative analysis of 100,000 tweets and around 10,000 Reddit posts to understand the themes associated with the expression of loneliness according to socioeconomic and personal-emotional topics. The number of Reddit posts was kept lower than the number of tweets because Reddit posts are lengthier. These 2 social media platforms are important because of their unique nature. Twitter allows short texts, while Reddit allows a freehand composition of one’s opinion and analysis. Analysis of the tweets and Reddit posts provided attributes to understand the associations of socioeconomic and personal-emotional factors with loneliness. These attributes included emotion, sentiment, emojis, and topics. The analysis demonstrated that such attributes could help gather evidence and analyze interactions on the topic of loneliness and other such related topics. The first attribute was emotion, which can serve as a guide in understanding people’s reactions. The second most common attribute was relationships. Other thematic areas, such as health, work, self-focused topics, and

XSL•FO
RenderX

insomnia-related topics, indicated the intimate nature of loneliness. The major finding of this study was that both social media platforms differed in the range of expressions of themes in association with loneliness.

There were similarities in the themes associated with loneliness on social media, but differences in platform usage are crucial for strategies to understand loneliness. Reddit was heavily focused on personal-emotional themes, with a higher frequency of these topics. Twitter, while also emphasizing personal-emotional themes, included a broader range of categories. The thematic associations with loneliness aligned with broader psychological linguistic features centered on mental health self-expression. The key difference was range. Twitter had a wider variety of associated topics, whereas Reddit concentrated on personal-emotional themes. These findings provide guidelines for future research using social media data to understand loneliness.

The methodology developed in this paper showed the association of loneliness with language, which was associated with mental health issues such as anger and depression. The tweets and Reddit posts analyzed prove that psychosocial linguistic features can be found in the self-expression of loneliness, which can identify the dynamics of loneliness [25,26]. Tweets containing keywords associated with loneliness represent a self-focused discourse, which affirms previous literature on loneliness [27,28].

The topics and categories involve linguistic expressions of underlying mental health and related emotions. The findings of this paper regarding the topics and themes associated with loneliness, including mental health, alcoholism, emotional dysregulation, and sociopolitical circumstances, are backed by the literature. The relationships between mental health issues, such as depression and suicidal ideation, and issues related to neurobiology have been discussed by Lam et al [29]. These include conformity with the literature on the association of loneliness with emotional dysregulation and trouble with relationships [30]. The LIWC was used for different thematic concerns for loneliness by previous authors [23]. The study presented in tabular form the related social and emotional supercategories and relevant subcategories of loneliness. Self-referential pronouns were associated with loneliness according to the study. This study also affirms this finding. Our data present such linguistic categories, which have been proven by previous research to be associated with the linguistic nature of loneliness [31].

Finding themes associated with mental health and other issues in public health, such as loneliness, through social media analysis is interesting because such an analysis can provide insights into the first-hand experiences of people. The primary question in this study was “Is there a significant difference in the use of different platforms when it comes to the expression of loneliness?” The answer to this question is not binary. When it comes to larger patterns of the association of topics with loneliness, both platforms can provide similar patterns. However, the difference lies in the range of topics expressed and the depth of a particular topic. This finding is in line with previous findings. A previous study found that Twitter and Reddit can provide different sentiment expressions after a while for opinions regarding vaccination [32].

Which platform is better to use for the analysis of topics associated with loneliness and other related public health issues? From the data analysis and results, we found that Twitter can provide access to a large number of tweets through its API, but special steps in data cleaning and the combination of different data frames have to be taken in order to carry out a meaningful analysis. Reddit, on the other hand, provides access to lengthier posts where users are free from the constraints of space, and multiple insights into the nature of loneliness can be gained from a single post. Therefore, Twitter provides access to a range of insights, while Reddit provides access to a depth of insights. We also found that Reddit posts, although lesser than tweets, provided a lot more topics, but the topics were constrained by the variety of themes and belonged to similar thematic areas.

This study has provided the following insights into the nature and dynamics of loneliness through the collection of data from different social media platforms (Twitter and Reddit):

1. Despite the limitations of the dataset, the varying nature of loneliness can be observed on both platforms. It gives investigators the opportunity to approach the data on the expression of loneliness on different social media platforms differently.
2. Reddit allows users to share their opinions without limits, and Reddit is built around communities. These communities allow people having similar experiences to share their stories in detail. Therefore, Reddit is more suitable for educational and other messaging services, while Twitter can provide a range of topics, which can further be investigated in depth.
3. The data returned by Twitter can be very large, and to use the data, special data cleaning tools and other steps, such as sentiment analysis, should be used. Reddit data are from communities, and as such, they can be directly analyzed. There can be posts from bots and other such automatic or malicious agents. We did not remove these in this study. These need to be removed before further analysis in future work.

Limitations

This study has a number of limitations. First, the data from Twitter and Reddit are self-reported and may not represent the broader population. Only English posts were analyzed, limiting generalizability. Future research should explore various platforms and languages for a more comprehensive understanding of loneliness. Second, the dataset size of both Twitter data and Reddit data was small. We used a limited dataset to determine whether loneliness has different expressions on these platforms. The point was not to be exhaustive but indicative. This limitation can be addressed in a future study by increasing the dataset size to verify or change the findings of this study. Third, the Reddit data were not geo-tagged, and thus, we were not able to determine the countries of the users. However, there are methods to identify the locations of the users of Reddit posts. In the future, these methods can be used to carry out a comparative analysis with geo-located Twitter data. Fourth, there was no control over the data returned by the

XSL•FO
RenderX

Twitter API regarding specifying a country for data collection. The data returned was not probabilistically sampled, and thus, there may be bias in terms of both content and the country or region from which the data are collected. Fifth, the sentiment analysis of Twitter data may have issues. The automatic classification of tweets into negative and positive through sentiment analysis may not be fully accurate. While this was the basis of the study to carry out automated analysis, the results of this automated sentiment analysis need to be validated by looking at a certain number of tweets that were identified as negative. Current models do not detect some linguistic expressions such as sarcasm and humor. New models can be developed, which can correctly classify the sentiment of tweets that use sarcasm and humor. With this approach, we will be able to know the confidence of the analysis and quantify errors. This is related to the methodology of the study, which did not analyze tweets with negative or neutral sentiments. There is a possibility that even a positive or neutral mention of loneliness is associated negatively with mental health, but for the sake of a coherent analysis of a large number of tweets, this has been removed. Validation of sentiment analysis is needed to determine how many tweets with positive sentiment actually had negative connotations.

Conclusion

This study aimed to compare data on loneliness from Twitter and Reddit to identify topics and themes associated with the expression of loneliness. The findings of this study suggest that Twitter provides a wide and diverse range of data related to loneliness, while Reddit shows the depth or extensiveness of a theme associated with loneliness. By analyzing the language used in tweets and Reddit posts, it was possible to identify common themes associated with loneliness, such as social isolation, mental health, and relationship issues. The results of this study provide valuable insights into the ways in which people express and experience loneliness on social media platforms. The ability to identify these themes and topics associated with loneliness could be useful for health professionals and researchers to understand the complex nature of loneliness and its impact on individuals.

Data Availability

The datasets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Abstract

Background: *Aedes aegypti* is an important vector that transmits dengue, Zika, chikungunya, and yellow fever viruses. Although research on *Aedes aegypti* has been conducted for decades, scientometric studies on *Aedes aegypti* are scarce, are limited to regions, and cover short periods. Thus, there is still a knowledge gap in the current trend, research focuses and directions, leading authors and collaboration, journal and citation impacts, countries, and worldwide collaborations.

Objective: The objectives of the study are to investigate the research trend, focus and directions, citation impact, leading authors and collaboration, journals, and countries of the published works on *Aedes aegypti* to inform the current knowledge gaps and future direction of the control of the vector.

Methods: In this study, we searched the Scopus database for articles on *Aedes aegypti* published from the year 1927 until April 5th, 2024, and included articles, reviews, books, and book chapters that were written in English. A total of 16,247 articles in 160 journals with 481,479 citations were included. Inconsistencies in authors' names were checked and cleaned using OpenRefine. The data were grouped into 4 periods; years 1927-1999, 2000-2009, 2010-2019, and 2020-2023. The relative growth rate and doubling time of publications were calculated. The analysis was conducted using VOSviewer, R bibliometrics, and citeSpace.

Results: The overall RGR was 0.1. Doubling time increased from 9.3 in 1978-1998 to 12.1 in 2000-2009. The main research clusters were "using Wolbachia," "Dengue Zika," "worldwide diversity," "community support," "larvicidal activity," "mosquito genotype-dependent," and "sterile insect technique." *Journal of Medical Entomology* was the leading journal (758/16,247, 4.7%). The most cited articles were authored by Halstead SB and team in *Science* (N=1355) and Kraemer MU and team in *eLife* (N=1324). The United States (5806/23,538, 24.7%) and Brazil (2035/23,538, 8.6%) were the top countries. Gubler DJ was the top co-cited author (n=2892) from 2000 to 2019. The co-cited author cluster patterns informed the significant specialty research on *Aedes aegypti* across time. Authors from various specialized research fields tended to collaborate across countries, especially neighboring countries. Countries with more research funding on the study of *Aedes aegypti* published more papers.

XSL•FO
RenderX

Conclusions: Researchers or entomologists could understand the current knowledge gap on *Aedes aegypti* and plan for future research pathways. This study contributed to the public health stakeholders in improving the vector control interventions and elucidated the extent of research subject areas.

KEYWORDS

relative growth rate; vector control; collaboration index; bibliometric; Aedes aegypti; Scopus; co-occurrence; author; dengue; Zika

Introduction

Aedes aegypti is a vector of several arboviruses, including dengue, Zika, chikungunya, and yellow fever. This species was discovered by Fredrik Hasselqvist in Egypt in 1757 [1]. Initially designated as Culex aegypti, the name was declared invalid by the International Commission on Zoological Nomenclature in 1956 and it was subsequently identified as Stegomyia fasciata followed by *Aedes aegypti* (Linnaeus) or *Aedes* (Stegomyia) *aegypti* (Linnaeus) [1]. Its distinguishing features are the presence of white rings around the leg articulations and abdomen and a white lyre-shaped marking on the dorsal surface of the thorax [2]. Originally native to sub-Saharan Africa, *Aedes aegypti* is now widespread in most tropical and subtropical locations across the world [3]. The most common habitats of the *Aedes aegypti* are artificial and natural containers, including plastic containers, flower pots, vases, tires, tree holes, and bromeliad plants [4,5]. They are common in high-density residential areas [3]. *Aedes aegypti* can potentially survive and establish in 215 of 250 countries and territories (86%) [6].

Scientometrics concerns the analysis of subjects and the development of research literature, the impact and process of scientific knowledge production, as well as the macroenvironment of research [7]. The aim is to discover hidden relationships between any single publication and citations [8]. Studies on animal species using the scientometric method revealed trends in the direction of research on animal species. Santos and Vianna [9], who conducted a scientometric analysis of the literature on 11 Western Atlantic species of Paralichthys in ISI Web of Science and SciELO, discovered the dominant fishery species of *Paralichthys dentatus* (46.1%) in Canada and *Paralichthys lethostigma* (32.1%) in the United States. Araújo [10] discovered the average number of total citations per paper was 16.05 (27.66) in the scientific literature on insect galls and galling species in Brazil from 1988 to 2017. Miguel, Calvão, Vital, and Juen [11], who examined the literature on insects of the order Odonata, found the majority of the study focused primarily on the adult stage and species level, and there were gaps in the biogeography, parasitism, competition within and across species, evolutionary and phylogenetic links, and studies of the larval stages.

To date, there is a lack of scientometric analysis of *Aedes aegypti* at the global level. Vega-Almeida et al [12] conducted a scientometric analysis of 5039 published articles about *Aedes aegypti* from the year 2006 to 2015 (10 years) in Scopus. The findings were distributed across 4 major domains, namely epidemiology, gene expression and biological control, larvicidal and insecticidal effects, and reproduction and insecticide resistance; however, the paper did not analyze the information on authorship, citation rates, journal, organization, and collaborations. Other studies focused solely on the diseases transmitted by *Aedes aegypti* [13], or the effects of climate change on *Aedes aegypti* [14]. Gupta and Tiwari [15] discovered from the 910 articles publications of dengue research in India for the duration of the year 2003 to 2012, with an average annual growth rate of 28.19%. A scientometric analysis of the Zika virus, yielded 567 publications, with the most productive countries being the United States, the United Kingdom, and the Netherlands [16]. Sindhania et al [17] focused on the publication on *Aedes aegypti* and *Aedes albopictus* extracted from the Web of Science, encompassing a collection of 4149 papers for 77 years. Focus on single species was crucial as the targeted vector controls of both species were differed due to the uniqueness of their preferable habitats, morphology, genetic profile, and virus replication characteristics [18,19]. Hence, a scientometric study on *Aedes aegypti* based on Scopus that covers a wider aspect, including author collaborations and cocitations, citation rate and impact, leading journals, and countries would enable researchers and entomologists to map the current knowledge gap on *Aedes aegypti* and to plan future research focus or priorities. The Scopus offers more multidiscipline contents than Web of Science [20]. For public health practitioners, this information would assist in improving vector control interventions and evaluating the extent of past and potential research areas.

This study aims to conduct a scientometric analysis of scientific articles on *Aedes aegypti* published worldwide from 1927 to 2023. The specific objectives are numerous; first, to analyze the general trends and annual growth rate of the articles published on *Aedes aegypti*; second, to identify prolific authors, their collaborative networks, and authorship patterns; third, to determine the co-occurrences, patterns of subject areas, and current research trends; fourth, to study the journals and their citation impact; and finally, to determine the countries of the published papers.

Methods

Data Source and Search Strategy

We conducted our search in the Scopus database for publications from the year 1927 to 2023 using the search term “Aedes aegypti” on April 15, 2024 (Textbox 1). The following search queries were used in the investigation in Scopus in two phases. First, search all the publications up to the year 2023.

Second, search the publications by 4 time periods, that was years 1927-1999, 2000-2009, 2010-2019, and 2020-2023.

XSL•FO
RenderX

Textbox 1.

(TITLE-ABS-KEY("Aedes aegypti") AND PUBYEAR > 1926 AND PUBYEAR < 2024 AND (LIMIT-TO (DOCTYPE,"ar") OR LIMIT-TO (DOCTYPE,"re") OR LIMIT-TO (DOCTYPE,"ch") OR LIMIT-TO (DOCTYPE,"bk")) AND (LIMIT-TO (LANGUAGE,"English"))).

The search was conducted within the title, abstract, and keywords fields and was limited to articles, reviews, books, and book chapters in English. Documents that did not match the inclusion criteria were excluded. The excluded articles included retracted articles, conference papers, letters, notes, editorials, short surveys, erratum, conference reviews, and data reviews. Data extracted from the search results included publication year, title, author, citation, keywords, organization, journal, and country, and were saved in 5 "csv" format files. Inconsistencies in authors' names were checked and cleaned using OpenRefine [21]. For quality control, a random sample of 10% of the extracted data was verified against the original source publication. Data merging, pivoting, and aggregation analysis were conducted with Microsoft Excel.

Data Analysis

Relative Growth Rate and Doubling Time

We calculated the relative growth rate (RGR) and doubling time of publications. RGR, which measures the change in the number of publications per year, was calculated using the following formula:

where, t_1 is the initial time period, t_2 is the final time period, N_1 denotes the number of publications at time t_1, and N_2 denotes the number of publications at time t_2.

Given the RGR, we computed the doubling time. Doubling time is the time it takes for the number of publications to double.

Authorship Analysis

Analysis of authorship and subject area and construction of the respective network graphs were conducted using VOSviewer software developed by Leiden University [22]. The coauthorship analysis was based on the full counting method, that was, each coauthor of a publication is assigned a weight of one; thereby, the total weight of a publication is equal to the number of its authors. Author contribution timelines, 3-field plots, and country collaboration maps were generated using the R bibliometrics package [23].

Impact Factor and Cocitation Analysis

Journal publications' 5-year impact factor was extracted from Web of Science Journal Information. Cocitation analysis tracks pairs of study that are cited together and suggest similarity as both items were cited by the same study, which helps in identifying the inner structure of research disciplines that represent the research focus [24]. The analysis was conducted using the VOSviewer and citeSpace [25]. The author's cocitation analysis was split into 4 time periods: years 1927-1999, 2000-2009, 2010-2019, and 2020-2023. To understand the recent trend of research focus, the citeSpace analysis zoomed in on the year 2021-2023. The higher silhouette score of a cluster means members in the cluster have more in common in terms of tightness and separation [26].

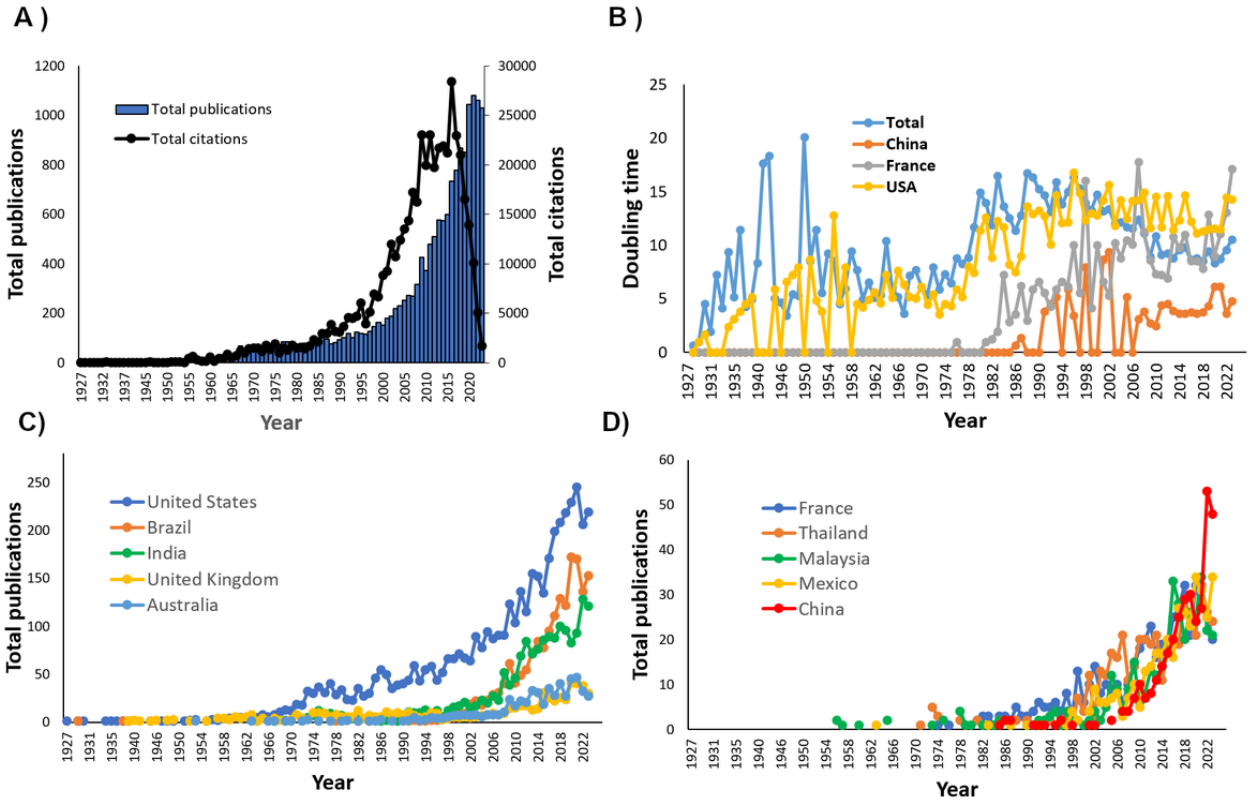
The current study focused solely on *Aedes aegypti*, with *Aedes albopictus* being the next target of investigation. This approach is due to the species-specific nature of biological control and the differing habitats of both species. Conducting a scientometric analysis on a single species, provides a clearer picture, which can later be expanded to compare trends between the 2 species.

Ethical Considerations

Ethical approval protocol from the Medical Research and Ethics Committee, Ministry of Health Malaysia was exempted (reference number KKM/NIH/22-01333-RCQ[1]).

Results

General Trends



The search strategy produced a total of 18,529 results, mainly in English (17,438/18,686, 93.3%), Spanish (506/18,686, 2.7%), Portuguese (278/18,686, 1.5%), French (203/18,686, 1.1%), and the other languages. For the articles in English (n=17,438), the document types were research articles (14,990/17,438, 86.0%), followed by review articles (1063/17,438, 6.1%), conference proceedings (366/17,438, 2.1%), letters (253/17,438, 1.5%), notes (191/17,438, 1.1%), and others. Finally, only research articles, reviews, letters, editorials, books, and book chapters were included (n=16,247). Figure 1A shows that articles were published at a steeply increasing trend with a total number of 14,990 (14,990/16,247, 92.26%). The review articles increased steadily and exhibited a doubling in number after the year 2014, contributing to a total number of 1063 papers (1063/16,247, 6.54%). There were 189 (189/16,247, 1.16%) book chapters and 5 (5/16,247, 0.03%) books on *Aedes aegypti*. The total number of articles in each of the time periods was 3183, 2506, 6345, and 4214, respectively. The number of authors expanded rapidly from 4490, 6459, and 19,495 to 18,064, respectively. The top countries published scientific articles on "Aedes aegypti" were the United States (5806/23,538, 24.7%), followed by Brazil (2035/23,538, 8.6%), India (1839/23,538, 7.8%), United Kingdom (1243/23,538, 5.3%), France (898/23,538, 3.8%), and Australia (779/23,538, 3.3%; Figure 1C). The other countries with a significant number of articles were Thailand (678/23,538, 2.8%), Mexico (548/23,538, 2.3%), China (541/23,538, 2.3%), and Malaysia (455/23,538, 1.9%), respectively (Figure 1D).

The overall RGR was 0.1. Doubling time increased from 9.3 in 1978-1998 to 12.1 in 2000-2009, and reverted back to 9.3 in 2020-2023 (Figure 1B). The RGR and DT varied across countries. Among the top 10 countries in total publications, France exhibited the longest doubling time, while China had the shortest doubling time. The Unites States has published

XSL•FO
RenderX

since 1927 and had a short doubling time initially, but the numbers reduced in recent years (Figure 1B).

Figure 1. Distribution by year of (A) total number of publications and citations on Aedes aegypti globally, (B) total and selected countries' publication doubling time, (C) total number of publications by the top 5 countries, and (D) total number of publications by the 6th-10th ranked countries.

Institutional Contributions

Authors affiliated with the Fundacao Oswaldo Cruz produced 3.4% of the overall *Aedes aegypti* research output, followed by those in the University of Florida (2.3%), CNRS Centre National de la Recherche Scientifique (1.8%), Institut Pasteur, Paris (1.7%), Colorado State University (1.6%), Mahidol University (1.6%), Centers for Disease Control and Prevention (1.5%), University of Notre Dame (1.5%), Universidade de São Paulo (1.5%), and University of California, Davis (1.5%).

Funding Agencies

There were 159 funding agencies for the *Aedes aegypti* research whilst 8914/19,883 (50.2%) articles did not disclose their sources of funding. The National Institute of Allergy and Infectious Diseases, United States (1716/19,883; 9.7%) and National Institutes of Health, United States (1183/19,883; 6.67%) contributed to a quarter of the publications. Four agencies sponsored more than 200 articles each, that was, Conselho Nacional de Desenvolvimento Científico e Tecnológico, Brazil (708/19,883, 4.0%); Coordenação de Aperfeiçoamento de Pessoal de Nível Superior, Brazil (576/19,883, 3.2%); National Science Foundation, United States (255/19,883, 1.4%); and Centers for Disease Control and Prevention, United States (255/19,883, 1.4%). For other regions and countries, the highest funders were National Natural Science Foundation of China (207/19,883, 1.2%); Wellcome Trust (158/19,883, 0.9%); National Health and Medical Research Council, Australia (149/19,883, 0.8%); Horizon 2020 Framework Programme, European Union (144/19,883, 0.8%); Department of Science and Technology, Ministry of Science and Technology, India (108/19,883, 0.6%); Natural Sciences and Engineering Research Council of Canada (78/19,883, 0.4%); Consejo Nacional de Ciencia y Tecnología, Mexico (77/19,883, 0.4%); and Agence Nationale de la Recherche, France (84/19,883, 0.5%).

Authorship Analysis

The top 20 productive authors who published articles related to *Aedes aegypti* originated from mixed countries, mainly the United States, for that were, Scott TW, Raikhel AS, Severson DW, Christensen BM, James AA, Becnel JJ, Tabanca N, Ali A, and Higgs S (Table 1). Three authors from Australia were among the first 10 productive authors, including Ritchie SA (n=126), Hoffmann AA (n=94), and O'Neill SL (n=79). The other authors were from France (Failloux A-B, n=95), Thailand (Chareonviriyaphap T, n=78), Italy (Benelli G, n=74), India (Govindarajan M, n=69), Malaysia (Lee HL, n=64), Mexico (Manrique-Saide P, n=63), Brazil (LourenÇo-de-oliveira R, n=55), and Trinidad and Tobago (Chadee DD, n=55). The author with the highest number of publications did not have the highest citation and H-index. The highest H-index author was Hoffmann AA (H-index=103) and the author with the highest total citation was Scott TW (n=14,100).

XSL•FO
RenderX

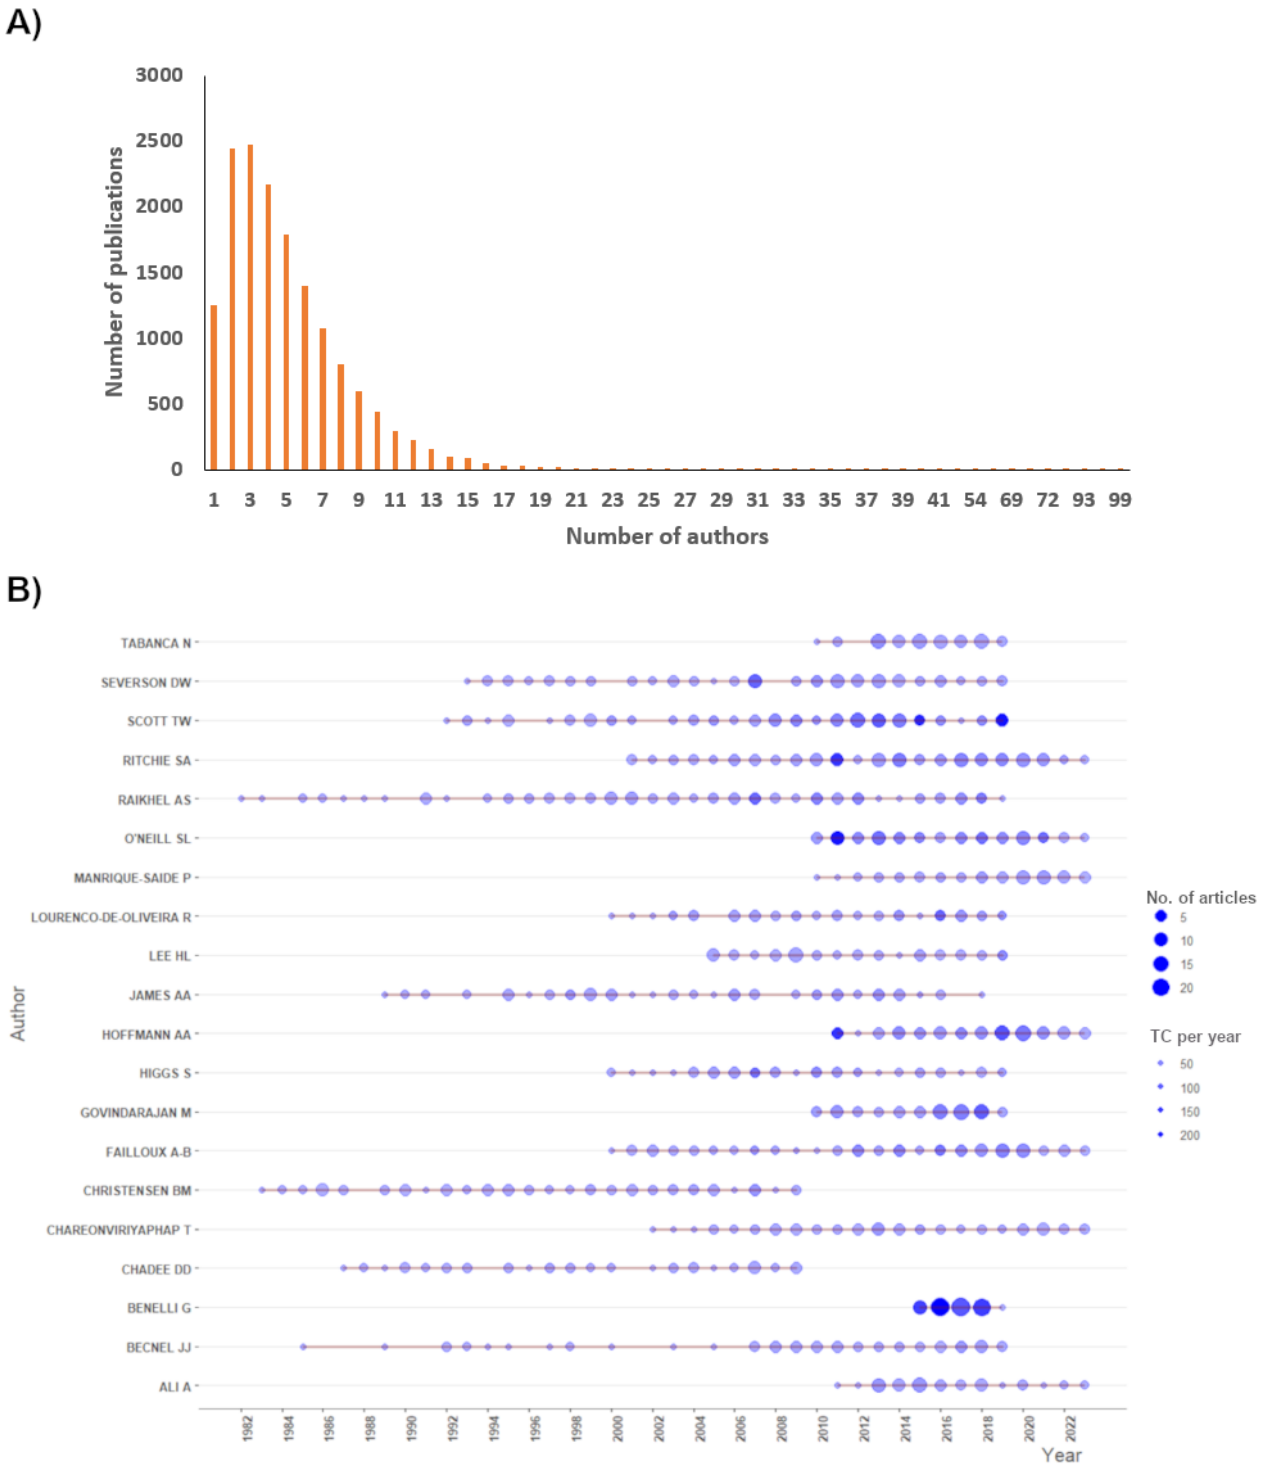


Table 1. Top 20 productive authors, citation, and Scopus H-Index.

Authors	Country	Total publication, n (%)	Total citation, n (%)	Scopus H-index (2024)
Ritchie SA	Australia	126 (0.78)	7522 (1.56)	59
Scott TW	United States	116 (0.71)	14,100 (2.93)	82
Raikhel AS	United States	115 (0.71)	9074 (1.88)	68
Severson DW	United States	108 (0.66)	5756 (1.20)	44

Hoffmann AA	Australia	94 (0.58)	5659 (1.18)	103
Christensen BM	United States	88 (0.54)	3923 (0.81)	49
O'Neill SL	Australia	79 (0.49)	8050 (1.67)	77
Chareonnviriyaphap T	Thailand	78 (0.48)	1807 (0.38)	37
James AA	United States	77 (0.47)	5618 (1.17)	59
Benelli G	Italy	74 (0.46)	5394 (1.12)	84
Becnel JJ	United States	74 (0.46)	2026 (0.42)	43
Govindarajan M	India	69 (0.42)	3440 (0.71)	59
Tabanca N	United States	66 (0.41)	1545 (0.32)	38
Lee HL	Malaysia	64 (0.39)	1618 (0.34)	30
Manrique-Saide P	Mexico	63 (0.39)	1161 (0.24)	24
Ali A	United States	57 (0.35)	1232 (0.26)	22
Lourenço-de-Oliveira R	Brazil	55 (0.34)	4396 (0.91)	49
Chadee DD	Trinidad and Tobago	55 (0.34)	1855 (0.39)	35
Higgs S	United States	54 (0.33)	5149 (1.07)	67

The majority of the publications had between 2 and 5 authors. The number of publications decreased exponentially with increases in number of coauthors. There were more publications by multiple authors than by single authors (Figure 2A). The top-ranked authors were Raikhel AS, Christensen BM, Becnel JJ, and Chadee, each of whom has published articles on *Aedes aegypti* since 1982 (Figure 2B). Benelli G published several articles with high citations in a span of 4 years. Hoffmann AA, Manrique-saide P, Ritchie SA, O'Neill SL, Failloux AB, Chareonviriyaphap T, and Ali A are still actively publishing study on *Aedes aegypti* (up to 2023; Figure 2B).

XSL•FO
RenderX

Figure 2. Author analysis. (A) Number of publications by number of authors, and (b) top 20 authors' production over time and total citations per year.

In the early years, of all the 8975 cited authors, Raikhel AS had the highest number of cocitation links with other authors (n=303), followed by Hagedorn HH (n=248) and James AA (n=204; Figure 3A). From 2000 through 2009, of all the 71,005 cited authors, Gubler DJ was the most cocited author (n=1272), followed by Beaty BJ (n=711) and Raikhel AS (Figure 3B). From 2010-2019, Gubler DJ remained as the top co-cited author (n=2892) among 219,499 cited authors. Scott TW was the second co-cited author (n=2885), while Beneli G was the third (n=1986; Figure 3C). From 2020 to 2023, out of 230,547 cited authors, Scott TW (n=1311) and Hoffmann AA (n=858) stayed the highest in the cocitation list, with Brady OJ (n=1086) came in third (Figure 3D). The varied color depicted authors' linkages with different clusters. Gubler DJ, Brady OJ, and Scott TW were in the same cluster, whereas Hoffmann AA and Ritchie SA were in another cluster.

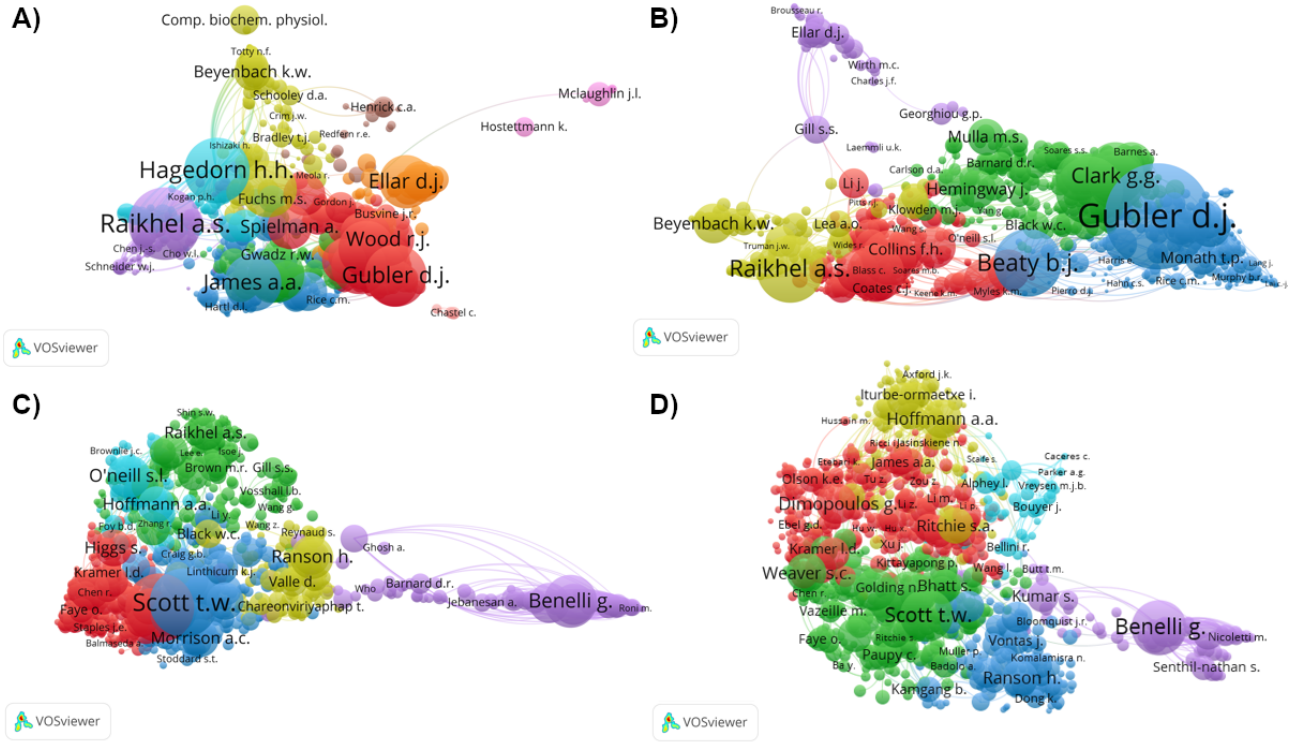
Figure 3. Cocitations network of authorship for the period of (A) 1927-1999, (B) 2000-2009, (C) 2010-2019, and (D) 2020-2023.



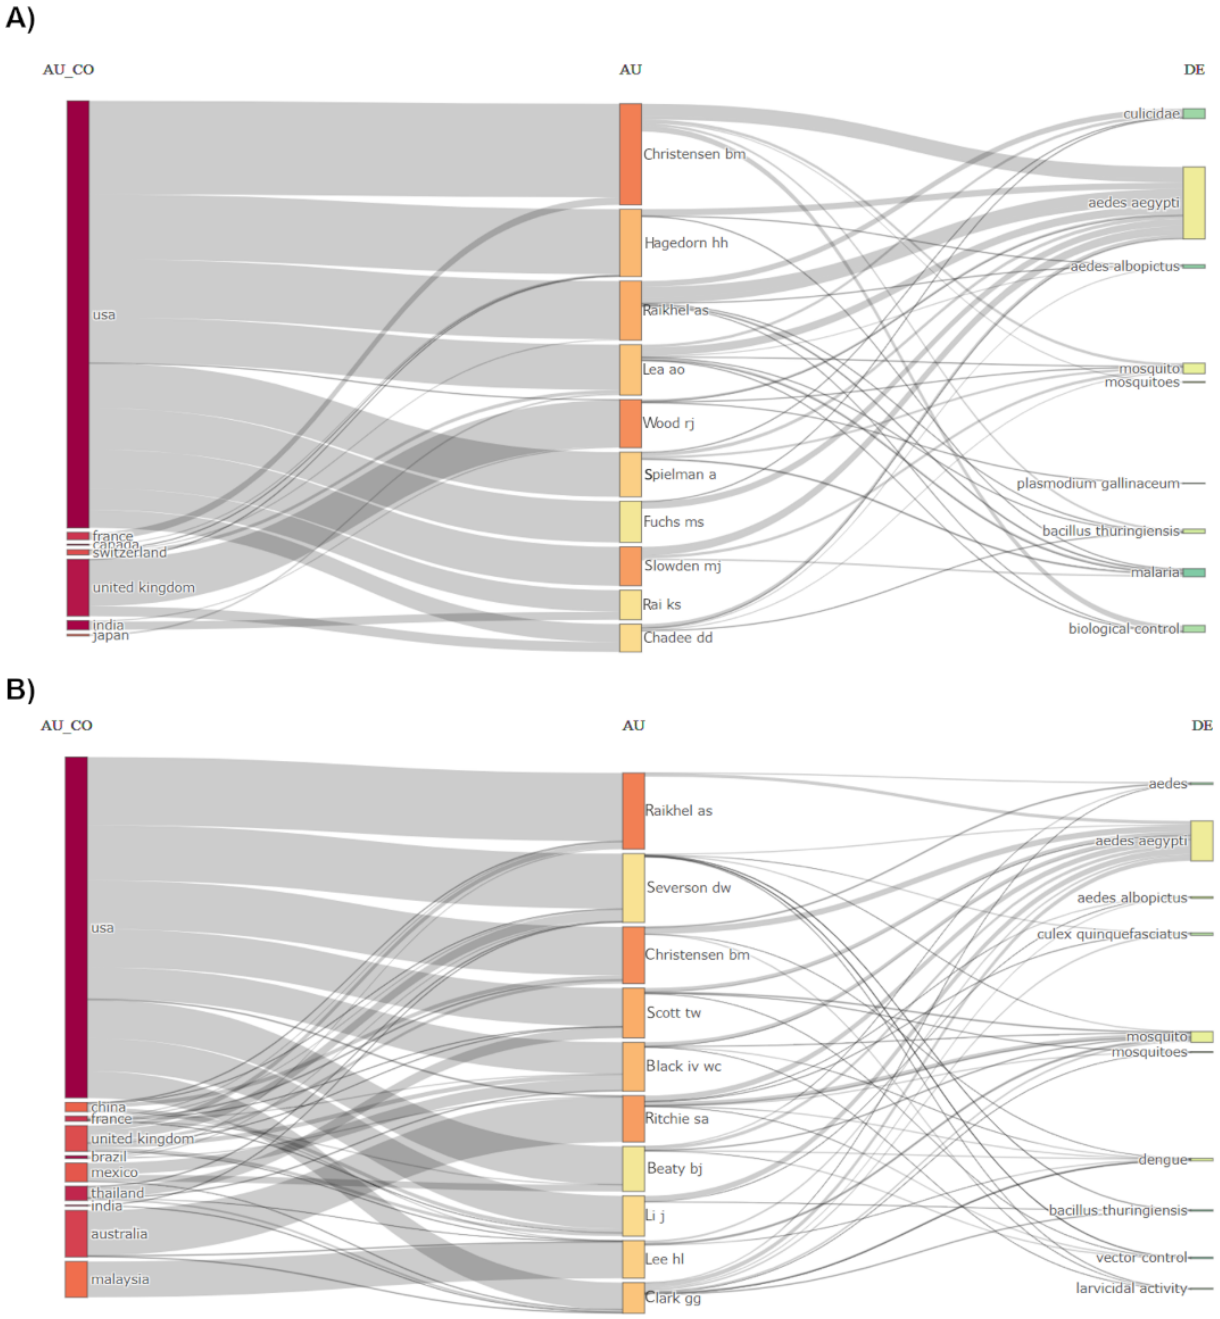


Figure 4 depicts the country of origin of the top authors and their research keywords for each period. In the initial period from 1927-1999, about 90% of the top 10 authors were affiliated with the United States and focused on the study of the Culicidae, *Aedes albopictus*, *Plasmodium gallinaceum*, *Bacillus thuringiensis*, malaria, and biological control (Figure 4A). From 2000 to 2009, more authors from other countries published on *Aedes aegypti*, that was Ritchie SA from Australia and Lee HL from Malaysia. The focus of research has shifted from Malaria to dengue and the additional species that was included was *Culex quinquefasciatus* (Figure 4B). The larvicidal activity was also the focus of the research. From 2010 to 2019, three main authors from Australia topped the productive list, namely Ritchie SA, O'neil SL, and Hoffmann AA, while authors from India contributed many articles, including Benelli G, Murugan K, and Govindarajan M. The top authors focused not only on dengue but also Zika virus (Figure 5A). In the recent period (2020-2023), authors from the United States, Australia, Mexico, China, Brazil, and India were equally productive in publishing their research on *Aedes aegypti* and on similar keywords as the previous periods (Figure 5B).

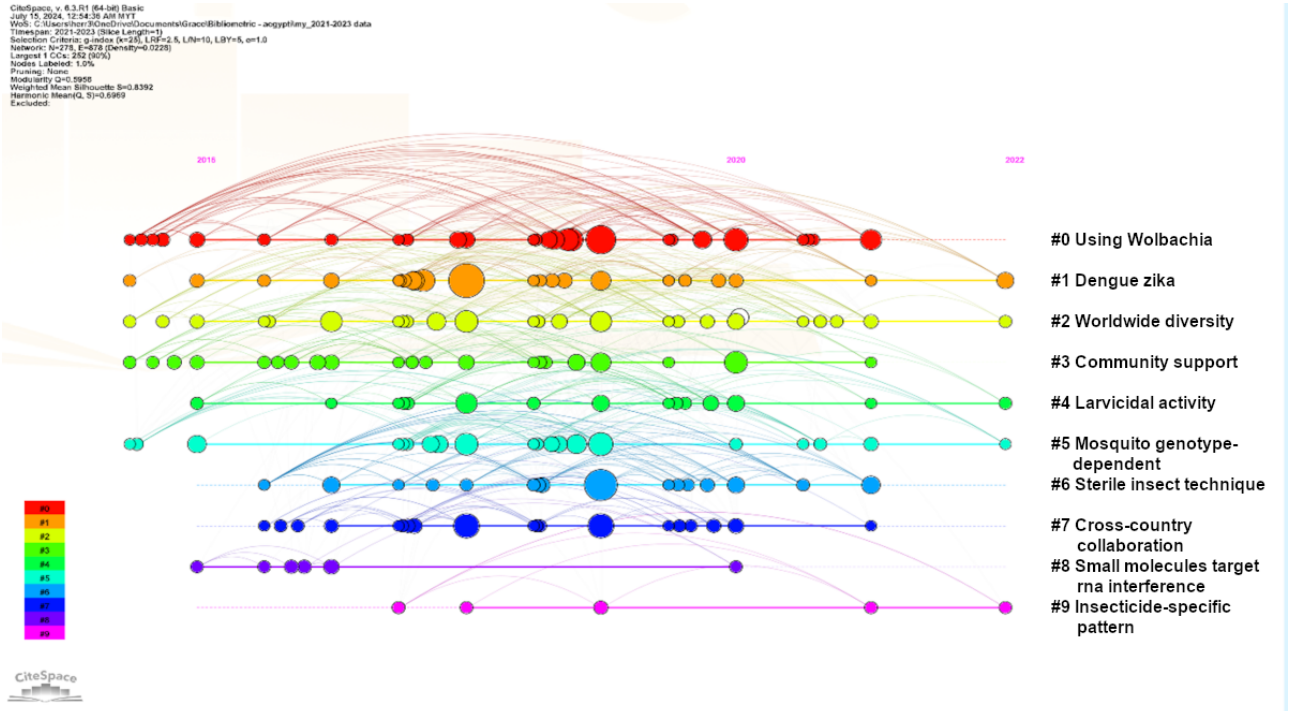
Figure 5. Three-field plot (Sankey diagram) of country, author, and keywords of the cited references for the 10 most productive authors from (A) 2010 to 2019 and (B) 2020 to 2023. AU: authors; AU_CO: countries; DE: keywords.

Subject Area and Research Trends

Most of the publications were in journals within the subject areas of medicine (7860/30,051; 26.2%); agricultural and biological sciences (5863/30,051; 19.5%); immunology and microbiology (5150/30,051; 17.1%); biochemistry, genetics, and molecular biology (4078/30,051; 13.6%); veterinary science (1513/30,051; 5.0%), and environmental science (1194/30,051; 4.0%). From 2000 to 2019, physics- and astronomy-related publications exhibited the highest growth rate (84), followed by engineering (9.7) and mathematics (8.54).



We identified 31 research clusters based on the cocitation reference network. From 2021 to 2023, the temporal evolution of the research topic clusters was discovered with the indication of the cluster silhouette score, size, and mean year of co-cited papers. The research clusters were categorized into 5 major research trends, that was, biological vector control, chemical vector control, and genetic of *Aedes aegypti*, disease-related and collaboration efforts. The main cluster, biological vector control, referred to the largest cluster, #0, concerning "using Wolbachia" (score=0.793; size=42; year=2018) [27] and cluster #6 on "sterile insect technique (SIT)" (score=0.856; size=25; year=2019) [28] (Figure 6). SIT started gaining attention after Wolbachia (#0), as one of the biological vector controls using sterilized male *Aedes aegypti* with either irradiation or exposure to a chemical sterilant in damaging somatic tissue to reduce the mosquito population [29]. The second major research trend concerning disease-related focused on "dengue Zika," #1,

XSL•FO
RenderX

(score=0.839; size=35; year=2019) [19]. The third major research trend was related to collaboration efforts, which referred to "worldwide diversity," #2, (score=0.814; size=33; year=2018) [30], "community support," #3, (Score=0.834; size=29; year=2017) [31] and "cross-country collaboration," #7, (score=0.8; size=24; year=2018) [32]. The research related to chemical vector control contributed to the fourth research trend: "larvicidal activity," #4, (score=0.883; size=26; year=2018) [33] and "insecticide-specific pattern," #9, (score=0.971; size=6; year=2019) [34]. The fifth research trend was related to genetics: "mosquito genotype-dependent," #5, (score=0.877; size=26; year=2018) [35] and "small molecules target RNA interference," #8, (score=0.932; size=6; year=2017) [36].

There were other significant subject areas from the analysis of keywords co-occurrences across 4 periods. Before the year 2000, the focused subject areas included *Bacillus thuringiensis*, electron microscopy, chromosome mapping, virus cultivation, and mosquito control (Figure S1 in Multimedia Appendix 1). From year 2000 to 2009, the research subject area related to *Aedes aegypti* focused on Culicidae, molecular sequence data, insecticides, bacterial toxins, larvae, insecticides, and dengue virus (Figure S2 in Multimedia Appendix 1). The subject areas were then extended to insecticidal activity, insect repellent, bioassay, plant extract, metabolism, genetics, insect proteins, physiology, disease transmission, and population density from the year 2010 to 2020 (Figure S3 in Multimedia Appendix 1). In the recent 4 years from 2020 to 2023, the subject areas focused on insecticide resistance, temefos, pyrethrins, larvicidal activity, metabolism, gene expression, reverse transcription polymerase, prevalence, vector control, arbovirus infections, and Zika virus (Figure S4 in Multimedia Appendix 1). The research focuses on *Aedes aegypti* linking with dengue stayed relatively important throughout the period. The number of publications focused on yellow fever were low and linked to *Aedes aegypti* solely (Figures S5-S8 in Multimedia Appendix 1). The research on chikungunya were not closely related to others research topics in the early period and were only started linking with dengue in the period of 2010-2019 and connecting with Zika in the period of 2020-2023. In 2010-2019, Zika started to become closely related topic with dengue and chikungunya in addition later on.

Figure 6. Visualization of the reference cocitation network time map (Year 2021-2023).

Citation Analysis

The top 10 papers with the highest number of citations are listed in Table 2. The top cited article was "Pathogenesis of dengue: challenges to molecular biology" authored by Halstead SB [37] (n=1355). The second highest cited article was "The global distribution of the arbovirus vectors Aedes aegypti and Aedes albopictus," authored by Kraemer et al [18] (n=1324), followed by the "A Wolbachia symbiont in Aedes aegypti limits infection with dengue, chikungunya, and Plasmodium. Cell. 2009" by Moreira et al [38] (n=1196).

Journals

The total number of journals that published papers on *Aedes aegypti* from 1928 to 2023 were 160. The leading journal that published articles on the *Aedes aegypti* were *Journal of Medical Entomology* (JME; 758/16,247, 4.7%), *PLOSNeglected Tropical Diseases* (NTD) (604/16,247, 3.7%), *Journal of theAmerican Mosquito Control Association* (AMCA) (505/16,247, 3.1%), *Parasites and Vectors* (493/16,247, 3.0%), and *PLOS One* (401/16,247, 2.5%; Table 3). The journal with the highest number of citations for their publication on *Aedes aegypti* was PLOS NTD (n=25,274), followed by JME (n=23,682) and the *American Journal of Tropical Medicine and Hygiene* (AJTMH; n=19,281; Table 3).

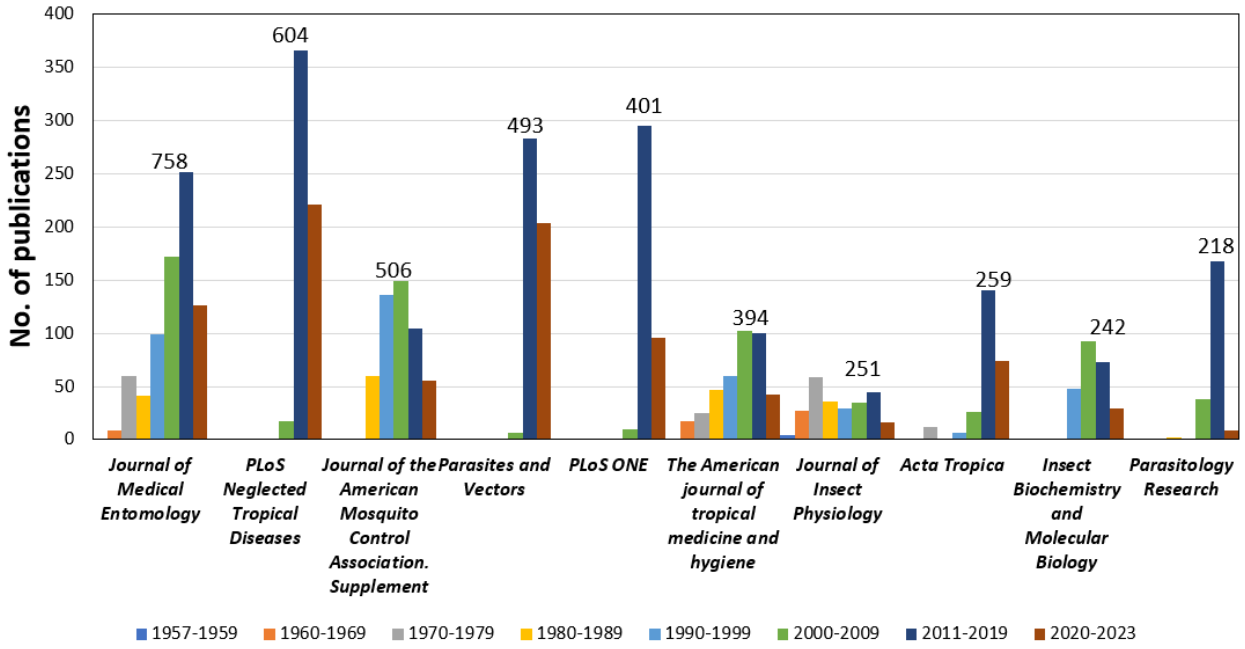

Figure 7 shows the distribution of publications on *Aedes aegypti* by journal across the years from 1957 to 2023. The *Journal of Insect Physiology* was the earliest to publish on *Aedes aegypti*, that was, since 1957, whereas the AJTMH and JME began publishing on *Aedes aegypti* between 1960 and 1970. From 2011 to 2019, most study were published in *PLOS NTD*, *Parasites and Vectors*, *PLOS One*, *Parasitology Research*, and *Acta Tropica*.

Table 3. Top 10 journals by number of papers on Aedes aegypti (from 1927-2023) and 5-year impact factor (2019-2023).

Journal	Number of papers (N=16,247), n (%)	Total citations (N=481,479), n (%)	5-year impact factor in 2023

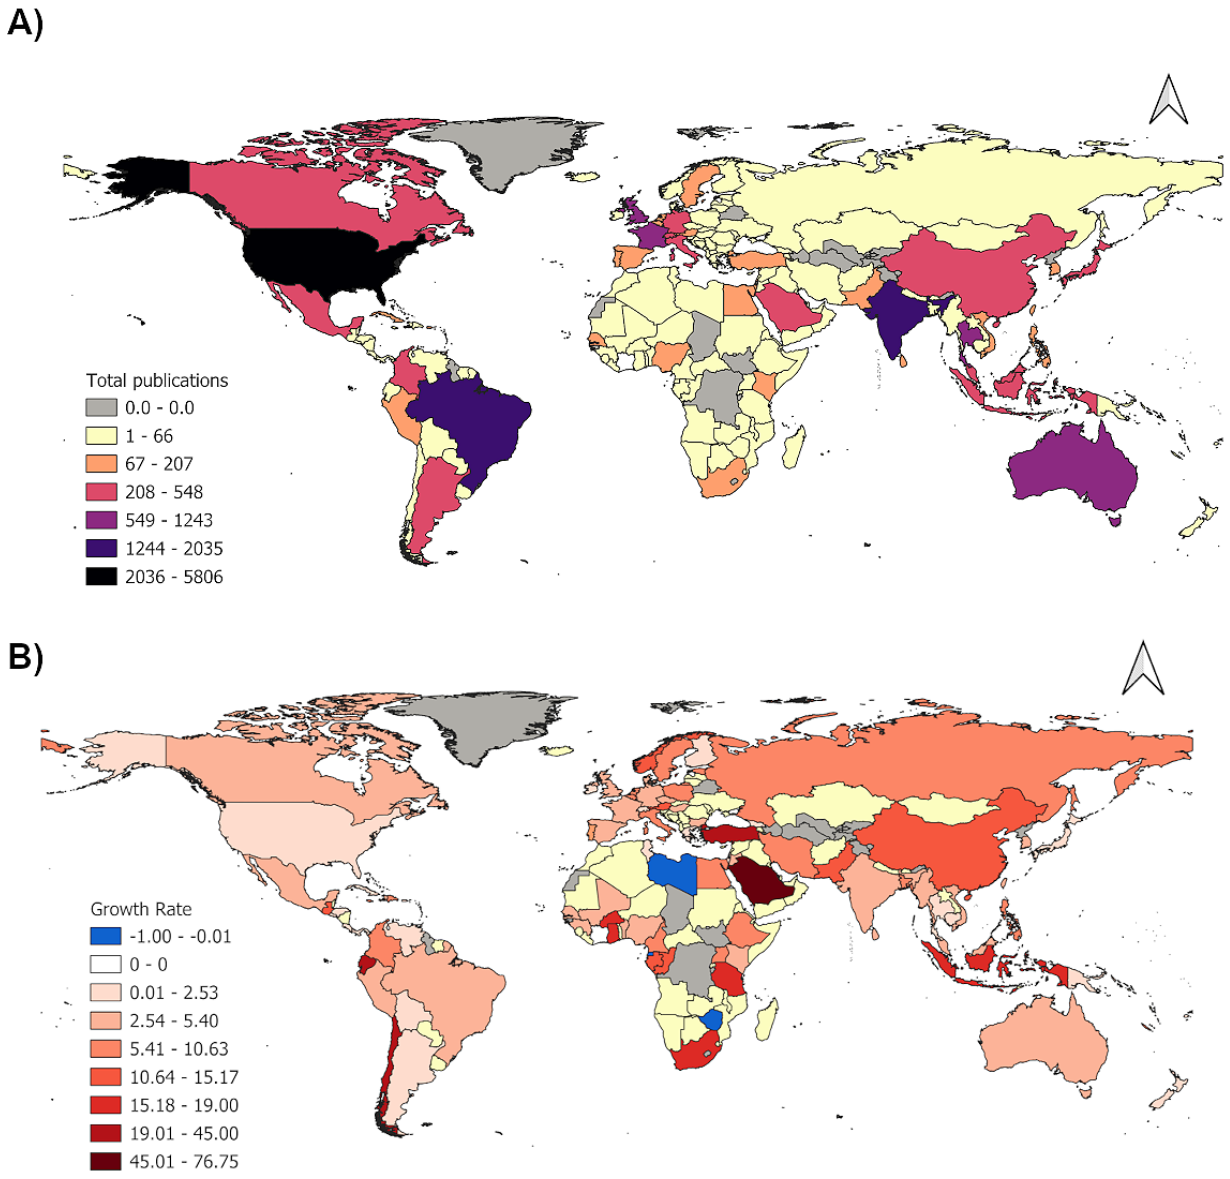
XSL•FO
RenderX

Figure 7. Number of publications by the top 10 journals by decade.

Country Analysis



More than one-third of the publications during the study period were by authors from the United States (5806/23,538, 24.7%), Brazil (2035/23,538, 8.6%), and India (1839/23,538, 7.8%). The next top 7 countries were from Europe (United Kingdom: 1243/23,538, 5.3%; and France: 898/23,538, 3.8%), Asia (Thailand: 678/23,538, 2.9%; Malaysia: 455/23,538, 1.9%; and China: 541/23,538, 2.3%), Mexico (548/23,538, 2.3%), and Australia (779/23,538, 3.3%). The decadal growth rate (from 2000 to 2019) of the articles by country was topped by Saudi Arabia (76.75), followed by Turkey (45), Chile (29), Ecuador (24), and Ghana (19) (Figure 8A). High decadal growth rates were also observed for Africa (Burkina Faso: 17.67; South Africa: 16.33; and the United Republic of Tanzania: 16), Asia (Hong Kong: 18; Indonesia: 16.6; and Pakistan: 14.5), Europe (Austria: 15.17; Norway: 13.5; and Estonia: 9), South America (Colombia: 9.52; French Guiana: 5.4; and Brazil: 4.82), Australia (4.17), and the United States (2.46; Figure 8B).

Coauthorship analysis of 131 countries revealed that the majority of coauthors were authors from the United States who collaborated with authors from Brazil and South America (Figure 9). Authors from India collaborated with Australian, Taiwanese, and South Korean authors. UK authors mainly collaborated with Thai, Malaysian, and Sri Lankan authors. Authors in France collaborated primarily with countries in Africa including Uganda, Congo, Cameron, Senegal, and Ghana. The European authors, that was, in Germany, Italy, and Spain worked closely with the collaborators from Saudi Arabia, Bangladesh, Egypt, and Turkey.

The country with the highest total citations was the United States (182,414/481,479, 37.89%), which was 5 times higher than the second highest country, Brazil (39,115/481,479, 8.12%). Switzerland (7469/481,479, 1.55%) and Italy (7,239/481,479, 1.50%) were both in the top 10 highest number of citations, even though they had low numbers of articles (Switzerland: n=302; and Italy: n=307). The rest of the countries in the top 10 list of total citation based on origin of corresponding author were India (32,646/481,479, 6.78%), United Kingdom (30,328/481,479, 6.30%), Australia (25,242/481,479, 5.24%), France (23,626/481,479, 4.91%), Thailand (12,154/481,479, 2.52%), and Mexico (6450/481,479, 1.34%).

Discussion

Principal Findings

The medically important mosquitoes, in particular, *Aedes aegypti*, has been studied for centuries. Female *Aedes aegypti* was one of the main vectors for transmitting viruses, including dengue virus, Zika virus, chikungunya virus, and yellow fever virus. In this study, the detailed evaluation of the *Aedes aegypti* published works informed the current knowledge gaps and future direction of the control of the vector. During the study period, 16,247 items were published and cited 481,479 times. In the recent 3 years, the literature focused on 5 areas: biological vector control studies, chemical vector control studies, genetic studies, disease-related studies, and collaboration efforts. The minor changes in the research trend were observed when comparing Vega-Almeida et al [12] (year 2006-2015) with the research focus on epidemiology, gene expression and biological control, larvicidal and insecticidal effects, and reproduction and insecticide resistance. The biological vector control using Wolbachia has been gaining more attention as many countries proved its efficiency in reducing dengue cases [44,46,47]. The

XSL•FO
RenderX

ongoing Sterile insect techniques pilot projects in many tropical and sub-tropical countries have shown the effectiveness of using irradiated mosquitoes in reducing the wild population [48]. The research direction will be the biological vector control projects at a larger scale or national operational level in the future. Lately, dengue, Zika, and chikungunya were emerging research topics related to *Aedes aegypti*. In recent years, there has been a noticeable rise in the number of articles addressing *Aedes aegypti* in discussing the effectiveness of vector control strategies. One of the control measures of the effectiveness of vector control strategies was the insecticide resistance of *Aedes aegypti*. Insecticides remain widely used in vector control interventions resulted in mosquito resistance to insecticides in 4 classes, including organophosphates, carbamates, pyrethroids and the organochlorine dichlorodiphenyltrichloroethane [49], and more in recent years. The insecticide resistance level of *Aedes aegypti* were conducted with various methods, for example, the WHO (World Health Organization) tube test [50], WHO bottle bioassay [51-53], the Centers for Disease Control and Prevention's bottle bioassay [54,55]. The WHO showed capital interest in the insecticide resistance study on malaria and dengue vector mosquitoes that several guidelines were provided to discuss the monitoring of insecticide resistance in mosquito vectors [56,57].

Genetic studies in relation to the gene knockdown of insecticides and the genomic profiles and relationship of the vector and patient were also the main research focus in recent years as the knowledge of genes requires more exploration and elucidation. The detailed genome mapping, RNA-seq data alignment, and gene expression quantification methods were investigated in detail to understand the relationship between mosquito genotype and the microbes in the science of vector mosquito genetic control [35,58,59]. Zika is still without cure and the symptoms could be severe, such as Guillain-Barré syndrome, congenital malformations in infancy, neuropathy, and myelitis in adults and older children. Many current studies focused on the vector competence of *Aedes aegypti*, particularly the Zika virus strain' infectivity, dissemination, and transmission rates as well as the influence of the larval microbiome on mosquito genotype-dependent [35,60]. Understanding the antiviral pathway in using the small molecule RNA interference and jak or stat signaling is crucial in controlling Zika virus infection in *Aedes aegypti* [36,61].

The booms of publications on *Aedes aegypti* after the year 2000 may be due to the increase in dengue cases globally, from 505,430 to 6.5 million from the year 2000 to 2023 [62,63]. Since 2007, there have been several Zika outbreaks in Africa, the Americas, Asia, and the Pacific. Zika was briefly declared as a Public Health Emergency of International Concern in 2016 [64]. The threat of chikungunya outbreaks in recent decades was unprecedented, especially in 2013-14 in the Caribbean and Latin America [65]. Moreover, the WHO declared the yellow fever as a global epidemic threat due to international travel [65]. The number of publications on *Aedes aegypti* and other vector is expected to increase in the future if infectious diseases caused by this vector remain uncontrolled or are exacerbated by climate change, rapid urbanization, and international human mobility. In the recent 2 decades, there was a surge of the growth rate of the publication on *Aedes aegypti*. The dengue endemic countries in the region of Western Asia, South America, and Western and Southern Africa produced more research output focus on the *Aedes aegypti*. However, countries in the northern and central Africa have been underrepresented in the research studies on *Aedes aegypti*. Studies in Burkina Faso, Ghana, South Africa, and Tanzania-countries with higher growth rate in publications on *Aedes aegypti*–can serve as the valuable references for other African nations with similar human environment in the study of origin, biology, behaviors, habitat, insecticide sensitivity of vectors, etc [66-70].

The analysis of coauthorship revealed that publications on *Aedes aegypti* were primarily collaborative efforts involving multiple authors from various specialized research fields. Authors from the United States constituted 45% of the top 20 most productive authors. This was likely due to increased access to funding resources. The top 20 productive authors originated from Australia, Asia (Thailand, India, and Malaysia), South America (Brazil and Trinidad and Tobago), and Europe (France and Italy). Authors who published on diseases transmitted by *Aedes aegypti* that are of global relevance, such as Gubler DJ and Halstead SB, had high numbers of citations and co-citations. During the Zika outbreak, authors who published on *Aedes aegypti* received more citations because of the increased public health interest in disease patterns, transmission links, and vector control methods related to Zika [42]. Often, authors gained more citations after years of experience in disseminating research findings [71].

The co-citation analysis provided a deeper understanding of vital research trends on *Aedes aegypti*. Gubler DJ was the highest co-cited author but was not among the top 20 productive authors. Gubler (H-index 94) was central in bridging researchers in the field for his significant works on dengue, antibody-dependent enhancement, flavivirus, Zika virus, microcephaly, and yellow fever. Gubler's review papers on dengue and dengue hemorrhagic fevers globally and locally were cited by the majority of dengue research papers, especially in the introduction sections [72]. The top co-cited article also highlighted a global study similar to Gubler DJ whereas Bhatt et al (2013) mapped and discussed the global distribution of the burden of dengue. Co-citation analysis can answer the research question, "Who are the central, peripheral, and bridging researchers in the field, and how has the structure developed over time?" [73] by connecting journals, authors, and various documents [74] regarding the intellective structure. The cocitation cluster patterns provide a new way to study the specialty structure of science [75]. Further studies on the cocitation trends by the years can provide insight and understanding of how the research developed over time.

There appeared to be links between authorship, citation impacts, collaborations, and funding. Higher funding support is strongly associated with higher citation impacts [76]. Funders were acknowledged in only 52.7% of the articles, based on the available information that showed the United States contribute to most of the top cited authors and articles on *Aedes aegypti*. The United States together with Brazil published the most study on *Aedes aegypti* aligning with other worldwide dengue bibliometric studies, showing these countries were the most

XSL•FO
RenderX

productive countries [77], given that *Aedes aegypti* is the main vector for dengue disease in the countries. Authors from neighboring countries tended to collaborate more within their regions. International coauthorship has a strong positive effect on the number of articles and citations a country produces [78,79]. This regional clustering is evident in Figure 8A, where the United States collaborated with Mexico, Colombia, Panama, and Argentina, while India worked with Sri Lanka, Thailand, and Bangladesh. Recently, China has shown a steep increase in publications on *Aedes aegypti* due to increased research funding and higher research focus on infectious disease [80-82].

Journal analysis provided information on the journals with the highest impact articles related to *Aedes aegypti* worldwide. The top journal, JME, a bimonthly publication focused on medical entomology and medical acarology, especially arthropods of public health importance, has published articles on *Aedes aegypti* since 1957 and exhibited an increasing trend in the number of articles for the past 60 years. JME's impact factor was 2 (The year 2019-2023) and was the second highest in total citations. Although PLOS NTD contributed the second highest number of publications on *Aedes aegypti*, it obtained the highest number of citations since its first publication on *Aedes aegypti* in 2008 and with a recent impact factor of 3.6 (for the year 2019-2023), indicating it has a great impact. PLOS NTD was also reported as the leading journal in publications on Leishmania [83] and neglected tropical diseases [84] in the Latin Americas and the Caribbean. However, these journals were grouped into different clusters as JME published more articles on *Aedes aegypti* physiology and vector control, whereas PLOS NTD articles covered more virus and genetic studies. The 10 leading journals mostly fell in the categories of agricultural and biological sciences, immunology and microbiology, and medicine of Clarivate's Journal Citation Report. Most of the journals that fell into multiple subject categories gained higher citations than those in single or dual categories [85].

The limitation of the current study should not be omitted. The study only sourced the data from Scopus due to the difficulties in combining the control measure across multiple databases, hence it may not capture all the papers from other databases such as Web of Science, Google Scholar, and Microsoft Academic. Besides, the qualitative components of the research were inaccessible in terms of peer review, ethical concerns and societal influence. Outputs from other academic discipline such as patents, produced systems developed and widely used, policy papers, white papers, reports produced for government and other public organizations, and exhibition were not included. In short, this study remains as valuable resources for comprehending the direction and significance of research.

Conclusions

In conclusion, the research on *Aedes aegypti* increased at a relative growth rate of 12.1 especially in the year 2000 to 2009, with a total number of 16,247 articles in 160 journals and were cited for 481,479 times. The prolific authors were mainly from the United States and the top co-cited authors across the years were elucidated. The coauthorship was collaborative involving multiple authors from various specialized research fields and countries, especially neighboring countries. Central and bridging researchers of the study on *Aedes aegypti* were identified and discussed based on the co-citation analysis, and this will provide better understanding how the research changed over time. The researchers' next area of interest may be the research direction. The leading journal were JME, PLOS NTD, AMCA, *Parasites and Vectors*, and *PLOS One*, with the top cited article titled "Pathogenesis of dengue: challenges to molecular biology" by Halstead SB in *Science*. Leading countries in published articles such as the United States and Brazil were also countries that funded higher number of published articles on *Aedes aegypti*.

The strengths of the study include the capability to identify the recent 3 years' research trends: "using Wolbachia," "Dengue Zika," "worldwide diversity," "community support," "larvicidal activity," "mosquito genotype-dependent," "sterile insect technique," "cross-country collaboration," "small molecules target RNA interference," and "insecticide-specific pattern." The recent research mainly focused on biological control, that is, an alternative to chemical control. This will be awareness for the scientific communities on the need to study the medicinal important vector, in which the researchers or entomologists could understand the current knowledge gap on *Aedes aegypti* and to plan for future research pathways. This study also contributed to the public health stakeholder and funder on the current research direction and knowledge gap for better decision-making and research priorities in determining the suitable intervention for vector control.

Acknowledgments

We would like to thank the Director General of Health Malaysia and the Director of the Institute for Medical Research (IMR) for their permission to publish this article. This work was accomplished under the project of the National Institute of Health, Ministry of Health Malaysia (NMRR-22-01333-RCQ).

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

YLC handled the conceptualization, data curation, formal analysis, methodology, visualization, and writing of the original draft. KHL worked on the conceptualization, methodology, supervision, visualization, review and editing of the writing. BSG worked

XSL•FO
RenderX

on the supervision, visualization, review and editing of the writing. MHMH, MKCI, AA, TYT and HLL worked on the data curation and formal analysis. SMG and YKC did the methodology, review and editing of the writing.

Conflicts of Interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Abstract

Background: Prone positioning has emerged as a crucial intervention in managing acute respiratory failure, especially in acute respiratory distress syndrome and patients with COVID-19. Given the increasing interest in this field, it is important to characterize global research trends and key contributors to identify future research directions.

Objective: This study aimed to analyze global research trends, collaboration networks, and research hotspots related to prone positioning in respiratory failure through a comprehensive bibliometric analysis.

Methods: Bibliometric analyses were conducted using CiteSpace and Biblioshiny software on publications up to December 31, 2023, from the Web of Science Core Collection, focusing on prone positioning in respiratory failure.

Results: A total of 1263 research articles were identified, published in 50 countries by numerous institutions. The United States, France, and Germany contributed the most publications, with the United States producing 21.9% (275/1263) of the total. Key authors such as Claude Guerin and Luciano Gattinoni were identified as major contributors to the field. Keyword co-occurrence analysis revealed the dynamic nature of prone positioning research in respiratory failure. It highlighted protective ventilation and COVID-19-related acute respiratory distress syndrome as emerging hotspots, indicating a shift in focus during the pandemic.

Conclusions: This study revealed a rapidly growing body of literature on prone positioning in respiratory failure, especially in the context of COVID-19. The findings underscore the importance of further multicenter clinical trials to validate current practices and refine treatment protocols. In addition, the application of prone positioning in non-intubated patients represents a potential future research direction.

(Interact J Med Res 2025;14:e67276) doi:10.2196/67276

KEYWORDS

acute respiratory distress syndrome; respiratory failure; acute respiratory failure; ARF; bibliometric analysis; critical care; bibliometrics; lungs; prone positioning; COVID-19; SARS-CoV-2; coronavirus; infectious; pulmonary; pandemic

Introduction

Prone positioning, defined as a posture in which the patient lies face down with the chest and abdomen in contact with the surface and the back facing upwards, is commonly used in clinical settings for respiratory support and surgical procedures. Recently, prone positioning has gained significant attention as a therapeutic intervention, particularly in the management of acute respiratory failure (ARF) [1]. Its effectiveness is rooted in the interplay between body positioning and pulmonary mechanics, a relationship that has been explored extensively in recent decades. Historically, respiratory management in patients with ARF has focused on methods to enhance oxygenation and reduce complications [2].

In 1974, Mellins et al [3] investigated how physical therapies and body positioning, including the prone positioning, could influence lung volumes and facilitate better secretion clearance in pediatric patients with pulmonary diseases, supporting the notion that posture significantly impacts respiratory mechanics. Subsequently Bryan [4] offered a critical perspective on the mechanical implications of body positioning, and suggested that the supine position could exacerbate loss of lung volume in dependent regions due to gravitational effects on the diaphragm, leading to diminished ventilation and potential airway closure. Over the following decades, the role of prone positioning in improving oxygenation in patients with acute ARF was further investigated. In 2001, Gattinoni et al [5] conducted a randomized clinical trial on prone positioning in patients with acute respiratory distress syndrome (ARDS). While the study showed improvement in oxygenation, it did not demonstrate a significant survival benefit; however, it laid the groundwork for further investigation. The pivotal PROSEVA trial in 2013, conducted by Guérin et al [6], demonstrated that

XSL•FO
RenderX

early and prolonged prone positioning significantly reduced 28-day and 90-day mortality in severe patients with ARDS, leading to its recommendation as a standard practice for managing ARDS.

The COVID-19 pandemic has renewed attention to prone positioning, not only for intubated patients but also, notably, for awake, nonintubated patients experiencing hypoxemia [7]. Studies during the pandemic have confirmed that prone positioning can improve oxygenation in patients with COVID-19 and can reduce the need for endotracheal intubation, which is confirmed by computed tomography scan and electrical impedance tomography [8]. The cumulative findings from these studies have shaped current respiratory care practices, where prone positioning is now routinely used in ARF management. This evolution in understanding highlights the interplay between pulmonary mechanics, perfusion distribution, and body positioning, establishing the prone intervention as a valuable tool in clinical practice [9]. As the evidence supporting prone continues to grow, it becomes increasingly important to assess its broader impact on clinical practice, thereby guiding future research and refining its application across diverse clinical settings.

Bibliometric analysis provides a quantitative approach to assessing the development and dissemination of knowledge within a particular field [10]. By mapping the trajectory of research on prone positioning and respiratory failure, it is possible to identify key trends, influential studies, and gaps in the existing literature. This, in turn, offers valuable insights into the evolution of clinical practice and the global impact of research efforts [11]. Previous bibliometric studies in respiratory failure have addressed various topics, none have specifically focused on prone positioning in respiratory failure [12,13]. This study aims to fill this gap by performing a comprehensive bibliometric analysis of the existing literature on prone positioning and its application in respiratory failure. Such insights are essential for guiding future research directions, promoting international collaboration, and ensuring that the benefits of prone positioning are fully realized in diverse clinical settings.

Methods

Data Source and Search Strategy

The data for this bibliometric analysis were sourced from the Web of Science Core Collection (WoSCC). A comprehensive search was conducted on August 21, 2024, using the following search strategy: “prone positioning” AND (“acute respiratory failure” OR “ARDS” OR “respiratory failure” OR “acute respiratory distress syndrome”). This strategy was designed capture studies on prone positioning in respiratory failure, using both general and specific terms. The initial search identified a total of 2143 records.

Inclusion and Exclusion Criteria

To refine the dataset for bibliometric analysis, specific inclusion and exclusion criteria were applied. Initially, 108 records from the year 2024 were excluded to ensure the analysis focused on more established literature, resulting in 2035 articles. The dataset was further refined by excluding the following types of publications: 360 review articles, 126 meeting abstracts, 121 editorial materials, 114 letters, 43 proceeding papers, 5 corrections, and 3 early access articles. These exclusions were made to retain only original research articles, which are more likely to contribute directly to the understanding and development of prone positioning in respiratory failure. After applying these criteria, 1263 articles were selected for subsequent analysis, and no duplicates were found.

Data Cleaning and Preprocessing

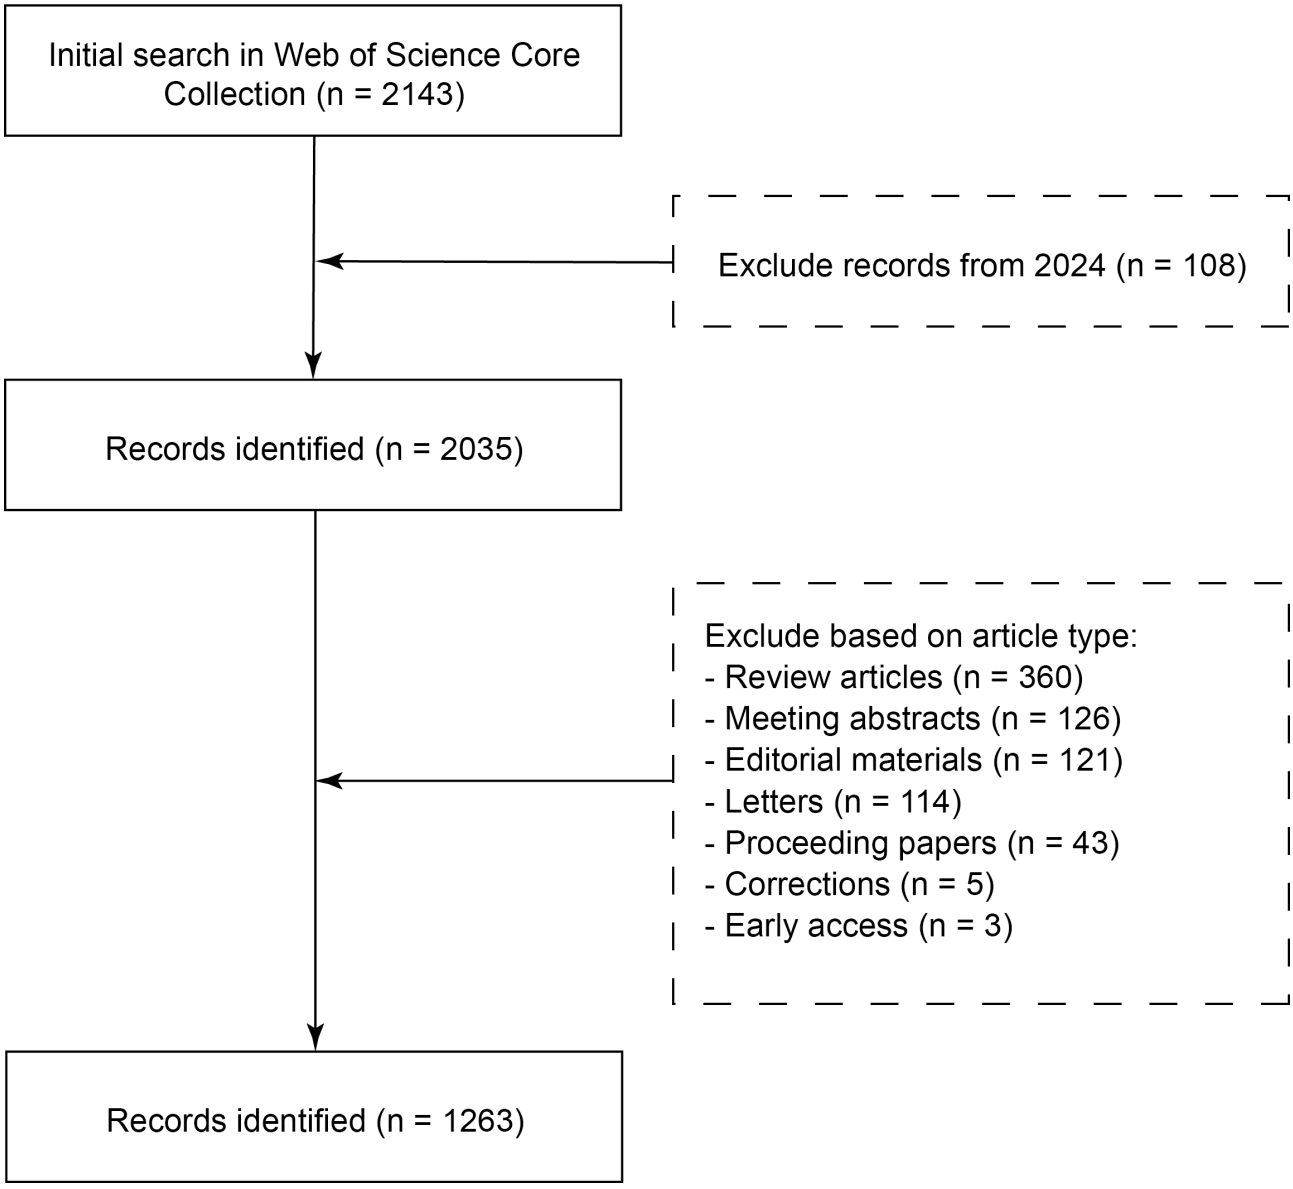
To ensure the accuracy and consistency of our dataset, we conducted a comprehensive data cleaning and preprocessing procedure. This process involved the removal of duplicate records, identified through digital object identifiers and study titles. We used the “biblioshiny” package in RStudio to standardize author and institutional names, consolidating any variations. In addition, the merge function was used to address synonyms, aliases, and singularor plural discrepancies in keywords. Noninformative keywords, such as “care,” “failure,” and “trial,” were removed using the remove function.

Bibliometric Analysis

Our bibliometric analysis followed a broad-to-specific framework, including an overview, countries or districts, authors or institutions, journals or most cited publications, keywords and trends. The collected data were imported into Biblioshiny (R version 4.3.3; Institute for Statistics and Mathematics, Vienna, Austria) [14], CiteSpace (6.3.R1; Drexel University, Philadelphia, PA, the United States for social network analysis and Burst detection [15], and Microsoft Office Excel 2016 for further analysis.

Biblioshiny is primarily used to visualize the analysis of global publication trends, countries, sources, and influential documents [16]. A range of bibliometric indicators are analyzed through biblioshiny to assess the output of countries, and journals. The number of publications was used to quantify productivity, while TC reflected academic influence. Local citations were examined to assess impact within specific subject areas. To evaluate the impact of sources, we assessed theh-index, g-index, and m-index [17]. The h-index provides a balanced view of productivity and citation impact, while the g-index emphasizes highly-cited articles. The m-index accounts for publication longevity, normalizing for years of activity. CiteSpace is a Java-based software developed by Chen for bibliometric analysis, supporting knowledge mining and data visualization. We used it to conduct author cocitation analysis, institution cocitation analysis, and keyword co-occurrence analysis. Visual network graphs were used to illustrate the relationships among nodes, where larger node sizes indicate a greater number of publications within a particular research area [18]. We also conducted keyword burst analysis to identify emerging research themes over time [19].

Results



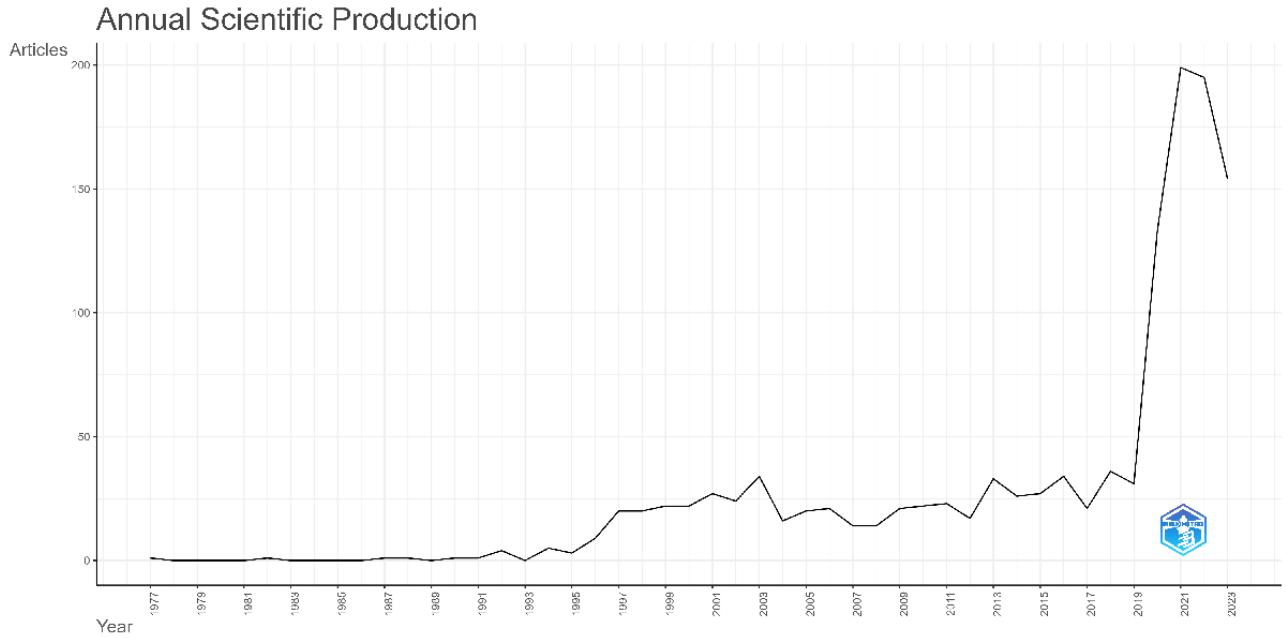
Search Results

A total of 2143 publications were identified from WoSCC. After excluding records from 2024 and filtering based on article type.

XSL•FO
RenderX

Finally, 1263 studies were identified for bibliometric analysis (Figure 1).

Figure 1. Record identification and selection.



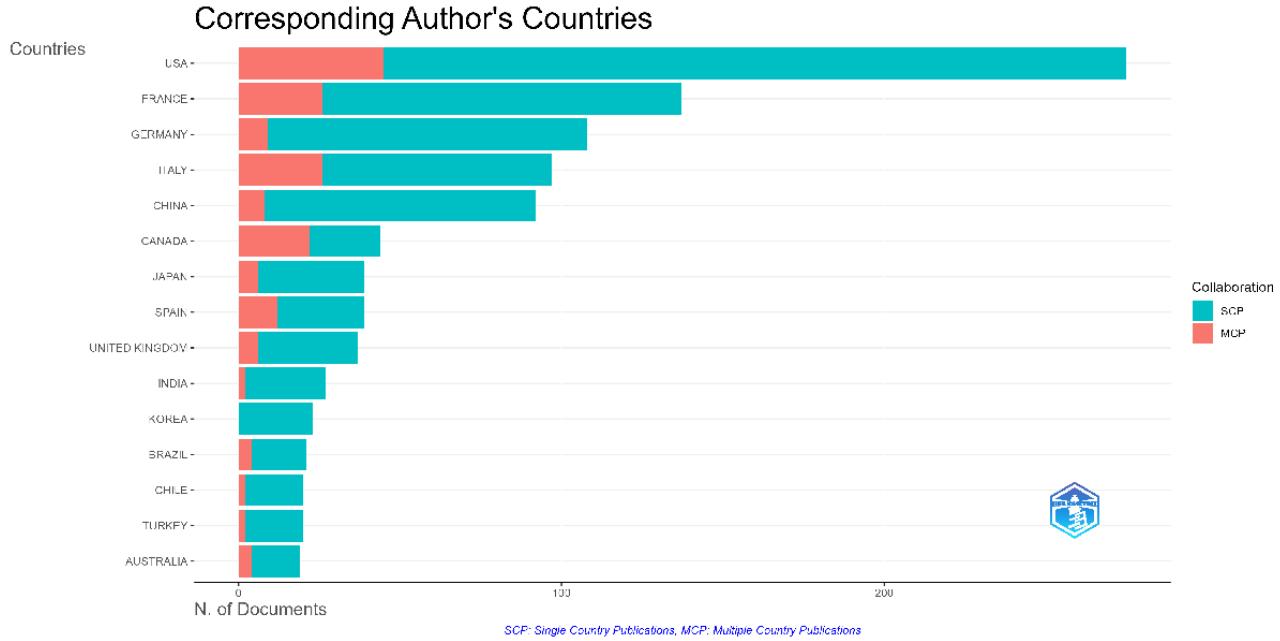
Global Publication Trends

The first publication on prone positioning in respiratory failure appeared in 1977, reporting that prone positioning significantly improves arterial oxygenation, allowing for reduced inspired oxygen concentrations in patients with ARF. In addition, there was only 1 to 5 publications per year before 1995. From 1995 to 2018, the number of publications showed a slow upward trend, whereas between2019 and 2023, there was a sharp increase, beginning with 31 publications in 2019 and peaking at 199 publications in 2021 (Figure 2).

XSL•FO
RenderX

Figure 2. Annual scientific production. This figure shows the annual number of publications on prone positioning in respiratory failure from 1977 to 2023. The first publication appeared in 1977, with only 1 to 5 articles per year before 1995. From 1995 to 2018, there was a gradual increase in publications. A significant rise in the number of publications occurred from 2019 to 2023, with 199 publications in 2021.

Countries and Districts



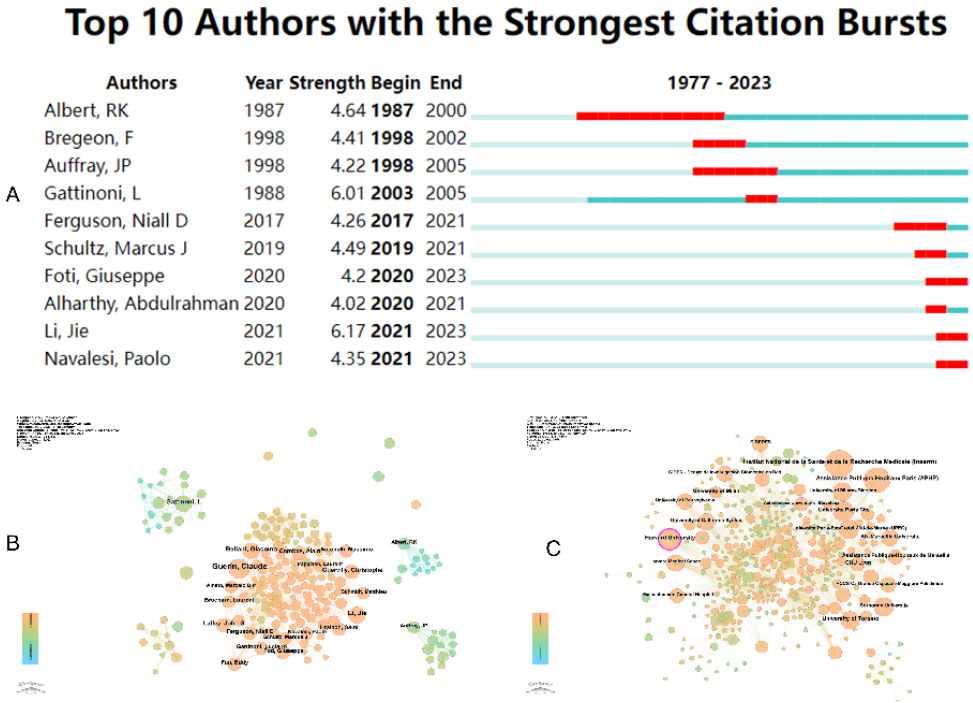
A total of 57 countries contributed to publications on prone positioning in respiratory failure. The United States was the leading contributor, with 275 publications (275/1253, 21.9% of the total), followed by France with 137 publications (137/1253, 10.9%), and Germany with 108 publications (108/1253, 8.6%). Italy contributed 97 publications (97/1253, 7.7%), and China contributed 92 publications (92/1253, 7.3%). Other major contributors included Canada (44/1253; 3.5%), Japan (39/1253; 3.1%), Spain (39/1253; 3.1%), the United Kingdom (37/1253; 3.0%), and India (27/1253; 2.2%).

In terms of citation impact, the United States had the highest total number of citations (10,146) with an average of 36.9 citations per document. France followed with 9229 citations and an average of 67.4 citations per document. Notably, Canada, despite contributing only 3.5% (44/1253) of the publications, had the highest average citations per document, reaching 132.5.

The analysis of corresponding authors' countries revealed varying patterns of domestic and international collaboration (Figure 3; Sheet 1 in Multimedia Appendix 1). The United States had the highest total number of publications, with 230 single-country publications and 45 multiple-country publications (MCPs), resulting in an MCP rate of 16.4% (45/275). Although Canada had a relatively lower publication count (44 articles), it exhibited the highest MCP rate among the top contributing countries, with 50% of its publications involving international collaboration. By contrast, India had the lowest MCP rate at 7.4% (2/27), reflecting a higher proportion of domestically authored publications.

XSL•FO
RenderX

Figure 3. Corresponding author's country distribution. This figure presents the distribution of single-country publications and multiple-country publications by country.



Authors and Institutions

A total of 553 authors contributed to publications on prone positioning and respiratory failure. Albert et al [20-23] published 6 articles and experienced a notable citation burst beginning in 1987 and continuing until 2000, with a burst strength of 4.64 (Figure 4A). Papazian et al [24,23] also experienced a citation burst from 1998 to 2005, with a strength of 4.22. Gattinoni demonstrated the highest citation burst strength of 6.01, occurring between 2003 and 2005. With 10 publications, Gattinoni has been a leading figure in this field since 1988, particularly in research on ARDS and prone positioning. More recently, Ehrmann et al [25] and Cammarota [26] have shown emerging influence, with citation bursts beginning in 2021 and continuing through 2023, and burst strengths of 6.17 and 4.35, respectively. Network analysis identified Claude Guérin as the most prolific and central author, with 16 publications and a centrality score of 0.03, underscoring his influential role in this research domain (Sheet 2 in Multimedia Appendix 1). Guérin's contributions have been especially significant since 2006 (Figure 4B). In the early stages of the field, authors such as Gattinoni et al [27], and Michelet et al [23] conducted research in relatively isolated clusters. However, since the onset of the COVID-19 pandemic, collaboration among researchers has increased notably, reflecting a shift toward more integrated global research.networks. Institut National de la Santé et de la Recherche Médicale and Assistance Publique–Hôpitaux de Paris, with 82 and 70 publications respectively, rank among the top institutions contributing to research on prone positioning and respiratory failure (Figure 4C). Harvard University leads with 51 publications and exhibits the highest centrality score (0.15), indicating its pivotal role in connecting diverse research clusters within the global collaboration network. Other institutions, such as Leipzig University and the University of Milan, also demonstrate relatively high centrality values (0.09 and 0.08, respectively), suggesting that they serve as important bridges across international research communities (Sheets 3 in Multimedia Appendix 1). An emerging contributor, Southeast University in China, reflects the growing involvement of Chinese institutions in this research domain.The analysis further reveals distinct collaboration patterns, with some institutions predominantly engaging in domestic (intracountry) collaborations, while others—such as Harvard University—participate extensively in international research partnerships, advancing global progress in the study of prone positioning.

XSL•FO

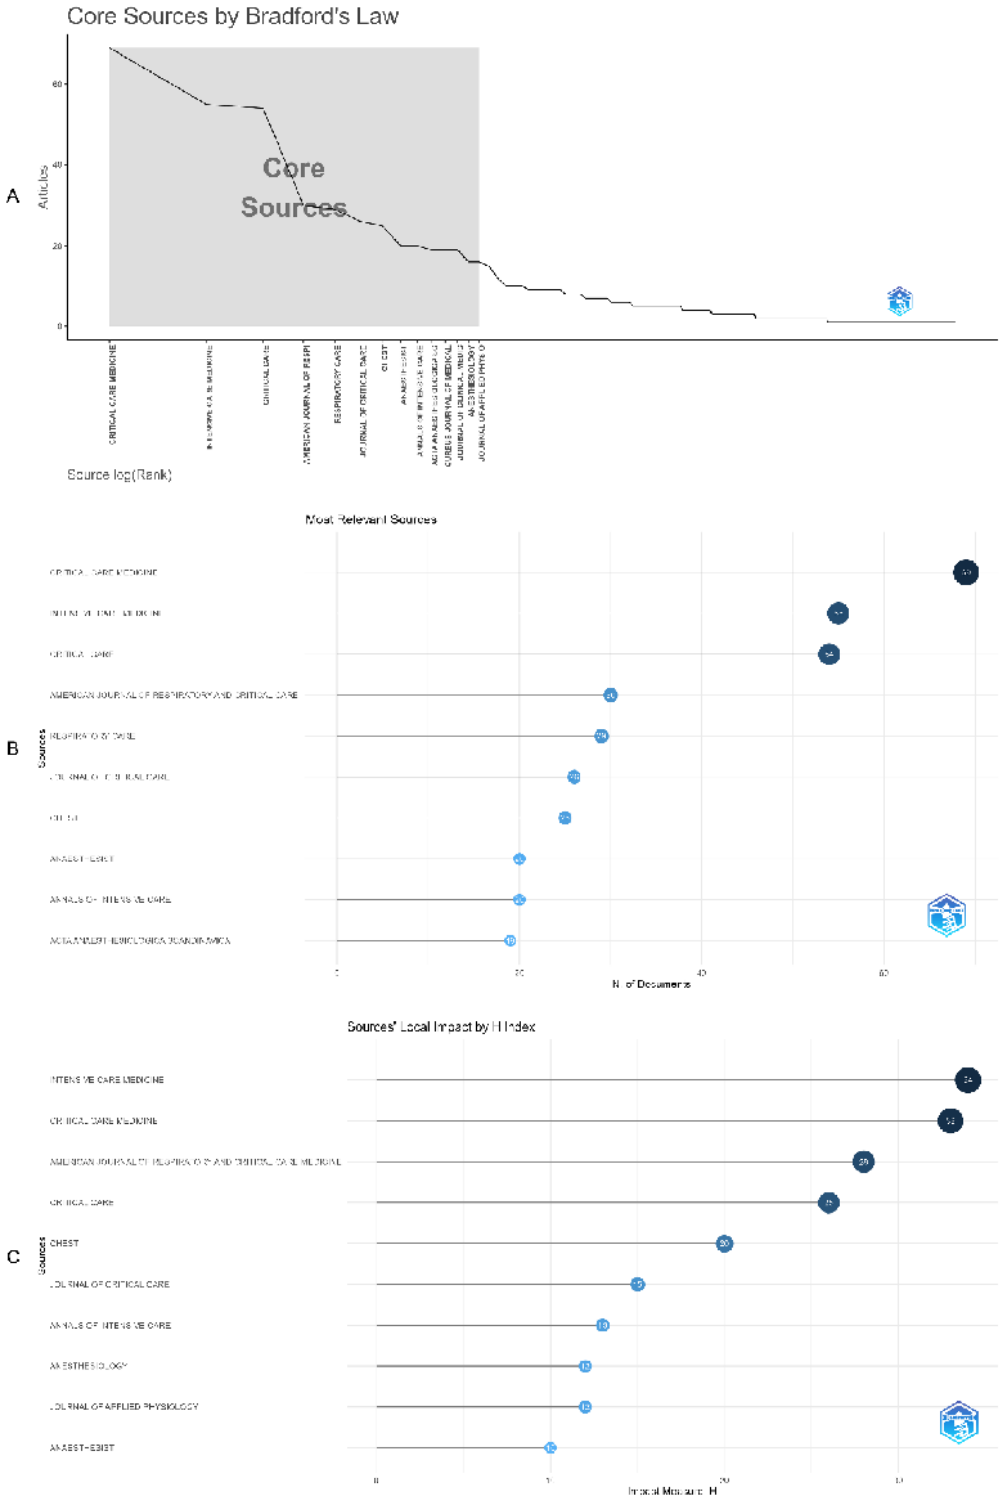
Figure 4. Authors and institutions. (**A**) Top 10 Authors with the Strongest Citation Bursts. This panel displays the top 10 authors with the strongest citation bursts in the field of prone positioning and respiratory failure. The red line segments represent the time periods of citation bursts, while the burst strength indicates the intensity of citation activity, with higher values reflecting stronger bursts. (**B**) Co-authorship network Visualization. This panel visualizes the co-authorship network in prone positioning research. Nodes represent authors, and edges between nodes represent co-authorship relationships. The network highlights key authors and their collaboration patterns over time.(**C**) Network of Co-authors' Institution Visualization. This panel illustrates the co-authorship network at the institutional level. Nodes represent institutions, and edges between them reflect collaborative publishing efforts. The network highlights prominent institutions and their involvement in global research initiatives on prone positioning and respiratory failure.



Journals and Most Cited Publications

Bradford's Law provides a framework for quantifying the distribution of articles across journals within a specific research field. It posits that publications can be grouped into a core set of journals contributing the largest number of articles, followed by successive zones with decreasing productivity. According to Bradford's Law Analysis, 13 journals were identified as core journals, The leading journal, *Critical Care Medicine*, has the highest frequency with 69 articles, followed by *Intensive Care Medicine* (55 articles), and *Critical Care* (54 articles). These journals constitute the core outlets for high-impact and frequently cited research on prone positioning and respiratory failure (Figure 5A). Further analysis of relevant sources confirmed *Critical Care Medicin*e as the most productive journal, followed closely by *Intensive Care Medicine* and *Critical Care*. *The American Journal of Respiratory and Critical Care Medicine* also ranked highly, with 30 articles published in this area (Figure 5B). In terms of source impact, *Intensive Care Medicine* demonstrated the highest h-index of 34, along with the highest TC of 5925. This was closely followed by *Critical Care Medicine* (h-index 33, TC 4307) and *The American Journal of Respiratory and Critical Care Medicine* (h-index 28, TC 4726) (Figure 5C).

XSL•FO
RenderX

Figure 5. Authors and institutions. (**A**) Bradford Law bibliometrix. (**B**) Most relevant journals. (**C**) Impact index of journals.

High values across h-index, g-index, and m-index indicate that these journals exhibit both substantial productivity and significant impact in the field of respiratory failure, particularly concerning prone positioning (Sheet 3 in Multimedia Appendix 1). *Critical Care Medicine* and *Intensive Care Medicine* had comparable m-index values of 1.179 and 1.172, respectively, suggesting sustained academic influence since their emergence in the mid-to-late 1990s. Their consistent growth in citations and publication output reflects their central role in disseminating research in this area (Sheet 4 in Multimedia Appendix 1). Despite its relatively recent entry into the field (established in 2015), *Annals of Intensive Care* recorded the highest m-index (1.3), indicating rapid growth in influence. In contrast, older, more established journals such as *CHEST* and *The Journal of Applied Physiology* have shown steadier but slower growth in impact over time.

The most cited publication in this analysis is the study by Bellani et al [28], published in *JAMA*, which received 3240 TCs, with

XSL•FO
RenderX

an average of 360 citations per year (TC/Y) and a normalized TC score of 23.25 (Table 1). This pivotal study presents large-scale data from the LUNG SAFE study, offering critical insights into the epidemiology, management, and outcomes of ARDS. Closely following is the work by Guérin et al (2013), published in *The New England Journal of Medicine*, with 2423 TC, a TC/Y of 201.92, and a normalized TC of 12.85. This landmark clinical trial established the efficacy of prone positioning in improving survival rates among patients with severe ARDS, and it fundamentally altered international treatment guidelines. A more recent publication by Schmidt et al (2021), appearing in *Intensive Care Medicine*, has already accumulated 476 citations, with a remarkable TC/Y of 119.00 and a normalized TC of 22.80. The rapid accumulation of citations reflects the high relevance of this study, particularly in the context of the COVID-19 pandemic, during which the management of respiratory failure and ARDS has become a global research priority.

Table . The most cited publication by top 10-record.

Co-Occurring Author Keywords

In the analysis of co-occurring author keywords related to prone positioning and respiratory failure, several critical terms emerged as focal points, reflecting the research trends and clinical focus areas over the years. Prone position (count: 592 and centrality: 0.08), was the most frequently occurring keyword, consistently central to discussions on improving oxygenation and outcomes in patients with ARDS and respiratory failure (Figure 6A). ARDS (count: 475, centrality: 0.1) is the second most frequent keyword, highlighting the prominence of ARDS in the context of respiratory failure, particularly in mechanically ventilated patients (Sheet 5 in Multimedia Appendix 1). The co-occurrence of mechanical ventilation (count: 292 and centrality: 0.12) further emphasizes the critical relationship between mechanical support strategies and the management of ARDS and respiratory failure. The inclusion of extracorporeal membrane oxygenation (count: 111) and inhaled nitric oxide (count: 79) among the top keywords reflects the exploration of advanced therapies for refractory hypoxemia, often in conjunction with prone positioning. Notably, COVID-19 (count: 58) and awake prone positioning (count: 18) have emerged as recent significant keywords, reflecting the shift in clinical focus due to the pandemic and the adaptation of prone positioning in nonintubated, awake patients to improve oxygenation without invasive mechanical ventilation.

Figure 6. Co-occurring author keywords analysis. (**A**) Co-occurring author keywords network Visualization. This panel visualizes the network of co-occurring author keywords related to prone positioning and respiratory failure. Nodes represent individual keywords, and edges between nodes indicate the co-occurrence relationships. The network highlights the most frequently mentioned and connected terms in the research field.(**B**) Top 25 Keywords with the Strongest Citation Bursts. This panel presents the top 25 keywords with the strongest citation bursts, reflecting trends in the research over time. The red line segments represent the time periods of citation bursts, while the burst strength indicates the intensity of citation activity, with higher values reflecting stronger bursts.

Based on the keywords burst analysis, the top 25 keywords revealed clear trends in the evolution of research on prone positioning and respiratory failure (Figure 6B).

Early Stage (around 2000)

During this period, keywords such as body position and gas exchange were prominent. These terms suggest that the research focus was centered on understanding the pathophysiology of ARDS and improving treatment strategies—particularly by optimizing mechanical ventilation. Researchers aimed to enhance survival rates among patients with ARDS by refining ventilatory support techniques.

Middle Stage (around 2010)

In this phase, the emphasis shifted toward prone position and lung protective strategy, indicating a growing consensus on the physiological benefits of prone positioning and its role within lung-protective ventilation frameworks.

Recent Stage (around 2020)

In the most recent phase, keywords such as COVID-19, awake prone positioning, and nonintubated patients emerged strongly. These bursts reflect the global urgency in treating ARDS in the context of the COVID-19 pandemic. The renewed interest in prone positioning—particularly for awake, nonintubated patients—underscores its adoption as a noninvasive, life-saving intervention for COVID-19-related respiratory failure.

Discussion

Principal Findings

The bibliometric analysis of research on prone positioning in respiratory failure offers a comprehensive view of the evolution, global trends, key contributors, and future directions in this important clinical area. Prone positioning has evolved over the past 5 decades from a theoretical concept to a widely adopted therapeutic intervention [29,30]. Early observational studies demonstrated its potential to improve oxygenation, a finding later corroborated by clinical trials [2,3]. Subsequently, numerous cohort studies and randomized controlled trials, confirmed its efficacy in respiratory failure [31-34]. The landmark PROSEVA trial in 2013 demonstrated a significant reduction in 28-day and 90-day mortality rates when early and prolonged prone positioning was applied to patients with severe ARDS [6]. This study established prone positioning as a standard intervention in patients with severe ARDS, where conventional supine ventilation often fails to maintain adequate oxygenation. With the onset of the COVID-19 pandemic, prone positioning was rapidly adopted in hypoxemic respiratory failure related to COVID-19. Studies have shown that prone positioning can improve oxygenation not only in patients with mechanically

XSL•FO
RenderX

ventilation but also in nonintubated, awake patients, suggesting a role in potentially delaying or preventing the need for invasive mechanical ventilation [35]. This trend underscores the importance of prone positioning in both traditional ARDS management and in the novel context of COVID-19, driving a surge in research output.

National Contributions and Global Distribution

The United States leads global contributions to research on prone positioning in respiratory failure, accounting for 21.9% of the total publications (Table 2). The United States research output is not only substantial in volume but also impactful, as evidenced by its 10,146 citations and an average citation per document of 36.9. This aligns with the country's leadership in critical care and respiratory research, as highlighted by key studies such as the LUNG SAFE study by Bellani et al [28]. The prominent role of European countries, including Germany, Italy, and France, reflects strong collaborations within the EU and international research networks, as exemplified by the PROSEVA trial [6]. Overall, the research landscape in prone positioning and respiratory failure is characterized by strong contributions from a mix of Western and Asian countries, with the United States, France, and Italy leading in terms of both quantity and impact of publications. The high average citation rates in countries like France, Canada, and the United Kingdom suggest that these nations produce particularly influential research, while emerging contributions from China and India highlight the increasing global interest and participation in this critical area of study [25,36-38].

Table . Distribution by country.

Rank	Country	Documents, n (%)	Citations, n	Average citations
1	United States	275 (21.9)	10146	36.90
2	France	137 (10.9)	9229	67.40
3..	Germany	108 (8.6)	2232	20.70
4	Italy	97 (7.7)	6008	61.90
5	China	92 (7.3)	1039	11.30
6	Canada	44 (3.5)	5831	132.50
7	Japan	39 (3.1)	348	8.90
8	Spain	39 (3.1)	1529	39.20
9	United Kingdom	37 (3)	3829	103.50
10	India	27 (2.2)	221	8.20

Influential Authors and Scientific Impact

The analysis identified several key authors who have made foundational contributions to the field of prone positioning and respiratory failure. (Figure 4). In the early stage Albert et al have significantly advanced the understanding of the physiological effects and clinical benefits of prone positioning in managing ARF, particularly in ARDS. His work spans from animal models to human studies, elucidating mechanisms that improve gas exchange and reduce lung injury, and identifying that one of the key benefits of prone positioning was the alleviation of lung compression caused by the heart, which have shaped modern critical care practices [20-22,39]. The researcher from France, Auffray JP has played a significant role in advancing the understanding of prone positioning and its interaction with other treatments for ARDS. Auffray's work, particularly from the late 1990s to the early 2000s, focused on exploring how the prone position, combined with adjunctive therapies like inhaled nitric oxide and pulmonary vasoconstrictors, could enhance oxygenation and improve clinical outcomes in patients with ARDS [23,24,40]. And his studies explored the variability in patient response to prone positioning, indicated that a short-term trial of prone positioning may not be sufficient to predict which patients will respond to the prone positioning therapy, showing the complexity of patient variability in ARDS management. He also examined the tomographic features of patients with ARDS, while prone positioning improved oxygenation in many cases, computed tomography scans could not reliably predict responders based on lung opacity [41,42].

Gattinoni L's research [43] on ARDS spans over several decades, beginning in the late 1980s and continuing into the present. His pioneering work has evolved alongside advances in medical technology and clinical understanding of respiratory failure. His earliest influential study on prone positioning was published in 1988, where he investigated how body position could improve oxygenation in patients with ARDS [43]. Throughout the 1990s and 2000s, Gattinoni's research expanded to establish the concept of the "baby lung," which revolutionized the approach to mechanical ventilation by emphasizing the need to protect the small, aerated portion of the lungs in patients with ARDS. This work also laid the foundation for understanding ventilator-induced lung injury and its prevention through lung-protective strategies [44]. Gattinoni, L's research into prone positioning, lung mechanics, and the differentiation between pulmonary and extrapulmonary ARDS continued well into the 2000s, with several landmark studies published in 2003. These studies helped shape modern ventilatory practices, emphasizing the importance of individualized ventilation settings and protective strategies [45-47]. His body of work remains highly influential in guiding the clinical management of ARDS, particularly in the context of critical care and mechanical ventilation.

XSL•FO
RenderX

Dr Claude Guérin, with the most publications and significant centrality in the coauthorship network, stands out as a pivotal figure in this area, particularly due to his work on the landmark PROSEVA trial, which demonstrated the survival benefit of prone positioning in patients with severe ARDS, provides robust evidence that prone positioning not only improved oxygenation but also led to significant reductions in 28-day and 90-day mortality rates [6]. Following the PROSEVA trial, Guérin continued to explore the physiological mechanisms and clinical applications of prone positioning. His subsequent studies addressed various aspects of prone positioning, including its effects on hemodynamics and respiratory mechanics [48]. Throughout his career, Guérin's research has consistently focused on optimizing the use of prone positioning and understanding its physiological benefits. His work has shaped clinical guidelines and transformed the standard of care for patients with ARDS, particularly in the context of the COVID-19 pandemic. The breadth and depth of his research, ranging from clinical trials to mechanistic studies, underscore his pivotal role in advancing critical care practices for respiratory failure [49]. The citation burst of more recent authors like Li Jie and Navalesi Paolo indicates that research on prone positioning continues to evolve, with current studies exploring newer dimensions, such as its use in nonintubated patients during the COVID-19 pandemic [25,50].

Institutional Landscape and Collaborative Networks

From an institutional perspective, several significant trends emerge that illuminate the global research landscape and collaboration dynamics in the field of prone positioning and respiratory failure. First, it is evident that highly productive authors are often affiliated with prestigious academic or medical institutions that drive global research efforts. For instance, Claude Guérin, one of the most prominent authors in this field, is affiliated with University of Lyon in France, which have contributed substantially to the field through several influential studies [6,51,52]. Institut National de la Santé et de la Recherche Médicale and Assistance Publique–Hôpitaux de Paris have been leaders in research output, while institutions such as Harvard University, Leipzig University, and the University of Milan exhibit high centrality, indicating their pivotal role in connecting global research networks [5,28,53-56]. These institutions often serve as research hubs due to their access to extensive clinical trial data and resources for conducting high-impact studies

Moreover, international collaboration is a hallmark of research in this field. European institutions, particularly those in France and Italy, demonstrate strong collaborative networks with North American institutions, such as Harvard University and the University of Toronto. These collaborations facilitate the sharing of clinical insights and promote the development of comprehensive guidelines, as evidenced by the high citation rates of multinational studies such as those by Guérin et al [6,49]. Chinese institutions, such as Southeast University, have shown a rapid increase in publication volume, signaling an emerging influence in global respiratory research [57,58]. These institutions drive forward clinical guidelines and research agendas, supported by strong international collaborations that enhance the global understanding of prone positioning in respiratory failure.

Research Focus and Keyword Evolution

The evolution of research keywords provides valuable insight into the shifting focus and progression of scientific inquiry in this field [59]. By analyzing keyword trends over time, distinct phases of research development can be observed, revealing the core themes and emerging topics that have shaped the understanding of prone positioning as a therapeutic strategy in respiratory failure. Early studies primarily explored the effect of prone positioning on oxygenation in patients with ARDS, with mechanical ventilation being at the forefront of therapeutic interventions. During this period, research often emphasized the physiological benefits of prone positioning, particularly its ability to improve ventilation-perfusion matching and reduce shunt fraction [27,37,44,60,61]. In the middle phase, research shifted toward prone positioning and lung protective strategies. Prone positioning was increasingly recognized not only for its oxygenation benefits but also for its role in mitigating ventilator-induced lung injury [61-63]. The onset of the COVID-19 pandemic marked a new phase in the research on prone positioning, with keywords such as "COVID-19" and "awake prone positioning" from 2020 onwards. This period saw an explosion of research, as prone positioning was adapted for use in both intubated and nonintubated patients with COVID-19-induced respiratory failure [64-66]. Awake prone positioning, in particular, emerged as a critical intervention to delay or prevent intubation in hypoxemic patients with COVID-19. This technique was rapidly incorporated into clinical practice due to its simplicity, cost-effectiveness, and demonstrated efficacy in improving oxygenation without the need for mechanical ventilation [38,67].

Research Challenges and Difficulties

Research on different body positions in the management of respiratory failure has evolved significantly over the years, with various positions being explored for their effects on oxygenation and ventilation. The supine position, while commonly used, can result in poor lung expansion in the dorsal regions due to the effects of gravity, leading to compression and collapse of these areas [68]. This can exacerbate ventilation inefficiency, particularly in patients with ARDS, where the lungs are already compromised by inflammation and fluid accumulation [27]. In contrast, prone positioning reverses the gravitational effects on the lungs. This position redistributes lung inflation along the gravitational axis, opening the collapsed dorsal lung regions while compressing the ventral regions. As a result, prone positioning enhances ventilation in the dorsal parts, which are typically underventilated in the supine position, thereby improving oxygenation. Yi Xin et al [69] demonstrated in a large animal model that prone positioning improves lung reinflation and recruitment, particularly in the dorso-caudal regions of the lung. Subsequent clinical applications have confirmed the effectiveness of prone positioning, and multiple clinical trials have been conducted to investigate its safety and efficacy in diverse patient populations [29]. However, despite its proven benefits, the application of prone positioning still faces several challenges. One major difficulty is the potential for complications associated with the physical maneuvering of patients into the prone position, which can result in inadvertent extubation or displacement of endotracheal tubes [70]. In

XSL•FO
RenderX

addition, patients with certain comorbid conditions, such as obesity, cardiovascular instability, or spinal deformities, may not tolerate prone positioning as effectively. Obesity, in particular, complicates the effectiveness of prone positioning due to altered lung mechanics and reduced functional residual capacity, making it more difficult to achieve adequate lung recruitment during positioning [71]. Furthermore, prolonged prone positioning can increase the risk of pressure ulcers and facial injuries, especially in patients who cannot maintain the position without significant support [9]. These challenges underscore the need for careful patient selection, individualized treatment plans, and vigilant monitoring during the application of prone positioning, particularly in the presence of severe comorbidities. Recent studies suggest that alternative techniques, such as sequential lateral positioning and bed tilting, can also improve oxygenation and serve as viable substitutes for prone positioning [72]. Sequential lateral positioning involves alternating between supine and lateral positions to improve lung recruitment, redistribute ventilation, and enhance oxygenation in patients with ARDS. Adjusting the tilt of the bed also enhances alveolar recruitment and improves blood flow redistribution; however, tilting beyond 30° may cause overdistension and lead to hemodynamic instability [73].

Recommendations for Future Work

Future research should focus on several key areas to advance the understanding and application of prone positioning in respiratory failure.

Awake Prone Positioning

While the benefits of prone positioning in intubated patients with ARDS are well-documented, more research is needed to understand its efficacy in nonintubated patients. The COVID-19 pandemic has prompted the use of awake prone positioning, but studies have reported inconsistent or even contradictory findings, highlighting the need for robust, multinational clinical trials to validate the results.

Personalized Prone Positioning Protocols

Research should explore whether personalized approaches to prone positioning, tailored to individual patient characteristics (eg, lung morphology, disease severity, lifestyle habits, nutritional status, BMI), can improve outcomes. Developing personalized prone positioning protocols could lead to more effective and targeted treatments for diverse patient populations.

Explore the Mechanisms Behind Prone Position

Future research should focus on understanding the physiological mechanisms underlying the effects of prone positioning on respiratory mechanics and cardiopulmonary interactions in patients with respiratory failure. Emerging technologies, such as electrical impedance tomography, offer opportunities for real-time monitoring of lung recruitment and ventilation-perfusion matching during prone positioning, which can further elucidate the physiological impact of this intervention.

Long-Term Outcomes

Most research to date has focused on short-term outcomes, such as oxygenation and survival rates. Future studies should examine the long-term impact of prone positioning on pulmonary function, quality of life, and psychological well-being in survivors.

International Collaboration

Given the complex, multidisciplinary nature of respiratory care, fostering international collaboration is crucial. Research efforts should prioritize cross-border partnerships to ensure that findings are generalizable across different health care settings and patient populations.

Limitations

While this bibliometric analysis provides a comprehensive overview of research trends, it is not without limitations. First, the analysis was limited to publications indexed in the WoSCC, which may have excluded relevant studies from other databases such as Scopus, PubMed, and Embase. This could potentially lead to an underrepresentation of research from regions or countries where publication in these databases are more prevalent.

Second, the exclusion of non-English publications may have limited insights into research conducted in non-English-speaking regions, particularly in countries like China, Japan, and India, which are emerging contributors to prone positioning research. The reliance on English-language publications could introduce a bias, potentially underestimating the global scope of research in this field. Third, bibliometric analyses are inherently quantitative and do not assess the quality or clinical impact of the studies themselves. While citation metrics provide a proxy for influence, they do not always reflect the practical applicability of the research findings in clinical settings. High citation counts may sometimes be driven by factors unrelated to the study's scientific rigor, such as controversies or methodological critiques.

Conclusions

This bibliometric analysis highlights the expanding body of research on prone positioning in respiratory failure, with significant contributions from leading countries, institutions, and authors. The findings underscore the critical role of prone positioning in managing respiratory failure and improving patient outcomes, particularly in the context of the COVID-19 pandemic. Although significant progress has been made in this field, key gaps remain, particularly in understanding the application of prone positioning in nonintubated patients and the long-term outcomes. Future research should focus on addressing these gaps by exploring personalized treatment approaches, fostering international collaboration, and further investigating the physiological mechanisms underlying prone positioning. By building upon the existing evidence base, the medical community can ensure that prone positioning continues to evolve as a more effective and widely adopted intervention in the management of respiratory failure.

Abstract

Background: Breastfeeding provides unmatched health, developmental, and economic benefits to both infants and mothers, yet breastfeeding continuation rates remain suboptimal in the United States, especially beyond the early postpartum period. Despite well-documented advantages, many mothers face challenges that lead to early cessation, including lack of access to skilled lactation support. International Board Certified Lactation Consultants (IBCLCs) are considered the clinical gold standard in lactation care, but their availability varies widely across states. Understanding how IBCLC access relates to breastfeeding outcomes at the population level is critical to informing equitable public health interventions.

Objective: The aim of this study is to determine whether state-level IBCLC density is associated with breastfeeding initiation and exclusive breastfeeding at 3 and 6 months.

Methods: This cross-sectional analysis used publicly available 2022 data from the Centers for Disease Control and Prevention, US Census Bureau, and the International Board of Lactation Consultant Examiners. IBCLC density per 100,000 women of childbearing age (15 - 49 years) was calculated for each of the 50 US states. Breastfeeding outcome data included initiation, exclusive breastfeeding at 3 months, and exclusive breastfeeding at 6 months. Simple and multiple linear regressions were conducted to evaluate the association between IBCLC density and breastfeeding outcomes, adjusting for income, education, and insurance coverage.

Results: IBCLC density ranged from 14.4 to 60.7 per 100,000 women of childbearing age across US states, with a national average of 25.5. Pearson correlation analysis indicated significant positive associations between IBCLC density and breastfeeding outcomes, including initiation (r=0.38; P<.001), exclusive breastfeeding at 3 months (r=0.52; P<.001), and exclusive breastfeeding at 6 months (r=0.32; P<.001). In multiple linear regression models adjusting for income, education, and insurance status, IBCLC density remained significantly associated with all 3 outcomes. For breastfeeding initiation, the adjusted β was 0.26 (95% CI 0.08-0.44; P=.005); for exclusive breastfeeding at 3 months, β was 0.43 (95% CI 0.23-0.63; P<.001); and for exclusive breastfeeding at 6 months, β was 0.25 (95% CI 0.12-0.39; P<.001). Adjusted R^2 values for the models ranged from 0.42 to 0.44, indicating moderate explanatory power.

Conclusions: Higher IBCLC density is significantly associated with improved breastfeeding outcomes at the state level, particularly exclusive breastfeeding at 3 months. These findings support initiatives to expand access to professional lactation support as part of public health strategies to improve breastfeeding rates.

KEYWORDS

breastfeeding; lactation consultant; exclusive breastfeeding; artificial baby milk

Introduction

Background

Breastfeeding is a complex, symbiotic process between a mother and child and breast milk is the one source of infant nutrition that is perfectly, biologically suited for an infant in its unadulterated form. The value of breastfeeding goes well beyond meeting nutritional needs and it is a mother's way to continue her uniquely profound role of nourishing and nurturing after childbirth. Although breastfeeding is the biological norm for humans, it is no longer the social norm. With the early 20th century commercialization of infant formula, which produces over US $55 billion in sales annually, mothers have been dissuaded from breastfeeding [1]. Infant formula marketing is partially to blame for the decrease in breastfeeding on a global scale—a drop from 90% in the 20th century to 42% in the 21st century [2]. Infant formula usage increasingly became the social

XSL•FO
RenderX

norm while mothers increasingly lost their innate ability to breastfeed. Mothers have fewer supporters of breastfeeding as fewer people breastfeed, including their role models and peers. Although breastfeeding is innate, it can be incredibly challenging, especially considering most mothers today do not grow up seeing others breastfeed regularly. The potential problems that mothers can encounter are numerous and often lead to a mother discontinuing breastfeeding prematurely [3].

In the United States, approximately 83% of infants have ever breastfed [4]. This figure even includes babies who have latched just once in their life after birth, but were never breastfed again. By 3 months, the proportion of infants exclusively breastfed drops to approximately 45%, and then to 25% at 6 months. Nearly one-fifth of breastfed infants have already been given infant formula (artificial baby milk) before they are 2 days old. In a study by Perrine et al [5], approximately 68% of the participants did not meet their intended breastfeeding goal. The overarching message is that most women are breastfeeding for shorter durations than they intended.

Lactation consultants are clinical health care professionals that make it their mission to help mothers meet their breastfeeding goals and make breastfeeding the social norm again.

Lactation consultants are extensively educated and trained to understand the biological, anatomical, physiological, psychological, and social mechanisms of breastfeeding—on the part of both the mother and the infant. They are typically employed by hospitals or pediatric clinics or work in private practice. Lactation consultants are effective at improving breastfeeding outcomes, including exclusivity, duration, self-efficacy, and maternal mental health [6,7]. Although lactation consultants do indeed solve many breastfeeding problems, the problem of access to care remains. The lactation consultant profession is fairly small (approximately 19,000 in the United States and 35,000 worldwide) but growing, and it can be difficult for a mother to have geographical access to a lactation consultant [8].

Research Questions and Hypotheses

This study aims to evaluate the relationship between the population density of lactation consultants and breastfeeding outcomes across US states.

Research question: Is there a correlation between the population density of lactation consultants and breastfeeding outcomes?

The H (null hypothesis) is that there is no correlation between the population density of lactation consultants and breastfeeding outcomes. The H_1 (alternative hypothesis) is that there is a correlation between the population density of lactation consultants and breastfeeding outcomes.

Study Rationale

Given that breastfeeding rates nationally and globally are low, especially for continuation of breastfeeding, the focus of this article examines access to lactation consultants, who are designated clinical breastfeeding professionals. Access to lactation consultants is a topic that has not been well researched. In the United States, postnatal support varies significantly depending on geographic location, health care provider networks, and insurance status. Unlike some countries with nationalized health care systems, the United States lacks a standardized postnatal care pathway, and support for breastfeeding often depends on fragmented services offered through hospitals, outpatient clinics, and community health programs. However, there is research indicating that the use of lactation consultants does contribute to better breastfeeding outcomes, including longer duration and fewer problems. The inclusion of key sociodemographic variables in this study—household income, education level, and health insurance coverage—reflects their importance as social determinants of health. These factors can significantly influence a mother's ability to access lactation support services. For example, lower-income mothers or those without insurance may face barriers such as out-of-pocket costs or limited availability of lactation consultants in their communities. Similarly, differences in educational attainment may affect awareness of available resources and breastfeeding best practices. One gap in the current literature is an examination of the relationship between the access to lactation consultants and breastfeeding outcomes. Access to lactation consultants is a different problem entirely than the effectiveness of lactation consultants.

The objective of this study is to examine access to lactation consultants in the United States by measuring their population density at the state level and analyzing its association with key breastfeeding outcomes.

Subsequently, if the results indicate a higher population density of lactation consultants (International Board Certified Lactation Consultants [IBCLCs]) in an area results in better breastfeeding rates, a case can be made for public policy and funding to support improved access to lactation consultants.

Methods

Study Design and Setting

This study used a cross-sectional ecological design to investigate associations between state-level availability of lactation consultants and breastfeeding outcomes across the 50 US states. Data were compiled from publicly available national sources representing the year 2022. No human participants were recruited, as the analysis was based on aggregated secondary data. The setting spanned all 50 US states, and data collection periods correspond to annual releases from the US Census Bureau, the Centers for Disease Control and Prevention (CDC), and the International Board of Lactation Consultant Examiners (IBLCE).

Participants and Eligibility

The unit of analysis was each individual US state. All 50 states were eligible and included in the study based on the availability of complete data across key variables. The District of Columbia and US territories were excluded to ensure consistency in health care infrastructure, population metrics, and reporting standards. As an ecological study, eligibility criteria were based on data completeness at the state level rather than individual characteristics.

XSL•FO
RenderX

Data Sources and Assessments

Workforce statistics for IBCLCs were obtained from IBLCE's published reports, which detail the number of actively certified professionals per state. IBCLC density, the primary exposure variable, was calculated as the number of IBCLCs per 100,000 women aged 15-49 years using 2022 US Census Bureau data [9,10]. Breastfeeding outcomes were obtained from the CDC's 2022 Breastfeeding Report Card, which draws on data from the National Immunization Survey. The 3 key outcomes assessed were breastfeeding initiation (defined as ever having breastfed), exclusive breastfeeding at 3 months, and exclusive breastfeeding at 6 months. These outcomes represent population-level estimates based on parent-reported data and are considered valid for surveillance purposes.

The Breastfeeding Report Card data are derived from the National Immunization Survey, a telephone-based survey of parents with children aged 19-35 months. The CDC uses standardized weighting methods to ensure national representativeness. Although this is a well-established source of breastfeeding surveillance data, it is important to acknowledge that self-reported data can be subject to recall and social desirability bias.

Additionally, the study used the World Health Organization's definition of women of reproductive age—15 to 49 years old—to calculate IBCLC density [11]. This aligns with global demographic standards and ensures comparability across public health data sources.

The study also included 3 covariates identified as potential confounders based on existing literature about social determinants of health: average household income, the percentage of the population without health insurance, and the percentage of women aged 25 years and older with a bachelor's degree or higher. These variables were extracted from the US Census Bureau's 2022 state-level data. Together, these measures were used to assess sociodemographic context and its potential influence on breastfeeding behaviors.

Study Size

The final study population included all 50 US states. This sample size was determined by the availability of complete and consistent state-level data for all variables of interest. As a fixed and exhaustive sample of all states, a formal power analysis or sample size calculation was not necessary or applicable to this ecological analysis.

Data Analysis

Descriptive statistics were used to summarize the distribution of IBCLC density and breastfeeding outcomes across states. Simple linear regression models were conducted to assess the unadjusted associations between IBCLC density and each of the 3 breastfeeding outcomes. Subsequently, multiple linear regression models were developed to control for the influence of income, insurance coverage, and educational attainment. The primary independent variable in all models was IBCLC density, while the dependent variables were breastfeeding initiation, exclusive breastfeeding at 3 months, and exclusive breastfeeding at 6 months.

Pearson correlation analyses were conducted to examine the strength and direction of linear relationships between IBCLC density and each of the 3 breastfeeding outcomes: initiation, exclusive breastfeeding at 3 months, and exclusive breastfeeding at 6 months. These analyses provided initial insight into bivariate associations and guided the selection of variables for subsequent regression modeling. Correlation coefficients (r) and P values were reported to assess statistical significance.

Regression results were reported as standardized beta coefficients (β) along with 95% CIs, P values, and adjusted R^2 values to assess statistical significance and explanatory power. All analyses were conducted using Python programming tools (version 3.11; Python Software Foundation).

Ethical Considerations

This research involved the secondary analysis of publicly available, deidentified datasets and did not include any interaction with human subjects or use of private, identifiable information. Accordingly, ethics board review was not sought, in accordance with US Department of Health and Human Services regulations (45 CFR 46.102), which state that such studies do not constitute human subjects research. Institutional policy at Rockhurst University confirms that publicly available and anonymized data analyses are exempt from institutional review board review. All data used in this study were obtained from official public sources, including the CDC, US Census Bureau, and IBLCE. The study adhered to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for transparent reporting of observational cross-sectional research.

Statistical Testing

To enable consistent cross-state comparisons, the researchers first calculated the density of IBCLCs per 100,000 females of childbearing age (15 - 49 years) using Microsoft Excel 2021 (Microsoft Corp).

Simple linear regression analyses were conducted in Python to evaluate the unadjusted relationship between IBCLC density and each of the 3 key breastfeeding outcomes:

1. Breastfeeding initiation.
2. Exclusive breastfeeding at 3 months.
3. Exclusive breastfeeding at 6 months.

Multiple linear regression was then used to control for potential confounding variables. The dependent (outcome) variables remained the same: breastfeeding initiation, exclusive breastfeeding at 3 months, and exclusive breastfeeding at 6 months. The independent variables in the adjusted models included:

- IBCLC population density (primary exposure)
- Average household income
- Proportion of the population without health insurance
- Proportion of the population with a bachelor's degree or higher

These covariates were selected based on their theoretical importance as social determinants of health, supported by prior research linking these factors to maternal and infant health

XSL•FO
RenderX

disparities [12]. Variables were added to the regression models simultaneously; no stepwise (forward or backward) selection methods were applied.

For each model, we report regression coefficients, *P* values, and adjusted R^2 values to assess the strength, significance, and explanatory power of the observed relationships.

For reader clarity, we have included definitions of relevant terms in Multimedia Appendix 1.

Results

The relevant demographic makeup for each state is shown in Table 1, along with measures for the United States on average.

The breastfeeding initiation, exclusivity at 3 months, and exclusivity at 6 months rates for each state and the United States averages are shown in Table 2.

[a]IBCLC: International Board Certified Lactation Consultant.

The average IBCLC density for the entire United States female childbearing age population is 25.5, while the state with the highest density of IBCLCs was Alaska at 60.7 and the lowest density was in Wyoming at 14.4.

The simple linear regression for IBCLC density and breastfeeding initiation shown in Table 4 yielded a correlation coefficient of 0.38 with a *P* value of <.001 and an R^2 of 0.26.

The simple linear regression for IBCLC density and exclusive breastfeeding at 3 months shown in Table 5 yielded a correlation coefficient of 0.52 with a *P* value of <.001 and an R^2 of 0.41.

The simple linear regression for IBCLC density and exclusive breastfeeding at 6 months shown in Table 6 yielded a correlation coefficient of 0.32 with a *P* value of <.001 and an R^2 of 0.41.

The multiple linear regression analysis for breastfeeding initiation shown in Table 7 has an adjusted R^2 of 0.44, and it produced a coefficient of 0.26 for IBCLC density with a *P* value of .005. Income had an extremely low coefficient of 0.0003 with a *P* value of .005. Lack of health insurance coverage yielded a very high coefficient of 47.93, but a *P* value of .14. Having a bachelor's degree or higher yielded a coefficient of −6.05 and *P* value of .82.

Discussion

Principal Findings

This study found a positive association between the population density of IBCLCs and key breastfeeding outcomes in the United States, including initiation, exclusive breastfeeding at 3 months, and exclusive breastfeeding at 6 months (Multimedia Appendix 2). The strongest relationship was observed for exclusive breastfeeding at 3 months. These findings align with previous research showing that IBCLCs are associated with improved breastfeeding duration and exclusivity. For example, Patel and Patel [7] reported significant increases in breastfeeding rates when lactation support was provided in both hospital and community settings, and our findings reinforce the importance of IBCLC access beyond the point of care delivery. Similarly, Chrzan-Dętkoś et al [6] found that lactation consultations not only improved exclusivity but also maternal mental health, suggesting multifaceted benefits that may partly explain the state-level effects observed in our analysis.

Importantly, our study adds to this body of work by analyzing IBCLC density as a structural factor at the population level. Although Perrine et al [5] showed that hospital practices aligned with the Baby-Friendly Hospital Initiative improve exclusive breastfeeding intentions, our data demonstrate that widespread IBCLC availability across an entire state is similarly associated with improved breastfeeding metrics. This macro-level perspective complements prior individual-level studies and offers a broader lens on access equity.

These findings suggest that increased access to professional lactation support may play an important role in promoting breastfeeding continuation during the critical early months of infancy.

Comparison to Prior Work

The association between IBCLC density and breastfeeding outcomes identified in this study is consistent with literature emphasizing the clinical effectiveness of professional lactation support. Previous studies have documented improvements in breastfeeding duration and maternal confidence following targeted lactation interventions [6,7]. However, these studies were conducted in localized or clinical settings. Our analysis broadens this understanding by showing that even at the population level, the presence of IBCLCs is significantly associated with improved breastfeeding outcomes, indicating that workforce distribution matters as much as clinical quality.

Additionally, Rollins et al [1] emphasized how gaps in health system structures and commercial pressures undermine breastfeeding support globally. Our findings offer a US-specific parallel, suggesting that one way to counteract these systemic barriers is to increase the geographic accessibility of IBCLCs. Unlike initiatives limited to single institutions, the presence of IBCLCs across regions may mitigate inequities in maternal health resources.

Furthermore, while Perrine et al [5] focused on hospital practices, we extend their insights by suggesting that system-level workforce planning (ie, ensuring every region has adequate access to IBCLCs) could serve as a complementary public health strategy. By embedding our results in this broader context, we highlight how both institutional practices and population-based interventions may be needed to achieve national breastfeeding goals.

Strengths and Limitations

This study has several strengths. It draws from comprehensive, publicly available national datasets, applies both simple and multiple linear regression models, and includes key sociodemographic variables as potential confounders. This enhances the reliability of the observed associations and provides a foundation for future public health policy exploration.

However, several limitations must be acknowledged.

First, the study relies on secondary data sources, which limits the inclusion of other relevant variables such as cultural norms, maternity leave policies, or maternal health conditions. Attempts were made to address this through the inclusion of known confounders (income, education, and insurance status), but unmeasured variables likely remain.

Second, the focus on IBCLCs exclusively excludes other types of lactation support providers (eg, Certified Lactation Counselors; Women, Infants, and Children Peer Counselors), which may result in an underestimation of lactation support availability in some regions. This may particularly affect underserved areas where IBCLCs are sparse but alternative supports are present.

XSL•FO
RenderX

Third, the breastfeeding outcome data are based on parent-reported responses collected through telephone surveys, which may be susceptible to recall or social desirability bias. Although the CDC's methods are well-established and designed to minimize such issues, this limitation is inherent in self-reported data.

Fourth, the analysis was conducted at the state level, which may obscure important regional disparities. Breastfeeding behaviors and IBCLC availability likely vary significantly within states, suggesting the need for future studies using data at the county or ZIP code level.

Future Directions

To build on these findings, future research should focus on more granular geographic data, such as IBCLC access by zip code or county, to better identify disparities masked by state-level averages. Linking provider registries with localized breastfeeding surveillance systems may also enhance understanding of the real-world accessibility of lactation support. Additionally, expanding the analysis to include other types of lactation professionals and examining awareness of services among postpartum individuals could provide valuable insights. Longitudinal research tracking changes in IBCLC workforce density and breastfeeding rates over time would further clarify the nature of these relationships.

Conclusions

Given that national breastfeeding rates remain subpar, widespread promotion of breastfeeding as the sociocultural norm is a paramount initiative. The statistical results of this research collectively indicate that IBCLC density plays a valuable role in promoting positive breastfeeding outcomes, even when considering potential confounding factors. The positive correlations between IBCLC density and breastfeeding rates at various time points are supported by the simple linear and multiple regression analyses, highlighting the significance of lactation consultants in achieving breastfeeding success. However, these findings should be interpreted in light of certain limitations, including the use of aggregated state-level data and exclusion of non-IBCLC lactation professionals. Future research would benefit from more granular geographic data, such as breastfeeding rates at the county or zip code level and IBCLC distribution. Such data would enable more precise correlation and may uncover regional disparities masked in state-level analysis. One approach to improve data granularity could involve integrating provider workforce registries with public health datasets at the substate level or collaborating with hospitals and health departments to collect real-time lactation support utilization data. Additionally, exploring longitudinal outcomes and incorporating combination feeding practices could enhance the ecological validity of future studies. Many mothers are not aware that they can receive comprehensive health care from a lactation consultant to prevent and solve breastfeeding complications. Even with a fair population density of IBCLCs in an area, not having an awareness of their services poses a barrier to that care. Improved public awareness and policy-level initiatives that fund and integrate IBCLCs into postnatal care structures may significantly boost breastfeeding continuation rates. Further research with more granular baseline data would be an excellent start for promoting the expansion of IBCLC care and improving breastfeeding rates.

Acknowledgments

This study utilized secondary public datasets from the Centers for Disease Control and Prevention (CDC), the US Census Bureau, and the International Board of Lactation Consultant Examiners (IBLCE) and would not have been possible without their efforts to make this data accessible. This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors. All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations.

In accordance with JMIR Publications' editorial policy on the use of generative AI tools, the authors affirm that no generative AI tools were used in the ideation, drafting, or editing of this manuscript. All content was written, reviewed, and fact-checked solely by the human authors. No text was generated or modified using AI assistance, and no AI-generated references were included.

Data Availability

All data used in this study are publicly available. International Board Certified Lactation Consultant workforce statistics were obtained from the International Board of Lactation Consultant Examiners, breastfeeding outcome data were sourced from the Centers for Disease Control and Prevention's 2022 Breastfeeding Report Card, and demographic data were obtained from the US Census Bureau. No individual-level or restricted-access datasets were used.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic disrupted sexual and reproductive health services, including family planning (FP) and contraceptive services. The World Health Organization conducted a multicountry study in India, Nigeria, and Tanzania to determine the impact of the pandemic on the health system's readiness to provide contraception services and trends in contraceptive uptake.

Objective: This study aimed to determine the status, availability, and health facility readiness to provide contraceptive services and to compare trends in contraceptive uptake before and during the pandemic.

Methods: This cross-sectional study was conducted by the Indian Council of Medical Research-National Institute of Research in Reproductive and Child Health (India), the University of Ilorin Teaching Hospital (Nigeria), and the Ifakara Health Institute (Tanzania). A total of 50 primary health facilities (11 in India, 6 in Nigeria, and 33 in Tanzania) were evaluated using a standardized facility assessment questionnaire, completed by the most knowledgeable senior health care provider or administrator at the facility. Monthly data on service utilization and contraceptive availability were collected to capture trends before and during the COVID-19 pandemic. Data were collected from May to August 2022. The study received ethical and scientific approval from the World Health Organization Ethics Review Committee and Research Project Review Panel and national regulatory bodies. Key outcomes included availability of FP guidelines and tools, service disruptions including contraceptive and abortion services, stock-outs, reasons for service disruptions, and mitigation measures to sustain service deliveries. Descriptive analysis was used to summarize the key trends and patterns.

Results: Health facilities in all three countries reported shortages of various contraceptives. Contraceptive services were partially disrupted in 91% facilities in India, 83% facilities in Nigeria, and 43% facilities in Tanzania. Abortion services were partially disrupted in all surveyed facilities offering these services in India and Nigeria and in 26.7% of facilities in Tanzania. Client visits declined in health facilities in 2020 compared to 2019 in India (30%) and Nigeria (11%), with a gradual recovery thereafter. In contrast, Tanzania experienced a 1% decline in client visits in 2020. Readiness measures such as telemedicine, task shifting, community outreach, triaging, and patient redirection were implemented to minimize service disruptions.

Conclusions: This study provides crucial insights into the challenges posed by the COVID-19 pandemic on contraceptive services and the measures taken to alleviate them. The findings can help countries to better prepare to prevent the disruption of FP and contraceptive services in future pandemics or emergencies.

KEYWORDS

facility assessment; COVID-19 pandemic; family planning; contraceptives; India; Nigeria; Tanzania; World Health Organization; contraceptive; COVID-19; primary health care; mixed method

Introduction

The COVID-19 outbreak was first reported in December 2019, rapidly spreading across the globe and being declared a pandemic by the World Health Organization (WHO) on March 11, 2020 [1]. In an effort to curb the virus's transmission, countries implemented various measures such as international travel restrictions, social distancing, and lockdowns. The virus's highly dynamic nature posed challenges for taking standard coping measures in response to the pandemic. Every nation responded differently to the pandemic. Countries worldwide mobilized their resources to diagnose and treat COVID-19 patients while implementing public health strategies to contain the spread of the virus. Although necessary, this response could disrupt the provision of sexual and reproductive health (SRH) services, including family planning (FP) and contraceptive services, especially in low- and middle-income countries, where health systems are more vulnerable.

Several studies show that the COVID-19 pandemic had a major impact on the availability and provision of contraception, abortion, postabortion, and other sexual health services [2-4]. Supply chain disruptions limited the production, distribution, and availability of contraceptive commodities, resulting in stockouts [5]. Some health care facilities reduced or stopped offering their services [6], some health care providers were redirected to COVID-19 duties [7], and many women were unable to visit health care facilities due to lockdowns or fear of exposure to COVID-19 [8]. Travel to hospitals was disrupted by movement restrictions or reductions in health workers as a result of increasing numbers becoming infected with COVID-19 [9]. This created significant access and availability issues for many individuals who required these services. If the contraceptive needs of women and couples are unmet, unwanted pregnancies will increase, with long-term consequences for both women and their families [10]. It was estimated that significant levels of lockdown-related disruption over 6 months would leave 47 million women in low- and middle-income countries unable to use modern contraceptives, leading to a projected 7 million additional unintended pregnancies [11]. Furthermore, studies have modeled that even a 10% reduction in essential SRH services could lead to an estimated 15 million unintended pregnancies, 3.3 million unsafe abortions, and 29,000 additional maternal deaths in 12 months [10,12,13].

Our study aimed to determine the impact of the COVID-19 pandemic on the health system's capacity to provide contraception services in India, Nigeria, and Tanzania. These countries were selected because they were part of the World Health Organization's FP Accelerator Project [14], with expressed interest from the Ministries of Health to conduct the study. In this paper, we present findings of a health facility assessment, examining the availability of contraceptive services at primary health facilities and their readiness to provide these services during the COVID-19 pandemic. Additionally, we analyze and compare trends in contraceptive uptake in the 3 countries, both before and during the pandemic.

Methods

Study Objectives

The larger study used a mixed methods approach, using both quantitative and qualitative methods. The detailed methods and objectives of the overall study can be found in the published study protocol [15]. There were no deviations from the published protocol. In this paper, we present findings from the cross-sectional health facility assessment (quantitative study). This assessment was conducted in primary health facilities across India, Nigeria, and Tanzania. The primary objectives of the health facility assessment were to (1) determine the status, availability, and health facility readiness to provide contraceptive services in regions or localities most affected during the COVID-19 pandemic and (2) assess trends in the provision and uptake of contraceptive services in the facilities over the past 12 months. In this paper, we compare the findings of the health facility assessment from the 3 countries.

Study Design

This study was a cross-sectional health facility assessment using a structured questionnaire. Health care providers from each health facility were purposively selected to assist in completing the questionnaire. As part of the health facility assessment, we reviewed records related to contraception services to determine the availability, type, and range of contraceptive methods offered.

Settings

In India, this study was conducted by the Indian Council of Medical Research-National Institute of Research in Reproductive and Child Health, in Nigeria by the University of Ilorin Teaching Hospital, and in Tanzania by the Ifakara Health Institute. In the selected geographies, representative rural and urban primary health care (PHC) facilities with qualified staff providing contraception services were selected.

In India, Thane district in the State of Maharashtra was selected because it was one of the worst affected districts by the COVID-19 pandemic in Maharashtra [1]. Administratively, Thane district is divided into 7 talukas. A large part of this district is urban and is administratively governed by 6 municipal corporations. One taluka from an urban area (Navi Mumbai Municipal Corporation) and one from the rural area (Ambernath) were randomly selected [16]. In each taluka, all public health facilities were considered for the study.

In Nigeria, 3 zones (ie, South-West, North-Central, and North-West) of the 6 geopolitical zones were selected purposively. Within each zone, 1 state that is a site for Gates-funded SRH interventions (the Nigerian Urban Reproductive Health Initiative intervention and the Challenge Initiative) was selected for the study: Kwara (North-Central),

XSL•FO
RenderX

Oyo (South-West), and Kano (North West) states. Two high-volume PHC facilities that were providing maternal and child health and FP services were selected within each state (1 in an urban and 1 in a rural/periurban LGAs).

In Tanzania, 3 districts from 3 regions were selected: Temeke district (Dar es Salaam), Nyamagana district (Mwanza), and Moshi urban district (Kilimanjaro). Moshi urban and Temeke districts were selected as they were a part of the Service Availability and Readiness Assessment and belonged to regions with a high number of COVID-19 cases. The Nyamagana district was chosen as it was thought that COVID-19 would impact the urban population more because of their frequent social interactions. All government hospitals, health centers, and a random sample of dispensaries that offered FP services were selected in each district. Data collection was done between May 2022 and August 2022.

Participants

In each health facility, the most knowledgeable respondent about FP and contraceptive services was identified in consultation with the facility-in-charge. This individual was typically a senior health care provider or facility administrator. To be eligible, respondents had to meet the following inclusion criteria: (1) employed at the facility for at least 6 months before the onset of the COVID-19 pandemic, (2) directly involved in the provision of FP and contraceptive services, and (3) knowledgeable about the facility's service readiness and availability of FP and contraceptive services.

Assessments

A structured questionnaire was developed to assess the readiness of health facilities to provide FP and contraceptive services during the pandemic. The questionnaire was adapted from the WHO's SARA tool [17] and the health facility checklist developed by the WHO Department of Health Emergency [18]. Key domains assessed included policies and plans, service maintenance and referrals, facility infrastructure, human resources, and availability of commodities. The questionnaire was translated into local languages at each study site: Hindi and Marathi in India, Yoruba and Hausa in Nigeria, and Kiswahili in Tanzania.

The primary outcomes of the facility assessment included the proportion of health facilities with FP guidelines and tools available, proportion of facilities where regular health services were disrupted during the pandemic, proportion of facilities that maintained FP services as part of essential health services, stockouts of contraceptives during the pandemic, reported reasons for disruption in FP service delivery (eg, interruption of contraceptive services due to facility closures or staff reassignments and supply chain disruptions affecting the availability of contraceptives), and measures taken by countries to mitigate the impact of the pandemic on FP service provision.

Study Size

Health facilities in each country were purposively selected based on geographical location (eg, ease of access and areas with a high incidence of COVID-19 cases), organization of FP and contraceptive service delivery, and epidemic status, where the COVID-19 pandemic was likely to have significantly disrupted service delivery. A total of 50 health facilities were assessed across the 3 countries: 11 in India, 6 in Nigeria, and 33 in Tanzania. Of the 33 health facilities in Tanzania, 3 were government hospitals, 9 were health centers, and 21 were dispensaries. In Nigeria, 4 PHC facilities, 1 district health unit, and 1 maternal and child health facility were included. Of the 11 facilities in India, 5 were urban health posts, 4 were PHCs, 1 was district hospital, and 1 was rural hospital. Table 1 presents the details of the study sites in each country.

XSL•FO
RenderX

Table . Description of study sites in India, Nigeria, and Tanzania.

Country and location	Setting
India (n=11)	
Navi Mumbai Municipal Corporation area, Thane district (urban)	5 urban health posts (PHCs[a] in urban areas) and 1 district hospital
Ambernath block (rural)	4 PHCs and 1 rural hospital
Nigeria (n=6)	
Kwara state, Ilorin LGA[b]	1 PHC (urban)
Kwara state, Afon LGA	1 district health unit (rural)
Oyo state, Ibadan north	1 PHC (urban)
Oyo state, Akinyele	1 PHC (periurban)
Kano state, Dala LGA	1 MCH[c] (urban)
Kano state, Kura LGA	1 PHC (rural)
Tanzania (n=33)	
Mwanza, Nyamagana district	6 dispensaries, 2 health centers, and 1 hospital
Kilimanjaro, Moshi urban district	7 dispensaries, 2 health centers, and 1 hospital
Dar es Salaam, Temeke district	8 dispensaries, 5 health centers, and 1 hospital

[a]PHC: primary health care.

[b]LGA: local government areas.

[c]MCH: maternal and child health.

Data Analysis

In India, data from facility assessments were entered into an electronic database and analyzed using SPSS (Statistical Package for Social Sciences). In Nigeria, the KoboCollect app was used on the research staff's phones to collect data, and it was analyzed using SPSS version 21, whereas in Tanzania, data were collected digitally on tablets using the Open Data Kit platform and analyzed using STATA version 15 software. Descriptive analysis was used to compare the characteristics of the various facilities, including the number of clients, the type of services provided, and the contraceptive stocks.

Ethical Considerations

The WHO Research Project Review Panel granted scientific approval, whereas the WHO Ethics Review Committee granted ethical approval (protocol IDs CERC.0103K, CERC.0103J, and CERC.0103I). In India, the Institutional Ethical Committee of Indian Council of Medical Research-National Institute of Research in Reproductive and Child Health, Mumbai (D/ICEC/Sci-166/175/2021) approved the study protocol. Additionally, permission was obtained from state and district government health officials to conduct the study at the selected sites. In Nigeria, the study was approved by the National Health Research Ethics Committee of Nigeria (NHREC/01/01/2007-07/09/2021), the University of Ilorin Ethical Research Committee (in Kwara state), and State Ministries of Health Ethical Committee (in Kwara, Kano, and Oyo States). In Tanzania, the study was approved by the Ifakara Health Institutional Review Board (IHI/IRB/NO. 44 - 2021) and the National Institute of Medical Research (NIMR/HQ/R.8a/Vol.IX/3916). In addition, the team received permission letters to visit the selected sites from the President's Office, Regional and Local Government.

All participants were informed about the study and signed a written consent before participation. Data were deidentified using unique ID numbers to maintain confidentiality. Participation was entirely voluntary, and no financial incentives were provided. Patients or the public were not involved in the design or conduct or reporting or dissemination plans of this research.

Results

Health Facility Assessment

We compare and summarize the health facility assessment findings from the 3 countries in Table 2 and present a heat map of these findings in Multimedia Appendix 1.

	Tanzania	Nigeria	India
Women who came to facility for postabortion care received FP counseling and services	57.6 %	50 %	69 %
Availability of contraceptive stocks (no stock out in the last 24 months)			
Combined oral contraceptive pill	48.5 %	16.7 %	90.9 %
Progestin-only contraceptive pill	46.9 %	33.3 %	Not applicable
Male condom	51.5 %	33.3 %	100 %
Female condom	43.8 %	16.7 %	Not applicable
Combined injectable contraceptives	63.3 %	16.7 %	Not applicable
Progestin-only injection	50 %	16.7 %	45.6 %
Centchroman	Not applicable	Not applicable	63.4 %
Cycle beads for standard days method	42.4 %	33.3 %	Not applicable
Vaginal ring	66.7 %	66.7 %	Not applicable
Subdermal implant	45.5 %	33.3 %	Not applicable
Copper IUD[h]	53.1 %	50 %	Not applicable
Levonorgestrel IUD	71.4 %	66.7 %	Not applicable
Diaphragm	78.9 %	33.3 %	Not applicable
Emergency contraceptive pill	41.9 %	50 %	100 %

[a]WHO: World Health Organization.

[b]SRH: sexual and reproductive health.

[c]Mainly due to the suspension of female sterilization services. Other contraceptive services were partially disrupted, leading to the upscaling of the community-based distribution of contraceptive commodities.

[d]Abortion services were available at only 2 of 11 facilities surveyed, and at both facilities, abortion services were partially disrupted.

[e]ANC: antenatal care.

[f]IMNCI: Integrated Management of Newborn and Childhood Illness

[g]FP: family planning.

[h]IUD: intrauterine device.

Availability of Policies and Funds for Essential Health Services

Before the COVID-19 pandemic, all facilities in Nigeria and India had policies on the national SRH essential health services package, compared to 94% of facilities in Tanzania (Table 2). All health facilities in India, 83% in Nigeria, and 64% in Tanzania identified a core set of essential health services to be maintained during the pandemic. Additional government funds were allocated to all facilities in India, 64% of facilities in Tanzania, and 83% in Nigeria to ensure the continuation of essential health services. Approximately half of Tanzania's facilities (54%) received the latest WHO guidelines on COVID-19 response and continuity of SRH services, compared to 100% in India and 83% in Nigeria. Overall, India demonstrated the highest preparedness and support for maintaining essential SRH services during the COVID-19 pandemic, with full policy coverage, guideline dissemination, and funding, whereas Tanzania lagged behind in all areas.

Maintenance of Essential Health Services

During the COVID-19 pandemic, the outpatient department (OPD) services functioned normally in all Indian facilities, 91% in Tanzania, and only 17% in Nigeria (Table 2). The OPD services were suspended in one facility in Tanzania. Inpatient services continued to operate as usual in 55% of facilities in India, 58% in Tanzania, and 17% in Nigeria, with suspensions reported in 1 facility each in India and Nigeria. Emergency health services had minimal disruptions in India and Tanzania but major disruptions in Nigeria (only 17% functioned as normal). Community-based care continued normally in most facilities (91%) in Tanzania, 1 in Nigeria (17%), and 4 (37%) in India. Most mobile clinics functioned normally in 73% of Tanzania's facilities, but none in Nigeria. In India, none of the included facilities offered mobile clinics. Thus, all essential health services were majorly disrupted in Nigeria, whereas India and Tanzania managed to maintain most services, with moderate disruptions in inpatient services.

Maintenance of Essential SRH Services

Contraceptive services continued as normal in only 1 facility each in India (9.1%) and Nigeria (16.7%) and 18 facilities

XSL•FO
RenderX

(54.5%) in Tanzania (Table 2). These services were partially disrupted by the pandemic in all 3 countries: 91% in India (mainly facility-based services such as sterilization services, which is the most common contraceptive method accepted overall in India); 83% in Nigeria; and 43% in Tanzania. One facility (3%) in Tanzania reported a complete disruption of contraceptive services, whereas no facility in India or Nigeria faced complete disruption of services. In fact, in India, outreach services were initiated through ASHAs for household distribution of condoms and OC pills. Abortion services were partially disrupted in both the facilities providing these services in India and Nigeria, and in 4 of the 15 (26.7%) facilities providing abortion services in Tanzania.

Antenatal care services were partially disrupted in 36% of facilities in India, 50% of facilities in Nigeria, and 33% of facilities in Tanzania. Facility-based births were not disrupted in India but experienced disruptions in 67% and 20% of facilities in Nigeria and Tanzania, respectively. Routine immunization services were partially disrupted in 46% of facilities in India, 67% in Nigeria, and 24% in Tanzania. One facility in India and Tanzania reported a complete disruption of immunization services. Inpatient critical care services were not disrupted in the Indian facilities, whereas they were partially disrupted in 33% of Tanzanian facilities. None of the included facilities in Nigeria offered inpatient critical care. In Nigeria, Tanzania, and India, emergency room services were partially disrupted in 67%, 16%, and 13% of the facilities.

Overall, Tanzania was the most successful among the 3 countries in maintaining essential SRH services during the pandemic, particularly contraceptive services, whereas India and Nigeria experienced partial disruptions, particularly in facility-based and abortion services. Nigeria was the most severely affected in maternal and child health services. Table 2 depicts the percentage of SRH services not disrupted during the pandemic.

Availability of National FP and Abortion Guidelines/Job Aids and Service Referrals

National FP guidelines, checklists, job aids, and contraceptive stocks were available in all facilities in the 3 countries except for FP national guidelines in 1 Nigerian facility (Table 2). Referrals for FP services were made in 92% of Indian facilities (especially for female sterilization) and 49% of Tanzanian facilities, but none in Nigeria. National abortion guidelines and safe abortion checklists/job aids were available at all facilities in India, whereas in Nigeria, national abortion guidelines were available in one facility (17%), and none had safe abortion checklists/job aids. Tanzania had 52% of facilities with the national abortion guidelines, and 39% with the safe abortion checklists/job aids. FP counseling and services for postabortion care were offered in 50% and 58% of facilities in Nigeria and Tanzania, respectively. In India, 69% (majorly in urban areas) of women received sterilization and IUCD services after an abortion at a health facility. Overall, India had the most robust infrastructure supporting FP and abortion services, including widespread availability of national guidelines, job aids, and referral systems. Nigeria exhibited significant gaps, particularly in abortion guidelines, checklists, and the absence of FP referrals during the pandemic, whereas Tanzania had moderate availability of national guidelines and job aids but limited referral services.

Availability of Contraceptive Stocks at Health Facilities

All 3 countries experienced contraceptive shortages during the pandemic (Table 2). Nigeria faced shortages of various contraceptives, including combined oral contraceptives (83%) and progestin-only pills (67%), injectables (both combined injectable contraceptives and progesterone only; 83%), male (67%) and female condoms (83%), and subdermal implants (67%). Approximately half of the facilities in Tanzania reported a shortage of both combined and progesterone-only pills, female condoms (56%), implants (55%), and emergency contraceptive pills (58%). India reported shortages of progestin-only injectables (55%) and centchroman (36%). Table 2 depicts the percentage of health facilities with no contraceptive stock out. Overall, Nigeria was the most severely impacted, with over two-thirds of facilities reporting shortages of multiple contraceptive methods. Tanzania experienced moderate contraceptive stockouts, whereas India reported fewer disruptions.

Trends in Clients Seeking FP and Contraceptive Services

Data from health facilities were used to track trends of modern contraceptive uptake before and during the COVID-19 pandemic (Figure 1 and Table 3). India saw a 30% drop in clients visiting health facilities for contraceptive services during Q2 2020 (first wave of the pandemic; Table 3), then a recovery with a 35% increase in Q2 2021 compared to Q2 2020. Tanzania showed minimal change with a slight dip (1%) in Q3 2020, whereas Nigeria experienced an 11% decrease in clients in Q4 2020, with a recovery in Q1 2021, followed by a second dip in Q2 2021 (17%). Overall, India demonstrated a strong recovery following an initial sharp decline. Tanzania maintained consistent service use with minimal fluctuation, whereas Nigeria experienced more prolonged disruptions.

Figure 1. Trends in contraceptive uptake at the included health facilities in India, Tanzania, and Nigeria.

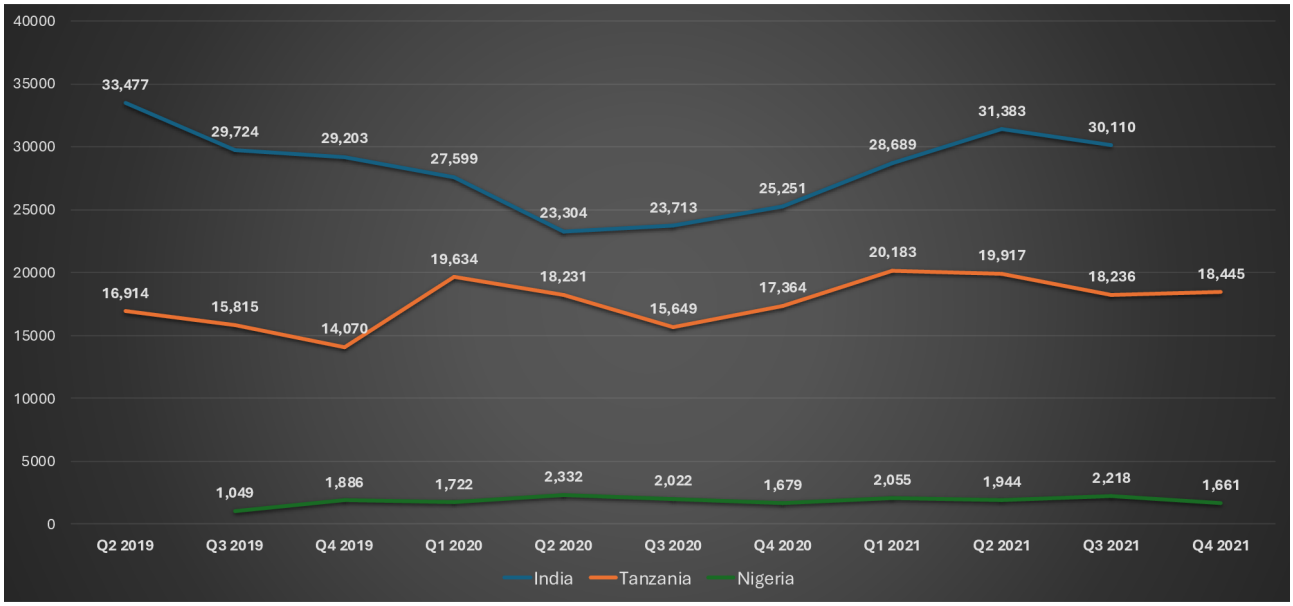

Table . Year-over-year percentage change in the contraceptive uptake at primary health facilities.

	Q1 2020 (%)	Q2 2020 (%)	Q3 2020 (%)	Q4 2020 (%)	Q1 2021 (%)	Q2 2021 (%)	Q3 2021 (%)	Q4 2021 (%)
India	[a]NA	−30.4	−20.2	−13.5	3.9	34.7	30	NA
Tanzania	20.1	7.8	−1	23.4	2.8	9.2	16.5	6.2
Nigeria	NA	NA	10.4	−11	19.3	−16.6	9.7	1

[a]Not applicable.

Main Causes of Disruption or Change in Service Utilization

The causes of service disruption varied among the 3 countries (Table 4). In Nigeria, essential health services were mainly disrupted due to insufficient staffing at health facilities (83%), staff being assigned to COVID-19 services (83%), lack of public transportation (83%), and decreased number of clients at OPD (83%). India experienced disruptions due to a decrease in outpatient volume (54.5%) and lack of public transportation (45.5%). In Tanzania, service disruption was attributed to decreased outpatient visits (68.2%), insufficient staff (68.2%), and inadequate personal protective equipment (PPE) kits (63.6%). Overall, Nigeria experienced severe disruptions driven by workforce and access-driven constraints. India faced moderate challenges due to reduced outpatient volumes and mobility issues, whereas in Tanzania, a combination of decreased demand, staffing limitations, and insufficient PPE were predominant factors. Table 4 compares the major reasons for disruption or change in service usage during the pandemic.

XSL•FO
RenderX

Table . Reasons for disruption/ change in service utilization in India, Nigeria, and Tanzania.

Major reasons for the change in health service utilization	India (%)	Nigeria (%)	Tanzania (%)
Closure of OPD[a] services	0	33.3	4.6
Closure of disease-specific consultation clinics	0	33.3	4.6
Decrease in OPD volume due to patients not presenting	54.5	83.3	68.2
Decrease in in-patient volume due to cancelation of elective care	18.2	50	22.7
Inpatient services are not available	18.2	0	0
Insufficient staff to provide services	36.4	83.3	68.2
Related clinical staff deployed to provide COVID-19 relief	36.4	83.3	50
Insufficient PPE available for healthcare providers	9.1	50	63.6
Stock out of essential medicines, medical diagnostics, or other health products	18.2	66.7	45.5
Changes in treatment policies for care-seeking behavior for fever symptoms	9.1	66.7	31.8
Government transport lockdowns hindering access to health facilities	45.5	83.3	18.2
Financial difficulties during outbreak/lockdown	18.2	66.7	27.3

[a]OPD: outpatient department.

Approaches to Mitigate/Overcome the Disruptions to Essential Health Services

Countries adopted various measures to ensure the continuity of essential health services (Table 5). In India, Nigeria, and Tanzania, 91%, 83%, and 42% of facilities, respectively, implemented task shifting. Telemedicine services were provided by 82% of facilities in India, 50% in Nigeria, and 24% in Tanzania. When services were unavailable, patients were redirected to alternate health care facilities by all facilities in India, 67% of facilities in Nigeria, and 42% of facilities in Tanzania. In Nigeria, 83% of facilities informed the community about service disruptions and changes, whereas this was done by 42% and 18% of facilities in Tanzania and India. All facilities in India and 67% and 55% of facilities in Nigeria and Tanzania triaged clients to identify priority. In Tanzania, Nigeria, and India, user fees were removed in 6%, 17%, and 46% of facilities, respectively.

Table . Approaches used by countries to overcome disruption to essential health services during the pandemic.

Approach	India (%)	Nigeria (%)	Tanzania (%)
Telemedicine	81.8	50	24.2
Task shifting	90.9	83.3	42.4
Novel supply chain for medicines	54.5	33.3	3
Triaging to identify priorities	100	66.7	54.6
Redirection of patients to alternate health facilities	100	66.7	42.4
Community outreach to inform on service disruptions and changes	18.2	83.3	42.4
Government removal of user fees	45.5	16.7	6.1

Discussion

Principal Findings and Comparative Evidence

We determined the availability of contraceptive services in selected primary health facilities during the COVID-19 pandemic and compared the trends in contraceptive uptake before and during the pandemic in India, Nigeria, and Tanzania. Our study revealed that the COVID-19 pandemic resulted in partial disruptions in contraceptive services across the majority of health facilities in India and Nigeria and less than half of the facilities in Tanzania, particularly during the first wave of the pandemic. Notably, 1 facility in Tanzania even reported a complete disruption in contraceptive services. According to the WHO Pulse Survey, conducted in 2020 and 2021, 59% and 44% of countries, respectively, experienced partial disruptions, whereas 9% and 5% reported severe disruptions in FP and contraceptive services [19,20]. A study from South Asia showed a 3% to 31% decline in FP coverage during the period of stringent COVID-19 restrictions in 2020 [21]. Another study from sub-Saharan Africa showed a reduction in FP consultations by 10% to 25% between March and July 2020 in 4 of the 7 countries [22]. Our study noted a decline of 17% and 30% clients seeking contraceptive services in Nigeria and India during the initial wave of the pandemic in 2020, with a subsequent recovery in the number of clients. Literature suggests that despite initial declines during the pandemic, many countries were able to maintain or restore access to essential health services, including FP [13]. A multicountry cross-sectional study (Nepal, Uganda, Niger, and Malawi) reported that the pandemic reduced the number of long-acting reversible contraceptive users from 5% in Nepal to 22% in Malawi [23]. Contrary to the disruptions observed in India and Nigeria, our study showed a consistent increase in the usage of contraceptive services in Tanzania from 2019 to 2021. This upward trend could be attributed to Tanzania's decision to refrain from imposing strict lockdown measures, allowing for unrestricted movement, which enabled them to maintain their FP clients. Similar results were reported from another study from Tanzania, which showed a slight dip in FP usage among existing users in 2020, followed by a rise in the number of new contraceptive users during 2020 and 2021 compared to the same period in 2019 [24]. All 3 countries experienced stock-outs of various contraceptives during the pandemic, affecting 36% to 83% of facilities. The United Nations Population Fund predicted in 2020 that most countries would experience stockouts of 1 or more modern contraceptive methods [8].

Our research identified several factors contributing to the disruption of contraceptive services during the COVID-19 pandemic. Main causes included a decrease in women visiting the facility, lack of public transportation, insufficient staff at health facilities, and staff being reassigned to COVID-19–related duties. These findings align with other studies that highlighted how the pandemic impacted women's access to contraception due to supply chain disruptions, health providers being reassigned to COVID-related duties, and transportation issues caused by lockdowns [20,25-28]. According to the 2020 WHO Pulse survey, the main reasons for disruption in health services were patients not presenting to outpatient care (76%), transport lockdowns hindering access (48%), and financial difficulties during the pandemic (33%). On the supply side, the common causes were cancelation of elective care (66%), staff deployed to provide COVID-19 relief (49%), and insufficient PPE equipment for health providers (44%) [19]. A scoping review on barriers to accessing contraceptive services during the pandemic included fear of infection, lack of transport, cost, longer waiting times, reduced home visits by health workers, and limited availability of contraceptive supplies as the main barriers [2]. Findings from another study in Tanzania indicate factors for disruption in contraceptive services as changes in clinic schedules, fear of COVID-19 infection, and a shortage of contraceptives [24].

Countries implemented different approaches to overcome disruptions owing to the pandemic, such as redirecting clients to alternative health facilities, triaging to identify priorities, task shifting to lower-level health workers, using telemedicine, and conducting community outreach to inform clients about service disruptions. These strategies align with those reported in the WHO Pulse Survey, where triaging was the most common response (76%), followed by telemedicine (63%) and task shifting (57%) [19].

While our study offers valuable insights into how the pandemic affected contraceptive services and the strategies used by countries to address the crisis, it is essential to recognize that the study's geographic coverage is limited, and the number of health care facilities examined was relatively small. These limitations could affect the generalizability of the study's findings. Nonetheless, the study offers crucial insights into the challenges posed by the pandemic and the measures taken to mitigate them.

Conclusions

Our study highlighted varying degrees of disruptions in essential health services and SRH services across the 3 countries. The most significant disruptions were observed in Nigeria, whereas Tanzania experienced comparatively fewer disruptions. Common factors contributing to service disruption in all 3 countries included reduced OPD visits and the lack of public transportation due to the lockdown. Mitigation strategies such as telemedicine, task shifting, triaging, community outreach, and redirection of patients proved effective in alleviating these disruptions. Moving forward, it is crucial for countries to implement and standardize these strategies to be better prepared for future pandemics.

Abstract

Background: By allowing for abortion bans and restrictions to take effect in the majority of US states, the 2022 *Dobbs v Jackson Women's Health Organization* decision portends to have lasting impacts on patient care and the physician workforce. Notably, it is already beginning to impact practice location preferences of US health care workers, evidenced by declining application rates to residency programs in abortion-restrictive states since 2022. Yet, there remains a gap in the literature regarding why this trend exists.

Objective: This study aims to describe what factors are driving the practice location preferences of medical students and physicians after the *Dobbs* decision.

Methods: This study analyzes qualitative data from a web-based, cross-sectional study. In August 2022, a nonprobabilistic sample of physicians and medical students were surveyed on social media about the impact of overturning *Roe v Wade* on practice location preferences, which included the free-text question "Please share your thoughts about the overturning of *Roe v Wade* and how it will affect your decision about your (residency/job or fellowship) programs." A total of 3 independent team members completed an inductive thematic analysis of 524 free responses, resolving differences by discussion.

Results: Approximately 1 in 4 survey respondents also completed the free-response item (524/2063, 25.4%); a total of 219 were medical students, 129 were residents and fellows, and 176 were practicing physicians. Of them, approximately half (261/524, 50.5%) resided in states where abortion bans were in place or anticipated. Those who answered the free-response item were relatively more likely to hail from states with restrictive abortion bans (P<.001) compared to those who did not, with other demographic characteristics being largely similar between the groups. Inductive thematic analysis yielded 2 broad thematic categories: patient-related and workforce-related factors influencing practice decision preferences. The 3 most common themes overall were respondent concerns regarding their patient's access to care (249/524, 47.5%), their desire not to practice or train in a state with abortion restrictions regardless of current residence (249/524, 47.5%), and their personal belief that abortion bans are human rights and/or body autonomy violation (197/524, 37.6%). Some respondents stated that the *Dobbs* decision would not impact their choice of practice location (41/524, 7.8%), and some supported it (35/594, 6.7%).

XSL•FO
RenderX

Conclusions: This study shows that abortion restrictions are having an impact on the practice location preferences of the physician workforce due to both patient care and personal factors. It is important that state policy makers and others who are considering abortion restrictions also consider how to address these concerns of physicians and medical students, to avoid worsening geographic maldistribution of physicians and worsening access to care from physicians for their citizens.

(Interact J Med Res 2025;14:e55035) doi:10.2196/55035

KEYWORDS

Introduction

The US landmark *Dobbs v Jackson Women's Health Organization* decision allowed for widespread restrictions on abortion care, with 14 US states now enforcing total abortion bans and 27 more with bans based on gestational age [1,2]. These include Targeted Regulation of Abortion Providers (TRAP) laws that hamper and criminalize the practice of abortion [2].

While evidence affirms that abortion restrictions have deleterious effects on patient care and public health [3-6], it is important to understand that such policies also impact the health of physicians. A majority of physicians and medical students plan to build families during or after medical training, with thousands desiring pregnancy each year [7,8]. Many rely on infertility treatments, which abortion restrictions hamper [9]. Abortion restrictions, therefore, may deny a significant proportion of the physician workforce comprehensive family planning services, placing them at risk of forced birth [10]. Furthermore, they may also create moral injury among physicians from conflict between personal and professional morals, uncertainty regarding allowable practices, and fear of prosecution [11]. Those who provide abortion care may face increased stigma or even criminalization, depending on the state in which they train or practice. Those who are in restricted states and are not able to provide abortion care may struggle to navigate what is right for their patients versus what is legal, potentially worsening burnout and compassion fatigue [11,12].

Recent analysis from the American Association of Medical Colleges (AAMC) shows that fewer US MD seniors applied for residency positions in abortion-banned states versus nonban states in 2023 [13]. This includes a small but significant decline in the number of applications to obstetrics and gynecology residency programs in restrictive states in 2022 and 2023 [14]. To date, no study has described why physicians hold such preferences. Using an inductive analysis of free-response survey questions from our previous survey, this study aims to describe how state abortion restrictions may influence physicians' and students' decisions about where to live and practice.

Methods

Overview

We conducted a web-based, cross-sectional study for 2 weeks in August 2022. A nonprobabilistic sample of physicians (practicing physicians, fellows, and residents) and medical students were recruited from dedicated physician communities on social media (Twitter [rebranded as X in July 2023], Facebook, and Instagram [Meta Platforms]) through platforms like the American Medical Women's Association and Inside The Match. All physicians and medical students in the United States were eligible to participate, including both those who practice or intend to practice in reproductive health care and those who do not. There was no minimum age for participation. Physicians completed a questionnaire about the impact of overturning *Roe v Wade* on practice location preferences [15]. Respondents reported demographic information and their location preferences for residency (medical students) or fellowship and jobs (physicians). No identifying information was collected.

This analysis focused on the study respondents' stated practice location preferences. Quantitative data from this study were previously published [15]. Survey respondents were offered a free-response question, "Please share your thoughts about the overturning of *Roe v Wade* and how it will affect your decision about your (residency/job or fellowship) programs." An inductive thematic analysis was used [10]. We consulted the Standards for Reporting Qualitative Research to report the study findings [16]. The free-response item was included to allow respondents to contextualize their practice location preferences [17]. The study team is comprised of a medical student pursuing obstetrics and gynecology (OBGYN; SMM), residents in radiation oncology (MSL) and OBGYN (SF), a fellow in Complex Family Planning (AL), and practicing physicians in psychiatry (SAB and JAG) and internal medicine (SJ and VMA). Some team members practice or are training in locations with abortion restrictions, and some practice in less restrictive locations. A total of 4 independent coders (MSL, SAB, SMM, and SF) coded responses until thematic saturation was reached (n=73 for medical students and n=102 for residents, fellows, and practicing physicians) and established the code book through consensus discussion. After establishing the code book, 2 authors coded all responses (n=524), and differences were resolved by discussion. Statistics were done in IBM SPSS (version 29), and group comparisons were calculated with chi-square testing. The CHERRIES checklist for the reporting of internet surveys guided the reporting of the study (Multimedia Appendix 1) [18].

Ethical Considerations

The study was approved as exempt from review by the Institutional Review Board at the University of Chicago (IRB22-1066). Participants provided consent with the opportunity to opt out of the study and were not compensated

XSL•FO
RenderX

for participation. Data were collected without identifiers and are only accessible to study team members.

Results

Demographics

Of the 2063 survey respondents, 524 (25.4%) completed the free-response item. Respondents consisted of medical students (n=219), residents and fellows (n=129), and practicing physicians (n=176). Most identified as cisgender women (391/524, 74.6%). The majority (453/524, 86.5%) of respondents were of reproductive age (less than age 44) and had no children (361/524, 68.9%). Approximately half (261/524, 50.5%) resided in states where abortion bans were in place or anticipated; half (256/524, 49.5%) resided in states where abortion remains legal [19]. Roughly a fifth (114/524, 21.8%) specialized in OBGYN, 13.2% (69/524) specialized in family medicine, and 65.1% (341/524) specialized in another field. The complete demographics of the sample who answered the free-response portion appear in Table 1.

Respondents who answered the free-response item were similar to those who did not by gender (P=.07), race (P=.13), or whether they intended to provide abortion care (P=.22). Respondents in states with restrictive abortion bans (50.5%) were more likely to respond (P<.001) compared with those in a state without restrictive abortion bans (41.7%).

Free-response rates suggest that these qualitative data appropriately represent the spectrum of views on abortion rights and access. Of the overall sample, 82.3% (1698/2063) indicated they would prefer to apply where abortion access is preserved; among them, 23.1% (393) answered the free-response item versus 76.9% (1305/2063) who did not (P<.001). However, of the 9.7% (200/2063) who did not prefer to apply where abortion access was preserved, 41.5% (83) provided a free response, while 58.5% (117) did not (P<.001). Of the 11.1% (229) who indicated that abortion restrictions do not impact their preferences, 32.8% (75) responded versus 67.2% (154) who did not (P<.001).

[a]Includes US medical students (n=188) and international medical graduates applying to US residency programs (n=31).

[b]Nationally, medical students are 47.9% female and 52.9% male, residents and fellows are 46.8% female and 53% male, and practicing physicians are 35.9% female and 64.1% male [20].

[c]Nationally, medical students are 0.2% American Indian or Alaska Native, 54.6% White, 21.6% Asian, 6.2% Black or African American, 5.3% Hispanic, 8% multiple races, and 3.5% other. Nationally, residents and fellows are 0.11% American Indian or Alaska Native, 48.9% White, 26.6% Asian, 6% Black or African American, 9.2% Hispanic, 4% multiple races, and 3.1% other. Nationally, practicing physicians are 0.1% American Indian or Alaska Native, 63.9% White, 19.2% Asian, 3.6% Black or African American, 5.5% Hispanic, 2% multiple races, and 5.6% other [20,21].

[d]Respondents who selected more than one option are considered multiracial for the purpose of this study.

[e]Age 15-44 years is defined as reproductive age per the Centers for Disease Control and Prevention [22].

[f]Includes all 50 states, Puerto Rico, and the District of Columbia. Excludes the 7 respondents who indicated "other" on their location [19].

[g]Alabama, Arizona, Arkansas, Florida, Georgia, Idaho, Indiana, Iowa, Kentucky, Louisiana, Michigan, Mississippi, Missouri, Montana, North Carolina, North Dakota, Ohio, Oklahoma, South Carolina, South Dakota, Tennessee, Texas, Utah, West Virginia, Wisconsin, and Wyoming [19].

[h]Alaska, California, Colorado, Connecticut, Delaware, District of Columbia, Hawaii, Illinois, Kansas, Maine, Maryland, Massachusetts, Minnesota, Nebraska, Nevada, New Hampshire, New Jersey, New Mexico, New York, Oregon, Pennsylvania, Puerto Rico, Rhode Island, Vermont, Virginia, and Washington [19].

Overview of the Inductive Analysis of Free-Response Survey Answers

There were 2 groups of themes and 2 stand-alone themes. One group described how practice location decisions impact patient care (Table 2), and the other captured workforce-related concerns (Table 3). The remaining themes included no impact and antiabortion sentiment.

XSL•FO
RenderX

Table 2. Patient factors influencing decisions about practice location emerging from the inductive analysis of the following: for students applying to residency, "Please share your thoughts about the overturning of Roe v Wade and how it will affect your residency application and ranking decisions below," and for fellows and practicing physicians, "Please share your thoughts about the overturning of Roe v Wade and how it will affect your decision about your job or fellowship programs" among respondents (n=524).

Theme	Students (n=219), n (%)	Example quote	Physicians (n=305), n (%)	Example quote
Patient access to abortion (or reproductive care)	84 (38)	I'm horrified when I imagine taking care of a teenager who is being forced to carry out a pregnancy. I'm terrified of the burden of caring for a NICU filled with babies who were born despite having anomalies that make their short lives painful. I can only hope I'm not assaulted or become pregnant without the option to terminate.	165 (54)	I want to be able to support my patients to make good decisions about pregnancy. I need to be able to refer people if they need termination of pregnancy. It goes against my ethics to have to deprive someone of that option. I care foremost about my patients. If one of my patients died because she couldn't get an abortion, I wouldn't be able to live with myself.
Did not want politics to interfere with medical care decisions	45 (20)	I never want to be in a situation where I face disciplinary and/or legal consequences for reporting a patient who is miscarrying (spontaneous or induced), and with the current climate, I genuinely fear that we may be moving toward the criminalization of abortion in many places. That risk is not worth it to me when I could train in so many other places.	78 (25)	A politician is unable to grasp the grey areas of obstetric care and the heartbreaking scenarios we encounter. It is bad enough that hospital administrators police our obstetric practice; we do not need another non-medical person telling us how to practice evidence-based medicine.
Challenges of providing any reproductive care to patients with an abortion ban	41 (19)	I was previously set on Ob-Gyn, but I am now looking seriously at other fields because of the politics surrounding women's health care. I don't want to have to worry about legal repercussions for providing the best care to my patients. This has strongly turned me away from Ob-Gyn as a medical specialty.	65 (21)	As an abortion provider, I know that as much as I care about serving a population with unmet needs, the inevitability of burnout working in a place where abortion is severely limited would be too much.
Challenges of providing patient care that is not reproductive in nature	15 (7)	It will significantly impact the ability of every physician to provide care to their patients, regardless of their specialty, as many medical conditions are exacerbated by pregnancy status	47 (15)	I'm a dermatologist, and this affects our practice, too! We prescribe Accutane every day, and if a patient does become pregnant while on this drug due to contraceptive failure, we recommend termination. We prescribe lots of other teratogenic drugs as well for many different cutaneous diseases, especially methotrexate. I don't know how I can practice in a state where pharmacists might refuse to fill MTX.

Table 3. Practice location decisions that are workforce-related emerging from the inductive analysis of the following: for students applying to residency, "Please share your thoughts about the overturning of Roe v Wade and how it will affect your residency application and ranking decisions below," and for fellows and practicing physicians, "Please share your thoughts about the overturning of Roe v Wade and how it will affect your decision about your job or fellowship programs" among respondents (n=524).

Theme	Students (n=219), n (%)	Example quote	Physicians (n=305), n (%)	Example quote
Not choosing to practice or train in a state with abortion restrictions	77 (35)	This decision has heavily affected my residency application process. Amazing programs that I've highly considered are now at the bottom of my list.	172 (56)	Just finished residency and specifically did not even consider jobs in states that ban the full spectrum of reproductive healthcare or states that looked like they would consider a ban. Overturning of Roe made me basically have to ignore half the country during my search. But given the job market today, finding a position in a state that allows me to actually care for my patients wasn't hard.
Personal belief that an abortion ban is a human rights/body autonomy violation	63 (29)	States that do not respect basic human rights are not places I wish to live or raise a family.	134 (44)	The overturning of Roe is the overturning of basic freedoms, the right to privacy, and bodily autonomy. It is the first step in overturning other rights. It is removing science from medicine. It threatens all doctors whether they provide abortion care or not. I'm likely to leave medicine, then practice in that environment and take those risks.
Access to training and education in abortion	43 (20)	I want to be part of a program where abortion training is easily accessible, and I will not have to go out of state to get this training. I also want to protect these rights for myself and my future patients.	15 (5)	One of my biggest decisions in choosing my state of residency was to allow me every opportunity to learn about women's care at all levels. The overturning will prevent students and residents from reaching their full potential of learning care for women. It is truly unfortunate that men outside of the walls of understanding of medical knowledge think they have the authority to control not only women's bodies but also the education of those to be able to treat women in emergency settings safely and holistically.
Personal or family access to abortion care or family building	36 (16)	I'm a guy, but what about my daughters in the future? What about a pregnancy complication with my wife? What about my patients? This is the problem when people claim moral high ground on the basis of their religion and are placed into positions of power; you end up with a sort of theocracy.	58 (19)	I was planning on looking for underserved community jobs in Idaho, but now that they have an early abortion ban, I will not be. I am actively trying to get pregnant and won't risk my life to pursue a job.
Geographic ties to states with abortion restrictions limiting relocation	18 (8)	I attend medical school in my home state, which hasn't banned abortion as of yet but might do so in the future. If abortion is banned here, I'll likely still rank in-state programs due to the proximity of my family, but I will not rank out-of-state programs where abortion is banned.	38 (12)	Unfortunately, my answers are influenced by the fact that I live in a state with some of the most restrictive policies and have no ability to move. I cannot simply uproot my life to another state due to my feelings on abortion access. I work here, and my husband works here. My family is here. His family is here. The best I can do is to advocate for change, but I must remain in place as the primary breadwinner in my family.
Challenges recruiting to states with abortion restrictions	0 (0)		18 (6)	I'm a program director and am concerned about how this will affect recruiting talented and eager physicians to our state. Our patients already have difficulty accessing the medical system, so if this decision leads to physicians leaving the state, it will only amplify disparities.

Patient Factors Influencing Decisions About Practice Location

Patient Access to Abortion or Full-Spectrum Reproductive Care

Many physicians and medical student respondents want patients to have access to safe and legal abortion. Respondents specifically highlighted concerns that adolescents, underrepresented minority groups, people in rural communities, and lower-income patients would increasingly face challenges in finding abortion providers, exacerbating health disparities (Table 2).

Physicians also noted that restrictions interfere with their ability to provide or refer patients for abortion care. For example, one stated, "I won't practice in a state that limits my ability to provide or refer my patients for care that is safe and necessary for their health and well-being."

XSL•FO
RenderX

Challenges of Providing Reproductive Care to Patients During an Abortion Ban

Reproductive health care providers anticipate moral distress if they are unable to provide abortion care in circumstances like lethal fetal anomalies or pregnancies resulting from rape or incest. An OBGYN physician explained, “Abortion care and prenatal care go hand in hand. This is a field with a lot of gray areas, and elimination of options will harm those who can get pregnant.” Many physicians feared legal repercussions and were disappointed by a perceived lack of institutional support for evidence-based health care.

Do Not Want Politics to Interfere With Medical Care Decisions

Some respondents expressed concern that lawmakers are interfering with medical care. Others emphasized the role physicians play in advocacy and supporting elected officials in favor of essential reproductive health care. A participant stated, “The government should have no standing in a medical decision between physician and patient.”

Challenges of Providing Patient Care That Is Not Reproductive in Nature

Physicians across various fields were concerned that abortion restrictions would adversely impact their clinical practice. For example, a pediatrician noted, “Working with fetal cardiac patients, it is imperative that my patients have access to abortion services if that’s the choice they make that’s best for their families.” In addition, an oncologist worried about restrictions on chemotherapy regimens, a dermatologist had questions about prescribing common medications (like Accutane) that are teratogenic, and a rheumatologist had concerns about prescribing methotrexate.

Workforce-Related Practice Location Decisions

Choosing Not to Practice or Train in a State With Abortion Restrictions

Many respondents living in states with abortion protections stated that they would be unwilling to move to a state with abortion restrictions (Table 3). Others living in restrictive states intend to move or preferentially apply to and rank training programs in states without abortion bans. Trainees described how these decisions compound their stress regarding the highly competitive match process. Some still felt pressured to apply everywhere, regardless of their personal preferences, stating, “Residency is already so competitive, so unfortunately, I feel like I have to apply everywhere, but I would definitely preferentially rank somewhere that I would have access to abortion care and that my patients would as well.”

Challenges Recruiting to States With Abortion Restrictions

Some residency and fellowship program directors and administrative leadership in states with restrictive abortion laws are concerned about recruiting and retaining residents, fellows, and faculty. Many foresee the reluctance of trainees and faculty to work in restrictive states. A program leader said, “I am an APD at an academic medical center in the Midwest. I have already been told by two residents that they had planned to stay in the state to practice but are now leaving solely because of the lack of reproductive rights in our state. I fear we will rapidly lose amazing physicians.”

Personal Belief That Abortion Restrictions Violate Human Rights and/or Bodily Autonomy

A substantial portion of respondents described the overturning of *Roe v Wade* as a human rights violation and criticized its negative impact on patients’ bodily autonomy. Others discussed the potential moral injury from practicing in a state whose laws and policies prevent clinicians from providing evidence-based medical care.

Respondents connected states’ abortion policies to their overarching sociopolitical climates, noting that bans and restrictions may portend other harmful (eg, racist, homophobic, transphobic) policies. A medical student said, “Extremely cautious about applying to these states who have denied abortion care. Not only because of abortion care but also because these states are notoriously anti-LGBTQ+ and hold racist values. I do not want to live and work and raise a family in that environment, where I am not respected and have less human rights than others.”

Access to Abortion Training and Education

Students applying to OBGYN and family medicine expressed that their application decisions would be shaped by access to proper training in abortion care. Applicants to residency and fellowship recognize that selecting programs in abortion-restricted states may limit access to adequate training. Multiple students noted that they intend to inquire about abortion training during the residency application process.

Some recognized that trainees in abortion-restricted states could seek abortion training out-of-state. For example, a respondent said, “I plan to first rank programs in states with full spectrum reproductive health access, followed by programs that are intentional about providing training for their residents with full support (financial, housing, etc) to leave the state for abortion training.” However, current trainees also discussed challenges in obtaining abortion training, including professional, administrative, and financial barriers.

Geographic Ties to States With Abortion Restrictions Limiting Relocation

Some noted that geographic relocation is a privilege not afforded to everyone equally. The decision to move is often influenced by distance to a support network, job benefits for the respondent or their spouse, housing, and childcare. Such geographic ties discourage or prevent many medical students and physicians from leaving their state of residence despite their personal or professional opposition to abortion restrictions.

Some said they understand the risks of staying in a state with abortion restrictions. If necessary, they would travel out of state to receive an abortion, again recognizing their mobility is a privilege. A respondent said, “I definitely would prefer to be in a state that maintains access to abortion. Unfortunately, those are not states where my family lives, and I am grateful that I

XSL•FO
RenderX

have enough privilege if I needed an abortion, I could leave the state."

Personal or Family Access to Abortion Care or Family Building

Respondents were concerned about practicing in a location that limits their options for receiving comprehensive reproductive health care. Multiple respondents highlighted that they did not want to be forced to carry a pregnancy if they could not get an abortion, especially during training. Others specifically cited medical conditions that would make pregnancy physically challenging and even contraindicated as a reason to ensure they had access to abortion care. A respondent said, "I am a medical student with chronic conditions that make pregnancy life-threatening for me. Although I am on contraceptives, nothing is 100%, and I want to be able to protect my life and well-being in case I do accidentally get pregnant."

In addition, physicians with infertility undergoing in vitro fertilization noted that practicing in a state where life is defined as beginning at fertilization would make family building significantly more challenging. Commonly, respondents stated they were concerned about care for themselves, their children, or their partners, underscoring the importance of recognizing that physicians, too, need access to care.

Additional Themes

No Impact

Few medical students and physicians stated that the *Dobbs* decision would not impact their choice of practice location (Table 4). Some indicated that the residency and fellowship match were too competitive to make decisions based on abortion legislation. For example, those who apply to every program in their field may end up applying to programs in states with abortion restrictions to increase their likelihood of matching.

Table 4. Practice location decisions that are workforce-related emerging from the inductive analysis of the following: for students applying to residency, "Please share your thoughts about the overturning of Roe v Wade and how it will affect your residency application and ranking decisions below," and for fellows and practicing physicians, "Please share your thoughts about the overturning of Roe v Wade and how it will affect your decision about your job or fellowship programs" among respondents (n=524).

Theme	Students (n=219), n (%)	Example quote	Physicians (n=305), n (%)	Example quote
No impact	30 (14)	Matching and getting into a program is challenging enough considering the various factors at play; this decision will not be part of deciding which states or programs I end up applying to.	11 (4)	It will have zero impact on my decisions regarding jobs/fellowships.
Expressed support for overturning *Roe v Wade*	17 (8)	The overturning of Roe v. Wade is long overdue. It was not right in the first place, as the Supreme Court made clear in its ruling. Babies deserve to live inside and outside the womb.	18 (6)	I am supportive of the overturn and believe it will be better for our patients and medical care to ban an inhumane practice like abortion. Human lives in the womb deserve protection just like all of our other patients at any age and ability.

Expressed Antiabortion Sentiment and/or Support for Overturning Roe v Wade

Physicians and medical students who expressed antiabortion ("pro-life") views supported the Supreme Court decision (Table 4). Multiple respondents noted that they would purposefully seek out practice environments where abortion restrictions existed. Reasons for this include not supporting abortion care for any indication, stating that they do not view abortion as health care, a desire to "preserve life," and a desire to "protect the unborn." Multiple respondents discussed that abortion is an issue that should be legislated at the state level.

Discussion

Principal Findings

Our study shows that abortion restrictions will have a substantial impact on the physician workforce in patient care and practice location decisions. The 3 most common themes were patient access to care, not choosing to practice or train in a state with abortion restrictions, and personal belief that an abortion ban is a human rights/body autonomy violation. This study enhances emerging literature about the impacts of abortion restrictions on the physician workforce, including physicians and medical students at all levels of training across all 50 states within both reproductive and nonreproductive health fields.

Respondents shared concerns that abortion restrictions will negatively impact their ability to provide high-quality, comprehensive reproductive care. This was evident among trainees who provide abortion care, like OBGYN residents, who expressed concerns about new or worsening barriers to obtaining foundational skills like first-trimester uterine aspiration at their primary institution [23,24]. OBGYN trainees also cited multiple barriers to obtaining foundational abortion care skills at their primary institutions. Some programs have created away rotation opportunities for residents unable to obtain comprehensive abortion training at their own institutions [25]. However, there are many barriers to these programs, including obtaining state-based medical licenses, getting funding and organizational affiliations in place, and disruptions to families when living in another state [25].

Even within nonreproductive health care fields, respondents shared concerns about the downstream effects of abortion restrictions on clinical training and practice. In the 2 weeks following the *Dobbs* decision, only 38.5% of a list of 187 societies across a wide variety of specialties had made a statement about the decision [26]. Respondents from specialties

XSL•FO
RenderX

that do not provide abortion care noted concern for restricted use of potentially abortifacient or teratogenic medications and worsening health among patients whose physical or mental health will be adversely impacted by restrictions.

Physicians and medical students also worried that abortion restrictions would deleteriously affect their personal health and well-being. Restrictions hold significant health implications for reproductive-age women, a large and growing demographic of the physician workforce [27]. Recent studies have reported that abortion is common among physicians, affirming that physicians, too, need safe, legal access to abortion [28]. This study informs future medical education and occupational health research by elevating trainees' and employees' concerns. As highlighted by the medical student responses on geographic ties and competitiveness of the match process, it is critical to recognize the multifactorial decision-making involved in where to complete residency training. While before the *Dobbs* decision, telehealth may have been able to bridge the gaps in access to abortion care, this is less likely to be possible in the current landscape [29]. Medical schools and hospitals, especially those in restrictive states, must recognize this and prepare to navigate the adverse health, financial, and legal repercussions their employees may face. Otherwise, disparate abortion access may increase health disparities within the physician workforce and threaten its diversity and resiliency [30].

If medical students do not want to practice in states with abortion restrictions in place, it is less likely that they will establish their practice in those locations. In 2022, 55.2% of those completing training established their practice in the same state where they completed residency [31]. The lack of physicians who are willing to practice in states with abortion restrictions can further poor health outcomes in maternity care deserts [32,33]. Idaho is a notable example, where 41% of OBGYN physicians consider leaving and cite restrictive abortion laws as a motivation [34,35]. Idaho has the lowest rate of physicians per 100,000 people in the entire country [34,35].

Some physicians stated that abortion restrictions would not impact them or that they support them. Notably, a subset of "no impact" responders shared that the scarcity of available positions, particularly within highly competitive specialties and for historically marginalized applicants, outweighs their personal opposition to abortion restrictions. Others acknowledged the futility of setting preferences since the match is ultimately complex and multifactorial.

Limitations

This study may be limited by self-selection bias, given its recruitment of medical students and practicing physicians on social media. Of the respondents who did not prefer to apply where abortion access was preserved, a substantial number (41.5%) provided a free response, indicating that we had a spectrum of views on abortion rights. Furthermore, this sample is focused on physicians and does not represent other health care workforce members who are likely also impacted by abortion restrictions.

Conclusion

The findings of this study captured responses to abortion restrictions before the 2023 Match cycle and provided context to the recent AAMC data showing that residency applications disproportionately decreased in restrictive states [13]. Narrative responses bolster our original quantitative data, affirming that access to full-spectrum reproductive health care was highly valued personally and professionally by most physicians [15].

This study shows that abortion restrictions are having an impact on the practice location preferences of the physician workforce due to both patient care and personal factors. It is important that state policy makers and others who are considering abortion restrictions also consider how to address these concerns of physicians and medical students, to avoid worsening geographic maldistribution of physicians and worsening access to care from physicians for their citizens.

Data Availability

The datasets generated during and/or analyzed during this study are not publicly to protect the anonymity of participants due to the sensitive subject matter of this manuscript but are available from the corresponding author on reasonable request.

Authors' Contributions

MSL and SAB contributed equally as cofirst authors. SAB and MSL had full access to all of the data in the study and took responsibility for the integrity of the data and the accuracy of the data analysis. SAB, MSL, JAG, and VMA contributed to the concept and design. All authors contributed to the acquisition, analysis, or interpretation of data. SAB, MSL, SMM, JAG, and VMA contributed to the drafting of the manuscript. All authors contributed to the critical revision of the manuscript for important intellectual content. MSL performed statistical analysis. JAG and VMA contributed to administrative, technical, or material support. JAG and VMA performed supervision.

Conflicts of Interest

None declared.

Abstract

Background: Stroke remains a major cause of death and disability worldwide. Ischemic stroke is the most common type of stroke. Readmissions after hospitalization increase the patient burden and waste health resources.

Objective: This study aimed to calculate rehospitalization rates and explore risk factors associated with rehospitalization in ischemic stroke.

Methods: In this retrospective cohort study, we identified 12,782 patients admitted for ischemic stroke at People’s Hospital of Ningxia Hui Autonomous Region between January 2017 and December 2021. Groups were determined based on the ID number. The most important factors were selected using the Least Absolute Shrinkage and Selection Operator regression model. Stabilized inverse probability of treatment weighting (SIPTW) was used to correct baseline imbalances between groups. The adjusted hazard ratios and Kaplan-Meier survival curves of significant factors after SIPTW were calculated using stepwise backward Cox regression.

Results: A total of 10,727 patients were included in the study. Among them, 12.7% and 7.2% were readmitted within 5 years and 1 year, respectively. Stepwise backward Cox analysis of SIPTW showed that diabetes was the influencing factor for rehospitalization within 5 years (1.15, 1.02 - 1.30) and 1 year (1.21, 1.03 - 1.43). Additionally, the female gender was identified as a protective factor against readmission within 5 years (0.83, 0.74 - 0.93).

Conclusions: Although the rate of rehospitalization varied among patients with ischemic stroke at different time points, the significant factors remained consistent. Therefore, early prevention and treatment methods may be consistent.

(Interact J Med Res 2025;14:e67522) doi:10.2196/67522

KEYWORDS

ischemic stroke; rehospitalization; Least Absolute Shrinkage and Selection Operator; stabilized inverse probability of treatment weighting; cox proportional hazards regression model

Introduction

Because of its high mortality and disability rate, cerebrovascular disease (CVD) seriously threatens human health and brings great pressure to the medical care system, especially in limited-income countries [1,2]. CVD is the primary cause of death and disability in adults in China [3,4]. It is estimated that about 330 million patients experience difficulties from CVD in China [5]. The Annual Report on Cardiovascular Health and Diseases in China (2021) shows that, in 2019, the total number of discharged patients with CVD was 26.8441 million. The total hospitalization expenses of CVD were RMB 136.028 billion.

XSL•FO
RenderX

After adjusting for price factors, the average annual growth rate of total hospitalization expenses for ischemic stroke and hemorrhagic stroke has been 18.82% and 13.51%, respectively, since 2004 [6]. Readmissions are common: up to 22% of individuals experience 30-day readmissions after neurologic hospitalization [7].

High readmission rates may indicate unresolved problems at initial discharge [8], the quality of immediate post-hospital care, a more chronically ill population, or combinations of these factors. High readmission rates are also associated with a substantial economic burden on the health care system and may represent opportunities to reduce avoidable costs [9]. Reduction of readmission rates has become the goal of national health care reform, health insurance, and Medicaid service centers.

To reduce rehospitalization rates in patients with ischemic stroke, it is essential to fully understand preventable and unpreventable predictors that may influence rehospitalization. Previous studies have reported that infection [10], advanced age [11], and diabetes [12] are the most common causes of rehospitalization in patients with stroke. Furthermore, because most readmissions were measured within 30 days of the event, it is unknown whether the reasons for long-term readmissions differ [13].

This study focused on 3 main areas to better understand the factors contributing to rehospitalization in patients with ischemic stroke: the rates of rehospitalization at various intervals (1 year and 5 years), the differences in patient characteristics between those who were rehospitalized and those who were not, and the factors influencing rehospitalization in patients.

Methods

Ethical Considerations

This study followed the principles of the Declaration of Helsinki and was approved by People's Hospital of Ningxia Hui Autonomous Region (2020-KY-053), and the informed consent was waived off by the review boards due to the nature of this research. All data in the manuscript and supplementary materials were anonymized in accordance with ethical standards, ensuring no personally identifiable information could be discerned.

Data Resources and Patients

This is a retrospective cohort study. In 2022, we examined electronic health record data from all patients who were discharged from People's Hospital of Ningxia Hui Autonomous Region between January 2017 and December 2021. The electronic health record data were anonymized and accessed in a secure environment. The data have a hierarchical structure, including medical record number, demographic characteristics, primary and secondary diagnoses, procedures, method of payment, and a total of 642 variables. The hospital enforces rigorous follow-up and intervention protocols for patients with stroke. Qualified specialists in brain and heart health provide guidance on exercise and rehabilitation after discharge via the WeChat app. Public health physicians conduct telephone follow-ups at 3 and 6 months post-discharge, while a professional doctor performs an in-person visit at 12 months. This visit primarily includes blood sample testing, carotid ultrasound examinations, and adjustments to the patient's medication regimen.

The criteria for data included in this study were as follows: (1) patients aged 18 years or older with a principal diagnosis of ischemic stroke (International Classification of Diseases, Tenth Edition [ICD]-10: I63); (2) patients readmitted to any hospital after discharge due to an ischemic stroke-related condition. The first onset of ischemic stroke was considered the index event, and readmission was the endpoint event. Patients discharged from the hospital who were deceased, under 18 years of age, or had incorrect ID numbers and encoding formats were excluded. If the same patient had multiple rehospitalization records, only the first 2 hospitalization records were retained.

Outcome Measures

Rehospitalization for ischemic stroke refers to the same individual being readmitted to the hospital with ischemic stroke as the primary diagnosis. The rehospitalization rate was calculated by dividing the number of patients readmitted after hospitalization by the total number of patients discharged alive during the same period [14].

Rehospitalizations were identified using ID numbers and the main diagnostic code for the disease from the electronic health data of The People's Hospital of Ningxia Hui Autonomous Region from 2017 to 2021. The primary outcome was a 5-year rehospitalization rate, and the secondary outcomes were 1-year rehospitalization rates.

Study Variables

Published relevant literature was reviewed to summarize and integrate the factors involved [7,9,11,12,15-20]. Covariates considered for confounding adjustment included sex, age (<60, 60 - 69, 70 - 79, ≥80), admission route, length of stay (LOS), anemia (D50-64), thyroid disease (E00-07), diabetes (E10-14), dementia (F00-03), parkinsonism (G20), transient ischemic attack and related syndrome (G45), hypertension (I10-15), coronary heart disease (CHD) (I20-25), paroxysmal tachycardia (I47), atrial fibrillation and flutter (I48), heart failure (I50), arteriosclerosis (I70), embolism and thrombosis (I74), acute upper respiratory tract infection (J00-06), pneumonia (J12-18), renal failure (N17-N19), and urinary tract infection (N39.000), treatment (anticoagulants, thrombectomy, thrombolysis, thrombectomy and thrombolysis), and NIH Stroke Scale (NIHSS) score.

Statistical Analysis

The variables of admission route and NIHSS score had missing values; the number of missing values was 5 (0.04%) and 10346 (96.4%), respectively. The missing mechanism was determined to be missing completely at random according to the correlation coefficient matrix between the missing values and other variables (Table S1 in Multimedia Appendix 1) [21]. Therefore, the incomplete data for admission route and NIHSS score were imputed simultaneously using multiple imputations (n=25) with the R package MICE (TNO and University of Twente) [22,23]. Based on the Akaike information criterion (AIC) value, one of the imputed datasets was selected for analysis.

XSL•FO
RenderX

Some previous studies have demonstrated that the Least Absolute Shrinkage and Selection Operator (LASSO) method was superior to traditional methods [24-26]. LASSO regression was used to avoid overfitting and collinearity [26]. Therefore, LASSO analysis was used to select variables to be included in the Cox proportional hazards regression model (Cox model). The "glmnet" package was used to analyze the LASSO regression model [27].

Stabilized inverse probability of treatment weighting (SIPTW) was used to achieve a balanced comparison between the readmission and non-readmission groups. This method helps maintain the original data's sample size and ensures an appropriate class I error rate [28]. Probability was estimated through a logistic regression model with rehospitalization as the dependent variable, considering variables such as age, anemia, hypertension, CHD, length of hospital stay, treatment, urinary tract infection, and NIHSS [29]. The balance of potential confounders at baseline was evaluated using the absolute standardized difference (SMD), where an SMD greater than 0.1 indicated a significant difference in potential confounders between cases and controls [30].

The Cox model was constructed by backward Cox regression using the AIC selection criteria, and the best model was chosen based on the least AIC [31-33]. The "survival" package was used for Cox analysis, and the "MASS" package was used to perform stepwise backward analysis. The log-rank test conducted stepwise backward Cox analysis of significant factors for rehospitalization rates for SIPTW. The Kaplan-Meier curve was obtained using the "survminer" package.

Model Evaluation

Calibration curves were plotted using the "rms" package, which compares the agreement between the model's predicted and observed probabilities [34].

Decision curve analysis was conducted using the 'ggDCA' package to assess the utility of a model in supporting clinical decisions [35].

Clinical impact curves were drawn using the 'rmda' package to evaluate the model's recognition value in rehospitalized patients [36].

A 2-sided *P* value of less than .05 indicated statistical significance. Data screening and extraction were performed using Excel version 2016, and other analyses were carried out using R (version 4.2.2).

Results

The results of the data inclusion procedure are shown in Figure 1. A total of 10,727 eligible patients with ischemic stroke were included in the study. Among all patients, 12.7% (1367) were readmitted within 5 years after discharge, and 7.2% (769) were rehospitalized within 1 year. The Kaplan-Meier curves are shown in Figure 2.

There was a significant imbalance in age, treatment, anemia, hypertension, CHD, and LOS between the 2 groups with or without rehospitalization within 5 years. After using the SIPTW, the SMD did not exceed 0.1. Baseline characteristics are shown in Table 1. Significant differences in age, anemia, hypertension, CHD, diabetes, LOS, and NIHSS were observed between the 2 groups with or without rehospitalization within 1 year. Following SIPTW adjustment, balance was achieved between the 2 groups (Table S2 in Multimedia Appendix 1).

On readmission within 5 years, sex, admission route, diabetes, heart failure, acute upper respiratory tract infection, paroxysmal tachycardia, LOS, embolism, and thrombosis were indicated for inclusion from a 5-year SIPTW LASSO regression. Analyzing the above variables mentioned above, stepwise backward Cox regression after SIPTW showed that the significant variable was diabetes, with a hazard ratio (HR) of 1.15 and a 95% confidence interval (95% CI) of 1.02 to 1.30. As shown in Figure 3, among 3175 patients with ischemic stroke with diabetes, 436 (13.7%) patients with ischemic stroke and diabetes were rehospitalized for treatment within five years. Sex (HR 0.83; 95% CI 0.74 - 0.93) was identified as a protective factor for rehospitalization in patients with ischemic stroke (Table 2). The Kaplan-Meier curves are displayed in Figure 3(B and C).

Sex, diabetes, paroxysmal tachycardia, and urinary tract infection were indicated for inclusion from a 1-year SIPTW LASSO regression (Figure S1 in Multimedia Appendix 1). In the stepwise backward Cox analysis of SIPTW, the significant factor was diabetes (HR 1.21; 95% CI 1.03 - 1.43).

Unweighted stepwise backward Cox analyses are listed in Table S3 in Multimedia Appendix 1.

[a]SIPTW: stabilized inverse probability of treatment weighting.

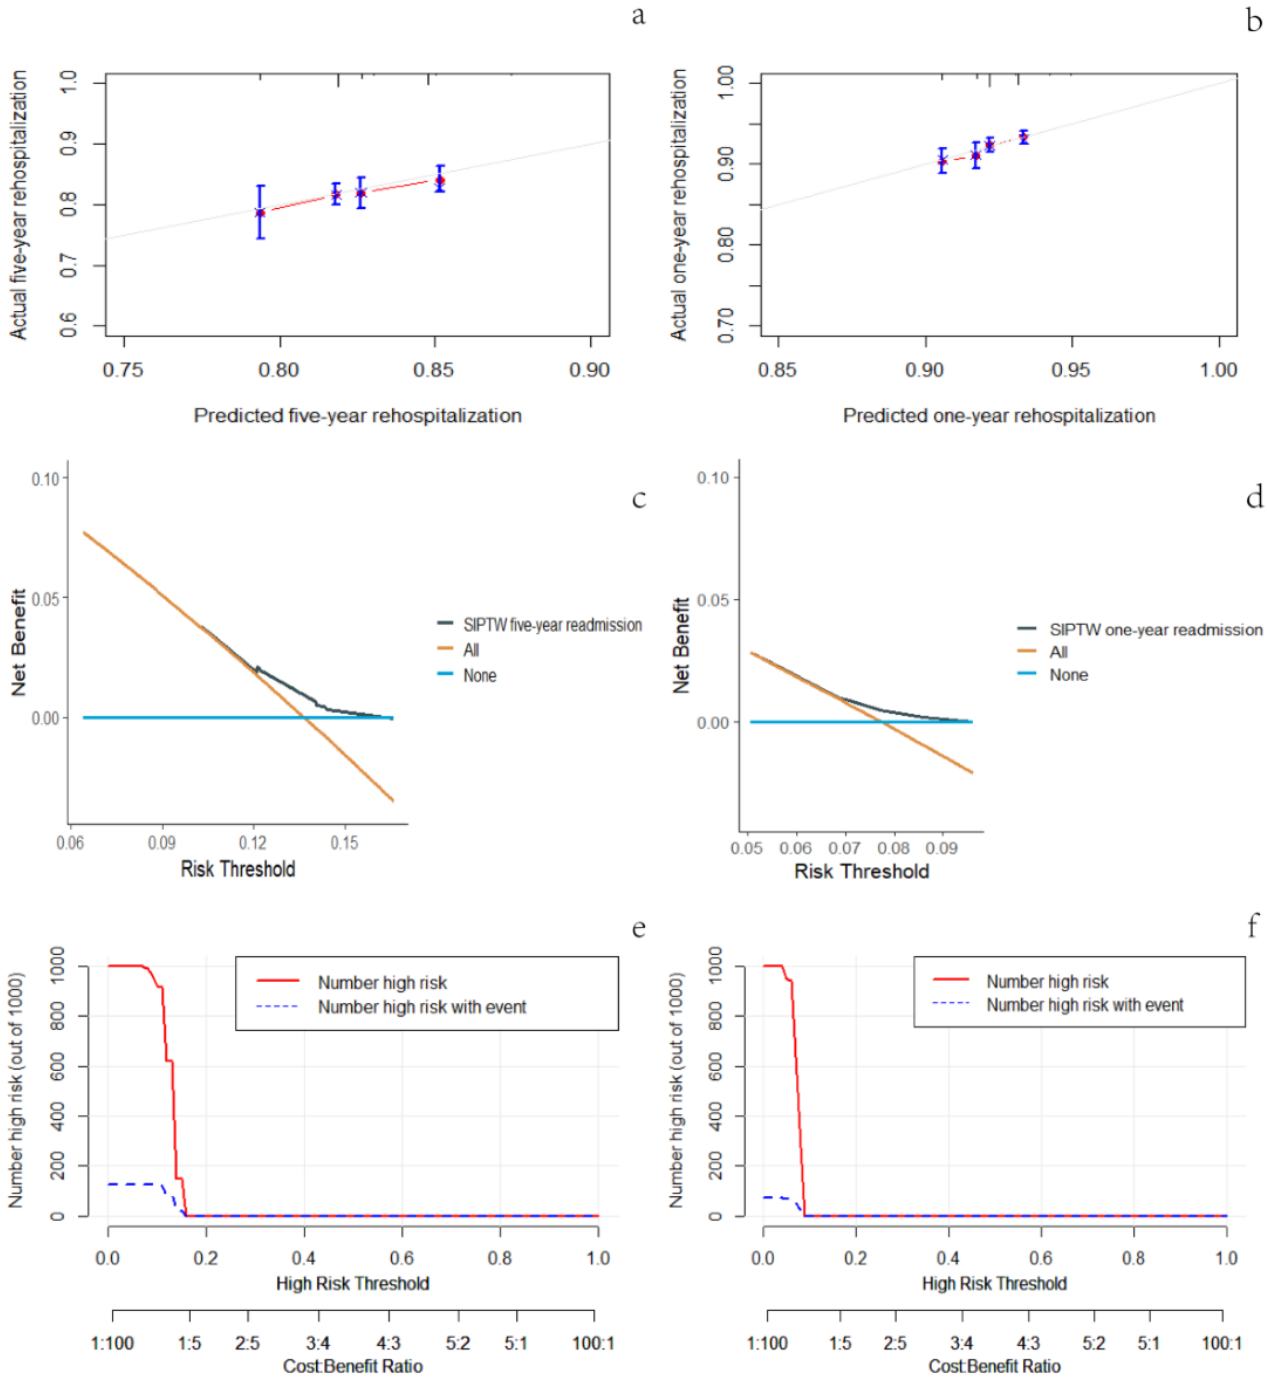
[b]HR: hazard ratio.

Model Validation



After performing SIPTW and stepwise backward Cox analysis, it can be observed from Figure 4(A and B) that the calibration curve of the model closely aligns with the diagonal line, suggesting that the model has good predictive power.

The decision curve analysis of the model indicated that if the patient's risk threshold probability for rehospitalization within 5 years was between 0.074 and 0.165 (Figure 4C), and within 1 year was between 0.057 and 0.096 (Figure 4D), then using the model to determine the need for rehospitalization offers added advantages over the options of full rehospitalization or no rehospitalization.

The clinical impact curve of the model showed that when the risk threshold was greater than 0.13, the high-risk rehospitalization cases of ischemic stroke predicted by the model within 5 years closely matched the true ischemic stroke rehospitalized cases (Figure 4E). When the threshold was above 0.07, the high-risk rehospitalization cases of ischemic stroke predicted by the model within 1 year closely resembled the true ischemic stroke rehospitalized cases (Figure 4F).

Discussion

Principal Findings and Comparison With Previous Works

In this study, there were similarities and differences in the influencing factors of rehospitalization at different times. The SIPTW and unweighted stepwise Cox analyses found gender to be significant among the LASSO regression factors for rehospitalization within 5 years.

A study in Sichuan Province included 1,066,752 patients with stroke with an average follow-up of 1.15 years, with a rehospitalization rate of 23% [37]. Between 1986 and 2001, there were 128,511 stroke hospitalizations in Scotland, and approximately 10.8% of patients were rehospitalized within 5 years due to stroke [38]. A study in Singapore included 12,559 patients with stroke, and the rehospitalization rate for recurrent stroke within 5 years was approximately 18.4% [39]. In our study, the low rate of rehospitalization may be attributed to the effective communication between medical staff and patients and their families upon discharge [40], which improved patient compliance with treatment and the professionalism of the accompanying staff. On the other hand, participants were from a single hospital, and in cases of acute illness, they may opt for medical care from nearby facilities like community general

XSL•FO
RenderX

practitioners or other urban areas in Ningxia or other provinces [41]. Additionally, these patients are typically managed by specialized palliative care teams and may choose not to be readmitted in the event of complications, opting instead for care at the palliative care facility. The COVID-19 pandemic also had an indirect impact on readmission rates, which is primarily reflected in the reduced accessibility of medical resources and changes in patient health care-seeking behavior. Our study did not systematically collect data on telemedicine usage during the pandemic, which may result in a potential underestimation of readmission rates. Future research should incorporate indicators of health care resource utilization to more comprehensively evaluate the long-term effects of the pandemic on the management of ischemic stroke.

Relevant meta-analyses have shown that common patient-related risk factors associated with increased readmission rates include age, heart failure, nephropathy, respiratory disease, peripheral arterial disease, and diabetes [42]. This aligns with the variables initially screened by LASSO regression in this study. In this study, the results of weighted stepwise Cox regression analysis and unweighted stepwise Cox regression analysis are inconsistent due to variations in the distribution of these variables between the non-rehospitalization group and the rehospitalization group in the original cohort data. Through the SIPTW method used in this study, the original dataset is preserved while adjusting for individual differences between groups, leading to a more balanced data distribution and more reliable results [43].

After adjusting for confounding variables, the study found that women patients had a lower risk of re-hospitalization within 5 years. In the analysis of both 5-year rehospitalization and 1-year rehospitalization, diabetes was considered a risk factor, which aligns with findings from previous studies [19,39,44]. This indicates that readmissions are more prevalent among men and individuals with diabetes, leading to higher health care costs [45]. Patients with diabetes exhibit a more pronounced procoagulant state [46] and experience delayed reperfusion of the ischemic penumbra [47], resulting in poorer recovery for patients with stroke. Experimental evidence suggests that hyperglycemia reduces the number of protective non-inflammatory macrophages, thereby increasing mediators of ischemic brain injury [48] and disrupting the blood-brain barrier [49], impacting the prognosis of patients with ischemic stroke.

Strengths

The main strength of this study is that we investigated patients with ischemic stroke at the People's Hospital of Ningxia Hui Autonomous Region over a 5-year period. We conducted follow-ups using electronic medical records from multiple hospitals. We included comprehensive details from the initial page of each patient's medical record for a comparative summary. Additionally, we used LASSO regression to screen factors, used SIPTW to adjust for confounding variables between groups, and conducted backward stepwise Cox analysis to refine the model.

Limitations

This study also has some potential limitations. First, we identified study subjects using ICD-10 diagnosis codes in the database. However, the coding accuracy may vary depending on the complexity of the disease or institution [50]. Second, risk adjustment may be inadequate due to limited information on the case's front page and a lack of clinical details, such as the disease's severity and death information. Laboratory tests for atmospheric environmental indicators are missing. Recent studies have suggested that neutrophil percentage, red blood cell distribution width, alkaline phosphatase [51], and ambient particulate matter pollution of different sizes (PM_1, $PM_{2.5}$, and PM_{10}) [37] influence the readmission of patients with stroke prognosis after discharge. Third, the data came from only 1 hospital, and the findings may not represent other geographical areas or medical institutions, limiting the universality of the results. However, the results of the preliminary screening of factors in this study align with previous research results in different regions. Finally, our study primarily focuses on outcomes during hospitalization and mid- to long-term outcomes. However, it does not include long-term follow-up data after discharge, which limits a comprehensive assessment of patients' long-term functional recovery, risk of recurrence, and quality of life.

Conclusions

In conclusion, our findings suggest inconsistent rehospitalization rates for ischemic stroke disease at different times and that the same factors influence rehospitalization rates. Early prevention and treatment of influencing factors are required for the prognosis of ischemic stroke. Future studies should evaluate whether targeted interventions in populations with high-risk factors reduce rehospitalization rates.

Abstract

Background: Cardiovascular diseases are one of the leading causes of mortality globally. Cardiac rehabilitation (CR) programs are crucial for patients recovering from cardiac events, as they help reduce the risk of recurrent events and support patient recovery. The patient's journey in CR spans the stages before, during, and after the program. Patients have to progress through each stage of CR programs successfully to complete the entire CR journey and get the full benefits of CR programs, but numerous barriers within this journey can hinder patient progression.

Objective: This study aims to explore the barriers to progression at all stages of the CR patient journey from the perspectives of health care providers involved in CR care.

Methods: This qualitative study involved semistructured interviews with health care providers involved in CR care from July 2023 to January 2024. A purposive maximal variation sampling method was used to target providers with diverse demographics and specialties. Snowball sampling was used to recruit participants, leveraging the existing networks of participants. Each interview lasted between 30 and 45 minutes. Interviews were recorded, transcribed verbatim, and analyzed using an inductive thematic analysis approach. Data analysis was conducted from August 2023 to February 2024.

Results: Ten health care providers, comprising 7 females and 3 males, were interviewed. Their roles included physician, program director, nurse manager, clinical manager, nurse coordinator, nurse, physiotherapist, and kinesiologist. The analysis identified four overarching themes related to barriers to progression in the CR journey: (1) patients not being referred to CR programs, (2) patients not enrolling in CR programs, (3) patients dropping out of CR programs, and (4) patients' lack of adherence to lifestyle changes post-CR programs.

Conclusions: In light of the growing interest in technological interventions in CR programs, we proposed 4 potential technological solutions to address the barriers to progression identified in our analysis. These solutions aim to provide a foundation for future research to guide the development of effective technologies and enhance patient progression within the CR journey.

Introduction

Cardiovascular diseases are one of the leading causes of mortality globally [1]. Cardiac rehabilitation (CR) programs are often recommended for patients who have experienced a cardiac event to reduce the risk of recurrent cardiovascular events and support patient recovery [2]. CR programs are comprehensive and multidisciplinary, encompassing exercise training, risk factor management, health education, and psychosocial support [3,4]. Research has shown that participation in CR programs significantly reduces morbidity and mortality associated with cardiac events [5,6] while also enhancing patients' health-related quality of life and psychological well-being [7,8].

The patient's CR journey begins even before enrollment and continues through maintaining lifestyle changes after completing the program [9,10]. It begins with a provider's referral to the CR program, made before discharge from the hospital following a cardiac event or surgery [11]. The journey then involves enrolling in, participating in, and completing the CR program [12]. After completing the program, the journey continues with integrating and maintaining the lifestyle changes and health habits learned throughout the program [13]. Patients must successfully progress through each stage to complete the entire CR journey in order to get the full benefits of CR programs. However, numerous barriers exist within the CR patient journey that could affect progression.

Previous research has identified various barriers in CR, such as low patient interest, comorbidities, travel complications, limited program availability, scheduling conflicts, and financial constraints [14-18]. However, these studies focused only on specific stages of the CR patient journey, such as referral, enrollment, completion, or postcompletion, but not throughout the entire CR patient journey. Understanding the barriers to progression throughout the entire CR patient journey is essential because each stage of the journey is interconnected, and barriers at one stage can influence subsequent stages [19,20]. Moreover, existing studies predominantly focus on the patient's perspective. It is equally important to consider the perspectives of the providers who deliver CR care, as they encounter a diverse range of patients with varying needs. Insights from those who deliver care can provide valuable information on improving CR delivery and addressing barriers effectively [21].

The aim of this study was to explore the barriers to progression throughout the CR patient journey from the perspectives of health care providers involved in CR care. We conducted semistructured interviews with 10 providers and identified 4 barriers to progression within the CR patient journey. In light of the growing interest in technological interventions in CR programs [20,22], we proposed 4 potential technological solutions to overcome the barriers to progression identified in our study. The novelty of our work lies in the identification of barriers to progression from the perspectives of health care providers and the proposal of potential solutions to address these challenges. We hope these potential solutions provide the foundation for future research and guide the development of effective technologies to overcome barriers to progression within the CR patient journey.

Methods

Ethical Considerations

This study protocol was approved by the ethics committees of Carleton University (clearance number 119779) and the National Research Council Canada (clearance number 2023-108). Ethical review was conducted per institutional guidelines, with no exemptions or waivers applied. Written informed consent was obtained before each interview. Participants were informed of their right to withdraw at any time without consequence. No secondary data were used. All data were anonymized to ensure privacy and confidentiality. No compensation was provided to the participants.

Overview

This qualitative study is reported in accordance with the COREQ (COnsolidated criteria for REporting Qualitative research) guidelines [23] (Multimedia Appendix 1). We conducted semistructured interviews to explore the barriers to progression in the CR patient journey from the perspective of the health care providers involved in CR care. We chose interviews to ensure that participants could freely share their thoughts and experiences. The semistructured format allowed us to ask follow-up questions in order to gain an in-depth understanding of their perspectives. In addition, the confidential nature of the interviews encouraged open and honest sharing [24]. Eligible participants included health care providers who refer patients to CR, those who provide CR services, and those who manage CR programs. Eligible participants were also required to be proficient in English. Exclusion criteria included individuals not involved in direct patient care or CR, such as administrative staff. To ensure that the perspectives of a diverse group of participants from various specialties in CR care were included, we used purposive sampling [25]. To further expand the participant pool, we used snowball sampling methods [26]. HF, who has extensive connections with health care providers involved in CR care and CR centers, shared the study objectives and recruitment details within her network. Through this process, she received the email addresses of potential participants. Subsequently, SHR contacted these potential participants via email, providing detailed information about the study and inviting them to participate. We contacted 11 potential participants, of whom 10 agreed to participate, while 1 did not respond. No participants dropped out after providing informed consent. No prior relationship was established between the researcher and the participants before the study commenced, and participants knew only that the researcher was conducting the study as part of an academic project focused on CR.

Data Collection

Data collection took place from July 2023 to January 2024. The interviews were conducted virtually via Microsoft Teams, with each session lasting between 30 and 45 minutes. No repeat interviews were carried out. Each participant was interviewed once during the study. The researcher (SHR), a female PhD student familiar with the subject matter and trained in qualitative

XSL•FO
RenderX

research, conducted the interviews, asked questions and follow-up questions as needed, and took notes during the sessions. While conducting the interviews, the researcher maintained a neutral stance, ensuring that her personal views or assumptions did not influence the questions asked or the participants' responses. The research team collaboratively and iteratively developed an interview script and questions (Multimedia Appendix 2). The questions were open-ended to allow for an in-depth exploration of the providers' perspectives on the barriers to progression in the CR patient journey, with follow-up questions asked when appropriate. We conducted a pilot test of the interview guide with a health researcher to ensure clarity, relevance, and logical flow of the questions. Feedback from this pilot test was used to refine the questions and the interview guide before data collection commenced.

Data Analysis

Our analysis was conducted from August 2023 to February 2024 inductively and did not aim to validate any preexisting theories or hypotheses. We followed a thematic analysis approach following the 6 steps outlined by Braun and Clarke [27]. Two analysts, SHR and a male undergraduate student (DJ) with subject knowledge and qualitative research training, were responsible for the analysis. Disagreements in coding and theme assignment were resolved through consensus facilitated by senior female researchers FR and HF, both of whom are familiar with the subject matter and hold PhDs with extensive experience in qualitative research. We adopted a reflexive approach, acknowledging the influence of researchers' views and experiences [28]. In step 1, both analysts read interview transcripts and took notes. In step 2, they reviewed the first 2 transcripts line by line and identified prominent codes to generate a codebook using NVivo software (version 14.23; Lumivero), which was then applied to subsequent interviews. Codes were iteratively refined every 2 interviews. Step 3 involved systematically grouping codes into candidate themes. In step 4, these themes were compared and refined. In step 5, other team members contributed to further theme refinement. Thematic saturation was assessed using a saturation table that documented the themes found in each interview. Finally, in step 6, we produced a report summarizing our findings. Transcripts were not returned to participants for comment or correction. The analysis was conducted based solely on the interview data collected during the sessions.

Rigor and Trustworthiness

Rigor and trustworthiness were achieved by ensuring credibility, transferability, dependability, and confirmability throughout the research process [29]. To address credibility, we conducted peer debriefing sessions within our research team, which provided an external check on our interpretation of the data, analysis, and coding decisions. Dependability was achieved through detailed documentation of themes and subthemes, providing transparency, and enabling replicability of the coding process. To support transferability, we provided comprehensive descriptions of our study design, participant selection criteria, and data collection methods, allowing others to evaluate the applicability of our findings to various CR settings. As Lincoln and Guba [30] highlighted, confirmability is achieved when credibility, transferability, and dependability are established. We ensured confirmability by documenting the rationale for theoretical, methodological, and analytical decisions throughout the study.

Results

Overview

Ten health care providers, comprising 7 females and 3 males involved in CR care, including a physician, a program director, a clinical manager, a nurse manager, a nurse coordinator, a nurse, 3 physiotherapists, and a kinesiologist, were interviewed (Table 1). The thematic analysis revealed four overarching themes concerning barriers to progression within the CR patient journey, as perceived by these providers: (1) patients not being referred to CR programs, (2) patients not enrolling in CR programs, (3) patients dropping out of CR programs, and (4) patients' lack of adherence to lifestyle changes post-CR programs. Multimedia Appendix 3 provides illustrative quotes within each of the themes identified. Thematic saturation was reached after analyzing 7 interviews [31] (Multimedia Appendix 4). This was determined using a saturation table, where no new themes emerged after the seventh interview. To ensure robustness, 3 additional interviews were conducted, which confirmed the saturation of themes. The early achievement of saturation reflects the shared perspectives of participants, despite their varied roles within CR care.

[a]CR: cardiac rehabilitation.

Patients Not Being Referred to CR Programs

One of the barriers to progression within the CR patient journey is patients not being referred to CR programs, as without referrals, patients may not have access to CR programs (Table S1 in Multimedia Appendix 5). Unintentional biases in referrals, such as those related to health conditions, geography, age, and gender, can contribute to patients not being referred to CR programs. As one provider noted, “There is a lot of inherent bias in terms of who is being referred to rehab” [P3]. Providers may hesitate to refer patients with comorbidities or complex health conditions to CR programs due to concerns about their ability to participate. In addition, if the patient is not residing near a CR center, the provider may assume that it is difficult for the patient to travel and, as a result, be hesitant to refer the patient to a CR program. Providers may perceive that older adults might be frail or disconcerted after a cardiac event or surgery, which may result in providers not referring these patients to a CR program. Some providers may be hesitant to refer certain patients to CR programs, considering their gender-specific responsibilities, such as work, family, and parental roles, which could contribute to women being overlooked for referrals.

Furthermore, another reason for not referring is the providers’ heavy workloads. The paperwork involved in referring patients to CR programs can be time-consuming, which may discourage some providers from making these referrals. Although automatic referral systems are available in some CR centers, providers’ endorsements are crucial for motivating patients; as one provider emphasized, “Endorsements from [providers] are key for [motivating patients]” [P1]. However, individually discussing the benefits of CR with every patient is time-consuming and requires much effort. Referring providers may also lack awareness of the various programs available at the CR center. As noted, “[Referring providers] just don’t know all the services that are available” [P8]. Consequently, providers may hesitate to refer patients due to uncertainty about the programs available. In addition, providers mentioned that it is important to carefully select a CR program that aligns with the patient’s needs, as some programs with high-impact exercises might be appropriate for immediate needs, whereas low-impact exercise-based programs could offer better long-term benefits. However, identifying the best CR program for each patient during referral can be challenging for providers without access to a wholesome list of CR programs.

Patients Not Enrolling in CR Programs

Another barrier to progression in the CR patient journey is patients not enrolling in CR programs after referral. After patients are referred, they must enroll and start the program to benefit from it. Providers mentioned various factors contributing to this nonenrollment (Table S2 in Multimedia Appendix 5). Providers often observed that a substantial number of patients lack awareness and knowledge about CR, with many patients being unaware of its importance and benefits. Providers also noted that patients sometimes hold misconceptions about CR, believing that they can recover by themselves at home or that

XSL•FO
RenderX

surgical treatment alone is sufficient without rehabilitation. Providers think that inconvenient waiting periods also contribute to patients not enrolling in CR programs. For some patients, the waiting period may be perceived as too short after surgery, leading them to feel unready to start the program. Conversely, for other patients, the waiting period between referral and the program's start may seem excessively long. In addition, CR programs are sometimes offered on fixed schedules, where groups of patients begin the program simultaneously. If patients miss the upcoming enrollment window, they will need to wait for the next scheduled start date, which can lead to delays in enrolling in CR programs.

Providers also think that cultural restrictions can prevent some patients from enrolling in CR programs, particularly when there is discomfort or disallowance in mixed-gender sessions due to cultural or religious beliefs. Providers have mentioned that financial barriers are a concern for some patients and can affect their enrollment. Some patients may not have insurance coverage, or they may be unaware of what services their insurance will cover. Financial barriers can also include the costs associated with transportation and parking. In addition, in some CR centers, patients have the option to participate in CR programs virtually through videoconferencing and web-based meeting platforms such as Zoom (Zoom Video Communications). Providers mentioned a lack of technical knowledge and equipment requirements as factors contributing to nonenrollment in these virtual CR (VCR) programs. They noted that patients may encounter obstacles due to the need for reliable Wi-Fi, laptops, tablets, email addresses, and smartwatches to monitor vitals such as heart rate for VCR, which may not be accessible to all patients.

While providers have mentioned several factors for patients not enrolling in CR programs, they believe that some factors remain hidden and express uncertainty about fully understanding why some patients do not enroll in these programs. Providers have also highlighted that while they try to find these factors through patient data recorded in electronic medical records (EMRs), they are unable to fully explore and uncover the underlying reasons solely from EMRs due to missing or insufficient data. As one provider noted, "We try and capture what we can from [the EMR], so we can count visits and things like that within the EMR. It is definitely not perfect" [P7]. Providers expressed the need for a tracking system to understand potential hidden factors that contribute to patients not enrolling. As one provider mentioned, "[We] do need a little bit of like...something to keep track of, because there's quite a few patients that come through. So just to have...what date they start...it is nice to have an overview of the patient's journey" [P8].

Patients Dropping Out of CR Programs

Dropping out of a CR program before completing it is also a barrier to progression in the CR patient journey, as it prevents patients from fully benefiting from the CR program (Table S3 in Multimedia Appendix 5). Providers observed that reproductive and hormonal conditions can deter female patients from completing or fully participating in CR programs. These conditions include concerns about the safety of exercise during pregnancy, managing pregnancy-related fatigue, menopause issues, and menstrual cycle discomfort, such as severe menstrual cramps. In addition, providers recognized that a lack of support is a factor for dropout, including insufficient family support to manage home obligations such as caregiving for children or older adult family members or a lack of peer support for mental and emotional well-being during the rehabilitation process.

Providers noted that low motivation, low self-efficacy, and a lack of belief in one's ability to perform exercises or improve one's lifestyle contribute to a lack of participation and eventual dropout from the program. As one provider mentioned, "They just don't [participate] because they have no motivation to" [P8]. In addition, providers have observed that low accountability in some patients, requiring an external push and motivation from family or providers, can also lead to dropout. Although providers make efforts to encourage patients by emphasizing the benefits of continuing rehabilitation, some patients may still find it challenging to stay engaged with their rehabilitation, which can contribute to dropouts. As one provider mentioned, "We try to help them understand that if they [continue rehabilitation], their health can get better" [P9].

Patients may face several challenges in reaching CR centers, particularly when they lack access to a car or public transportation or when adverse weather conditions, such as extreme heat or cold, are present. Providers mentioned that these challenges in reaching CR centers can contribute to patient dropouts. In addition, the lack of multilingual support and translators in some CR programs can be challenging for patients who need services in other languages. Providers mentioned that these language barriers can also contribute to dropouts. Providers highlight that some patients may be frail due to medical conditions such as shortness of breath, arthritis, or chronic pain, which can prevent them from performing the required exercises, leading to frustration and dropout. Furthermore, in VCR, patients often need to interact with digital interventions for extended periods. Providers mentioned that this prolonged interaction can be one of the factors contributing to dropouts, particularly in VCR.

Patients' Lack of Adherence to Lifestyle Changes Post-CR Programs

Providers recommend that patients continue following the lifestyle changes they learned during the CR program even after finishing the CR program cycle to achieve better health-related quality of life. However, patients sometimes struggle to adhere to these recommendations, which becomes a barrier to progression in their journey (Table S4 in Multimedia Appendix 5). Providers noted that patients could experience persistent feelings of sadness, hopelessness, stress, and anxiety about daily life and responsibilities, which could lower their motivation and hinder their adherence to lifestyle changes. A lack of personal drive could also contribute to not adhering, as patients may struggle to set and achieve personal health goals independently. Providers noted that financial constraints may impact adherence to post-CR programs, with high costs for healthy food, gym memberships, medications, and inadequate insurance coverage preventing patients from fully following recommended lifestyle changes. Providers try to emphasize the importance of physical exercise in maintaining a healthy

XSL•FO
RenderX

lifestyle, but only a small portion of patients follow this advice. As one provider noted, "The reality is that a small percentage of patients, once they graduate rehab, remain as physically active as they were during rehab" [P3]. In addition, providers mentioned that some patients face challenges in performing physical exercises due to factors such as lack of space at home, exercise-induced pain or discomfort, and a lack of resources to fully understand and perform exercises without pain or discomfort. These challenges lead to frustration and doubts about their ability to perform exercises, as mentioned by a provider: "I do get a few [patients] that tell me they're just not interested because exercise is just not for them" [P9]. Providers think that a lack of monitoring and follow-up clinical appointments could also contribute to nonadherence, with insufficient regular feedback on health progress and areas for improvement leading to decreased adherence to lifestyle changes.

Discussion

Technological Solutions

In this study, we explored the barriers to progression in the CR patient journey from the health care providers' perspectives. We identified four barriers that hinder progression in the CR patient journey, such as (1) patients not being referred to CR programs, (2) patients not enrolling in CR programs, (3) patients dropping out of CR programs, and (4) patients' lack of adherence to lifestyle changes post-CR programs. Based on our findings, we recommend 4 potential technological solutions to overcome these barriers: monitoring patients' progress throughout the CR journey using interactive data visualization systems, monitoring physical exercises through automated video analysis–based feedback systems, matching the patients to the right programs using machine learning (ML)–driven predictive analysis, and supporting patients with self-management using targeted natural language processing (NLP) and large language model (LLM) tools. These potential solutions could provide the foundation for future research and guide the development of effective technologies to overcome barriers to progression in the CR patient journey.

Monitoring Patients' Progress Throughout the CR Journey Using Interactive Data Visualization Systems

Health care providers have noticed that some patients in CR programs do not show adequate improvement in their progress, which could be due to the loss of motivation over time. In addition, they have mentioned that there may be other hidden reasons within the CR programs that are impacting patients' progress, making it difficult for patients to take necessary actions to improve progression. Effective monitoring of the patient's progress can help patients stay motivated [32-34] and help providers identify any hidden reasons affecting patients' progress [35,36]. Research has shown that interactive data visualization systems are effective in monitoring patients' progress for both patients [37,38] and providers [39,40]. Based on the success of these systems, we propose the development of interactive data visualization tools for monitoring patients' progress in CR. Patients and providers have different goals and require varying levels of detail in monitoring patients' progress [41]. Therefore, visualization systems should be developed targeting the unique needs of patients and providers with a human-centered approach [42] while involving them in the process of design and development.

For patients, visualization systems can enable them to monitor their progress throughout the CR journey by using EMR and personally collected health data in CR, such as vital signs, exercise performance, attendance, and assessment results. The system can include gamified visualizations [43] and real-life object representations [44] to make it engaging and easier for patients to understand their progress, rather than using complex charts. For example, a patient who visually sees an improvement in heart rate rhythm and blood pressure after regular exercise may feel more encouraged to actively participate throughout the CR journey.

For providers, visualization systems can assist them in monitoring the progress of patients in CR journey and help them identify any underlying reasons that affect patient progression by using aggregated EMR data of patients in the CR center. Providers can use the visualization system to filter and drill down into specific patients or groups based on demographic characteristics, particular cohorts, or specific CR sessions to analyze patients' attendance patterns and improvements or declines in progress [45]. For instance, providers might discover a trend where patients older than 65 years show better progress in heart rate rhythm when exercise sessions are coupled with meditation than when they are offered solely.

Monitoring Physical Exercises Using Automated Video Analysis–Based Feedback Systems

Providers noticed that many patients in CR struggle to perform physical exercises correctly, particularly during VCR and after completing CR programs, where direct supervision from health care providers is not available. Without this supervision and real-time feedback, patients often find it challenging to understand proper exercise techniques, leading to uncertainty about their form and an increased risk of adopting incorrect postures or unsafe practices, which could result in injuries. Recent studies show promising results for monitoring physical exercises with artificial intelligence–powered feedback systems that analyze posture [46,47] and provide real-time exercise feedback through video analysis [48-50]. Building on the success of previous artificial intelligence–powered feedback systems, we suggest developing automated video analysis–based physical exercise feedback systems to guide and monitor patients' exercise techniques and provide immediate corrective feedback.

The system can leverage pose estimation algorithms such as DensePose [51], YOLO-Pose [52], and OpenPose [53] to identify patient posture by detecting joints in real-time video. These algorithms can be trained on a dataset including correct and incorrect postures, as demonstrated and annotated by health care providers [54]. The system can then incorporate mathematical algorithms that calculate the angles between various body joints to classify whether a posture is correct or incorrect [47]. Patients can perform physical exercises while the system captures video through their web cameras. The system would analyze the video feed in real time, classifying the exercise form as correct or incorrect. If an incorrect form is

XSL•FO
RenderX

detected, the system will identify the specific area of the body that is not aligned properly and provide immediate feedback. This feedback could be delivered through text and image overlays, offering suggestions such as "You are doing a great job, but bend more," alongside visual corrections that highlight the areas needing adjustment. In addition, real-time voice prompts could be integrated to help patients quickly understand and adjust their form during the exercise. For example, if a patient is performing a lunge and their front knee extends too far forward over their toes, the system might display a red overlay on the knee area with a voice prompt saying, "Step back slightly to keep your knee aligned with your ankle."

Matching the Patients to the Right Programs Using ML-Driven Predictive Analysis

Health care providers mentioned that patients often drop out early from CR programs, which could be because they are not matched to a program that meets their needs during referral [55,56]. Providers face challenges in identifying which patients are at risk of dropping out and selecting the appropriate program that aligns with those needs, as this process is complex and time-consuming. Previous research has demonstrated the efficacy of predictive algorithms in successfully predicting dropout rates and selecting appropriate programs. For instance, predictive algorithms have been used to predict dropout rates in health care programs [57,58], such as cognitive behavioral therapy for insomnia [59], chronic disease management programs [60], rehabilitation programs [61-63], and for selecting appropriate treatment plans [64,65]. Building on previous research, we suggest that ML-driven predictive analysis algorithms can be developed to proactively identify patients at heightened risk of dropping out from CR programs based on their characteristics and historical program outcomes and suggest the most suitable CR programs for each patient.

These algorithms can be developed using various ML models. For example, logistic regression [66] or naive Bayes models [67] can assess how specific patient factors influence the likelihood of dropout. Random forests [68], or eXtreme Gradient Boosting models [69], can be used to identify which factors (or combinations of factors) are most predictive of dropouts. Gradient boosting machines [70] or support vector machines [71] can then predict dropout risk and recommend the most suitable CR programs based on the identified factors. These algorithms can be trained using historical patient data such as age, gender, location, marital status, education level, socioeconomic status, comorbidities, and previous CR program and health outcomes (eg, completion, dropout, improvement in cardiac health, readmission, or relapse). Once trained, the algorithm can be used to match new patients to the right CR program at the point of referral. By comparing the characteristics of new patients with those of previous patients who dropped out, the algorithms can pinpoint factors associated with dropout risks, such as irregular attendance or poor performance in rehabilitation sessions. The algorithm can generate risk scores that indicate the new patients' likelihood of dropout. It can then recommend the CR program that has historically yielded the best outcomes for patients with similar profiles. For instance, a 65-year-old patient with a history of diabetes and hypertension and a 90% dropout risk due to long travel distance might be matched with a program offering fewer inpatient visits or a virtual option, emphasizing dietary management and low-impact exercises based on the success of similar profiles in historical data.

Supporting Patients With Self-Management Using Targeted NLP and LLM Tools

Providers observed that many patients in CR face difficulties in self-management. This includes difficulties in independently setting their health goals and finding reliable answers to their health-related questions outside of their scheduled appointments with providers. To help patients set their health goals on their own, NLP-based automated goal-setting tools have been shown to be effective in various medical conditions such as hypertension [72], HIV [73], stroke [74], and aphasia [75]. Similarly, to help patients find answers to their health-related questions, LLM-based chatbot solutions have been shown to be successful, particularly, for patients managing chronic diseases [76], inflammatory bowel diseases [77], and breast cancer [78]. Building on the effectiveness of these tools in various medical conditions, we suggest developing targeted NLP- and LLM-based tools specifically for patients in CR. NLP-based tools, such as mobile apps or web interfaces, can assist patients in setting personal health goals in CR. LLM-integrated chatbots can help patients find answers to their questions and enhance their understanding throughout their CR journey.

For goal setting, NLP-based tools can allow patients to input detailed information about their health conditions, preferences, goals, and obstacles in their own words. Using NLP techniques, the tool can use intent recognition [79] to identify patient objectives, entity extraction [80,81] to categorize health conditions and challenges, and sentiment analysis [82,83] to assess emotional states and motivation levels. Based on this analysis, the technology can generate personalized goals using the SMART (Specific, Measurable, Achievable, Relevant, Time-bound) framework [84]. Patients can also review, refine, prioritize, and track their goals over time. For example, if a patient wants to "exercise more" but struggles with "low energy levels," the technology could suggest a goal based on the SMART framework, such as "Walk for 20 minutes, three times a week, and gradually increase the duration as energy improves."

To provide answers to patients' questions, targeted LLM-based chatbots can be trained on CR-specific educational resources, a database of frequently asked questions by patients in CR, and anonymized patient-provider conversations specific to CR. The chatbot should be capable of providing CR education, detailed explanations to patients' questions; offering empathetic responses and coping strategies for managing stress, anxiety, and other emotional challenges; and assisting patients in finding support groups and educational materials tailored to their needs. If patients have questions anytime throughout the CR patient journey, they can access the chatbot. For instance, if a patient asks how to safely continue their exercise routine at home while experiencing menstrual cramps, the chatbot could recommend gentle stretching exercises or advise reducing workout intensity while encouraging confirmation of this guidance with their provider at their next appointment [85].

Limitations

While our study aimed to capture the perspectives of health care providers from various specialties involved in CR care, the use of snowball sampling may have introduced selection bias, as participants were primarily recruited based on a research collaboration network. Although we reached thematic saturation after 7 interviews, indicating common barriers across providers from different specialties, the small sample size of 10 participants may not fully reflect the diversity of perspectives, particularly as we did not include providers from other countries. In addition, despite following rigorous methodological standards, the qualitative analysis remains interpretative by nature and may be subject to researcher bias [84]. As with any qualitative study, the rigor of our findings should be judged by their resonance and plausibility rather than their generalizability. Furthermore, our findings may not be transferable to other CR centers that differ in resources, cultures, or geographical settings [85].

Conclusions

The objective of this study was to explore the barriers to progression in the CR patient journey from the perspectives of health care providers involved in CR care. Our findings show that patients not being referred to CR programs, patients not enrolling in CR programs, patients dropping out of CR programs, and patients' lack of adherence to lifestyle changes post-CR programs are the 4 barriers to progression as perceived by providers. We also proposed 4 potential technological solutions to overcome the barriers identified through our study. Future work should focus on designing, developing, and evaluating the technological solutions proposed in this study to overcome the barriers to progression in the CR patient journey.

Acknowledgments

This study was funded by the National Research Council Aging in Place program and the Natural Sciences and Engineering Research Council (NSERC) Discovery Grant. The authors are grateful to all the participants for sharing their invaluable perspectives, without whom this study would not have been possible.

Abstract

Background: The transtheoretical model (TTM) explains behavior changes through sequential stages influenced by the balance of perceived benefits and barriers. Although previous studies have identified the inhibitors and facilitators of exercise behavior, only a few have elucidated how these factors vary across the stages of behavior change.

Objective: This study aimed to identify the inhibitors and facilitators of each stage of behavior change using text mining.

Methods: A nationwide cross-sectional study was conducted using an internet-based questionnaire with a panel of approximately 2 million members. From this panel, 93,460 individuals were randomly selected and invited to participate via email and app push notifications. A total of 1500 valid responses were included in the analysis through stratified sampling based on sex, age group, and geographic region. The participants self-assessed their stages of change. Two open-ended questions captured the perceptions of inhibitors and facilitators of exercise behavior. Text responses were analyzed in a 4-step process: morphological analysis to extract frequently used words, correspondence analysis to visualize relationships between frequently used words and the 5 change stages, conceptual categorization with coding rules, and creation of heat maps to illustrate stage-specific categories in inhibitors and facilitators.

Results: Out of 1500 respondents, 754 (50.3%) were males and 355 (23.7%) individuals were in the 50 - 59 age group. Stage percentages were precontemplation 24.3% (365/1500), contemplation 23.5% (352/1500), preparation 21.3% (320/1500), action 5% (75/1500), and maintenance 25.9% (388/1500). The inhibitors and facilitators were described using 9893 words and 8372 words, respectively. Inhibitors clustered into 7 categories; most frequent were time (408/1500, 27.2%), motivation (253/1500, 16.9%), health (189/1500, 12.6%), and working (158/1500, 10.5%). Facilitators formed 8 categories; most frequent were subjectivity (155/1500, 10.3%), relationship (93/1500, 6.2%), opportunity (84/1500, 5.6%), reward (78/1500, 5.2%), and record (78/1500, 5.2%). Stage-specific patterns emerged: inhibitors shifted from motivation and health (precontemplation) to family, time, and working (contemplation and preparation), opportunity (action), and weather and health (maintenance). Facilitators of reward, health, and record rose progressively from precontemplation to maintenance.

Conclusions: This study enhances our understanding of the dynamic mechanisms underlying exercise behavior change by identifying how specific inhibitors and facilitators vary across behavioral stages. The findings underscore the need to tailor interventions based on individuals' readiness to change, rather than relying on one-size-fits-all strategies. For both practitioners and policymakers, incorporating behavioral stage frameworks into assessments and interventions, such as those conducted during health checkups or workplace programs, may improve the effectiveness and sustainability of physical activity promotion.

KEYWORDS

transtheoretical model; text mining; exercise; inhibitor; facilitator

Introduction

Exercise habits can improve mental and cardiovascular health [1,2]. A key health policy guideline for Japan, "Health Japan 21," placed a high priority on exercise habits, with the goal of increasing the percentage of people with exercise habits from 28.7% in 2019 to 40% by 2032 [3]. In this guideline, "exercise habits" are defined as engaging in exercise for at least 30 minutes per session, at least twice a week, and continuing for at least 1 year. Despite this policy target, the exercise habit rate has decreased to 27.3% in 2023 due to the coronavirus disease

XSL•FO
RenderX

2019 epidemic [4]. The focus is on providing effective interventions to promote exercise habits.

The behavior change process is explained using the transtheoretical model (TTM) [5,6]. The model categorizes the process of behavior change into 5 stages—precontemplation, contemplation, preparation, action, and maintenance—assigns individuals to one of these stages, and conceptualizes each stage as dynamically evolving over time. Various factors are associated with the acquisition of exercise habits, including individual characteristics, societal norms, culture, and the environment [7]. In the TTM, the psychologically influential factors are categorized into cognitive process of change, intrinsic mental shifts, and behavioral process of change, which are influenced by environmental and external support [8]. In addition, a person's stage can change depending on the balance between perceived benefits and barriers to exercise. Interventions designed using the TTM have been shown to be highly effective in changing behaviors [9]. Unlike other models that focus solely on intention or beliefs, such as the health belief model or the theory of planned behavior, the TTM is uniquely suited to capture temporal changes and stage-specific factors. This makes it particularly appropriate for identifying which facilitators and inhibitors are most relevant at each stage of exercise behavior. Furthermore, in Japan, the TTM has been applied in public health efforts such as the implementation of "tokutei-kenko-shinsa" (specific health checkups), a nationwide preventive health screening program targeting metabolic syndrome. Thus, the TTM has both theoretical and practical relevance for understanding and promoting exercise behavior in the Japanese population [10].

Factors influencing behavior change can be divided into inhibitors and facilitators [11]. Inhibitors include diseases, psychological barriers, time constraints, and poor access to exercise environments. Facilitators include self-efficacy, positive feelings toward exercise, good health, and social support [11]. The extent to which these factors influence exercise behavior varies depending on the individual stages of behavior change [12]. A previous study has found that physical, mental, and environmental barriers have a significant influence on the precontemplation and contemplation stages, perceived behavioral control is significant in the contemplation stage, and self-efficacy and social support play a significant role in the action and maintenance stages [13]. The relationship between these factors and the stages of behavior change is complex [14].

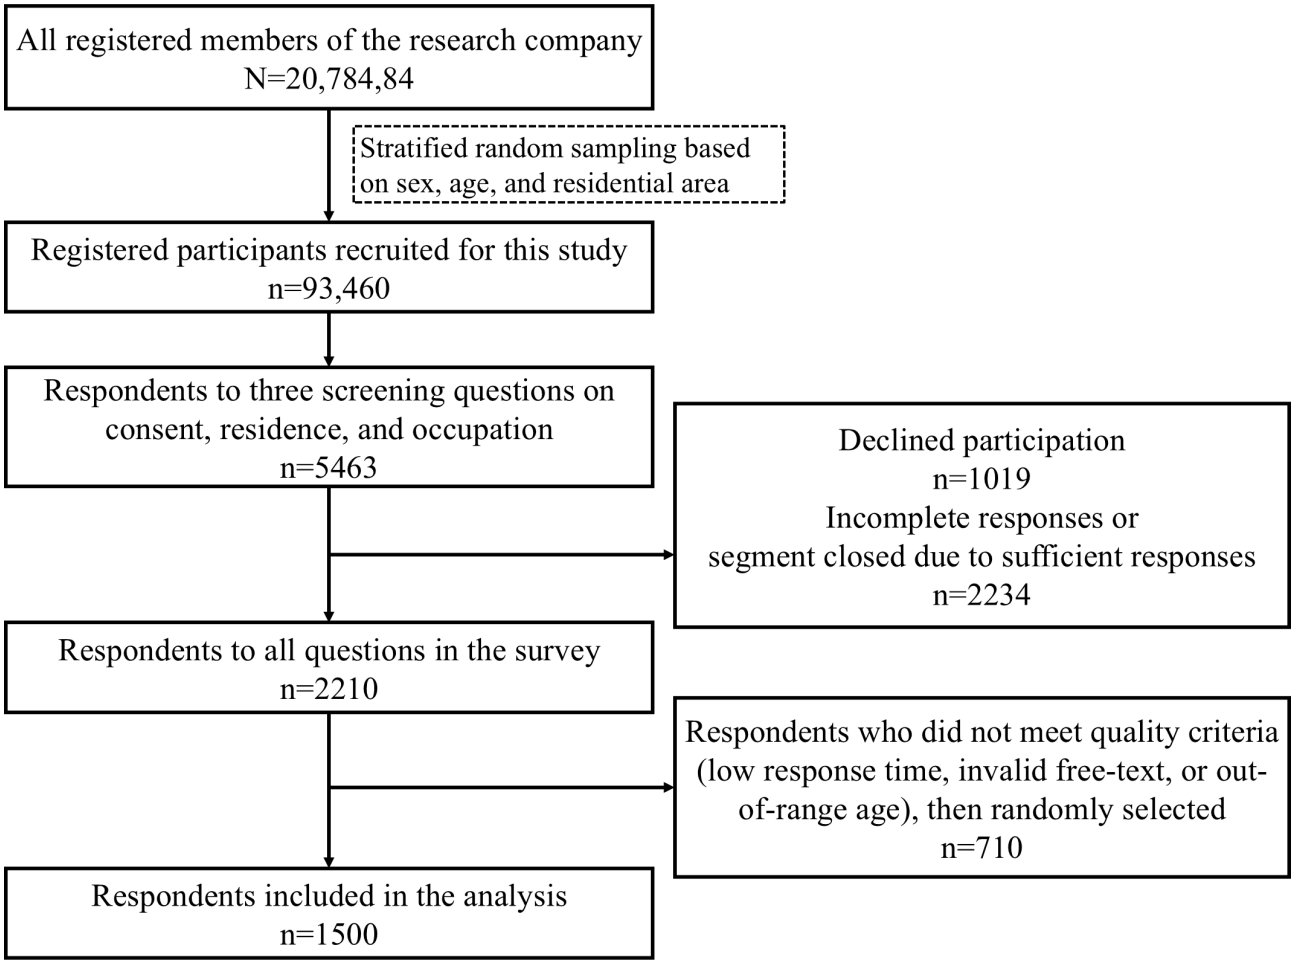
Recently, text mining has been recognized as an effective method for elucidating increasingly complex phenomena [15,16]. Previous studies aiming to identify inhibitors and facilitators of exercise habit have collected qualitative data through semistructured interviews and focus group discussions, which were then analyzed and interpreted by researchers to identify and categorize key concepts [11,13,17,18]. Text mining enables the visualization and quantitative evaluation of relationships between words in free-text responses and respondents' demographic characteristics. Text mining has been used in various public health studies, leveraging its high reproducibility and capacity to process large volumes of data [19,20]. Studies using text mining to analyze the influential factors in the exercise habits have been limited to college students and workers in specific occupations [21,22]. To the best of our knowledge, no previous studies have used this method to analyze the relationship between behavior change stages and both inhibitors and facilitators. Text mining may yield valuable insights into the inhibitors and facilitators, as well as elucidate the complex relationships between these factors and their respective stages.

This study aimed to identify the inhibitors and facilitators of each stage of behavior change using text mining. Unraveling the complexity of the factors influencing behavior change will deepen our understanding of exercise habit formation and support the development of individualized interventions.

Methods

Study Design and Participants

This was a nationwide cross-sectional study in Japan using an internet questionnaire survey, which was administered in November 2024. The survey was conducted by Rakuten Insight Inc, a web-based research firm in Tokyo, Japan. It was one of the largest and most widely used web-based research providers in the country, with a panel of approximately 2 million members. The company has also been used in previous peer-reviewed public health research [23,24]. This study was reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for cross-sectional observational studies (Checklist 1) and the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist for Internet-based surveys (Checklist 2) [25,26].



The participants were recruited from the company's registry. The inclusion criterion was aged 20 - 69 years living in Japan. To ensure a representative sample, stratified sampling was used across 200 segments based on sex (male and female), 5-year strata age groups, and 10 geographical regions (Hokkaido, Tohoku, North Kanto, South Kanto, Hokuriku, Tokai, Kinki, Chugoku, Shikoku, and Kyushu) in accordance with the distribution of population estimates from the 2020 census [27]. Surveys were conducted until 1500 valid responses were obtained, with target sample quotas established for each segment. The sample size was determined pragmatically as the maximum number of responses that could be obtained within the available budget. The questionnaire consisted of one question per page, totaling 21 pages. Respondents were able to review and change their answers before final submission.

Figure 1 illustrates the process of selecting participants for the final analysis. From a pool of 2,078,484 registered members of the survey panel, 93,460 participants were invited to take part in the study via email and push notifications through the company's app. These participants were selected using stratified random sampling based on sex, age, and residential area. Of these, 5463 individuals responded to 3 initial screening questions regarding their consent to participate, place of residence, and occupation. A total of 3253 individuals were excluded at this stage due to declining participation, providing incomplete responses, or belonging to quota-saturated demographic segments. Among the 2210 individuals who responded to the

XSL•FO
RenderX

survey, 1500 were randomly selected for analysis using the following procedure. First, a validity flag was assigned to samples that met predefined criteria. Before flagging, respondents were excluded if they (1) had response times below a threshold (defined as less than the median response time multiplied by 0.3 for PC users or 0.2 for smartphone users), (2) provided clearly inappropriate answers in free-text fields, or (3) reported an age outside the target range (18 - 79 y). Next, a random number was assigned to each valid sample using the RAND function in Excel, which generates a random number between 0 and 1. The samples were then sorted in ascending order based on the random number, and the top 1500 were selected for inclusion in the final dataset. Cookies and IP addresses were not used in this survey. This was a closed survey conducted through a commercial Internet survey company. Respondents were required to log in with their unique panel ID before accessing the questionnaire. Once a panelist had completed the survey, the questionnaire was no longer displayed upon subsequent logins, thereby preventing duplicate entries.

Figure 1. Flowchart of participant selection for analysis.

Assessment of Behavior Change Stage in the Transtheoretical Model

Behavior change stage was measured using the Japanese version of the Stages of Exercise Behavior Change Scale, which has been validated in Japanese populations and shown to have acceptable reliability and construct validity [28]. This required respondents to select the appropriate item from the following 5 options: precontemplation, "I currently do not exercise and do not intend to exercise for the next 6 months;" contemplation, "I currently do not exercise, but I intend to exercise within the next 6 months;" preparation, "I currently exercise but not regularly;" action, "I currently exercise regularly, but I have only begun to do so within the past 6 months;" and maintenance, "I currently exercise regularly and have been doing so for >6 months." Regular exercise was defined as exercise lasting >20 - 30 min per set, 2 - 3 times per week.

Assessment of Inhibitors and Facilitators for Exercise

We collected free responses regarding the inhibitors and facilitators of exercise using 2 open-ended questions. To elicit open-ended responses, participants were presented with the following prompts: (1) For inhibitors: "What kinds of obstacles do you face in continuing your exercise habits? Please describe them in as much detail as possible." (2) For facilitators: "What kinds of things have helped or supported you in continuing your exercise habits? Please describe them in as much detail as possible."

Participants were instructed to list as many ideas as they could think of and were encouraged to be specific. These questions were mandatory, and respondents could not proceed to the next section without entering a response.

XSL•FO
RenderX

Assessment of Respondents' Characteristics

The demographic information of the respondents, including sex (male and female), age (20 - 69 y) at the date of response as identified by date of birth, marital status (married, never married, and divorced or deceased), education (junior or high school, vocational school or junior college, university, graduate school, currently enrolled, and other), and household income (<2.0, 2.0 - 3.9, 4.0 - 5.9, 6.0 - 7.9, 8.0 - 9.9, 10.0 - 13. 9, and ≥14.0 million Japanese yen; US $1 = ¥150, based on the average exchange rate in November 2024), was collected.

Statistical Analyses

The text mining analyses were performed in 4 steps. Statistical analysis was performed using KH-coder (version 3.02c official package, SCREEN Advanced System Solutions Co, Ltd) [29]. KH Coder was initially developed as an open-source software for academic research and gained wide recognition due to its accessibility and functionality. Over time, its analytical methods were validated through numerous peer-reviewed publications across fields such as public health and social sciences [16,19,20,30]. Its core methods—such as morphological analysis, co-occurrence networks, and correspondence analysis—have been repeatedly used to analyze publicly available text data, thereby ensuring transparency and reproducibility. The consistency of results reported across independent studies provides evidence supporting the methodological validity and reliability of this software. We analyzed the descriptions in Japanese and translated the words into English.

Morphological Analysis

In the first step, we performed a morphological analysis to determine frequently used words, their parts of speech, and the number of occurrences using the text-mining dictionary ChaSen Morphological Analyzer, which was the default engine in KH Coder and has been widely selected for its compatibility and proven utility in academic research settings [16,20].

Correspondence Analysis

In the second step, we performed a correspondence analysis to visualize the relationship between the top 40 most frequent words and the 5 stages of change, stratified by inhibitors and facilitators. Correspondence analysis was classified as a multivariate analysis and selected when the variables were categorical data. This method aids in visually understanding the relationships among categorical data, which can be represented using a 2D scatterplot [31]. Categories located farther from the origin and closer to the direction of self-rated health levels were considered more specific. Correspondence analysis is often used in marketing to visualize the associations between multiple categorical variables and consumer characteristics. In the field of public health, we have applied this method in our previous research to identify key personnel responsible for employee health management in the workplace and to determine appropriate marketing strategies through various media channels [30].

Conceptualization and Coding Rules

In the third step, we conceptualized the descriptions into several categories from the frequent word lists of inhibitors and facilitators. The coding rules were developed through an iterative process by the first author (KS) who has published multiple peer-reviewed studies using text mining, in collaboration with KF. To ensure the contextual validity of the coding rules, all free-text responses were read in full before conducting morphological analysis. After extracting the frequently used words through morphological analysis, 2 researchers independently reviewed all responses containing those words to understand the specific contexts in which each word was used. Similar words were grouped together, and each group was assigned a conceptual label that reflected the underlying theme. After drafting the initial coding rules, the researchers revisited all responses in which those words appeared to confirm the appropriateness of the assigned categories. Words that were used in multiple or ambiguous contexts were excluded from the coding rules to preserve specificity. After a 1-month interval, the researchers repeated the process to refine and finalize the coding scheme, thereby improving consistency and minimizing potential bias. These processes were carried out through discussions between the 2 researchers. In cases where disagreements arose during the categorization process, the supervising author (MT) was consulted to provide a third opinion and reach consensus. Coding rules were established for each category based on words that appeared at least 10 times. We excluded stop words, such as conjunctions and prepositions and words used in a variety of contexts, such as Nothing, Not, and Exercise. We calculated the number of responses for each category based on coding rules.

Heat Maps

In the fourth step, we created heat maps to visualize how each category varied across the stages of change. The heat maps visualized the variation in the mentions of each category using Pearson's residual scales. Percentages were calculated using the number of responses in each stage as the denominator and the number of responses mentioning each category as the numerator. Pearson residuals indicate the degree to which observed values deviate from expected values in the analysis of mentions in a particular category. The heat map displays the color intensity when mentions of a particular category occur more or less frequently than expected.

$$\text{Pearson residual} = (O - E)/\sqrt{E}$$

O: observational number of responses mentioning the category.

E: expected number of responses mentioning the category.

The process of developing coding rules and visualizing conceptual categories through heat maps has been effectively applied in our previous studies, such as an investigation into the supportive behaviors of supervisors with high work engagement and an analysis of trends in occupational health research over the past three decades [16,19]. These applications have demonstrated the utility and validity of the approach.

RenderX

Sensitivity Analysis

To assess the robustness of the findings, we conducted sensitivity analyses stratified by sex (males and females) and education (less than university and university or more). The same coding rules and analytical procedures described above were applied separately to each group to examine whether the stage-specific distribution patterns of inhibitors and facilitators were consistent.

Ethical Considerations

This study was approved by the Research Ethics Committee of the Tokai University School of Medicine (24R109). Informed consent was obtained from all the respondents before their participation in the questionnaire survey. To incentivize participation, respondents who passed the screening questions received 2 points, and those who completed the full survey received from 15 to 17 points. These points were equivalent to 1 yen per point and could be exchanged for merchandise on an affiliated online platform. All responses were anonymized by the survey company before being provided to the researchers, and no personally identifiable information was collected.

Results

Characteristics of Respondents

Respondents' characteristics are listed in Table 1. Of 1500 respondents, 754 (50.3%) were males. In addition, 23.6% (178/754) males and 23.7% (177/746) females were in their 50 s. A total of 50.8% (383/754) males and 56.7% (423/746) females were married. Household incomes between 4 million and 5.99 million yen (US $1 = ¥150) were reported by 30.1% (227/754) men and 23.5% (175/746) women. In terms of the stage of change, 29.6% (223/754) men were in maintenance, 23.9% (180/754) in preparation, and 22.5% (170/754) in precontemplation; 28.6% (213/746) women were in contemplation, 26.1% (195/746) in precontemplation, and 22.1% (165/746) in maintenance. Because all questionnaire items were mandatory, there were no missing values among the analyzed participants.

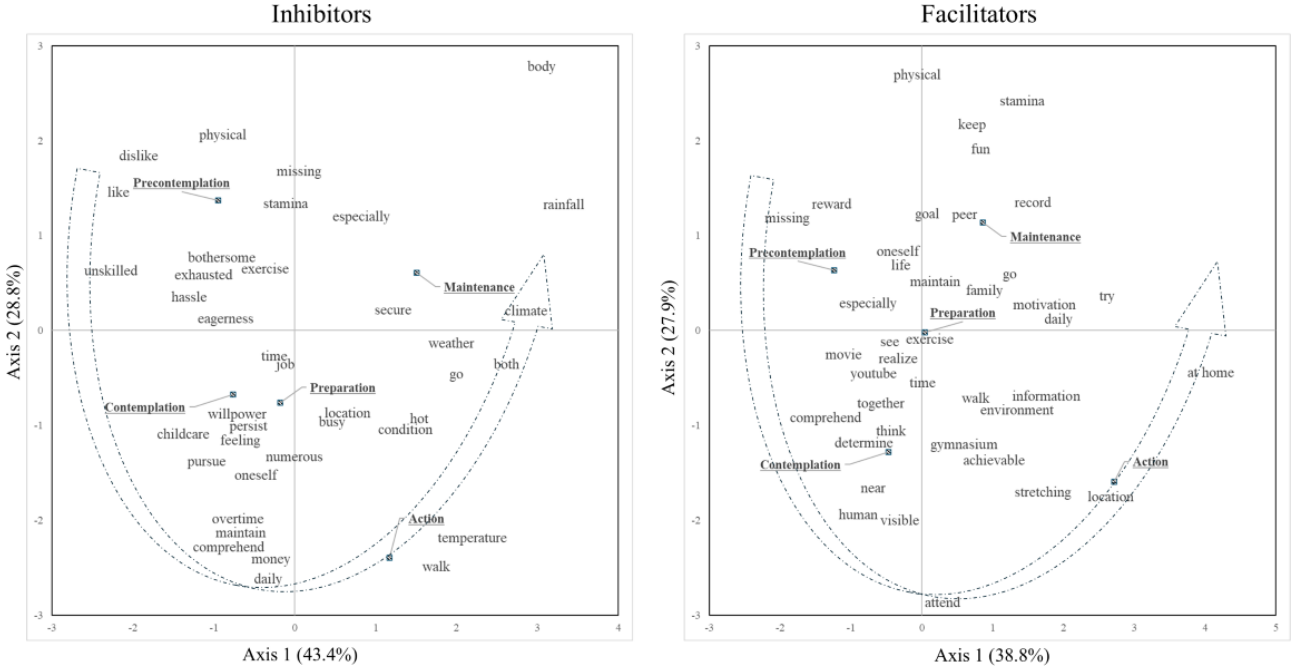
Morphological Analysis

In the first step, we detected inhibitors using 9893 extracted words and 1157 unique words and facilitators using 8372 extracted words and 1241 unique words. Frequent words described for inhibitors, those appearing at least 10 times, are shown in Multimedia Appendix 1, and frequent words described for facilitators are shown in Multimedia Appendix 2. The inhibitors included time (N=387), job (N=154), exhausted (N=58), eagerness (n=49), troublesome (n=46), and busy (n=44). The facilitators included nothing (n=542), gymnasium (n=56), time (n=52), together (n=48), understand (n=44), application (n=38), and goal (n=32).



Correspondence Analyses

In the second step, Figure 2 presents the results of the correspondence analyses to visualize the relationship between the stages of change and the 40 specific words in the inhibitors and facilitators. The stages of change were arranged counterclockwise for both the inhibitors and facilitators. A spectrum was drawn from the appearance of the word characteristics at each stage. In the inhibitors, dislike, like,

XSL•FO
RenderX

bothersome, and unskilled appeared in the precontemplation period; childcare, willpower, overtime, and money appeared in the contemplation and preparation; walk and temperature appeared in the action period; and body, rainfall, and climate appeared in the maintenance period. In the facilitators, missing and reward emerged in precontemplation; near, human, and visible emerged in contemplation; location and stretching emerged in action; and stamina, fun, record, and peer emerged in maintenance.

Figure 2. This figure presents the results of the correspondence analysis, illustrating the relationship between the stages of behavioral change and frequently mentioned words related to inhibitors (left panel) and facilitators (right panel) of exercise habits.

Conceptualization and Coding Rules

In the third step, the inhibitors and facilitators were structured into several categories using coding rules, as shown in Table 2. The inhibitors were divided into seven categories (motivation, health, weather, family, time, opportunity, and working). In response to the inhibitors, 408 (27.2%) respondents referred to the category of time, including words, such as time, busy, and capacity. Similarly, 253 (16.9%) respondents mentioned motivation, 189 (12.6%) mentioned health, and 158 (10.5%) mentioned work. A total of 572 (38.1%) participants did not use any of the words included in the coding rules. After reading all the responses in the category of no coding, we observed that 255 respondents answered, “I do not know” or “nothing in particular.” The facilitators comprised 8 categories (reward, subjectivity, opportunity, relationship, health, record, digital device, and time). Among the facilitators’ responses, 155 (10.3%) referred to the category of subjectivity, which included words such as understand, achievable, comprehend, and determine. Similarly, 93 (6%) and 84 (6%) participants mentioned the relationship and opportunity categories, respectively. There were 956 (63.7%) responses not referring to any categories (no coding), and 617 of these responses had no meaning, such as “I do not know” or “nothing in particular.”

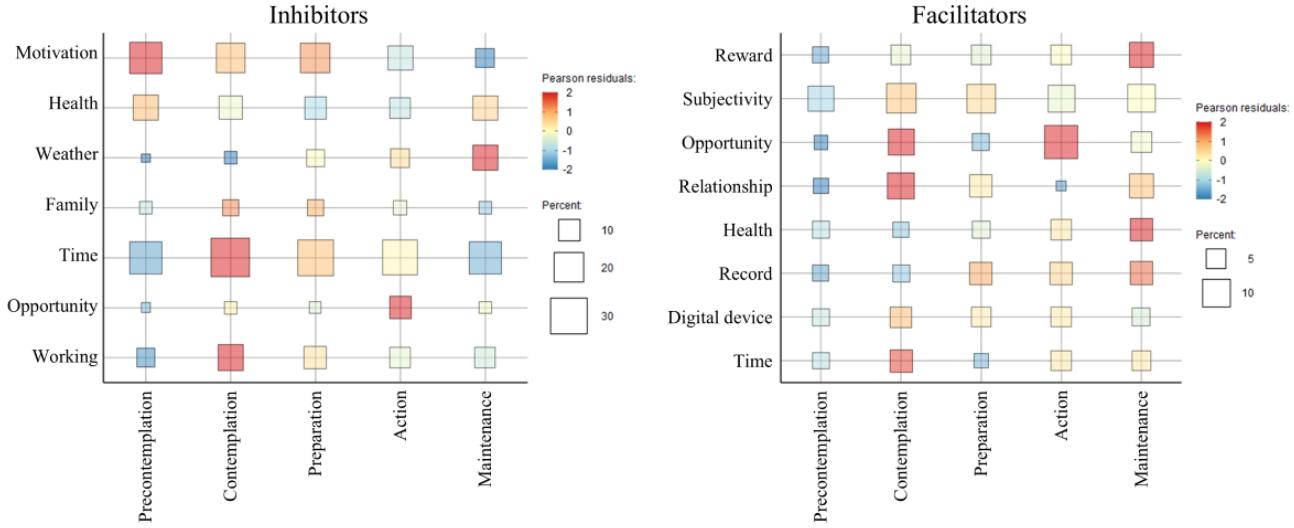
Table . Conceptualization, coding rules, and reference conditions on inhibitors and facilitators.

Factors and categories		Words in coding rules	Reference counts and rate, n (%)
Inhibitors			
	Motivation	eagerness, troublesome, hassle, motivation, feeling, bothersome, willpower, like, dislike, unskilled	253 (16.9)
	Health	exhausted, stamina, condition, physical, knee, fatigue, backache, body	189 (12.6)
	Weather	weather, climate, rainfall, hot, chilly, temperature	98 (6.5)
	Family	chores, parenting, caregiving, childcare	71 (4.7)
	Time	time, busy, capacity	408 (27.2)
	Opportunity	gymnasium, location, money	48 (3.2)
	Working	job, overtime	158 (10.5)
	No coding[a]		572 (38.1)
Facilitators			
	Reward	point, motivation, fun, effect, reward, capable	78 (5.2)
	Subjectivity	understand, achievable, comprehend, determine	155 (10.3)
	Opportunity	gymnasium, location, environment, institution	84 (5.6)
	Relationship	together, peer, human, family	93 (6.2)
	Health	health, stamina, body, physical	68 (4.5)
	Record	goal, weight, record, strides	78 (5.2)
	Digital device	application, YouTube, movie	70 (4.7)
	Time	time, job	68 (4.5)
	No coding[a]		956 (63.7)



[a]No coding: responses that did not use any of the words listed in the coding rules above.

Relationship Between the Stages of Change and the Categories of Inhibitors and Facilitators

In the fourth step, the heat map in Figure 3 shows the association between the stages of change and the categories of inhibitors and facilitators. The color indicates the bias of the distribution in each category in the horizontal direction, and the size of the square indicates the percentage of mentions at each stage in the vertical direction. In terms of inhibitors, motivation decreased and weather increased as the behavior change stage progressed. The categories of family, time, and work were mentioned in contemplation and preparation, whereas opportunity was mentioned in action. Among the facilitators, reward, health, and record increased as the behavior change stage progressed. Opportunity was mentioned in contemplation and action, whereas relationship and time were mentioned in contemplation. The numbers and percentages of mentions of the categories by stage are detailed in Multimedia Appendix 3.

XSL•FO
RenderX

Figure 3. This heat map illustrates the relationship between the stages of behavioral change and the categories of inhibitors (left) and facilitators (right).

	Precontemplation	Contemplation	Preparation	Action	Maintenance
Inhibitors	Motivation and health	Time, working, and family	Time, working, and family	Opportunity	Weather and health
Facilitators	–	Opportunity, relationship, and time	Record	Opportunity	Reward, health, and record

The results of the sensitivity analysis stratified by sex and education are presented in Multimedia Appendix 4 (inhibitors by sex), Multimedia Appendix 5 (facilitators by sex), Multimedia Appendix 6 (inhibitors by education), and Multimedia Appendix 7 (facilitators by education). For inhibitors, similar trends in category–stage associations were observed, even when the data were stratified by sex and educational attainment. For facilitators, the frequency of mentions across all categories remained consistently low in the precontemplation stage across all sensitivity analyses. However, beyond the precontemplation stage, the associations between facilitator categories and stages of change varied by sex and education, and no consistent patterns were observed.

Discussion

Principal Findings

In this study, a text-mining analysis of open-ended responses about the inhibitors and facilitators of exercise behavior revealed a complex relationship between the stages of change and these factors. Inhibitors were structured into 7 categories (motivation, health, weather, family, time, opportunity, and working) and facilitators into 8 categories (reward, subjectivity, opportunity, relationship, health, record, digital device, and time). The inhibitors included motivation and health in the precontemplation; time, working, and family in the contemplation and preparation; opportunity in the action; and weather and health in the maintenance. As precontemplation progressed to action, reward, health, and record emerged as facilitators. The findings of this study will contribute to a better understanding of the complex mechanisms underlying exercise habit formation and will inform the development of personalized interventions.

The following inhibitors changed as the behavior change stage progressed: motivation, health, flexibility (time, working, and family), opportunity, and weather. Overcoming these inhibitors makes it possible to acquire exercise habits. Similar inhibitors have been reported previously. A systematic review of the determinants of physical activity among adults in the United Kingdom identified lack of time, health problems, and language barriers as inhibitors [32]. A study of individuals with musculoskeletal disorders identified health conditions, time constraints, psychological barriers, and limited access to opportunities, including weather, as inhibitors [11]. To support the acquisition of exercise habits, these inhibitors need to be overcome. In a systematic review and meta-analysis, interventions involving motivational interviewing have been reported to be effective in promoting physical activity and exercise and reducing sedentary time [33]. Motivational interviewing of patients with cancer has reported effects on the acquisition of exercise habits over a period of ≥6 months [34]. Continuous sessions with a physiotherapist and motivational interventions are effective in improving exercise adherence in older adults with chronic low back pain to improve exercise adherence [35]. However, interventions using digital devices that have emerged in recent years have not been proven effective in promoting exercise in patients with musculoskeletal pain [36]. These results indicate the need for ongoing support from specialists. Time management and opportunities such as work–life balance, access to gyms, and financial resources can contribute to the development of exercise habits only when individuals are in good health and sufficiently motivated to exercise.

In the correspondence analyses, the facilitators showed no more fluid relationships with the behavior change stage than the inhibitors. In addition, the results of sensitivity analysis stratified by sex and education for the relationship between facilitators and stages were inconsistent. One possible reason for this is that facilitators vary according to the individuals' backgrounds. In a qualitative study of individuals with chronic back pain, professional supervision and group practice served as facilitators, because pain was the primary inhibitor [18]. For

XSL•FO
RenderX

those with depressive symptoms, emotions, beliefs about capability, and intentions were barriers; therefore, improving the emotional domain was a facilitator [37]. The facilitators depended on the inhibitors possessed by individuals.

As the behavior change stage progressed, reward, health, and record emerged as facilitators. Recording this process is expected to facilitate the observation of changes in the acquisition of exercise habits. As individuals build stamina, notice physical changes, and experience positive emotional rewards, they may progress to the maintenance stage. Setting goals and tracking weight and step counts enhance intervention effectiveness [38]. A cycle was observed in which self-efficacy increases as individuals progress through the behavior change stages, further boosting their motivation to exercise [38]. Tracking progress may act as a trigger for this cycle.

Facilitators were more frequently described in relation to behavioral processes that involve specific actions to modify and maintain behavior rather than experiential processes that focus on changing thoughts, emotions, and awareness of behavior. As previously mentioned, the process of change in the TTM can be categorized into experiential and behavioral aspects, with the latter having a stronger association with physical activity [39]. Among the facilitators in this study, behavioral aspects can be classified into the following categories: reward, opportunity, relationship, record, digital device, and time. Without efforts to develop exercise habits, facilitators are likely to remain unrecognizable. All categories in the heat map of facilitators had few mentions of precontemplation. In contrast, mentions of facilitators increased during the behavior change stage following the contemplation stage, suggesting that respondents can write about the facilitators based on their own experiences. An interview study examining the relationship between behavior change stages and influencing factors reported more statements about barriers and fewer about the benefits of exercise during precontemplation [40]. A telephone study of middle-aged Australian women reported that people in the precontemplation period lacked knowledge and family support [41]. Based on these results, interventions during the precontemplation stage should focus on providing knowledge and increasing awareness.

Applications and digital devices were mentioned as facilitating factors. Digital health interventions are becoming increasingly prevalent in exercise routines and positively associated with increased physical activity [42]. Mechanisms are being established to acquire user data through digital devices and to further encourage behavior change [38]. Text mining is actively used in this context. For example, text-mining analysis of messages from sexual and reproductive health information services in Kenya revealed distinct patterns of interest based on sex and age [43]. This study provides valuable insights into tailoring information dissemination based on the attributes of the target audience. Further studies are required to clarify the mechanisms of behavior change through digital devices.

Strengths and Limitations

This study has several strengths. First, it visualizes fluid variations in the inhibitors and facilitators during the process of acquiring exercise habits. Inhibitors that need to be overcome step-by-step to acquire exercise habits were identified. Second, this study offers a new perspective for evaluating effective exercise interventions. The findings of this study can be used to develop intervention strategies based on inhibitors and facilitators. A meta-analysis of intervention studies on exercise habit formation found that interventions tailored to an individual's stage of behavior change were not necessarily more effective than those that were not [43]. Furthermore, interventions focusing on self-efficacy are more effective than those based solely on behavior change stages. Interventions should consider the stage of change and factors, such as decisional balance, self-efficacy, and the process of change [44]. Third, text mining was used to clarify the behavior change process. A text-mining study analyzing free-text descriptions of exercise motivation among college students found that the high-motivation group referred to enjoyment, sports, and participation, whereas the low-motivation group mentioned dislike, rivals, and partners [21]. A previous study on coal miners applied latent Dirichlet allocation with a topic model to identify key factors, including physical and psychosocial environments, individual characteristics, and health beliefs [22]. Unlike previous studies that either focused on comparing subgroups (high vs low motivation) or identifying general themes using topic modeling, our study integrated multiple analytical approaches to comprehensively examine the dynamics of behavior change. Specifically, we applied correspondence analysis to visualize fluid transitions in frequently mentioned words across the stages of change, enabling the identification of stage-specific language patterns. Furthermore, we interpreted the extracted terms and inductively developed conceptual categories, which were then linked with participants' behavioral stages through heat maps. This multifaceted approach allowed for a deeper understanding of how inhibitors and facilitators evolve during the process of acquiring exercise habits, contributing new insights to the theoretical and practical development of stage-based interventions.

This study has several limitations. First, due to the cross-sectional design of this study, causal relationships between behavior change stages and the reported inhibitors or facilitators cannot be inferred. To establish temporal sequences and better understand the dynamics of exercise behavior change, future longitudinal studies are warranted. Second, researchers' subjectivity may have influenced the results, particularly in the process of categorizing inhibitors and facilitators and developing coding rules. However, to minimize this influence, we enhanced the validity of the categorization by having 2 researchers independently review the responses that included all frequently used words. Third, because this study was conducted among individuals registered with an internet panel, the generalizability of the findings may be limited. To assess potential biases, we compared the distribution of household income and behavior change stages in our sample with those reported in national datasets. Compared with the general Japanese population, respondents in this study tended to have higher household income and were more likely to be in the preparation and subsequent stages. These results suggest that the participants in our study may represent a subgroup with higher internet literacy, greater financial resources, and a stronger interest in health behaviors. Detailed comparisons with national statistics

XSL•FO
RenderX

are presented in Multimedia Appendix 8 and Multimedia Appendix 9. Fourth, all data, including the self-assessment of behavior change stages and the open-ended responses, were self-reported and therefore may be subject to recall bias or social desirability bias. Fifth, the survey was conducted during a period influenced by the COVID-19 pandemic, which may have affected respondents' exercise behaviors, perceived barriers, and available opportunities. These external factors could have shaped both the frequency and content of the reported inhibitors and facilitators.

Conclusions

These findings contribute to a deeper understanding of the dynamic mechanisms underlying behavior change, particularly in relation to exercise habit formation. By identifying how specific inhibitors and facilitators shift across behavior change stages, this study emphasizes that exercise promotion cannot be effectively approached through one-size-fits-all strategies. Instead, the results highlight the importance of tailoring interventions to individuals' readiness to change, as defined by their current stage.

For health practitioners, this suggests the need for careful stage-based assessment prior to intervention, enabling the provision of timely, stage-appropriate support—for example, motivational strategies for those in early stages, and more structural or logistical support (eg, time management, opportunity creation) for those further along the change process. In addition, insights into emerging facilitators, such as the use of personal rewards and health monitoring, can inform the development of new tools and counseling techniques to support sustained engagement.

For policymakers, the findings advocate for integrating behavioral stage frameworks into the design and implementation of public health initiatives. By incorporating simple assessments of behavioral readiness into national health checkups or workplace wellness programs, interventions can be more effectively segmented and personalized. Such approaches have the potential to improve program efficiency, maximize behavioral impact, and ultimately contribute to long-term increases in population-level physical activity and health outcomes.

Abstract

Background: The generalizability of clinical research hinges on robust study designs, which include the recruitment and maintenance of a representative study population. This study examines the evolution of the demographic characteristics of 329,038 participants who enrolled and participated in The *All of Us* Research Program (AoURP), a decentralized study aimed at representing the diversity of the United States.

Objective: The primary objectives of this study were to assess alterations in the demographic composition of the cohort at different protocol stages within AoURP, while analyzing completion rates and timeframes for survey and substudy completion. Additionally, we examined how participant interactions with the program impacted engagement and survey responses.

Methods: We conducted a longitudinal analysis of the AoURP data, tracking changes in demographic composition, completion rates, and completion times for surveys and substudies. Comparative analyses were performed to assess differences in engagement and survey completion based on sociodemographic characteristics of participants involved in postenrollment study components.

Results: The sociodemographic composition of the cohort that participated in the postenrollment study (eg, optional components) differed significantly from that of the recruited population. The proportion of self-identified White participants increased by 21.2%, whereas the proportion of Black or African American participants decreased by 12.18% (P=.02). Participants who identified as White (n=93,614, 52.7%) and NonHispanic (n=109,279, 42.21%) were more engaged compared to those identifying as Black or African American (n=10,887, 15.76%), Asian (n=4274, 38.72%), or Hispanic (n=12,530, 20.7%; P=.006). Participants' response times to study surveys and completeness varied across all demographic groups (P<.001). Furthermore, those identifying as White skipped fewer survey questions (1.19) compared to those identifying as Black or African American (1.40) or other racial and ethnic identities (P<.001).

Conclusions: The AoURP dataset serves as an exceptional resource for investigating diverse public health concerns. However, the longitudinal analysis of participant-level data underscores a significant skew in population diversity, suggesting the need for targeted strategies to enhance engagement and retention across all groups. Ensuring diversity in the cohort is essential for maintaining the study's representativeness and the broad applicability of its findings.

Introduction

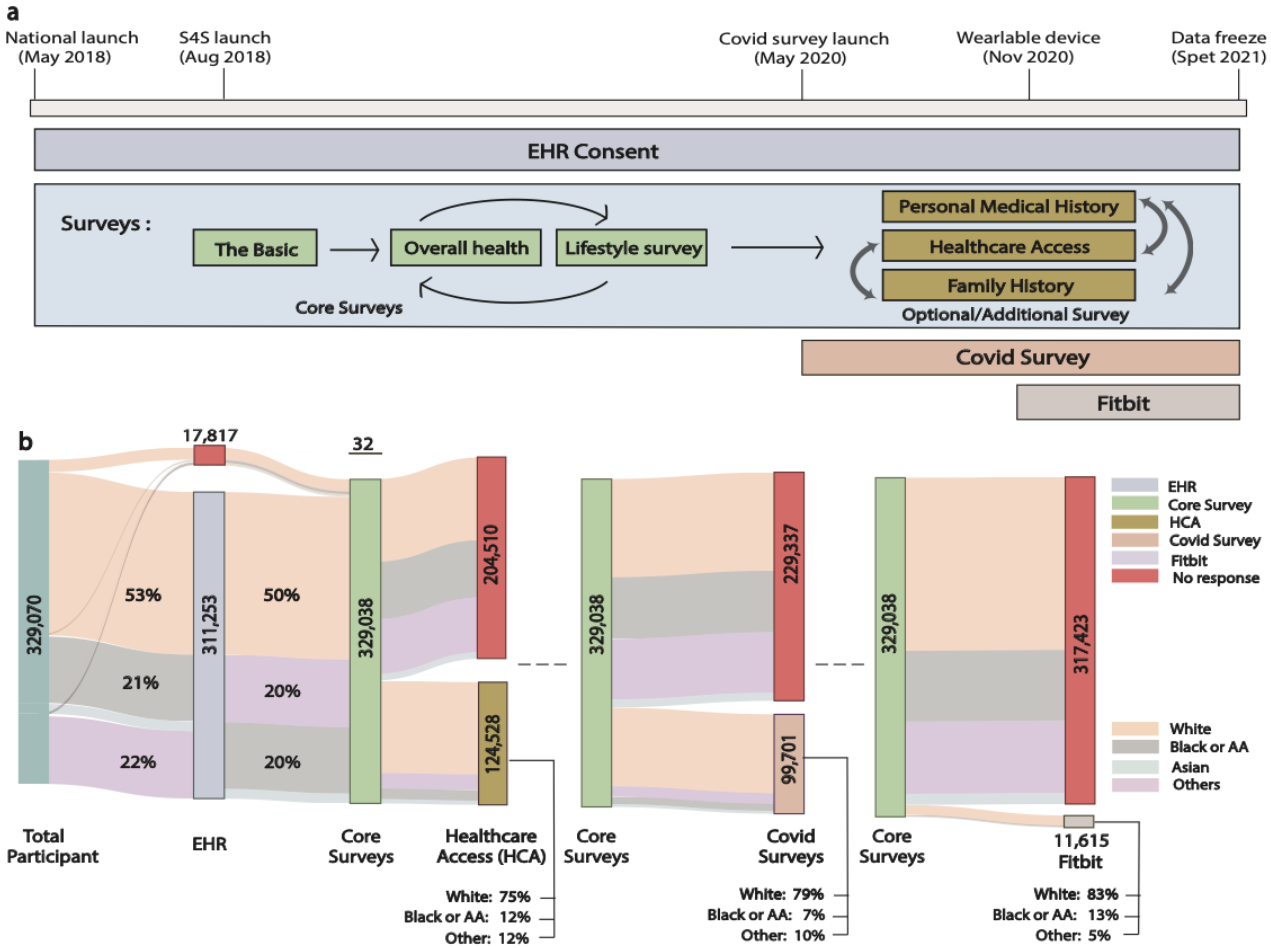
There is a history of lack of racial, ethnic, and gender diversity in health studies [1,2]. This lack of diversity can lead to issues related to the generalizability of research findings and equity in health care. However, lack of plurality has decreased in the last three decades, partially due to regulatory and policy efforts within government agencies, such as the National Institutes of Health [3], Food and Drug Administration [4], and Department of Health Services [5], that have sought to enhance minority participation in clinical research as well as identified scientific need [6]. As the demographic makeup of the United States is becoming more pluralistic, diverse study populations are necessary to have representative and translatable observations. Much of the effort to increase minority representation in research has focused on the recruitment of diverse study populations. However, the recruited population is not always representative of the population that is ultimately studied, due to engagement rates being different across sociodemographic groups. This has been demonstrated in remote observational studies, where there is less direct interaction with participants compared to studies which require in-person visits [7]. Poor engagement can lead to study failure due to reduced sample sizes, causing loss of power or imbalanced study populations. Prior research has

XSL•FO
RenderX

shown that remote-only studies demonstrate different engagement rates based on demographic features including disease presence or absence, age, race or ethnicity, and recruitment methods [6-8]. When the engagement rates vary across different populations, there is a risk that the effective study population (ie, the population with longitudinal data) becomes unrepresentative of the originally recruited cohort.

The *All of Us* Research Program (AoURP) was launched in May 2018, with an aim to recruit more than 1 million participants living in the United States to accelerate health research and precision medicine. AoURP has specifically focused on recruiting demographic categories that have historically been underrepresented in biomedical research (UBRs) and has largely succeeded in this objective through partnership with more than 340 recruitment sites nationwide [3]. During the first year of the AoURP, 80% of recruited participants self-identified as belonging to one or more UBR populations [9]. In this study, we explore long-term engagement within AoURP by exploring participation in optional components of the AoURP study (eg, surveys and substudies that could be performed post enrollment), the time that it takes participants to complete optional surveys, and survey response completeness. We hypothesize that this information, combined with data on specific interactions of participants with the AoURP can be used to improve and develop strategies that promote sustained engagement across the diverse demographics. This study primarily assesses changes in cohort demographics across AoURP protocol stages, completion rates for surveys and substudies, and the influence of participant interactions on engagement and responses. These insights provide actionable strategies for sustaining diverse, representative cohorts.

Methods



Study Design and Participants

This study is a longitudinal study that analyzes data from participants in the AoURP, encompassing individuals aged 18 and older residing in the United States, irrespective of race, ethnicity, sex, gender, or sexual orientation [10,11]. Data from the 329,038 participants in the September 2021 AoURP data freeze were analyzed. The AoURP protocol has evolved since its launch in 2018 (Figure 1A). At present, after consenting, participants are given the option to share their electronic health record (EHR) data, provide a biosample, and answer 3 core surveys (ie, The Basics, Overall Health, and Lifestyle) [12]. Participants can also respond to additional optional health surveys including Healthcare Access (HCA), Personal Medical History (PMH), and Family Medical History (FMH), at any time and in any order after enrollment (Table S1 in Multimedia Appendix 1) [12]. In addition to these components, AoURP included two additional optional substudies, at the time of analysis: (1) a COVID-19 survey and (2) a "bring your own device" (BYOD) Fitbit study, which allows participants to share data from any Fitbit wearable device (Google Inc, Mountain View, CA) owned by them. The AoURP also collects additional data, such as physical measurements; however, our analysis is restricted to recruitment and engagement characteristics based on participant-provided information (eg, health and demographic surveys) and BYOD Fitbit data.

The core surveys included information about the participants' self-reported demographics, which was used to explore differences in participation. Specifically, we used responses to the questions on (1) date of birth; (2) What was your biological sex assigned at birth; (3) Which categories describe you (race); (4) Which categories describe you (ethnicity); and (5) What is your annual household income (from all sources) [12]. Based on the *All of Us* (AoU) Researcher Workbench, we categorized age into three bands: younger (18 - 44 years), middle aged (45 - 64 years), and older adults (≥65), and household income into 4 bands (<$50,000, $50,000-$100,000, $100,000-$200,000, >$200,000). For other multiple-choice questions, we included categories with at least 1.8% respondents. This resulted in the following categories: male and female for biological sex at birth; White, Black or African American, and Asian for race; and NonHispanic and Hispanic for ethnicity. These categories were used to assess changes in cohort demographics during the course of the study, with the primary outcomes under investigation being (1) engagement (ie, number of participants who remain engaged by completing optional components after enrollment), (2) response time (ie, time between invitation and completion of optional components), and (3) completeness of response (ie, how often participants chose to answer specific questions). Understanding these changes is essential for examining shifts in participant demographics and engagement over time, which helps identify trends and biases, ensuring the cohort representativeness and development of targeted strategies for improved engagement and retention.

Figure 1. Protocol and changes in engagement across components in study. (A) Timeline for components of protocol and journey of a participant in the AoU program. Based on respective protocol launch dates, participants had the option to consent to share EHR data, participate in COVID-19 surveys, and share data from a BYOD Fitbit data. Each survey block reflects the ordering of core and additional surveys configured in the program. (B) Sankey diagram showing the population distribution within the AoURP throughout the protocol journey. The nodes represent different types of events (eg, EHR consent, completion of optional surveys, BYOD Fitbit data sharing). Flows between notes are color-coded by self-identified race (ie, White, Black, or African American, Asian, or other). The width of the nodes and links provide quantitative information. AA: African American, AoURP: *All of Us* Research Program; BYOD: bring your own device; EHR: electronic health records; HCA: Healthcare Access survey.

Data Processing

For the primary analysis, we built an engagement cohort consisting of participants who successfully enrolled in the study and responded to the demographic questions using the AoU Researcher Workbench [13]. Since all components of the study were not launched at the same time (eg, BYOD Fitbit and the sharing of electronic health records using Sync4Science [14] were added later; see Figure 1A for the timeline), we conducted a secondary analysis using enrollment dates extracted from the observation table to evaluate the effect of timing of enrollment on these components. Specifically, this secondary analysis included individuals who enrolled after Sync4Science launch (August, 2018) and after the BYOD Fitbit protocol being launched (November, 2020). For all cohorts, activities where participants completed the surveys were considered as "active/engaged" events. All survey questions included a "prefer not to answer" option. Survey completeness was analyzed across participants by counting the number of questions answered as "prefer not to answer".

Statistical Analysis

Various statistical techniques were used for the three different analyses. Whenever possible we favored the use of nonparametric statistical tests and resampling techniques to avoid relying on distributional assumptions. These included the Kruskal-Wallis test (instead of analysis of variance), Mann-Whitney tests for pairwise group comparisons), bootstrapping for computation of confidence intervals, and permutation tests for calculating statistical significance. For all analyses, a significance level of $P<.05$ was used with Bonferroni correction for multiple testing [15].

To analyze engagement across self-reported age, sex at birth, race, household income, and ethnicity groups, we compared the proportion of participants responding in each demographic group between the core survey and optional components using a χ^2 test for homogeneity.

Participants' response time, as measured by the number of days between joining the study and completing (or joining) an optional component, was analyzed using the nonparametric Kruskal-Wallis one-way analysis of variance for each optional

XSL•FO
RenderX

component separately, as the data was not normally distributed [16]. To further understand the variability between each group, pairwise differences between groups were analyzed using the Python language (version number 3.9; Python Software Foundation), including the *statannotation* package (version 0.4.2) [17], along with the with Mann-Whitney integrated statistical test and Bonferroni for multiple testing correction [18,19].

To better understand the relationship between various self-reported demographic variables, a linear mixed model (LMM) was used to analyze the response time across the 3 surveys concomitantly. To improve the fit of the model, response time data was log-transformed before feeding into the model. All self-reported demographic variables were fitted into the model to evaluate the effect produced by each predictor. Age was treated as a continuous variable, while other variables were fitted as categorical variables. The coefficient of relative change for each variable was reported by the LMM model, and the log-transformed relative change between each group was back-transformed to a percentage change in response time across groups for all the categories, using formula $100(e^{\text{coefficient}}-1)$. To further evaluate confidence intervals, bootstrapping was used. To account for the repeated measurements of each subject, the bootstrap confidence intervals for the LMMs were constructed based on 1000 iterations of the following couple of steps. First, we obtained a bootstrap sample from the original data by sampling with replacement at the subject level (ie, assuming that our dataset contains data from *N* subjects, we grouped the repeated measurements of each subject as a "subject block," and then sampled with replacement N "subject blocks" out of the N blocks in the original dataset.) Second, for each bootstrap sample, we fit a LMM and computed the coefficient of relative change of each variable as described above. Finally, we computed 95% CI for the coefficients of relative change using the percentile interval method, where the lower and upper confidence bounds correspond to the 0.025 and 0.975 quantiles of the distribution of coefficients generated across the 1000 bootstrap iterations.

We independently examined outliers in the response time for optional surveys to check if these outliers were the cause of any systematic differences. Outliers comprised any individual who had a response time less than the first quartile (Q1)–1.5×IQR or greater than Q3+1.5×IQR. To evaluate the differences, we computed the proportion of outlier participants for each demographic group and then conducted a χ^2 test (test of homogeneity) for testing the equality of outlier participants proportion across different demographic groups.

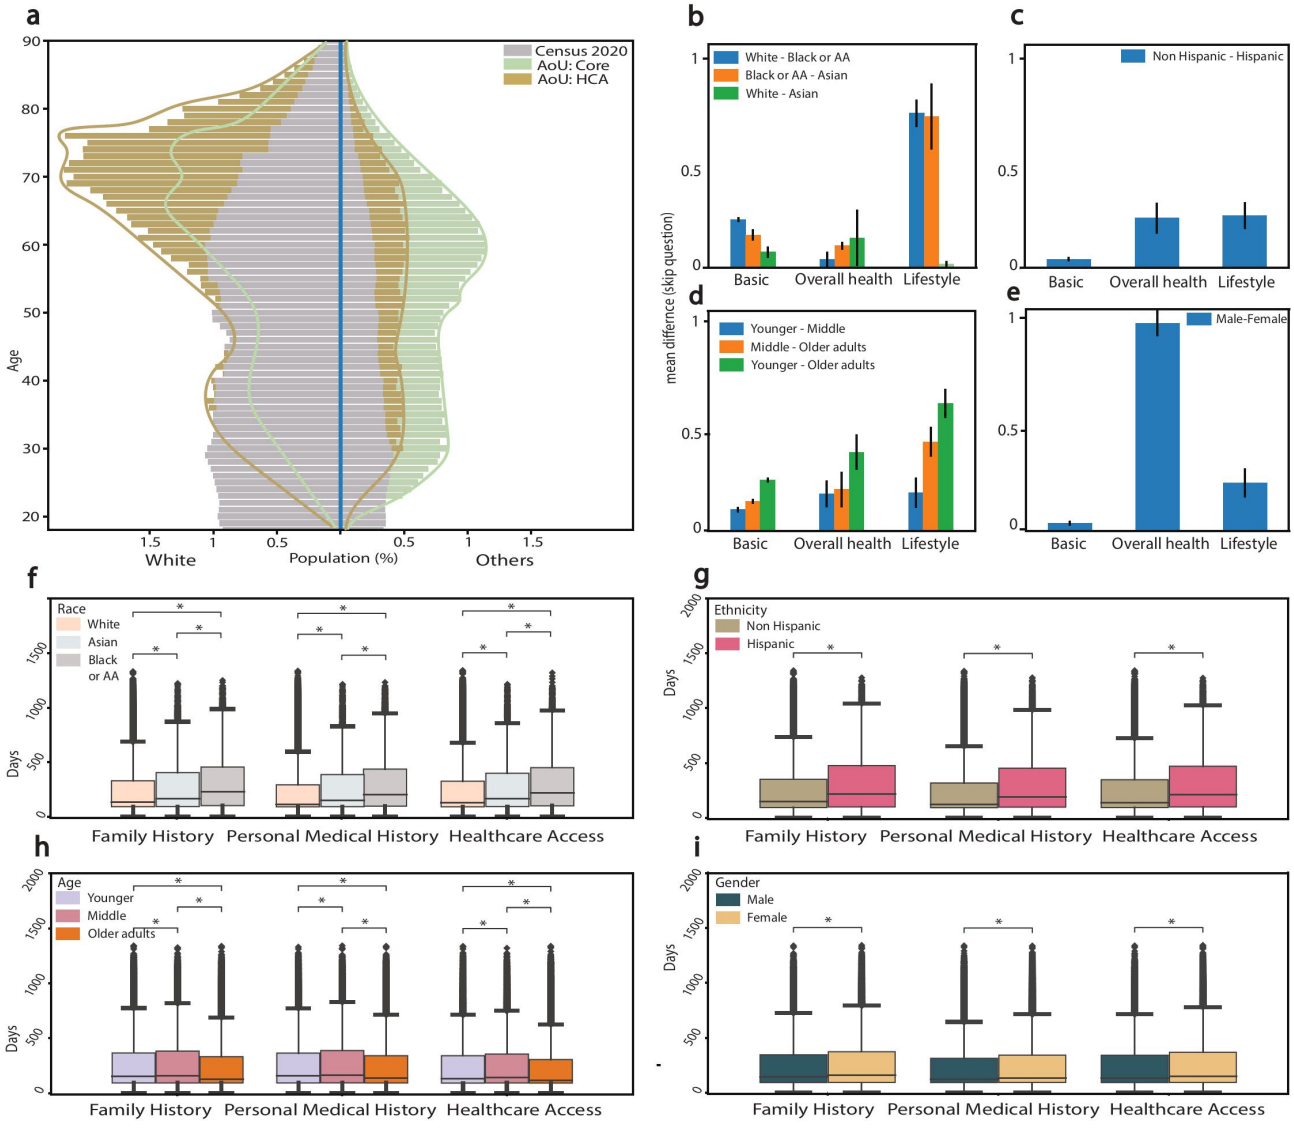
Completeness of response was evaluated by counting the number of questions where a participant responded "prefer not to answer." First, the nonparametric Kruskal-Wallis test was used to evaluate variability across different groups (since the data was not normally distributed). However, due to ties in the completeness of the response variable, we adopted a permutation test to assess differences between the groups [12]. The permutation test was conducted by comparing the observed value of the ANOVA F-statistic computed in the original data (F_{obs}) against the permutation null distribution of the F-statistic computed on permuted versions of the data (F*), where the group labels were randomly shuffled. The test was based on 1000 data permutations and the permutation *P* value was computed as the proportion of times the permuted F-statistic was greater or equal to the observed test statistic (ie, $P=(1+\text{sum}\{i=1..B \text{ indicator}\{F^*>=F_{obs}\}\})/(1+B)$, for B=1000). Due to the large sample set, it is possible that we may be detecting very small effect sizes with very high statistical significance across different categories. To assess the effect size, 95% CI were computed using nonparametric bootstrapping for the pairwise group mean difference for each group [20].

Ethical Considerations

This study used deidentified data from the *All of Us* Research Program, which obtained institutional review board (IRB) approval and informed consent from participants for secondary research [21]. The original data collection was approved by the AoURP IRB [21], and no additional IRB approval was required for this secondary analysis. According to the All of Us Responsible Conduct of Research training, analyses using deidentified data on the Researcher Workbench do not require a separate IRB review [22], as the research involves no direct interaction with participants. All analyses adhered to ethical principles, ensuring privacy and confidentiality as outlined by the AoURP.

Results

Population Characteristics



Data from 329,078 consented participants were made available as part of the version 5 data release [23] by AoURP. Of the total consented participants, 329,038 (99.98%) completed all core surveys and were considered successfully enrolled in the program. Additionally, 311,253 participants (94.59%) consented to share all their electronic health records; including retrospective medical records from before the AoURP study was launched. Post completion of core surveys, participants had the option to complete three optional health surveys. A significantly smaller proportion completed these three optional surveys: (1) HCA-37.84% (n=124,528/329,078), (2) FMH-117,693 (35.76%), and (3) PMH-113,830 (34.59%) (Figure 1B). Both the COVID survey and the BYOD Fitbit data collection were launched at later stages of the study (Figure 1A). A total of 99,701 (30.3%) people participated in the first COVID survey and 11,615 (3.52%) participated in BYOD Fitbit data sharing. Participants who enrolled before the BYOD Fitbit data collection protocol was launched were less likely to consent to share their BYOD Fitbit data compared to those who enrolled after the protocol launch (3.51% vs 6.51%, respectively).

The AoURP aims to recruit persons from the UBR populations, and recruitment was successful, with 24.36% (n=80,154) of the participants responding to the core surveys with a self-reported race of Black or African American and Asian, while 53.98% (n=177,615) self-reported as White. We compared the distribution of ages and race to the 2020 US Census data [24], which showed the enrichment of self-identified races other than White, as well as middle-aged individuals, in the AoU cohort (Figure 2A) at baseline. Additionally, more participants reported

XSL•FO
RenderX

being female (Figure S1a in Multimedia Appendix 1) and Hispanic ethnicity (Figure S1b in Multimedia Appendix 1) compared to the census.(However, this initial enrichment of people self-identifying as belonging to one or more UBR populations diminished as participants engaged with optional components of the protocol. Distributions across demographic variables for each component of the study is shown in Table 1. Moreover, a total of 1416 (0.4%) deaths were reported by the end of version 5 data release.

Figure 2. (a) Population pyramids divided by self-reported race (White vs other) see Multimedia Appendix 1 for additional populations pyramids. Three different pyramids are displayed for comparison for three different populations representing: those who responded to: AoURP core survey, one optional survey (HCA) and the 2020 US census. At baseline, based on response to the core survey) cohorts tend to be older and less white compared to the 2020 US Census, while responses to later optional surveys showed that the proportion of self-reported White participants increased significantly and a sudden drop in participants self-identifying from other racial groups. (B-E) represents the mean difference of number of skipped questions between demographic groups specific to each survey for: (b) *Race*, (c)*: Ethnicity*, (d)*: Age*, (e)*: Sex at birth*. The bar plot with the error bar represents the bootstrap (1000 iterations) 95% confidence interval for pairwise group mean differences. (f): Race, (g): Ethnicity, (h): Age and (i): Sex at birth) represent pairwise statistically significant differences (P<.001) across all the self-reported demographic groups of the participants responded to the additional surveys. AA: African American; AoU: All of Us. HCA: Health Care Access. *P<.001.

[a]Core Survey at enrollment.

[b]HCA: Health Care Access.

[c]EHR: electronic health records.

Differences in Engagement

The relative shift in the proportions of participants is reported as percentage changes. We observed an increase of 21.2% in the proportion of self-identified White participants and correspondingly a decrease of Black or African American respondents by 12.18% in the HCA compared to the Core surveys. Similarly, the proportion of participants who identified as NonHispanic (of all races) increased by 9.1%, to 87.8% (n=109,336) of the total respondent pool in the HCA survey, while people self-identifying as Hispanic decreased by 8.33% to 10.1% of the respondent pool (Table 1 and Figure 2A). To explore the engagement further, we compared the percentage of each self-identified demographic group that continued in each optional component of the study (ie, optional surveys, EHR consent, COVID Surveys, and BYOD Fitbit) and observed that the engagement varied across most components except the BYOD Fitbit (Table 2). The engagement with optional surveys

XSL•FO
RenderX

was 3 times higher among people who identified as White, with 52.7% (n=93,614) of White participants who enrolled and also completed the optional surveys (HCA), compared to Black or African American participants (n=10,887, 15.8%), and nearly twice as high as those identifying as Asian (n=12531, 38.7%) (*P*<.001). Similarly, 42.2% (n=109,279) of those self-identifying as nonHispanic (of all races) engaged with optional surveys as compared to 20.7% (n=12,531) of self-identified Hispanic participants (*P*<.006). 63.4% (n=12,681) of participants who self-identified with high household income engaged in the optional surveys compared to 27.4% (n=38,190) of self-identified with low household income (*P*<.001). A total of 47% (n=46,743) of older adults (aged >65 years) engaged with optional surveys compared to 34.64% (n=37,504) and 33.05% (n=40,096)of the middle-aged and younger groups, respectively. Engagement was 40.8% (n=81,460) for participants who self-identified as female at birth engaged in the optional surveys compared to 33.66% (n=42,137) of self-identified male at birth. However, neither self-reported age nor sex at birth were statistically significant indicators of engagement using the χ^2 test.

The first COVID survey showed large differences in participation across age (*P*=.02), race (*P*<.001), household income (*P*<.001), and ethnicity (*P*<.001), but not by sex at birth (*P*=.45), Older individuals participated at higher rates, with 43.2% (n=42,964) of self-reported older adults compared to 27.8% (30,099) of middle-aged and 21.3% (n=25,841) of younger participants completing the first survey. Self-reported White participants (n=79,048, 44.5%) participated at more than 4 times higher levels than self-identified Black or African American participants (n=7281, 10.54%) and nearly twice those identifying as Asian (n=2880, 26.09%). Self-identified high-income participants (n=10,485, 52.4%) participated at more than approximately 2.5 times higher levels than self-identified low household income participants (n=27,876, 20%). Similarly, participants self-identifying as nonHispanic (n=89,552, 34.59%) engaged at almost 3 times higher rates than those identifying as Hispanic (n=7876, 13.01%).

We did not observe any statistically significant differences in engagement by self-reported age, race, ethnicity, or sex in participation rates for the BYOD Fitbit substudy or the consent to share EHR data.

[a]Core survey at enrollment.

[b]HCA: Health Care Access.

[c]EHR: electronic health records.

[d]Fitbit was launched later in the study (see Figure 1). For a comparison of engagement rates between participants who joined before and after the launch of the Fitbit component (see Table S5 in Multimedia Appendix 1).

Response Time to Optional Surveys

In addition to differences in engagement, we also analyzed how long it took for participants to participate in optional surveys as measured by the time in days between enrollment and completion of the optional component. Given that only the three optional surveys (ie, HCA, PMH, and FMH) were available,

XSL•FO
RenderX

and the COVID Surveys and BYOD Fitbit, were unavailable at the launch of the study, we were only able to explore the delay for these surveys. We found differences in the response time based on self-reported age, sex at birth, race, ethnicity, and household income (all *Ps*<.001 based on Kruskal-Wallis one way analysis of variance). These results are summarized in Table S2 in Multimedia Appendix 1. Overall for the optional surveys, response times ranged from 0 to 1342 days with a mean of 247.9 (SD 233) days and median value was 141 (IQR 314.55) days. Self-reported older adults (median 117, IQR 213) took less time to respond to optional surveys compared to younger (median 135, IQR 251) and middle aged (median 138, IQR259) participants. People who identified as male at birth (median 120, IQR 221) took less time compared to people who self-identified as female at birth (median 133, IQR249). People who self-identified as White completed surveys sooner after enrollment (median 115, IQR 202) in comparison to those who self-identified as Black or African American (median 202, IQR 340), and Asian (median 153, IQR 295). People who identified as nonHispanic of any race (median 123, IQR 225) responded sooner to optional surveys as compared to people who self-identified as Hispanic (of all races) (median 188, IQR 335). People self-identified with high household income (median 119, IQR 195) took less time compared to people with low household income (median 150, IQR 279). We performed a secondary analysis to determine pairwise differences using the nonparametric Mann-Whitney test to illustrate which groups had quicker participation (Figure 2F–I). The linear mixed effect results presented in Table 3 provided valuable insights into the relationships between various demographic variables and their impact on response time. The table displays the estimated effects in terms of coefficients and relative percentage changes, with the use of bootstrap for accuracy. When examining age groups, individuals aged 45-64 years exhibited a 3.04% increase in response time compared to the reference group (18-44 years), while those aged ≥65 years displayed a decrease of −2.76%. Gender differences were also notable, with women showing a 5.65% increase in response time compared to men. In terms of race, African Americans exhibited a substantial 33.5% increase in response time compared to White individuals, while Asians and other racial groups also displayed significant differences. Ethnicity played a role as well, with Hispanics experiencing an 18.41% increase (Table 3) . Finally, income levels showed a consistent trend, with higher income brackets associated with decreased response times, highlighting the influence of socioeconomic factors on response behavior. These results offer important insights into the complex interplay between demographics and response times, shedding light on potential areas for further investigation and intervention. We conducted a secondary analysis to check if outliers were responsible for any significant difference and found no difference in the demographics. Distribution across demographic data is shown in Table S3 in Multimedia Appendix 1. We also explored the interaction effect (see Table S4 in Multimedia Appendix 1) between other demographic features and household income. The study found that the effect of age, gender, race, and ethnicity on response time was moderated by income. The response time was slower for people with higher income in all age groups, except 18-44 years. The difference was most pronounced for people aged ≥65 years. The interaction effect between gender and income was only significant for people who identify as neither male nor female. The interaction effect between race and income was significant for all race groups except White. The interaction effect between ethnicity and income was only significant for people who were not in plurality.

XSL•FO
RenderX

Table . Estimated effect (coefficient and relative % change using bootstrap) on response time.

Variables	Model	
	Coefficient	Percent change (95% CI)
Age (years)		
18-44	0	0
45-64	0.03	3.04 (2.99-3.09)
>65	–0.028	–2.76 (–2.78 to –2.69)
Gender		
Male	0	0
Female	0.055	5.65 (5.55-5.65)
Race		
White	0	0
African American	0.289	33.50 (33.40-33.57)
Asian	0.169	18.41 (18.30-18.54)
Ethnicity		
NonHispanic	0	0
Hispanic	0.169	18.41 (18.26-18.49)
Income (USD)		
<50,000	0	0
50,000-100,000	–0.045	–4.79 (–4.91 to –4.56)
100,000-200,000	–0.066	–6.39 (–6.45 to –6.31)
>200,000	–0.05	–4.88 (–4.96 to –4.78)

Completeness of Responses

To evaluate the frequency of skipped questions in each survey (survey completeness), we counted skipped questions and compared those across self-reported demographic groups (Table S5 in Multimedia Appendix 1). Skipped questions were relatively rare, with approximately 124,000 skipped questions out of 34 million answered; on average 329,038 participants skipped a mean of 1.32 (SD 0.74) questions per survey. We reported the results of "completeness of response" based on core surveys only, given that all the questions in the optional surveys were already answered except for one participant, who skipped one question. Using a nonparametric test, we observed differences in completeness for all self-reported demographic groups in the three core surveys. Mean values are reported for missing data (ie, skipped questions). Middle-aged participants skipped more questions (1.72 questions) compared to 1.54 for younger and 1.6 for seniors (P<.001). Participants who identified as female at birth skipped fewer questions (1.58) compared to participants who identified male at birth (1.99) (P<.001). Participants who self-reported as Black or African American race (1.86) and people self-reporting nonHispanic ethnicity of any race (1.71) skipped more questions compared to people of self-identified White (1.62) and Asian (1.62) race, and those who self-reported Hispanic (1.57) ethnicity of any race (P<.001). Participants with high household income skipped fewer questions (1.58) compared to participants with low household income (1.61) (P<.001). Also, we conducted pairwise group mean differences to further estimate the effect size which returned significant results (Figure 2B-E).

Secondary Analysis on Effect of Timing of Enrollment on Engagement

As all protocols were not launched at the same time, time of enrollment may have affected the engagement behavior of the participants who joined before and after the launch of the specific study components. We conducted a secondary analysis to evaluate if there were any differences in engagement between individuals who enrolled before and after the launch of BYOD Fitbit and Sync4Science separately. We found no significant differences in the demographic groups. Distribution across demographic variables for pre- and postlaunch of BYOD Fitbit (Table S6 in Multimedia Appendix 1), and for Sync4Science is shown in Table S7 in Multimedia Appendix 1.

Discussion

Principal Finding

The utility and translatability of studies is dependent on the study being carried out on a representative population. The AoURP has enrolled an extremely large cohort that aims to be representative of the diversity of the broader US population [25]. However, the data collected over time is not as representative as the enrolled population, with differences in engagement across demographic groups. This pattern is observed in both, the demographics that remained engaged and the degree

XSL•FO
RenderX

to which participants completed optional substudy components and how quickly they responded [26]. These variations are driven by socioeconomic, cultural, and structural factors, underscoring the need for tailored strategies to mitigate participation disparities [27]. Addressing these disparities is essential to maintain the cohort's representativeness, which directly impacts the validity and generalizability of the findings [28].

Comparison to Prior Work

This study builds on prior research by highlighting demographic engagement disparities in longitudinal cohort studies, an issue that has been well-documented in other population-based research efforts [29,30]. Previous studies have reported similar challenges, such as the underrepresentation of minority groups and the overrepresentation of higher socioeconomic status in voluntary participation metrics [31]. However, unlike earlier research, this study leverages the unique scale and diversity of the AoURP cohort to provide deeper insights into how engagement patterns vary over time and across demographic groups. By emphasizing socioeconomic and structural drivers of engagement disparities, this work highlights the need for target interventions necessary for retaining participants and ensuring equitable representation [32].

Strengths and Limitations

Our study benefits from a large, diverse cohort and longitudinal data, providing valuable insights into participation patterns. However, there are limitations that must be acknowledged. First, there may be biases due to self-selection and varying dropout rates among demographic groups. Overrepresentation of more engaged participants with higher socioeconomic status in optional surveys could skew health outcome estimates [7]. Second, the high dropout rates observed among underrepresented groups over time pose a challenge to maintaining sample diversity, which could limit the generalizability of findings to the broader US population [33]. Third, reliance on self-reported data, which may introduce reporting biases that affect the accuracy of the findings [27]. To address these limitations, efforts should focus on implementing strategies such as over-recruiting populations with higher attrition rates, developing tailored retention programs, and validating self-reported data through objective measures such as linked medical records [29]. These steps can enhance the reliability and applicability of the study's findings, ensuring their broader impact.

Future Directions

Based on our findings, decentralized studies such as AoURP should prioritize interventions that address engagement disparities. Over-recruiting populations with higher attrition rates and implementing targeted outreach strategies for underrepresented groups can enhance participation. Importantly, these strategies should be codesigned with input from participants to address specific barriers effectively [30]. Addressing challenges such as the digital divide, cultural differences, and logistical barriers is critical to fostering equity in research participation [31,34]. Innovative approaches such as bidirectional engagement where participants actively contribute to study design and receive meaningful feedback could further strengthen retention. Additionally, leveraging digital health tools and adaptive technologies can facilitate participant engagement while addressing socioeconomic barriers [35].

Conclusion

This study underscores the importance of maintaining representativeness in large, decentralized cohort studies such as AoURP. By identifying participation disparities and their underlying drivers, we provide actionable insights to improve cohort retention and engagement strategies. Future research should continue to explore and validate these interventions to ensure equitable and impactful scientific discoveries that benefit all segments of the population.

Abstract

Background: Dengue fever remains the most significant vector-borne disease in Southeast Asia, imposing a substantial burden on public health systems. Global warming and increased international mobility may exacerbate the disease's prevalence. Furthermore, the unprecedented COVID-19 pandemic may have influenced the epidemiological patterns of dengue.

Objective: This study aimed to evaluate epidemiological changes in dengue incidence in Southeast Asia.

Methods: We conducted a retrospective, multicountry ecological study analyzing trends in dengue incidence in 7 Southeast Asian countries from January 2000 to December 2023. Data were extracted from official World Health Organization reports and national health department databases. Countries with data that were incomplete, inconsistent, or not publicly available were excluded from the final analysis. Annual incidence rates were analyzed, and linear trends were calculated to assess long-term patterns.

Results: Epidemiological data from 7 Southeast Asian countries, comprising Thailand, Singapore, Vietnam, Malaysia, the Philippines, Cambodia, and Taiwan, were analyzed across the 24-year study period. A notable nadir in dengue cases was observed coinciding with the COVID-19 pandemic. Significant increasing trends in dengue incidence were identified in Singapore, Vietnam, Malaysia, and the Philippines (slopes: 8.243, 6.513, 8.737, and 8.172; R^2 values: 0.14, 0.34, 0.345, and 0.46, respectively, all $P<.05$).

Conclusions: Dengue fever continues to pose a significant public health challenge in Southeast Asia. Our analysis demonstrates a substantial increase in dengue cases in several countries over the study period. While a temporary decline was observed during the COVID-19 pandemic, a subsequent resurgence of cases highlights the persistent threat of dengue in the region. These findings underscore the critical need for sustained surveillance and innovative control strategies to mitigate the impact of dengue in Southeast Asia.

KEYWORDS

dengue; COVID-19; epidemiology; Southeast Asia; public health

Introduction

Dengue fever, a vector-borne disease transmitted primarily by *Aedes aegypti* and *Aedes albopictus* mosquitoes, remains a significant global health challenge, particularly in Southeast Asia [1]. This arboviral infection presents a wide spectrum of clinical manifestations, ranging from self-limiting febrile illness to severe, life-threatening complications [2]. The global burden of dengue is substantial, with an estimated 400 million infections annually, of which approximately 100 million result in symptomatic disease and 21,000 in fatalities [3,4]. Dengue transmission is closely associated with ambient temperature, and Southeast Asia remains a hyperendemic region [5]. According to a global systematic review of dengue disease

XSL•FO
RenderX

burden, Southeast Asia exhibited significantly higher incidence rates than other world regions [6]. During the decade of 2001 to 2010, the region reported an estimated annual average of 2.9 million dengue cases and 5906 associated deaths [7]. The economic burden, including direct medical costs and productivity loss, along with substantial disability-adjusted life years, further underscores the considerable public health impact in this region. Despite this impact, specific antiviral treatments remain elusive, and effective vaccination strategies are not yet widely implemented, making dengue a persistent threat [8].

The dynamics of dengue transmission are intricately linked to environmental factors, making the disease particularly susceptible to the effects of global climate change. According to the World Meteorological Organization, global mean temperatures have shown a consistent upward trend over the past 2 decades, with an average increase of 0.2 °C per decade [9,10]. This warming trend has significant implications for the epidemiology of vector-borne diseases, including dengue [11,12]. Multiple studies have documented an increase in dengue prevalence correlated with rising temperatures and altered precipitation patterns, suggesting a potential exacerbation of disease burden in the context of ongoing climate change [11-16].

Concurrently, the unprecedented COVID-19 pandemic has dramatically reshaped the landscape of global health, influencing the epidemiological patterns of various infectious diseases [17]. The implementation of stringent public health measures, including lockdowns, international travel restrictions, and nonpharmaceutical interventions, led to a marked reduction in the incidence of several droplet- and contact-transmitted diseases, such as influenza and enterovirus infections. However, the easing of these restrictions has been associated with a resurgence of many infectious diseases, highlighting the complex interplay between public health interventions and disease dynamics [18].

In this context, the epidemiological trends of dengue during and after the COVID-19 pandemic remain largely uncertain. The potential impact of climate change and the disruptive effects of pandemic-related interventions create a unique scenario that warrants thorough investigation. Understanding these trends is crucial for public health planning, resource allocation, and the development of targeted prevention strategies. To address this knowledge gap, we conducted a comprehensive retrospective study examining epidemiological changes in dengue across several Southeast Asian countries from January 2000 to December 2023. The findings of this research have the potential to inform evidence-based policies for dengue control and prevention, contribute to our understanding of the complex interactions between dynamics, pandemics, and vector-borne diseases, and ultimately improve public health outcomes in Southeast Asia and beyond.

Methods

Study Design and Data Sources

We conducted a retrospective, multicountry ecological study analyzing trends in dengue incidence in 7 Southeast Asian countries from January 2000 to December 2023. Data on annual dengue cases were extracted from the following sources: (1) the World Health Organization (WHO) Global Health Observatory data repository [19], (2) the national centers for disease control and prevention of the respective countries, and (3) the ministry of health databases of the selected countries [19-26]. We first screened the WHO Global Health Observatory database to identify countries with available annual dengue incidence data [27]. Subsequently, we cross-validated the data with official national sources, including the websites of ministries of health or national centers for disease control. Countries with data that were incomplete, inconsistent, or not publicly available were excluded from the final analysis. In parallel, we retrieved national annual average temperature trends from publicly accessible climate databases [28]. A flowchart detailing the country selection process is provided in Multimedia Appendix 1.

Data Collection and Processing

For each country, we compiled the annual number of reported dengue cases and population estimates to calculate incidence rates. Crude dengue incidence rates (cases per 100,000 population) were calculated by dividing the annual number of reported cases by the corresponding national population estimates, allowing for cross-country comparability. Population data were obtained from the publicly available United Nations demographic database [29]. Further standardization by age and sex was not performed, as the primary objective of this study was to assess overall national dengue incidence. In cases of data discrepancies between sources, national health authority reports were prioritized, followed by WHO data. Cross-verification between multiple sources was conducted for validation and quality control by 2 authors independently. Dengue is a notifiable communicable disease in all countries included in this study. We used Taiwan as an example, where the diagnosis of dengue is based on a combination of clinical, epidemiological, and laboratory criteria. Genetic typing is performed in specific scenarios, such as the identification of index cases in endemic regions or during outbreak investigations. Confirmed cases are further classified as either imported or locally acquired. In this study, both imported and local cases in Taiwan were included to characterize the composition of reported dengue cases. In addition, national annual average temperature data during the study period were retrieved from publicly accessible meteorological databases.

Statistical Analysis

Statistical analyses were performed using R statistical software (version 4.1.0). Annual incidence rates per 100,000 population were calculated for each country, and epidemiological trends were visualized using the *ggplot2* package. Linear regression models were applied to assess the trends in dengue incidence over time, with the model specified as $Y=\beta0+\beta1X+$, where Y is the annual dengue incidence, X is the year, β0 is the intercept, β1 is the slope, and is the error term. Model parameters, including the slope and R^2 values, were evaluated to determine the direction and strength of the trends. A *P* value less than .05 was considered statistically significant.

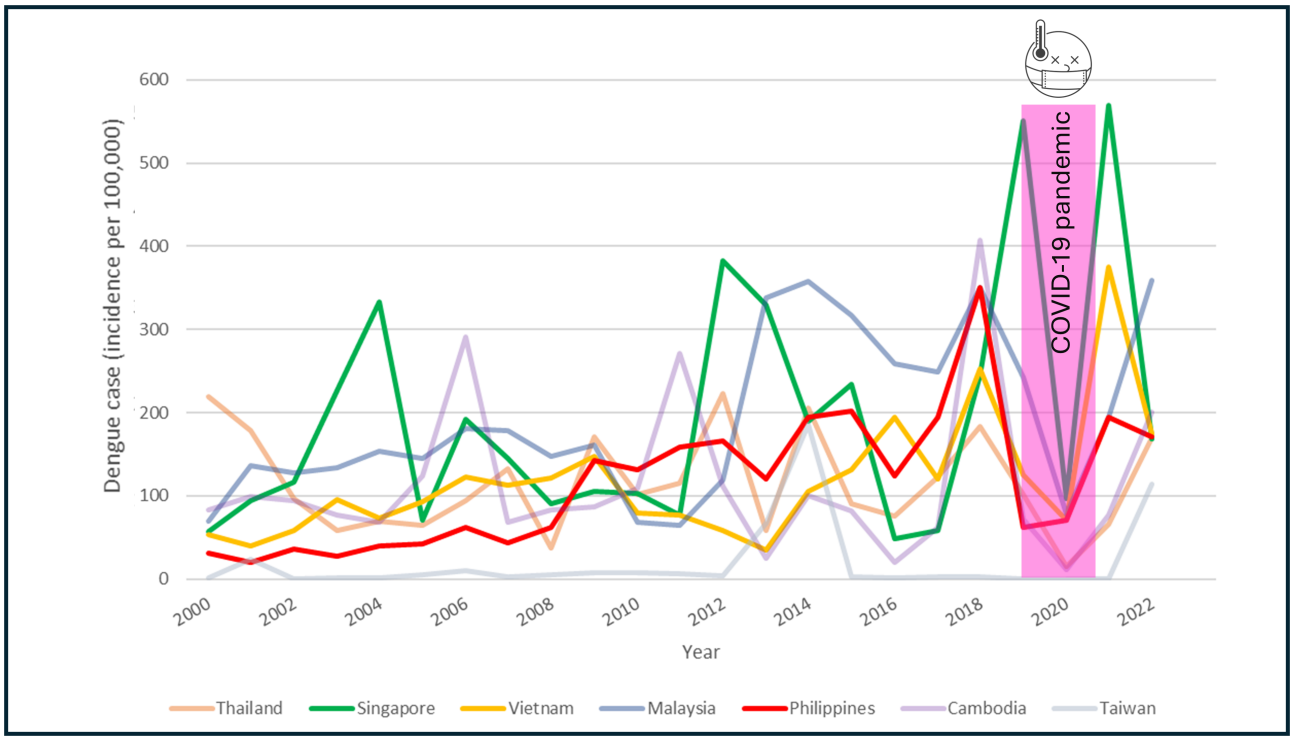
Ethical Considerations



This study was conducted in accordance with the ethical standards of the Declaration of Helsinki [30]. Our study was approved by the institutional review board of MacKay Memorial Hospital, Taipei, Taiwan (20MMHIS140e). This study used publicly available, aggregated data and did not involve individual patient information. We adhered to the principles of ethical research practice throughout the study.

Results

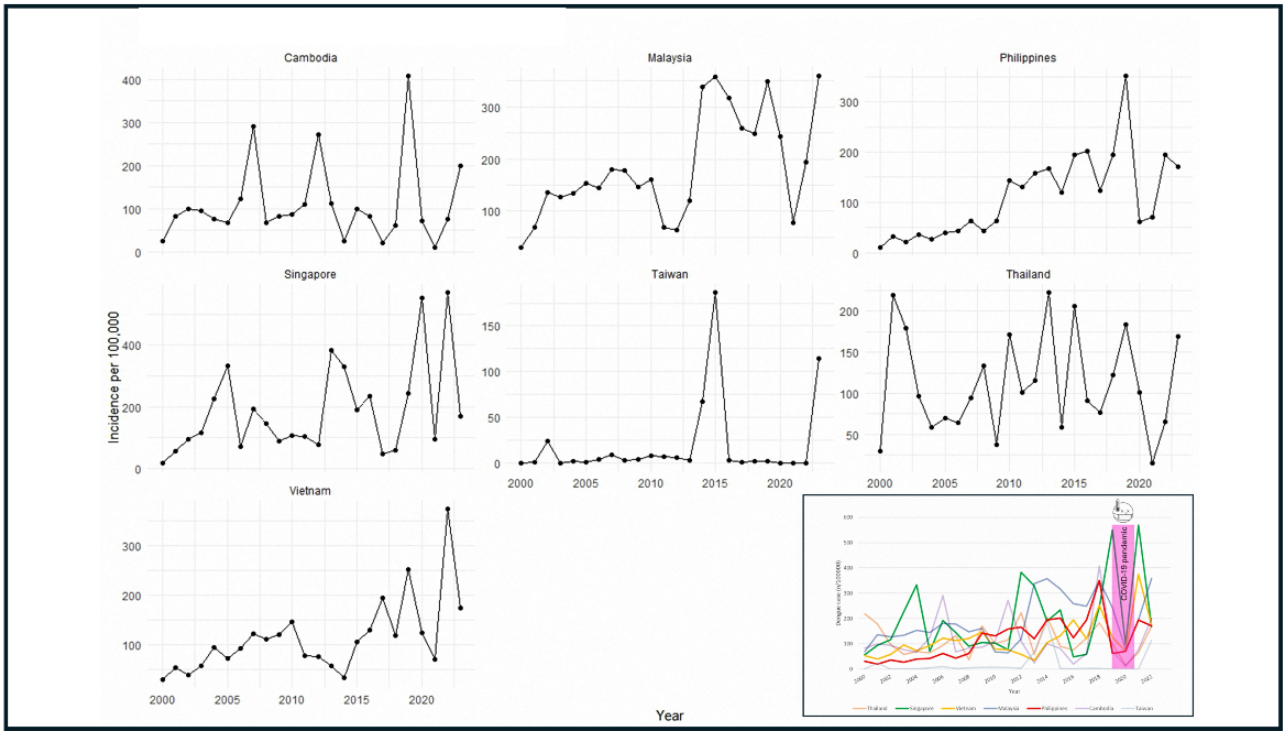
After excluding countries with incomplete data, including Laos, Myanmar, Brunei, Indonesia, and Timor-Leste, 7 countries were included in the final analysis: Thailand, Singapore, Vietnam, Malaysia, the Philippines, Cambodia, and Taiwan. A schematic illustration of the included countries is shown in Multimedia Appendix 2. The annual trends in average temperature across these countries over the 24-year study period are presented in Multimedia Appendix 3, demonstrating an overall temperature increase ranging from 0.97 °C to 2.22 °C. The dynamic trends in dengue cases for the countries are plotted in Figure 1 and Multimedia Appendix 4. Fluctuations in dengue incidence were observed across countries, and dengue was more prevalent in Malaysia, Singapore, and Vietnam. A nadir of dengue cases occurred during the COVID-19 pandemic in 2020, and a resurgence of dengue cases was reported after 2022. Dengue incidence in individual countries is plotted in Figure 2; most countries had a rising incidence during the 24 years. There was no multicountry cluster. The peak incidence was approximately 500 cases per 100,000 inhabitants, observed in Singapore. We further examined the linear trend of dengue incidence in each country and summarize the slopes and R^2 values in Multimedia Appendix 5. All slopes were positive, except for Thailand. Significant increasing trends in dengue incidence were identified in Singapore, Vietnam, Malaysia, and the Philippines (slopes: 8.243, 6.513, 8.737, and 8.172; R^2 values: 0.14, 0.34, 0.35, and 0.46, respectively; all P values <.05).

The epidemiological trend for imported and local cases in Taiwan is plotted in Figure 3. Sporadic imported cases with an increasing trend were observed before COVID-19 (2000 - 2019: slope=0.15; R^2=0.46). A significant surge of local cases was observed in 2014, 2015, and 2023. However, a substantial decline in both imported and local cases was found during the COVID-19 pandemic. A gradual increase in imported cases occurred after the ease of restrictions in 2022, followed by an exponential surge in local cases in 2023.

Figure 1. Dynamic trends in dengue incidence in Southeast Asia.

XSL•FO
RenderX

Figure 2. Trends in dengue incidence in individual countries in Southeast Asia. The inset figure illustrates the annual trends of each country and indicates that no multicountry clusters were observed.



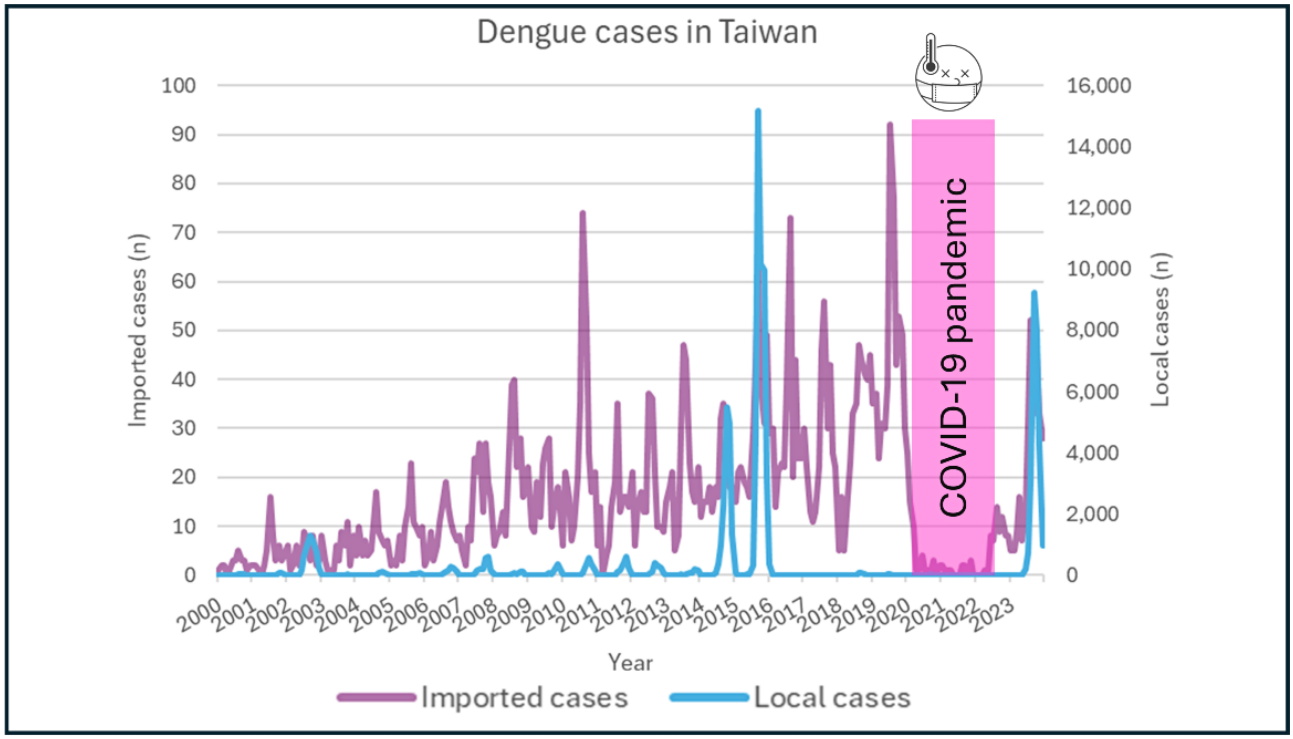


Figure 3. Epidemiological changes in imported and local cases in Taiwan.

Discussion

Principal Findings

The disease burden of dengue is unquestionably substantial. Our study elucidates the epidemiological changes in an endemic region over a 24-year period. Despite advances in public health, we observed a significant increase in dengue incidence in several Southeast Asian countries, including the Philippines, Vietnam, Malaysia, and Singapore. Other countries demonstrated relatively stable endemic patterns. While dengue cases declined during the COVID-19 pandemic, a notable resurgence was observed across all studied countries, underscoring dengue's continued significance as a critical public health threat in the postpandemic era.

A marked nadir in dengue incidence was observed during the COVID-19 pandemic. Public health strategies, implementation

XSL•FO
RenderX

of nonpharmaceutical interventions, and social and international restrictions likely contributed to this observed reduction. In Sri Lanka, for instance, national dengue case numbers significantly decreased during lockdown periods [31]. In Australia, dengue cases nearly disappeared during the pandemic [32]. Our study revealed that Thailand, Cambodia, and Taiwan reported fewer than 30 cases per 100,000 inhabitants during this period. However, the apparent decrease in reported dengue cases may be attributable to underreporting due to several factors: inadequate medical resources, compromised communication systems, limited diagnostic capabilities, and reduced health care–seeking behavior. Most dengue infections present with mild symptoms such as fever, headache, arthralgia, and skin rashes, and individuals with mild illness may have been less likely to seek medical attention due to reduced health care services and concerns about potential COVID-19 exposure. Additionally, health care providers were primarily focused on COVID-19 diagnostics, potentially leading to decreased dengue screening and testing. During the COVID-19 pandemic, neither the virus nor vector-borne mosquitoes disappeared; instead, they remained latent within communities, waiting for opportunities to resurface. In the aftermath of the COVID-19 pandemic, an "immune debt" phenomenon has emerged, leading to the resurgence of numerous infectious diseases, including influenza, enterovirus, respiratory syncytial virus, and dengue fever. Multiple countries, such as Brazil, Australia, Egypt, and Taiwan, have experienced significant dengue fever outbreaks following the relaxation of pandemic-related restrictions [32-37]. Our research has uncovered similar trends: during the COVID-19 pandemic, stringent preventive measures and reduced international travel disrupted typical epidemiological patterns. Consequently, the health threat posed by dengue fever remains a critical public health concern in the postpandemic era.

Climate change and global warming may contribute to the expanded distribution of vector mosquitoes and increased dengue incidence [11,12,35,38-41]. The optimal temperature for *Aedes albopictus* and *Aedes aegypti* is approximately 25 °C to 30 °C [10]. Warmer temperatures can shorten viral replication incubation periods in mosquitoes, accelerate mosquito growth, and increase biting frequency. Our study showed an overall temperature increase ranging from 0.97 °C to 2.22 °C. Consequently, climate change may expand vector habitat ranges and potentially increase infection transmission zones. Theoretically, dengue is more prevalent in tropical regions. Our study showed a relatively lower incidence in Taiwan, a subtropical country. However, dengue prevalence is influenced by multiple complex factors. We found that the dengue incidence rates significantly increased over the study period in the Philippines, Vietnam, Malaysia, and Singapore. However, these countries were not those with the lowest latitudes or the highest average temperatures among the study sample. Urbanization may reduce breeding sites, alter water accumulation patterns, and impact vector proliferation. Population density and international travel resumption potentially contribute to disease spread [42]. Interestingly, some research has explored correlations between economic indicators like gross domestic product (GDP) and dengue transmission, though findings remain inconsistent [43,44]. Countries with lower GDP often have limited investment in public health infrastructure, medical services, and vector control programs, which may contribute to higher dengue transmission. Conversely, widespread dengue outbreaks may negatively impact national economies by reducing tourism revenue and workforce productivity, thereby further decreasing GDP. In brief, the incidence of dengue epidemics is fueled by multiple complex factors [45,46]. Data from the past 24 years indicate that these evolving trends cannot be explained by any single factor alone.

Limitations

Our study possesses notable strengths, primarily stemming from its comprehensive analysis of national databases that systematically tracked epidemiological trends across 7 countries over an extensive 24-year period, encompassing both pre- and post–COVID-19 pandemic epochs. However, the research is not without limitations. The study was unable to comprehensively characterize the severity of dengue infections, which range from asymptomatic to severe. Moreover, multiple complex and potentially influential factors remained unaccounted for in this analysis, including nuanced variations in climate patterns, urbanization levels, international travel dynamics, economic indicators, and vaccination status. These unexamined variables could potentially modulate dengue transmission in ways not fully captured by our current methodological approach. Due to the unavailability of reliable data, several countries were excluded from the final analysis. Consequently, while our findings provide valuable insights into regional dengue epidemiology, they also underscore the necessity for future research that can more comprehensively integrate these multifaceted determinants of disease transmission.

Conclusion

Our 24-year epidemiological analysis of dengue fever in Southeast Asia reveals the complex dynamics of disease transmission. The COVID-19 pandemic temporarily disrupted transmission patterns, but the subsequent resurgence highlights the virus's resilience. Ongoing, multicountry surveillance efforts are essential for the effective prevention and control of dengue.

Acknowledgments

We sincerely thank the World Health Organization and the respective national health authorities for their efforts in disease surveillance and data collection, which made this research possible. We acknowledge the use of generative language tools (ChatGPT and Claude) for language translation and polishing.

Abstract

Background: The human capacity to process information is limited. During the COVID-19 pandemic, people were exposed to a large amount of uncertain and complex health information. This situation made some people experience perceived information overload, which made them unable to adopt appropriate preventive behaviors.

Objective: This study aimed to examine the individual characteristics, abilities, and attention to informational media that predict the perception of information overload during a pandemic.

Methods: We conducted a longitudinal study with 2 time points, August 2020 and August 2021, among residents of Japan under a COVID-19 emergency declaration. The sample had the same proportions for sex, age, and prefecture as the general Japanese population. We used a web-based survey to measure sociodemographic characteristics, health literacy (HL), attention to 6 different types of information channels, and participants' perception of information overload. Hierarchical multiple regression analysis was conducted with information overload as the objective variable.

Results: A total of 784 participants responded to the survey at both time points, with a follow-up rate of 78.4% (784/1000). Hierarchical multiple regression analysis showed that younger age (β=−0.084, 95% CI −0.142 to −0.013), male sex (β=−0.163, 95% CI −0.008 to −0.003), lower HL (β=−0.084, 95% CI −0.114 to −0.011), paying less attention to television news (β=−0.118, 95% CI −0.038 to −0.001), and paying greater attention to social media (β=0.089, 95% CI 0.000-0.027) significantly predicted information overload 1 year after exposure to information during the pandemic.

Conclusions: Public health communicators should aim to provide concise and understandable information in consideration of a target population that is vulnerable to information overload during a pandemic. A high level of attention to social media may increase the perception of information overload. By contrast, HL may reduce the cognitive load in information processing. Providing an environment during normal periods that allows people to develop the skills to critically interpret health information will help them to prepare for future infodemics.

Introduction

Background

The unexpected occurrence of the COVID-19 pandemic caused a serious and prolonged threat to human health and life. To cope with this threat, people consumed information from diverse media sources to stay informed about this emerging infectious disease [1,2]. At the 2020 Munich Security Conference, the World Health Organization (WHO) director general stated that the world was not only dealing with a pandemic, but also with an infodemic [3,4]. The COVID-19 pandemic occurred amid the ongoing proliferation of new media platforms, such as social media, where anyone can disseminate any type of information. Fake news, misinformation, and conspiracy theories spread faster than ever via these new media channels [3,5,6]. In addition, information during a pandemic is often uncertain. It has become apparent that ensuring that the public can adequately perceive information to protect their own lives and well-being during a pandemic is an enormous challenge within public health communication.

Information Overload

The human capacity to process information is limited [7-10]. Therefore, a rapid influx of information can impose a psychological burden. Information overload can be defined as a situation where the amount of information provided within a certain time frame exceeds an individual's capacity to process the information [11]. Information overload affects people's decision-making accuracy, time to reach a decision, and general performance [12]. More specifically, with information overload, a person can become overly selective, ignore large amounts of information, have difficulty understanding the relevance of details with respect to the overall perspective, and require more time and effort to acquire information [12]. Similarly, when people are faced with overly complex health information, they may not recognize the information as personally relevant or valuable, and may be unable to infer what information is needed to engage in appropriate behavior [13].

Information Overload and Health Behavior

People experiencing information overload tend to have negative attitudes toward health information [14,15]. Consequently, they are less motivated to seek out and digest such information, which ultimately reduces their health knowledge and associated skills [15,16]. In the field of health, the problem of information overload has been studied in recent years. For example, a study of cancer information seeking showed that information overload leads to the avoidance of cancer screening and a lack of appropriate preventive behavior [17]. A study of patients with newly diagnosed coronary artery disease suggested that information overload has a direct negative impact on their intention to read self-management materials [18]. Previous cross-sectional studies conducted during the COVID-19 pandemic showed that information overload is associated with vaccine hesitancy [19,20]. Information overload in the COVID-19 era has also been reported to cause negative emotions, such as anxiety and depression [21,22]. These findings show that information overload is a health communication concern as a factor that influences health behavior.

Predictors of Information Overload: Theoretical Framework

Cognitive load theory is an important framework for understanding the causes of information overload [23]. This theory was originally introduced in the field of educational psychology and has contributed to the development of educational environments for the retention of knowledge and information [24]. As an application of learning theory, it is also useful for understanding the process by which humans acquire knowledge from news and other sources. In this theory, cognitive load is composed of 3 conceptualized factors: intrinsic, extraneous, and germane load [24]. Intrinsic cognitive load is related to the natural complexity of the information or learning materials that must be understood with respect to a specific topic. Extraneous load can be expressed as the load imposed by information from suboptimal media. When extraneous cognitive load is high, the information seeker disproportionately uses their working memory (WM) resources to deal with the provided media rather than with information seeking itself, so the attention devoted to essential information is reduced. Germane load refers to the WM resources that the information seeker expends to deal with the intrinsic cognitive load of the information. Germane load is related to individual characteristics [24].

Not all individuals experience information overload. The relationship between age and cognitive function, an individual characteristic, has been the focus of research in the fields of neuroscience and gerontology [25-27]. Related studies have shown that cognitive function declines with age in adulthood [28,29]. This suggests that the cognitive load from processing complex information in adulthood is greater with older age. However, a cross-sectional study conducted in Korea during the COVID-19 pandemic found no association between age and information overload [30]. The relationship between age and information overload in the context of health information and pandemics has not been clarified. However, evidence from the field of neuroscience shows that the cognitive load of information increases with age. It is likely that older people were more likely to perceive information overload during the pandemic, when they were exposed to a large amount of complex health information.

Our first hypothesis (hypothesis 1) is that older adults are more likely to experience information overload 1 year later in a pandemic information environment.

Previous studies have indicated that men and women have different psychological adaptations to extreme situations, such as pandemic lockdowns [31]. The WHO has emphasized the differential impact of a pandemic on men and women and the need for research on the effects of the COVID-19 pandemic from a sex-based perspective [32]. The relationship between information overload and sex has been reported in contexts of exposure to news. These studies have shown that women tend to experience greater information overload than men owing to news exposure [4,33,34]. It has been found that men and women use different cognitive resources with respect to news story structures, with women having slower reaction times to news stories [35]. The sex differences in cognitive load are also

XSL•FO
RenderX

supported by research reporting functional magnetic resonance imaging data [26]. When men and women were given the same verbal and visuospatial WM tasks, women experienced greater task demands and higher cognitive load than men. However, as mentioned, the relationship between sex and information overload in the context of health information and pandemics remains unclear. Studies conducted in the context of exposure to early COVID-19 and cancer information reported no significant differences in the perception of information overload between men and women [36]. These studies also had limitations, such as having a cross-sectional design or having limited participant demographics. In the context of the COVID-19 pandemic, news continues to be disseminated daily. Evidence regarding the processing of WM tasks and news suggests that women may be more likely to recognize information overload in the information environment within a pandemic context.

Our first hypothesis (hypothesis 2) is that women are more likely to experience information overload 1 year later in a pandemic information environment.

Health information frequently contains complex medical wording [37,38]. This can especially affect the processing of information, especially for people with reading and writing difficulties [39]. Furthermore, the information released during a pandemic is fraught with uncertainty and is continually revised as new findings emerge. People must engage in repeated information processing each time information is updated. The intrinsic cognitive load caused by this complexity of information is affected by the learner's previous psychological state and knowledge [23]. Therefore, it has been reported that having relevant previous specialist knowledge reduces the learner's intrinsic cognitive load [40]. The degree to which an individual is able to find, understand, and use information and services that are useful for making decisions and taking action regarding their health is referred to as health literacy (HL). There are 3 aspects to HL. Functional HL refers to basic reading and writing skills, communicative HL refers to the ability to extract information from various forms of communication and apply it to changing situations, and critical HL refers to the ability to critically evaluate and use information to exert greater influence [41]. HL has been noted to be related to the experience of information overload as well as health status [41]. For example, previous studies conducted in the context of information seeking regarding cancer and weight management have reported that lower HL correlates with a higher perception of health information overload [42-44]. A cross-sectional study conducted in the United States during the COVID-19 pandemic also reported that individuals with lower HL were more likely to perceive information overload [45]. It is rational to consider that longitudinal analyses would similarly find that high levels of HL are likely to prevent information overload.

Our first hypothesis (hypothesis 3) is that people with higher HL are less likely to experience information overload 1 year later in a pandemic information environment.

When faced with an unknown infectious disease, people pay attention to information provided through various types of media to fill gaps in their knowledge [1,2]. It has been reported that processing information presented by diverse media sources is cognitively difficult [46]. There have been various reports on the impact of social media on users' cognitive load. For example, there are reports on intrinsic cognitive load factors, such as fear of missing out (FOMO), privacy concerns, anxiety, and depression [47]. There have also been reports of extrinsic cognitive load factors, such as parental influence, cyberbullying, complexity, technology-related factors, and social overload [48]. In a study examining news attention and information overload, television viewing lowered the perception of information overload, whereas the use of a PC or Facebook increased perceptions of information overload [33]. During the COVID-19 pandemic, social media has been used daily as a platform for information exchange [49]. Social media users are constantly searching, receiving, identifying, reading, and processing a continuous flow of information. Users have been reported to experience a drain on cognitive energy, feeling overwhelmed and fatigued by the cognitive demands of social media [48,50]. Several cross-sectional studies have reported that people who follow COVID-19-related information on social media are more likely to experience information overload [51,52]. It is rational to assume that a longitudinal analysis would find that attention to social media leads to a greater perception of information overload than exposure to old media.

Our first hypothesis (hypothesis 4) is that greater exposure to social media information increases the experience of information overload 1 year later in a pandemic information environment.

The information flow during a pandemic differs in quantity and quality compared with that during a normal search for information on diseases, such as cancer. There is a need to identify the characteristics of individuals and information channels that predict information overload during a pandemic. Combined with skills that can reduce cognitive load owing to complex information, this information would provide important resources for the design of public health communication strategies to increase appropriate preventive behaviors. However, to the best of our knowledge, no previous studies have longitudinally examined the predictors of information overload during the COVID-19 pandemic.

This Study

The purpose of this study was to longitudinally examine predictors of information overload during the COVID-19 pandemic in terms of individual characteristics, health information–handling skills, and exposure to information as an available resource for information processing. Identifying the factors that influence information overload is essential to the theoretical understanding of these associations and to improving the efficiency of public health communication.

Methods

Study Design

We conducted a longitudinal study in Japan using a web-based survey administered at 2 time points: in August 2020, soon after the WHO's declaration of the COVID-19 pandemic, and 1 year later, in August 2021. The state of emergency declared by the Japanese government was in effect at both times.

XSL•FO
RenderX

Data Collection

A sample was drawn from a panel of 2.2 million Japanese residents using the platform of the research firm Rakuten Insight, Inc. This study was conducted as part of a multipurpose longitudinal survey to examine multiple research questions during the pandemic. We used nonprobabilistic quota sampling for age, gender, and place of residence to match the Japanese population distribution. The sample had a similar distribution for sex, age, and prefecture as the general Japanese population. People eligible to participate in the study were those (1) who lived in areas where a state of emergency had been declared at our study time points, (2) who were not infected with COVID-19 and had no family members who were infected, and (3) who were aged 18 years or older.

We conducted the first survey (T1) on August 15 and 16, 2020, and the second survey (T2) on August 15 to 17, 2021. The 1820 members of the survey panel who met the inclusion criteria were invited via email to respond to the screening questions. As part of the screening process, participants were required to read a web page that outlined our research. After agreeing to participate, participants were given a URL to access the online questionnaire, and then they completed the questionnaire manually. This survey was a closed survey that required participants to enter their ID and password to complete. The survey form developed in this study was sent to 10 participants who had been recruited using the convenience sampling method, and we checked for any items that were difficult to answer or inappropriate before the main survey. Using adaptive questioning, we minimized the number of questions displayed to individuals. All questions displayed were mandatory, and the next question was displayed after the participant had completed the previous question. There was a page where participants could review their answers after completing all the questions, and they could make corrections before submitting their answers.

The T1 closed when 1000 participants from 8 prefectures (Chiba, Hokkaido, Hyogo, Kanagawa, Kyoto, Osaka, Saitama, and Tokyo) completed the questionnaire. The T2 was conducted among the participants recruited in T1. The areas surveyed were under a state of emergency during both survey periods. An analysis was conducted among the 784 participants who completed both surveys. The follow-up rate was 78.4% (784/1000).

Measurements

Independent Variables

Sociodemographic Data

Data on age (continuous), sex (0=male, 1=female), level of education (categorical), household income (categorical), history of infection (binary), and cohabiting family (binary) were collected during T1.

Health Literacy

HL was measured using the 5-item version of the Communicative Critical Health Literacy instrument developed by Ishikawa et al [53]. This instrument uses a 5-point Likert scale ranging from 1 (completely disagree) to 5 (strongly agree) and was applied in T1. The score was the average of 5 items (continuous variables), with higher scores indicating higher HL. The SD in this study was 0.6. The Cronbach α in this study was 0.88.

Attention Paid to Information Channels About the COVID-19 Pandemic

The T1 assessed the frequency of exposure to 7 types of media information channels: newspapers, television news, television tabloid shows, news websites, official websites of the government and medical professional organizations, video-sharing sites, and social media. For each channel, respondents were asked a single question about the extent to which they had paid attention to COVID-19–related information on that media channel over the past week (eg, “How much attention did you pay to information about COVID-19 in newspapers?”). Each item was rated on a 10-point scale that ranged from 1 (paid no attention at all) to 10 (paid a great deal of attention), which was adapted from a previous study [53]. The score was a continuous variable ranging from 1 to 10, with higher scores indicating greater attention to that information channel.

COVID-19 Information Overload

Information overload was assessed using the Corona Information Overload Scale developed by Sarkhel et al [54]. This scale is an adaptation of the Cancer Information Overload scale, modified for the COVID-19 setting [54]. Example items include statements, such as “There are so many different recommendations for the prevention of COVID-19 that it is difficult to know which ones I should follow.” The scale comprises 8 items, with each item rated on a 4-point Likert scale ranging from 1 (do not at all agree) to 4 (very much agree). The score is the average of 8 items (continuous variables), with higher scores indicating a greater perception of information overload. Information overload was assessed at T2. The SD in this study was 0.4. The Cronbach α in this study was 0.89.

Ethical Considerations

A protocol for this study was approved by the ethics review committee of the Graduate School of Medicine, University of Tokyo, based on guidelines for clinical trials involving human subjects (11270). Participants were provided with an explanation of the study and completed a web-based consent form. All participants were given the right to withdraw from the study at any time during the study period. Data were provided to researchers by the research company in a linked but anonymized form. Participants in the online survey were offered points that could be used as 1 yen (US $0.009) per point on the Rakuten e-commerce site as an incentive.

Statistical Analysis

Descriptive statistics were calculated for each sociodemographic variable. We then performed single linear regression analysis as a crude analysis, with the objective variables being information overload, sociodemographic characteristics, HL, and attention to media information.

Hierarchical multiple linear regression analysis was performed as an autoregressive model. In model 1, we included information overload (T2) as the outcome variable and sociodemographic

XSL•FO
RenderX

characteristics, including age (continuous; sex, 0=male, 1=female), level of education (categorical), household income (categorical), history of infection (binary), and cohabiting family (binary), as independent variables. In addition to the variables in model 1, we included HL (T1) as an independent variable in model 2. In addition to the variables in model 2, we included various information channels (T1: news, television tabloid shows, newspapers, news websites, nonnews websites, and social media) as independent variables in model 3. All variables entered as independent variables for all models were forced into the model based on previous studies or theory as variables associated with information overload.

No missing values were observed because the online survey was designed such that respondents could not proceed to the next question if values were missing. Participants who only responded to T1 were not included in our analysis. All tests were 2-sided, and the significance level was set at 5%. We used IBM SPSS (version 25; IBM Corp) for the analysis.

Results

Participants' characteristics are presented in Table 1. The breakdown of characteristics by sex, age, and prefecture of residence was similar to that of the general population in Japan, as stated in the Methods section. The minimum age was 21 years and the maximum age was 76 years. The proportions of participants with an education level lower than a university degree and with a university degree or higher were similar. Approximately half of the participants were full-time employees. The demographic characteristics of participants who were included in the analysis did not differ statistically from the characteristics of those who were excluded owing to not having completed T2.

Table 1. The characteristics of the study participants (N=784).

Participant characteristics	Values
Age (y), mean (SD)	47.14 (12.8)
Sex, n (%)	
Male	396 (50.5)
Female	388 (49.5)
Education, n (%)	
Junior high school	12 (1.5)
High school	156 (19.9)
Vocational school or junior college	175 (22.3)
University	379 (48.3)
Graduate school	62 (7.9)
Household income, n (%)	
<JP ¥2,000,000 (<US $15,000)	64 (8.2)
JP ¥2,000,000-¥6,000,000 (US $15,000-$43,500)	320 (49)
>JP ¥6,000,000 (>US $43,500)	334 (42.6)
Unclear	66 (8.4)
Previous infection, n (%)	21 (2.7)
Cohabiting with family, n (%)	613 (78.2)
Health literacy[a], mean (SD)	3.822 (0.6)

[a]Health literacy was measured by the Communicative Critical Health Literacy.

Table 2 shows the results of the single regression analysis of sociodemographic characteristics, HL, and attention to media information channels in terms of COVID-19 information overload. Significant simple associations with information overload were found for age, sex, education, HL, television news, television tabloid shows, newspapers, and social media.

Social media	0.011	0.068 (0.006; 0.000 to 0.021)	.06

[a]The estimates were calculated by simple regression analysis.

[b]Health literacy was measured by the Communicative Critical Health Literacy instrument.

Table 3 shows the results of hierarchical multiple regression analysis. The results of model 1 showed that younger age (β=−0.084, 95% CI −0.142 to −0.013) was significantly more highly correlated with information overload 1 year later. For sex, information overload was significantly higher for men than for women (β=−0.163, 95% CI −0.008 to −0.003). Lower household income was associated with significantly higher information overload (β=−0.083, 95% CI −0.115 to −0.009). The model 2 results showed that the lower the HL, the higher the information overload (β=−0.084, 95% CI −0.114 to −0.011), which was significant. As the results of model 3 show, information overload was significantly higher for those who paid less attention to television news (β=−0.118, 95% CI −0.038 to −0.001) and for those who paid greater attention to social media (β=0.089, 95% CI 0.000-0.027).

Discussion

Overview

In this study, we examined predictors of information overload during the COVID-19 state of emergency declaration in Japan. The results suggest that predictors of information overload include individual characteristics, skills for handling health information, and the information channels to which individuals are exposed. These results are important findings for developing public health communication strategies that take into account people who are more likely to perceive information overload during a pandemic.

Individual Characteristics That Predict Information Overload

The results of this study did not support our hypothesis that older people are more likely to experience information overload during a pandemic. There are 2 possible reasons why younger people were more likely to experience information overload during the prolonged COVID-19 pandemic conditions. First, young people had fewer health problems before the pandemic than older people. As a result, younger people may have had less experience searching for and processing health information themselves. Previous studies have reported that people with less experience in information processing are more likely to perceive information overload [12,14]. When appropriate resources are lacking, it becomes difficult to integrate new information with an individual's existing knowledge; therefore, the individual does not know how to react to new information [14]. Second, new media channels, such as social media, have developed rapidly in recent years. Younger people are likely to be exposed to older types of media but also use multiple new media channels [55]. During the COVID-19 pandemic, people were exposed to a greater volume of information from a variety of sources, media, and platforms than they were during previous pandemics [52]. This diversity and complexity of platforms can lead to exposure to irrelevant information and the need to allocate extra

XSL•FO
RenderX

WM [40,48,56]. This may have resulted in a greater cognitive burden on younger people. The results of this study suggest that, in the special information environment of a pandemic, young people may experience greater cognitive load than older people.

Contrary to our hypothesis, men were more likely to perceive information overload than women in this study. Although previous studies have demonstrated sex differences in behaviors related to the COVID-19 pandemic, the relationship between information overload and sex has been unclear [31,36]. During a prolonged pandemic, people are affected psychologically and behaviorally by various external triggers. Similar to information overload, one of these triggers is pandemic fatigue, which is more often perceived by men [57]. Pandemic fatigue has been described by the WHO as a loss of motivation owing to the chronicity of a pandemic situation and reportedly comprises 2 concepts: neglect of preventive behaviors and boredom with overexposure to information [58]. Fatigue from repeated exposure to similar information is reportedly associated with information overload [59]. It is possible that men are more vulnerable than women to fatigue owing to repeated exposure to similar information.

In future pandemics, more diverse information may be disseminated than during the COVID-19 pandemic, and more people may perceive information overload. As the results of this and previous studies have shown, younger people and men may not be able to acquire appropriate and correct knowledge owing to information overload and may have difficulty adopting appropriate preventive behaviors. It is necessary to consider information provision strategies that are appropriate for these populations.

Effect of Health Information–Handling Skills With Information Overload

The results of this study support the hypothesis that people with higher levels of HL are less likely to experience information overload. This finding is consistent with the results of 2 cross-sectional studies conducted in the United States during the COVID-19 pandemic [45,59]. Those results suggest that previous skills in handling health information may reduce the intrinsic cognitive load of complex information in a special information environment, such as a pandemic [40]. The HL scale used in our study measured 2 aspects of HL: communicative literacy, which is the ability to extract information and derive meaning, and critical literacy, which is the ability to critically analyze information. It has been reported that critical thinking is an important skill in mitigating information overload [60]. Critical thinking is closely related to information mastery competencies, such as problem-solving and self-management [61].

As a skill that individuals can develop in advance, HL is an important resource to help combat information overload during a pandemic. HL can be improved through intervention [62]. Therefore, education in developing the skills needed to appropriately process health information should be promoted. Although not addressed in this study, functional literacy is also an important aspect of HL. The variance in functional literacy among Japanese people is small, and it is not suitable for predicting health-related behavior and outcomes. However, additional findings on this aspect will lead to the development of information provision strategies for people with limited functional HL [63].

Information Channels That Predict Information Overload

Regarding the association between the degree of attention to each information channel and information overload, our study results support our hypothesis that greater attention to social media information is a predictor of information overload. In addition, we found that survey respondents who were attentive to television news had a significantly lower perception of information overload. This result can be explained by the characteristics of the information provided by both types of media, as follows. First, the characteristics of the media content differ between these types of media. Television news involves mainly objective facts that have been scrutinized by the news organization, whereas social media information involves mainly subjective perspectives and interpretations by individuals. The 2018 Edelman Trust Barometer Special Report concluded that only 41% of people trust social media [64]. When obtaining information from another individual on social media, there is a cognitive load involved in determining whether that information is worth believing [55]. Concerns about the quality of information may contribute to increasing the cognitive load in information processing [43,65]. A cross-sectional study conducted in the United States during the COVID-19 pandemic reported that individuals receiving information through 2 channels, social media and interpersonal communication, were less likely to perceive information overload than those receiving information through social media alone [65]. Social media information may reduce the cognitive load when provided through interpersonal communication. Second, the originator of information differs among these media sources. Television news is transmitted from a news broadcasting agency by professional news readers, whereas social media information can be transmitted by anyone, including laypersons, and is often put forth by people who are closer and more connected to the individual receiving the information. One cause of the intrinsic cognitive load with social media is FOMO, which can occur when people exchange information among connected individuals [66]. FOMO is defined as a person's experience of pervasive anxiety that others may be having rewarding experiences that they themselves are not experiencing, and is characterized by a desire to continuously connect with what others are doing [67]. This makes it difficult for some individuals to reduce or stop using social media for fear of missing important information and activity on social media [68,69]. From the perspective of cognitive load, personal informational media to which the user has an emotional attachment (eg, social media) may involve a high cognitive load, whereas informational media that provides objective information with no emotional attachment (eg, television news) may produce a lower cognitive load.

On the basis of the results of this research and the findings of previous studies, we propose several approaches to reducing information overload during a pandemic from the perspectives of intrinsic, extrinsic, and germane cognitive load. First, health information about a pandemic is uncertain and changes over

XSL•FO
RenderX

time, which means it has a high intrinsic load. One factor that reduces intrinsic load is previous specialist knowledge and skills. Encouraging people to develop skills, such as HL, information literacy for reading information critically, and slow reading under normal circumstances, will help to reduce the cognitive load caused by the complexity of information during a pandemic [60,70]. Approaches to reducing extrinsic load using technological methods have been proposed. These include methods that improve conciseness, consistency, and understandability of information content, as well as increasing findability, a technique that makes it easier for users to find content based on their needs [60,71]. Finally, for people who have characteristics that make them more susceptible to cognitive overload from complex health information during a pandemic, it may be possible to provide information that is less likely to cause overload by segmentation according to sex and age. These approaches can be adopted as part of an information delivery strategy by public health communicators to mitigate information overload during a pandemic.

Limitations

Several limitations should be considered when interpreting the results of this study. First, because this was an observational study, a causal relationship between individual characteristics or attention to media information and information overload cannot be established from these results. Therefore, we relied on previous studies and existing theories in our discussion. However, given the considerable difficulty in conducting a randomized controlled trial during a public health crisis, the results of this study represent important findings. Second, study participants were registered members of a survey panel recruited by an internet company, and their educational background tended to be higher than that of the general Japanese public. We adjusted for the influence of educational background using multiple regression analysis; however, there is a possibility that there are still unadjusted factors related to self-selection. In addition, considering the R2 scores of each regression model, there may be unknown variables that can better explain information overload. Finally, single-item, unvalidated scales were used in this study to assess the degree of attention to media information. We adopted items that have been commonly used in previous studies to enable comparisons with results from other infectious disease pandemics and findings from other countries. In the future, we anticipate the development of scales that will measure these factors.

Conclusions

During the COVID-19 pandemic, people have been exposed to a great deal of information through multiple media channels, constituting an infodemic. The results of this study have longitudinal implications in terms of the characteristics of individuals and types of informational media that can predict information overload in a specific informational environment. Public health communicators should consider younger people, men, and people with low HL when developing public health communication strategies during a pandemic. High levels of social media attention may increase the perception of information overload. Therefore, public health communicators can incorporate technical approaches to prevent information overload during a pandemic, such as improving the findability of appropriate information and preparing concise, understandable content. Moreover, providing opportunities for educating the public about critical reading of health information during normal periods will help individuals to prepare for future infodemics during which anyone can disseminate information.

Abstract

Background: Stratified health care systems are used globally to optimize medical resource allocation and enhance patient care experiences. Although successfully implemented in countries like the United Kingdom, Australia, and Canada, China's introduction of stratified health care in 2015 has achieved progress in disease management but still faces challenges due to the lack of a comprehensive referral evaluation system and patients' preference for higher-tier medical institutions.

Objective: This study aims to investigate the factors influencing Chinese rehabilitation physicians' referral decisions for outpatient rehabilitation patients. The findings may provide empirical evidence for developing stratified rehabilitation triage tools and constructing a referral evaluation system in China.

Methods: This cross-sectional study, conducted from September 2023 to January 2024, examined the patient factors (diagnosis, functional impairments, disease status, condition stability, duration of illness, and functional status measured via the Longshi Scale) impacting physicians' referral decisions for outpatient rehabilitation services in China. Data were collected through convenient stratified sampling from physicians and outpatient rehabilitation patients across 12 medical institutions in 5 cities in China.

Results: A total of 131 rehabilitation physicians conducted diversion assessments for 1984 outpatient rehabilitation patients in this study. In total, 45.5% (902/1984) of outpatient rehabilitation patients were considered by physicians to be referred to rehabilitation outpatient clinics, 19% (376/1984) to primary health care institutions, 20.4% (405/1984) to secondary institutions, and 15.2% (301/1984) to tertiary institutions. Single-factor analysis indicated that age, disease, functional impairment, disease control, disease stability, and Longshi Scale results were significantly associated with physicians' decisions regarding the referral institutions for outpatient rehabilitation patients. Logistic regression analysis showed that neurological disorders (odds ratio [OR] 1.88, 95% CI 1.02 - 3.43; *P*=.04), cardiopulmonary diseases (OR 2.91, 95% CI 1.07 - 7.93; *P*=.04), geriatric conditions (OR 0.40, 95% CI 0.23 - 0.68; *P*<.001), disease control (OR 0.23, 95% CI 0.13 - 0.34; *P*<.001), and Longshi Scale results for the bedridden (OR 0.10, 95% CI 0.14 - 0.34; *P*<.001), and domestic groups (OR 0.24, 95% CI 0.14 - 0.34; *P*<.001) as independent factors for referrals to tertiary versus primary institutions. Orthopedic diseases (OR 3.27, 95% CI 1.89 - 5.67; *P*<.001), geriatric conditions (OR 0.58, 95% CI 0.33 - 1.87; *P*=.009), cognitive impairments (OR 1.98, 95% CI 1.17 - 3.36; *P*=.01), multiple impairments (OR 0.35, 95% CI 0.18 - 0.70; *P*=.002), and disease control (OR 0.26, 95% CI 0.15 - 0.37; *P*<.001) were key factors for tertiary versus secondary referrals.

Conclusions: In advancing China's rehabilitation triage in the future, gaining a deep understanding of the key factors influencing physicians' decisions and quickly establishing a referral evaluation system will facilitate the accurate diversion of outpatient rehabilitation patients, enabling them to receive convenient, high-quality, and low-cost medical services. In addition, it will assist the government in reasonably and effectively allocating medical resources, thus achieving the optimization and coordination of the health care system.

Introduction

Stratified health care systems have garnered significant attention globally as a pivotal strategy to optimize medical resource allocation and enhance patient care experiences. Countries like the United Kingdom, Australia, and Canada have implemented stratified triage models within their health care frameworks, showcasing successful applications in improving medical efficiency and patient satisfaction [1-3]. These systems prioritize timely treatment for emergency cases while streamlining nonemergency care, thereby alleviating the burden on health care resources and ensuring equitable access to quality care across diverse geographic regions [4,5]. However, despite the widespread adoption of stratified health care models internationally, challenges persist, including the need for standardized patient referral evaluation systems and addressing patient preferences for seeking care at higher-tier facilities [6,7]. Stratified health care, also known as hierarchical medical care, is a system designed to optimize the allocation of medical resources by categorizing health care delivery into primary, secondary, and tertiary levels based on disease severity, treatment needs, and institutional capacity. The core principles of stratified health care include graded diagnosis and treatment, bidirectional referrals, and collaborative care among different health care tiers. In the context of rehabilitation services, stratified health care plays a critical role in ensuring that patients with varying levels of functional impairment and disease complexity receive appropriate and timely interventions. By directing routine or stable cases to community-based institutions and reserving higher-level hospitals for complex, resource-intensive rehabilitation needs, this model enhances care efficiency, reduces medical costs, and improves patient outcomes. The implementation of stratified health care systems is especially important in aging populations with increasing demand for long-term rehabilitation and chronic disease management.

In China, notable progress has been made in advancing stratified health care initiatives since the State Council introduced the concept of stratified health care in 2015 [8]. This approach, characterized by "primary care as the entry point, bidirectional referral, classification of urgency and seriousness, and coordination between upper and lower levels," has demonstrated considerable potential in improving the management of common diseases like stroke [9]. However, the absence of a comprehensive patient referral evaluation system poses challenges to informed decision-making among health care providers within the stratified health care framework. Furthermore, patient preferences for seeking care at higher-tier facilities remain a barrier to the effective implementation of stratified health care, hindering the equitable distribution of medical resources [10].

Within the context of stratified health care, the decision-making process for outpatient rehabilitation patient referrals by physicians plays a critical role in optimizing resource use and enhancing patient care experiences [11]. Yet, there is a paucity of research exploring the factors influencing physician referral decisions for rehabilitation patients across different health care institutions. Therefore, this study aims to investigate the factors influencing Chinese rehabilitation physicians' referral decisions for outpatient rehabilitation patients, with the findings expected to provide preliminary insights for optimizing referral processes in China's rehabilitation system or similar health care systems worldwide.

The decision to focus specifically on outpatient rehabilitation patients was driven by the unique referral challenges and service demands associated with this population. Unlike acute care patients, rehabilitation patients often present with chronic or progressive conditions requiring continuous, multidisciplinary management across institutional levels. Their care pathways are more dependent on timely and appropriate referral decisions to ensure functional recovery and long-term quality of life. Furthermore, rehabilitation services are increasingly being decentralized to primary and community-level institutions in line with health system reforms, making referral decisions a critical juncture for aligning patient needs with institutional capabilities. Despite this, existing literature rarely explores how physicians determine the most suitable rehabilitation setting within stratified health care frameworks, leaving a significant gap in understanding referral behavior specific to this domain.

Methods

Ethical Considerations

This study received ethical approval from the Clinical Research Ethics Committee of the Second People's Hospital of Shenzhen (2023-226-02PJ). Electronic informed consent was obtained from all participants before their inclusion in the study. All collected data were anonymized to protect participant privacy. Personal identifiers were removed, and data were stored securely in password-protected systems accessible only to the research team. Participants received no financial compensation for their time and participation.

Study Design

This study used a cross-sectional design to investigate the factors influencing physicians' referral decision-making for outpatient rehabilitation services within the Chinese health care context. Data were collected from September 2023 to January 2024 across 12 medical institutions in 5 cities, which were Shenzhen (Guangdong Province), Linfen (Shandong Province), Chengdu (Sichuan Province), Haikou (Hainan Province), and Changzhou (Jiangsu Province). A convenient stratified sampling method was used to recruit physicians and outpatient rehabilitation patients.

The term "stratified sampling" in this study refers to the selection of medical institutions across multiple administrative levels and geographic regions to ensure representativeness and diversity in the data. Specifically, stratification was conducted based on two key dimensions: (1) institutional tier (primary, secondary, and tertiary health care institutions) and (2) geographic location, involving 5 representative cities across different provinces (Shenzhen, Linfen, Chengdu, Haikou, and Changzhou). Within each stratum, a convenience sampling approach was applied to recruit rehabilitation physicians and patients who met the inclusion criteria. This stratified strategy aimed to capture variations in physician referral decision-making

XSL•FO
RenderX

across different health care settings and regional contexts, thereby enhancing the generalizability and validity of the study findings.

The 12 participating medical institutions in this study were selected to reflect a diverse range of health care settings in China. These included 4 tertiary general hospitals, 3 secondary-level regional hospitals, and 5 primary-level community health centers or township hospitals. All institutions were publicly funded, aligning with the dominant structure of China's public health care system. Tertiary hospitals included urban academic medical centers with comprehensive rehabilitation departments and multidisciplinary teams. Secondary hospitals were typically municipal or district-level facilities offering intermediate rehabilitation services, while primary institutions focused on basic rehabilitative care and chronic condition management. This institutional diversity allowed for the assessment of referral behaviors across different tiers of medical care and ensured that the findings could be generalized to a broad spectrum of health care providers within the Chinese public health system.

In the context of China's hierarchical health care system, medical institutions are categorized into primary, secondary, and tertiary levels based on their scale, service scope, and technical capabilities. Primary health care institutions, such as community health service centers and township health clinics, primarily provide basic medical care, health education, and rehabilitation services for common and chronic diseases, focusing on prevention and routine functional maintenance. Secondary health care institutions, typically regional hospitals, offer more specialized rehabilitation services, including early-stage post-discharge rehabilitation, physical therapy, and occupational therapy, and serve as referral hubs between primary and tertiary levels. Tertiary health care institutions are large general or specialized hospitals equipped with advanced medical technology and multidisciplinary rehabilitation teams. They provide comprehensive and intensive rehabilitation services for patients with complex, severe, or multiple comorbid conditions, including postsurgical recovery, neurological rehabilitation, and interdisciplinary care. These tiered definitions guided the physician referral decisions analyzed in this study.

Study Population

Physicians included in the study were those actively engaged in referring patients to rehabilitation outpatient services within the selected medical institutions. Patients eligible for participation were those seeking rehabilitation outpatient services during the study period. The study participants consist of licensed physicians from relevant institutions who possess clinical experience and voluntarily participate in the research, as well as outpatient rehabilitation patients. The inclusion criteria for patients are as follows: (1) in need of rehabilitation therapy during hospitalization, (2) able to complete questionnaires cooperatively, (3) outpatient status, and (4) voluntary participation in the study.

In the Chinese medical system, physicians' professional titles reflect their level of clinical expertise, academic qualifications, and years of practice and are typically categorized into 3 levels. Entry-level titles (eg, Resident Physician or Physician-in-Training) usually indicate junior practitioners with fewer years of clinical experience and who may still be under supervision. Intermediate-level titles (eg, Attending Physician or Physician) are held by those with several years of independent clinical practice, typically responsible for routine diagnosis, treatment, and initial referral decisions. Senior-level titles (eg, Chief Physician or Associate Chief Physician) denote highly experienced practitioners who often serve in leadership roles, participate in policy development, and handle complex cases requiring multidisciplinary expertise. These distinctions in professional title were considered during the data collection process and may potentially influence physician decision-making behavior.

The required sample size was determined through an a priori power analysis based on our primary hypothesis that physician referral patterns differ significantly across institutional tiers. The proportions from 3 groups were compared in our study, thus "Tests for Multiple Proportions" were used to calculate the total sample size. A sample of 1404 subjects, divided among 3 groups, achieves a power of 0.90. This power assumes a chi-squared test from an analysis with 2 degrees of freedom is used at a significance level of 0.05. The group proportions under the alternative hypothesis are 0.5, 0.6, and 0.6. The effect size is 0.07 [12-15]. The final patient sample in our study (n=1984) exceeded requirements.

Data Collection

This study used a customized survey embedded within the WeChat Longhai Rehabilitation Mini Program to gather data. The survey content for this study includes 2 parts: the physician questionnaire and the patient questionnaire. The physician questionnaire covers the physician's gender, age, education level, specialty, professional title, and years of work experience. The patient questionnaire includes the patient's gender, age, and medical condition, including the reason for the current visit, the Longshi Scale assessment, the course of the disease, whether there is functional impairment, whether the condition is stable, and the physician's diversion recommendations. The Longshi Scale, designed by the Rehabilitation Medicine Department team at the Shenzhen Second People's Hospital, is a graphical scale for assessing the daily living abilities of patients with functional impairments. It has been shown to have good reliability and validity [16]. Participating physicians voluntarily completed a preproject questionnaire to provide their personal information before the commencement of the study. In addition, participating physicians received training on the Longshi Scale to ensure proficiency in its assessment. After the initiation of the project, physicians collected patient questionnaires from eligible individuals to obtain patient characteristic information and to assess the Longshi Scale. Furthermore, physicians recorded their recommendations regarding appropriate medical institutions for patient diversion.

Data were collected using the WeChat Longhai Rehabilitation Mini Program, a secure, mobile-based health data platform embedded within China's widely used WeChat app (Tencent). The program was jointly developed by the Rehabilitation Medicine Department of Shenzhen Second People's Hospital and a certified medical IT provider. It is designed to facilitate

XSL•FO
RenderX

clinical data entry, patient self-assessment, and rehabilitation tracking in both hospital and community settings. For this study, a customized electronic questionnaire was integrated into the platform to allow participating physicians to complete assessments and record patient data in real time using their smartphones or tablets. The platform includes built-in data encryption and access control features to ensure data privacy and security, and all data were stored on a password-protected hospital server compliant with Chinese medical data protection regulations. Before the study, physicians received standardized training on using the platform and conducting assessments to ensure uniformity in data collection. The training included video demonstrations, practice cases, and a short quiz to assess comprehension. Physicians had to pass this quiz before proceeding to data collection.

The data collection link for the physician questionnaire, embedded within the WeChat Longhai Rehabilitation Mini Program, was distributed through institutional communication channels. Specifically, the research coordination team at each participating hospital sent the link to eligible physicians via official WeChat workgroups, which are commonly used in Chinese clinical settings for internal communication. The invitation message included a brief description of the study, an ethics approval notice, and instructions for voluntary participation. The link was shared up to 3 times over a 2-week recruitment period to ensure adequate response rates without exerting undue pressure.

To prevent multiple submissions from the same participant, the survey platform incorporated a real-name login system requiring physicians to enter their unique employee ID number and name, which were verified against institutional staff lists. For patients, duplicate submissions were prevented by requiring patient IDs during registration, which were cross-verified with hospital records. The system automatically flagged and rejected multiple submissions under the same patient ID, ensuring only 1 response per participant was recorded. In addition, the system restricted each ID to 1 completed submission, and duplicate entries were automatically blocked. Data consistency and completeness were reviewed weekly by the research team to detect and address any anomalies in the submission records.

Before formal data collection, the complete questionnaire—including both the physician and patient components—was pilot tested among a small sample of participants to assess clarity, relevance, and usability. Specifically, 5 rehabilitation physicians and 15 outpatient rehabilitation patients from a tertiary hospital not included in the main study were invited to complete the survey via the WeChat Longhai Rehabilitation Mini Program. Feedback was collected on the comprehensibility of the items, the logic and flow of the electronic form, and the usability of the platform interface. Minor modifications were made based on this feedback, including clarifying the wording of several items and optimizing the layout for mobile devices. The pilot phase confirmed the feasibility of using the digital survey format and supported the content validity of the questionnaire before its broader deployment across study sites.

Variable Measurement

The variables of interest encompassed a broad spectrum of factors potentially influencing physicians' referral decisions. These included demographic characteristics of physicians, patient demographics, clinical factors, and institutional characteristics. Variables were carefully defined and operationalized to ensure consistency and reliability across data collection instruments. By comparing personalized patient health care–seeking factors with physicians' experiences, key influencing factors in the decision-making process were analyzed.

The primary outcome was self-reported referral decisions by physicians (including referral to tertiary, secondary, or primary institutions), which was collected by the Longhai Rehabilitation Mini Program in the WeChat app. Exposures included: (1) Physician characteristics, including demographics (gender, age categorized as <40, 40 - 50, and >50 y), work setting (primary, secondary, and tertiary health care institution), education level (college, undergraduate, master, and doctor), professional title (entry-level, intermediate-level, and senior-level), clinical experience (1 - 5, 6 - 10, 11 - 20, and >20 y), and specialty (Western medicine, traditional Chinese medicine, integrative medicine), were collected via self-reported electronic questionnaires; (2) Patient factors were assessed by trained physicians using standardized electronic questionnaires. The assessment included patient demographics (gender, age categorized as <40, 40 - 60, and >60 y), clinical diagnosis (orthopedic, neurological, cardiopulmonary, geriatric, and cancer disease), functional impairment (cognitive, speech, swallowing, cardiopulmonary, motor, and multiple functional impairments), disease status (controlled or uncontrolled), vital signs (stable or unstable), illness duration (less than 12 mo or more than 12 mo), Longshi Scale (bedridden, domestic, or community group). It should be noted that these findings reflect physicians' referral intentions rather than actual patient follow-through, as China's tiered health care system implementation remains incomplete.

The Longshi Scale is a graphical assessment tool used to evaluate the daily living abilities of patients with functional impairments and is widely applied in rehabilitation settings in China. It categorizes patients into three functional levels based on their capacity for self-care and participation in daily activities: (1) the community group, in which patients are able to perform basic daily tasks independently and participate in community or social activities; (2) the domestic group, in which patients are able to care for themselves partially and perform some domestic tasks but are mostly limited to the home environment; and (3) the bedridden group, in which patients are fully dependent on caregivers for mobility and daily care and are confined to bed for most activities.

In this study, physicians used the Longshi Scale to classify patients into one of these three groups, which served as a proxy for functional impairment severity in the regression analysis.

Statistical Analysis

All statistical analyses were conducted using SPSS (version 26.0; IBM Corp). Descriptive statistics were used to summarize physician and patient characteristics. Categorical variables were

XSL•FO
RenderX

expressed as frequencies and percentages, and continuous variables were presented as mean (SD) after normality testing using the Shapiro–Wilk test. Group comparisons for categorical variables were assessed using χ^2 tests or Fisher exact tests where appropriate.

For bivariate analysis, Pearsons χ^2 test was used to assess associations between patient characteristics and physician referral decisions across health care levels. Variables that showed significant associations (P<.05) in univariate analyses were entered into a multinomial logistic regression model to identify independent predictors of referral destination (tertiary vs primary or secondary institutions).

Before regression modeling, multicollinearity was assessed using the variance inflation factor (VIF), and no significant collinearity was detected (all VIFs <2). The assumption of independence of errors was tested using the Durbin-Watson statistic, and model goodness-of-fit was evaluated using the likelihood ratio test and pseudo R^2 values (Nagelkerke).

Confounding control was performed by simultaneously including clinically and statistically relevant variables in the multivariate model based on literature review and bivariate significance. Subgroup analyses were planned based on disease type (eg, orthopedic, neurological) and functional impairment status. However, due to limitations in sample size for certain subgroups, interaction effects between key predictors (eg, disease type×Longshi Scale group) were not formally tested in this version of the analysis and will be considered in future studies.

Missing data were minimal (<5%) and assumed to be missing at random. Listwise deletion was applied in multivariate analyses, and sensitivity checks confirmed that the exclusion of cases with missing values did not significantly alter the main findings.

A 2-tailed P value of less than .05 was considered statistically significant.

Results

Characteristics of Participants

Initially, a total of 148 rehabilitation physicians and 2117 outpatient rehabilitation patients were screened for inclusion. After applying eligibility criteria, 17 physicians were excluded due to insufficient involvement in referral decision-making, incomplete demographic data, or lack of informed consent. Similarly, 133 patients were excluded based on the following reasons: inpatient status during recruitment (n=54), incomplete questionnaires (n=41), inability to provide informed consent due to severe cognitive or communication impairments without a caregiver (n=26), or concurrent participation in conflicting research protocols (n=12). The final analysis thus included 131 physicians and 1984 patients who met all inclusion criteria and completed the required assessments.

Table 1 summarizes the demographic characteristics of physicians. This study included 131 physicians, comprising 57 males (43.5%) and 74 females (56.5%). Regarding age distribution, there were 86 physicians aged 40 years and younger (65.6%), 39 aged between 40 and 50 years (29.8%), and 6 aged 50 years and older (4.6%). Among them, 51 worked in tertiary medical institutions (38.9%), 36 in secondary institutions (27.5%), and 44 in primary institutions (33.6%). In terms of educational background, 1 had a doctoral degree (0.8%), 32 had master's degrees (24.4%), 94 had bachelor's degrees (71.8%), and 4 had associate degrees (3.1%). There were 51 physicians with senior professional titles (38.6%), 36 with intermediate titles (27.5%), and 44 with junior titles (33.9%). Regarding work experience, 17 physicians had 1 - 5 years of experience (13%), 35 had 6 - 10 years of experience (26.7%), 52 had 10 - 20 years of experience (39.7%), and 27 had over 20 years of experience (20.9%). Please see Table 1 for details.

This study enrolled a total of 1984 outpatient rehabilitation patients. Among them, 376 patients (19%) opted for primary health care institutions, 405 patients (20.4%) for secondary health care institutions, 301 patients (15.2%) for tertiary health care institutions, and 902 patients (45.5%) attended rehabilitation outpatient clinics. Of all patients, 1122 were male (56.6%) and 862 were female (43.4%). Regarding age distribution, 39.4% (781/1984) were ages 40 years and younger, 29.3% (582/1984) were between ages 40 and 60 years, and 31.3% (621/1984) were ages 60 years and older. Diagnosis-wise, 41.6% (825/1984) had orthopedic conditions, 27.2% (549/1984) neurological disorders, 4.2% (84/1984) cardiopulmonary diseases, 12% (238/1984) geriatric conditions, and 1.2% (24/1984) had cancer. In terms of functional impairments, 31.8% (631/1984) had cognitive impairments, 30.4% (603/1984) had speech impairments, 9.2% (183/1984) had swallowing difficulties, 6.2% (123/1984) had cardiopulmonary issues, 65.7% (1304/1984) had motor impairments, 19.5% (/1984) had other impairments, and 37.9% (752/1984) exhibited multiple functional impairments. Disease control was inadequate in 14.5% (288/1984) of patients, and 1% (19/1984) exhibited unstable vital signs. Patients with a disease duration of less than 12 months accounted for 82.5% (1637/1984). According to the Longshi Scale assessment, 23.7% (470/1984) were bedridden, 16.6% (329/1984) required family care, and 59.7% (1185/1984) were integrated into social life. Table 2 summarizes the demographic characteristics of patients.

Single-Factor Analysis of Physicians' Decisions Regarding Patient Referrals

Patient age, sex, and diagnosis type significantly influence physician decisions, including orthopedic, neurological, cardiopulmonary, and geriatric conditions. Functional impairments such as cognitive, speech, swallowing, cardiopulmonary, and motor impairments also exhibit significant differences in physician decision-making (*P*<.001). In addition, factors such as multiple functional impairments, disease control status, stable vital signs, and assessments using the Longshi Activities of Daily Living (ADL) scale significantly impact physician triage decisions (*P*<.001). See Table 2 for detailed findings.

Multinomial Logistic Regression Analysis of Factors Influencing Physicians' Decisions on Patient Referral Destinations

The results in Table 3 represent the multivariate regression analysis comparing the triage decisions of tertiary health care institutions with primary and secondary health care institutions, respectively.

Comparing the triage decision results between primary and tertiary healthcare institutions, neurological disorders (odds ratio [OR] 1.88, 95% CI 1.02 - 3.43; *P*=.04), cardiopulmonary diseases (OR 2.91, 95% CI 1.07 - 7.93; *P*=.04), geriatric conditions (OR 0.40, 95% CI 0.23 - 0.68; *P*<.001), disease uncontrol (OR 0.23, 95% CI 0.13 - 0.34; *P*<.001), and Longshi Scale assessment results for bedridden group (OR 0.10, 95% CI 0.14 - 0.34; *P*<.001) and domestic group (OR 0.24, 95% CI 0.06 - 0.18; *P*<.001) were identified as independent influencing factors for physician decision-making on the destination of rehabilitation outpatients (*P*<.05).

Comparing the triage decision results between secondary and tertiary health care institutions, factors such as orthopedic diseases (OR 3.27, 95% CI 1.89 - 5.67; *P*<.001), geriatric conditions (OR 0.58, 95% CI 0.33 - 1.87; *P*=.009), cognitive impairments (OR 1.98, 95% CI 1.17 - 3.36; *P*=.01), multiple functional impairments (OR 0.35, 95% CI 0.18 - 0.70; *P*=.002), and disease uncontrolled (OR 0.24, 95% CI 0.15 - 0.37; *P*<.001) were identified as independent influencing factors for physician decision-making on the destination of rehabilitation outpatients (*P*<.05).

Discussion

Principal Findings

This study was designed to identify key clinical and functional factors that influence physician referral decisions for outpatient rehabilitation patients in the context of China's hierarchical health care system. By systematically analyzing physician and patient data across multiple institutional levels and regions, the study aimed to inform the development of stratified referral evaluation tools. The findings directly address this aim by highlighting that disease type (eg, neurological and orthopedic), functional impairment (eg, cognitive and multifunctional), disease control status, and Longshi Scale classification are independently associated with referral destinations. These results confirm the hypothesis that physician referral behavior is shaped not only by institutional factors but also by patient complexity and functional needs. Furthermore, the study adds to the current literature by quantifying these influences through multinomial regression and suggesting potential criteria for standardizing rehabilitation referral decisions.

The results of the multinomial logistic regression analysis offer valuable insights into the determinants influencing physicians' decisions regarding the referral destinations of rehabilitation outpatients. These findings underscore the importance of specific medical conditions and functional impairments in the decision-making process for patient triage between different levels of healthcare institutions.

This study reveals significant differences in referral decisions for orthopedic, neurological, cardiopulmonary, and geriatric diseases. In particular, when comparing tertiary with primary and secondary health care institutions, patients with geriatric diseases and poor disease control are more likely to be referred to higher-level tertiary institutions. In contrast, those with neurological or cardiopulmonary diseases are more likely to be referred to secondary institutions. This may reflect the fact that geriatric patients may face more health problems and complex rehabilitation needs, prompting physicians to refer them to

XSL•FO
RenderX

higher-level medical institutions for more specialized and comprehensive treatment [17]. Similarly, patients with poor disease control require more extensive resources and specialized medical teams [18].

The complexity and specificity of different diseases in rehabilitation also influence referral strategies. Professional referral is a key factor because orthopedic diseases typically require specialized orthopedic physicians and equipment for treatment and rehabilitation. Therefore, physicians may be more inclined to refer these patients to secondary institutions that offer the necessary specialized orthopedic services and resources [19]. In addition, cardiopulmonary diseases are often chronic and require long-term management and monitoring. Patients with cardiopulmonary diseases and functional impairments are more likely to be referred to secondary institutions because these facilities are better suited for managing chronic diseases, integrating community medical resources, providing specialized services for the elderly, and meeting comprehensive rehabilitation needs [20].

The study also found that patients with cognitive impairments are more likely to be referred to secondary institutions. Patients with cognitive impairments, motor impairments, and multiple functional disabilities are more likely to be referred to secondary institutions. For patients with cognitive and motor impairments, physicians may focus on their specialized rehabilitation needs. The referral decisions of physicians may be influenced by the need for and availability of specialized services. In addition, when dealing with patients with multiple functional impairments, physicians tend to refer them to higher-level medical institutions to access more comprehensive and complex rehabilitation services [21]. These differentiated referral decisions reflect physicians' consideration of the type of functional impairment in providing more specialized, personalized, and comprehensive rehabilitation services [22]. This difference may be influenced by specialization, resource allocation, and the complexity of multiple functional impairments.

Although this study primarily used multinomial logistic regression to identify independent predictors of referral destination, we recognize that an essential aim of a stratified care model is to ensure that case complexity appropriately drives referrals to higher-tier institutions. To explore this alignment, we performed a post hoc stratification analysis that compared the referral destinations among patients categorized by complexity indicators—such as the presence of multiple functional impairments, poor disease control, or bedridden status. The results showed that a substantial proportion of patients with high complexity (eg, Longshi bedridden group or unstable vital signs) were indeed referred to tertiary institutions, suggesting general consistency with stratified care principles. However, we also observed that certain high-need groups—such as patients with cognitive impairments—were frequently referred to secondary institutions. This raises the possibility of partial misalignment between patient complexity and referral level, potentially due to institutional resource constraints or physician referral preferences. While regression modeling helps quantify associations, future studies should consider incorporating appropriateness analyses or concordance rates to directly evaluate the extent to which physician decisions adhere to stratified care principles. This would offer a more practice-oriented perspective and strengthen evidence for policy-level recommendations.

The findings of this study are generally consistent with previous literature that highlights the influence of disease type and functional impairment on referral decisions. For example, Longley et al [20] emphasized that patients with severe mobility limitations were more likely to be directed to tertiary rehabilitation centers, aligning with our results regarding bedridden and domestically dependent patients. Similarly, Guo [17] reported that physicians often consider disease controllability and chronicity when determining the referral pathway, supporting our observation that patients with poor disease control were more often triaged to higher-level institutions.

However, some discrepancies exist. For instance, Labberton et al [21] found that cognitive impairments were strongly associated with referrals to tertiary care, whereas our study showed that such patients were frequently referred to secondary institutions. This divergence may stem from institutional differences in service structure—where secondary hospitals in China increasingly offer specialized neurocognitive rehabilitation services, reducing the need for tertiary-level referral. In addition, previous studies in developed healthcare systems such as Norway and Canada often emphasize patient autonomy and shared decision-making in the referral process, which contrasts with the physician-centered model observed in China. These differences underscore the importance of contextual factors—such as institutional capacity, policy incentives, and clinical practice norms—in shaping referral behavior.

The results of the Longshi Scale assessment indicated that patients assessed as bedridden or homebound were more likely to be referred to tertiary medical institutions. This may be because such assessments indicate significant functional limitations in daily activities [23]. These limitations might require more specialized and detailed rehabilitation services, leading physicians to refer these patients to higher-level institutions capable of providing more comprehensive care. The Longshi Scale assessment results provide physicians with a strong basis for understanding patients' daily living abilities and rehabilitation needs, aiding in more precise and comprehensive rehabilitation treatment decisions.

In addition to clinical and functional characteristics of patients, physicians' demographic and academic attributes may also play a significant role in shaping referral decision-making. Although this study collected comprehensive data on physicians' gender, age, education level, professional title, years of experience, and medical specialty, these variables were not included in the primary statistical analysis. This represents a limitation of the current study, as such factors could offer important perspectives on potential variability in referral behaviors across physician subgroups. For example, senior physicians with more than 20 years of clinical experience may demonstrate different triage patterns compared to entry-level physicians, possibly due to differences in clinical judgment, familiarity with tiered systems,

XSL•FO
RenderX

or risk tolerance. Similarly, physicians trained in traditional Chinese medicine or integrative medicine may prioritize different rehabilitation needs or institutional choices than their counterparts trained in Western medicine. Future research should incorporate multivariable analyses to explore how these practitioner characteristics intersect with referral decisions. Such analyses could uncover underlying patterns that inform more targeted physician training and policy interventions aimed at standardizing referral practices across diverse provider profiles.

To address whether more complex cases are in fact being referred to tertiary care facilities—a concern noted in recent literature and clinical guidelines—we conducted a focused review of the referral patterns based on proxies for case complexity. These included clinical indicators such as multiple functional impairments, uncontrolled disease status, unstable vital signs, and low Longshi Scale scores (eg, bedridden status). Our data demonstrated that patients exhibiting these complex characteristics were more likely to be referred to tertiary institutions. For example, patients classified as bedridden on the Longshi Scale were significantly more likely to be triaged to tertiary-level care (OR 0.10, 95% CI 0.14 - 0.34; $P<.001$), reflecting a recognition of their higher rehabilitation needs. Similarly, patients with uncontrolled disease or unstable vital signs were disproportionately represented among tertiary referrals, suggesting that physicians do consider clinical severity and complexity in their referral decisions. These findings support the appropriateness of current referral practices to some extent. However, there remains a subset of patients with cognitive and multiple impairments who were frequently referred to secondary rather than tertiary institutions, raising questions about possible mismatches between patient needs and referral destinations. This highlights the necessity for clearer referral criteria and physician decision-support tools to improve referral consistency and precision.

Recommendations

Enhancing Physician Training and Education

To improve physicians' decision-making in rehabilitation tiered medical services, it is recommended to strengthen their training and education [24]. This involves regular specialized lectures, seminars, and online learning platforms to provide physicians with the latest clinical guidelines and research findings, particularly focusing on key factors such as multiple functional impairments, disease control, vital signs, and Longshi Scale assessment. By continuously improving physicians' professional levels, their decision-making accuracy and scientific basis in rehabilitation tiered medical services can be enhanced.

Establishing Clear and Scientific Tiered Standards

It is suggested to develop more explicit and scientific tiered standards within the rehabilitation tiered medical service system. This requires in-depth research on patients' rehabilitation needs, revising promotable assessment tools and standards, and incorporating expert consensus. The standard-setting process should track the latest research findings in rehabilitation, address the diversity of patient needs, and consider changes in patients' rehabilitation needs at different stages. Clear referral tools for rehabilitation tiered medical services help physicians make more accurate referral decisions, increasing the scientific and precise nature of the system and better meeting the rehabilitation needs of patients in various medical institutions [25].

Promoting Information Technology Application

To enhance the scientific basis and data support for physicians' decisions in tiered medical services, the active promotion of information technology is recommended. Introducing electronic health record (EHR) systems to achieve comprehensive and accurate management of patient medical information [26]. Through digitalization, physicians can access key patient information more promptly, improving decision-making accuracy. Integrating assessment tools and standards related to rehabilitation tiered medical services into EHR systems provides physicians with more comprehensive, multidimensional analytical bases [27]. The application of information technology is expected to enhance the scientific and accurate nature of physicians' referral decisions while promoting the sharing and collaboration of medical information, thus improving the efficiency and quality of the rehabilitation tiered medical service system.

Limitations

This study focuses on the decision-making of rehabilitation outpatient physicians in China regarding patient referrals and analyzes the factors influencing their decisions, partially filling the research gap on outpatient referral decisions by rehabilitation physicians. This study is innovative to some extent. However, it still has certain limitations. First, this study used convenience sampling and included only 12 medical institutions in 5 cities, which might introduce selection bias and limit the generalizability of the results. Second, most of the outpatient patients included in this study were from the general population and primarily had motor function impairments, with relatively mild cognitive, speech, cardiopulmonary, and swallowing impairments. Therefore, the representativeness of the study sample is limited. Third, this study only used structured questionnaires for data collection, with a limited range of variables. Future research should consider conducting qualitative interviews with physicians to deeply explore the underlying factors influencing their patient referral decisions. Finally, although systemic factors (eg, health care policies and reimbursement schemes) may shape physician decision-making, these variables were not formally assessed in this study. Future research should incorporate such contextual factors to better understand referral patterns within China's evolving rehabilitation landscape. A notable limitation of this study is that the majority of patient-related variables—such as disease status, functional impairment classification, and Longshi Scale results—were completed by physicians rather than the patients themselves. While this approach ensured consistency and clinical accuracy in classification, it limited the incorporation of the patient perspective into the analysis. Factors such as patients' personal preferences for care setting, perceived accessibility, cost considerations, and trust in specific institutions were not assessed. These elements may play a significant role in shaping actual referral outcomes and deserve further investigation. Future studies could benefit from integrating patient-reported data alongside clinical assessments to provide

XSL•FO
RenderX

a more comprehensive picture of referral decision-making. Mixed-methods approaches, including structured patient surveys or qualitative interviews, may help uncover how patient preferences align—or conflict—with physician recommendations within the context of a tiered rehabilitation system.

To enhance the generalizability of future research, it is recommended that studies incorporate more diverse patient populations across broader geographic regions, including rural and under-resourced areas. This would help account for potential variations in referral practices that stem from regional disparities in medical resource availability, institutional capacity, and health policy implementation. In addition, stratified sampling strategies could be refined to include private healthcare institutions and specialized rehabilitation centers to better capture the full spectrum of referral behaviors.

Furthermore, while this study is situated within the context of China's public-tiered health care system, its findings may offer insights applicable to other countries pursuing similar rehabilitation reforms. For instance, countries with decentralized or mixed health care financing models—such as Brazil, India, or South Africa—face analogous challenges in aligning patient needs with institutional capacity. The clinical and functional indicators identified in this study (eg, disease control, Longshi Scale classification, and multi-impairment status) may serve as a reference framework for developing locally adapted referral tools. Future comparative studies could examine how such models perform across different health systems, ultimately contributing to a more globally informed understanding of rehabilitation referral strategies.

To operationalize these recommendations, several implementation strategies are proposed. First, integrating decision-support algorithms into existing EHR systems can help standardize physician referral behavior. For example, by embedding Longshi Scale results and disease-specific severity indicators into EHR templates, the system can automatically suggest referral destinations based on predefined criteria, thereby enhancing consistency and reducing subjectivity in triage decisions. This function could be further enhanced with real-time alerts or dashboard-style interfaces that highlight mismatches between patient status and current institutional capacity.

Second, the application of information technology should be piloted through regional health platforms that link primary, secondary, and tertiary institutions. For instance, the "Hierarchical Diagnosis and Treatment Information Platform" successfully deployed in cities like Shanghai and Chengdu has enabled real-time patient transfer, data sharing, and insurance coordination across institutional levels. These models can serve as scalable blueprints for implementing rehabilitation referral systems nationwide.

Finally, developing regional rehabilitation referral centers that provide training, feedback loops, and case review systems may enhance physician awareness and adherence to tiered service pathways. Such mechanisms, combined with policy incentives and reimbursement alignment, could significantly improve the feasibility and sustainability of the proposed tiered rehabilitation model in China's evolving health care landscape.

Conclusions

In the field of rehabilitation, implementing tiered medical services is crucial for the rehabilitation outcomes of patients and the rational use of medical resources. Rehabilitation tiered medical services can effectively triage patients based on comprehensive, accurate, and standardized referral decision tools. This helps ensure that patients receive more precise and professional rehabilitation treatment at suitable medical institutions, improving treatment outcomes and enhancing the convenience of seeking medical care for patients. Furthermore, this practice aids the government in rationalizing the use of medical resources, improving the efficiency and quality of medical services, and reducing health care costs. To thoroughly and comprehensively understand the key factors influencing physicians' decisions to refer rehabilitation patients, and to develop standardized rehabilitation tiered medical service tools, future research could consider conducting large-scale, multicenter, cluster-randomized controlled trials at the city and national levels. This would facilitate better optimization and development of the rehabilitation tiered medical service system.

Despite its strengths, this study has certain limitations that may affect the generalizability of its findings. The use of convenience sampling and inclusion of institutions from only 5 cities may introduce selection bias. In addition, the analysis did not include system-level variables such as policy implementation strength or institutional resource availability. These factors should be examined in future studies to enhance the comprehensiveness of the referral decision framework. Nonetheless, this study makes a valuable contribution by being one of the first large-scale, multicenter investigations into the determinants of physician referral decisions within China's rehabilitation tiered health care system. By identifying specific clinical and functional characteristics associated with referral destinations, it provides an empirical foundation for developing standardized referral tools, refining triage protocols, and informing policy design in the field of rehabilitation medicine.

Acknowledgments

We are grateful to the individuals from each medical institution for their support and advice in the provision of data. This research was funded by the Sanming Project of Medicine in Shenzhen (SZSM202111010), Shenzhen Key Medical Discipline Construction Fund (SZXK048), Shenzhen Science and Technology Program (JCYJ20240813141037048), and Shenzhen Health Economics Society 2025 Scientific Research Fund Project (2025343).

Abstract

Background: Taiwan's categorization of hospital emergency capability (CHEC) policy is designed to regionalize and dispatch critical patients. The policy was designed in 2009 to improve the quality of emergency care for critical time-sensitive diseases (CTSDs). The CHEC policy primarily uses time-based quality surveillance indicators.

Objective: We aimed to investigate the impact of Taiwan's CHEC policy on CTSDs.

Methods: Using Taiwan's 2005 Longitudinal Health Insurance Database, this nationwide retrospective cohort study examined the CHEC policy's impact from 2005 to 2011. Propensity score matching and difference-in-differences analysis within a generalized estimating equation framework were used to compare pre- and postimplementation periods. The study focused on acute ischemic stroke (AIS), ST-segment elevation myocardial infarction (STEMI), septic shock, and major trauma. AIS and STEMI cases, monitored with time-based indicators, were evaluated for adherence to diagnostic and treatment guidelines as process quality measures. Mortality and medical use served as outcome indicators. Major trauma, with evolving guidelines and no time-based monitoring, acted as a control to test for policy spotlight effects.

Results: In our cohort of 9923 patients, refined through 1:1 propensity score matching, 5566 (56.09%) were male and were mostly older adults. Our analysis revealed that the CHEC policy effectively improved system efficiency and patient outcomes, resulting in significant reductions in medical orders (–7.29 items, 95% CI –10.09 to –4.48; *P*<.001), short-term mortality rates (–0.09%, 95% CI –0.17% to –0.02%; *P*=.01) and long-term mortality rates (–0.09%, 95% CI –0.15% to –0.04%; *P*=.001), and total medical expenses (–5328.35 points per case, 95% CI –10,387.10 to –269.60; *P*=.04), despite a modest increase in diagnostic fees (376.37 points, 95% CI 92.42-660.33; *P*=.01). The CHEC policy led to notable increases in diagnostic fees, major treatments, and medical orders for AIS and STEMI cases. For AIS cases, significant increases were observed in major treatments (β=0.77; 95% CI 0.21-1.33; *P*=.007) and medical orders (β=15.20; 95% CI 5.28-25.11; *P*=.003) compared to major trauma. In STEMI cases, diagnostic fees significantly increased (β=1983.75; 95% CI 84.28-3883.21; *P*=.04), while upward transfer rates significantly decreased (β=–0.59; 95% CI –1.18 to –0.001; *P*=.049). There were also trends toward increased major treatments (β=0.30; 95% CI –0.03 to 0.62, *P*=.07), medical orders (β=11.92; 95% CI –0.90 to 24.73; *P*=.07), and medical expenses (β=24,275.54; 95% CI –640.71 to 4,991,991.78; *P*=.06), although these were not statistically significant. In contrast, no significant changes were identified in process or outcome quality indicators for septic shock. These findings suggest policy spotlight effects, reflecting a greater emphasis on diseases directly prioritized under the CHEC policy.

XSL•FO
RenderX

Conclusions: The CHEC policy demonstrated the dual benefits of reducing costs and improving patient outcomes. We observed unintended consequences of policy spotlight effects, which led to a disproportionate improvement in guideline adherence and process quality for CTSDs with time-based surveillance indicators.

(Interact J Med Res 2025;14:e54651) doi:10.2196/54651

KEYWORDS

categorization of hospital emergency capability; quality; time-sensitive diseases; emergency care; difference-in-differences

Introduction

Background

The Agency for Healthcare Research and Quality proposed the concept of time-sensitive diseases [1] using scientific data to maintain up-to-date guidelines and launched the Get with the Guidelines campaign to establish it as the basis for surveillance indicators of process and outcome quality [2]. Critical time-sensitive diseases (CTSDs) refer to life-threatening illnesses or injuries that require immediate emergency care, where rapid intervention is paramount to mitigate morbidity and mortality [3]. The various guidelines for managing time-sensitive events emphasize the crucial importance of time. In the context of acute ischemic stroke (AIS), the “time is brain” [4] goal focuses on the timely reperfusion treatments, including intravenous thrombolysis and mechanical thrombectomy; in ST-segment elevation myocardial infarction (STEMI), the “time is muscle” goal focuses on early reperfusion [5]; in septic shock events, the “early goal” focuses on early resuscitation [6]; and in major trauma cases, the “golden hour” goal focuses on the window of opportunity in which patients can undergo rescue operations [7].

The American Medical Association issued the categorization of hospital emergency capability (CHEC) guidelines [8] to classify hospitals according to their emergency care capabilities, thereby regionalizing and providing emergency medical services with references for transport emergency patients to the nearest appropriate hospitals [9], aiming to reduce preventable deaths. Most studies investigating the effects of this categorization, designation, and regionalization policy reported positive findings [10,11]. However, these studies mainly focused on a single disease entity [10,11] or region [11]. The CHEC policy often implements rigid time-based surveillance indicators. These indicators can affect disease-specific guideline adherence in clinical practice because they may reshape the behaviors of emergency department (ED) medical providers [12]. This phenomenon is related to the so-called policy spotlight effects, which influence medical care providers’ assessment of how others perceive them [13]. More specifically, the policy spotlight effects refer to the perception of medical care providers regarding how policy makers interpret surveillance indicators and adjust their process-related behaviors accordingly [14]. Current emergency care policies often use time-based criteria as process quality indicators, which may exacerbate the policy spotlight effects [13]; however, the unintended effects or safety concerns generated by these effects remain unclear. Therefore, our study targeted 4 CTSDs: AIS, STEMI, septic shock, and major trauma [7]. Our research hypothesizes that emergency care providers might inadvertently give more attention to diseases under active surveillance while potentially neglecting those not thoroughly incorporated in this observation. This focus might be based on their perception of observer expectations [15].

Objective

We aimed to examine the effects of the CHEC policy on process quality and outcomes for CTSDs, addressing three research questions: (1) How does the CHEC policy impact the quality of diagnosis, treatment, and outcomes for these diseases? (2) How do policy spotlight effects influence the prioritization of diseases under active surveillance and impact emergency care providers’ behaviors in this context? and (3) What are the potential consequences of policy spotlight effects?

Methods

Setting, Study Design, and Data Source

Taiwan’s National Health Insurance is a single-payer, compulsory social insurance system that primarily operates on a fee-for-service basis. This study is based on the National Health Insurance 2005 Longitudinal Health Insurance Database (LHID2005), which contains 1 million random cases, including medical records and hospital information, collected since 1995. The LHID2005 was validated to represent medical use, diagnosis and treatment process, and outcome quality for CTSDs [16].

This nationwide retrospective cohort study uses propensity score matching (PSM) and difference-in-differences (DID) analysis to evaluate the impact of the CHEC policy on CTSD care quality and outcomes. The CHEC policy was initiated in August 2009, which integrated 190 hospitals into a network focusing on acute conditions such as stroke, myocardial infarction, major trauma, and perinatal care [17]. We divided our analysis into 2 periods: before CHEC (August 1, 2005, to July 31, 2009) and after CHEC (August 1, 2009, to July 31, 2011). This division aimed to assess the CHEC policy’s effects distinctly from the ED quality improvement plan introduced in 2012. Well-established guidelines exist for AIS, STEMI, and septic shock. In contrast, the guidelines for major trauma are continuously evolving due to the variability in injury mechanisms, locations, and severity. Moreover, AIS and STEMI events are stringently monitored under the CHEC policy with specific time-based quality indicators, whereas septic shock and major trauma events are not (Table 1).

[f]PCI: percutaneous coronary intervention.

[g]NIHSS: National Institute of Health Stroke Scale or Score.

[h]ICU: intensive care unit.

[i]ISS: Injury Severity Score.

Thus, we selected major trauma events as a reference for our study because they were not monitored under the CHEC policy with rigid indicators. We adopted pre- and postimplementation of a CHEC policy, using 1:1 PSM to control for confounding variables. We used the DID estimation approach to estimate the association of the CHEC policy on process and outcomes for AIS and STEMI. For the counterfactual, we used major trauma cases unexposed to the clinical guideline or CHEC policy time-based quality indicators as the basis for comparison.

Identification of Study Cohort

This study identified CTSDs based on ED visits accompanied by a primary diagnosis using the appropriate disease code. The identification of AIS (ie, codes 433 and 434), STEMI (ie, code 410), and septic shock (ie, codes 038, 785, and 995) was based on the *International Classification of Diseases, Ninth Revision, Clinical Modification* (*ICD - 9 - CM*). Major trauma cases were classified following the American Academy of Surgery Committee guidelines (ie, codes 800-959) [19]. Due to the absence of trauma severity data in the LHID2005 database, primary *ICD-9-CM* codes served as our initial method for identifying major trauma incidents. This identification was further refined by including cases where patients received rescue surgery or were admitted to the intensive care unit, serving as additional criteria for major trauma [20]. We excluded cases before the study period and those without hospital or patient sociodemographic information. We also excluded hospitals with a volume of <5 CTSD cases per year [21]. We used the date of the first ED visit as the index date.

Definition of Variables

The independent variable in this study was exposure to the CHEC policy intervention. Events related to AIS and STEMI were subject to rigid time-based quality indicators and regular surveillance under the CHEC policy. In contrast, despite having well-developed clinical guidelines, septic shock was not included under the CHEC policy's stringent time-based quality indicators. Similarly, major trauma cases, which lack well-developed clinical guidelines, were not subject to these policy indicators and were used as counterfactuals in this study. The dependent variables were divided into primary and secondary outcomes. Primary outcomes included guideline adherence to diagnostic and treatment process quality indicators. For diagnostic adherence, AIS was assessed by the completion of brain imaging (eg, computed tomography or magnetic resonance imaging) within 60 minutes of hospital arrival, while

XSL•FO
RenderX

STEMI was evaluated based on the completion of electrocardiography within 10 minutes. For treatment adherence, AIS required the administration of intravenous thrombolysis within 3 hours of symptom onset, and STEMI was assessed according to whether percutaneous coronary intervention was performed within 90 minutes of hospital arrival. Secondary outcomes included upward transfer rates, diagnostic fees, medical orders and expenses, and mortality rates. Upward transfer rates were defined as the proportion of patients transferred from lower-level hospitals to higher-level facilities. Diagnostic fees referred to the total costs incurred from diagnostic procedures during ED care. Medical orders and expenses represented the number and costs of medical interventions performed during ED visits. Mortality rates were measured as 30-day mortality, indicating the percentage of patients who died within 30 days from the index date (the emergency visit date), and 1-year mortality, representing deaths occurring within 1 year.

Covariates included patient-related predisposing factors, such as age, sex, and occupation. The enabling factor was the insured salary, while the Charlson Comorbidity Index, calculated using *ICD-9-CM* codes from primary diagnoses recorded in inpatient and outpatient claims data up to a year before the index date, served as a measure of health needs. Furthermore, external environmental factors, including urbanization and regional emergency resources, were considered. For hospital-level variables, the input-throughput-output model of Asplin et al [22] was used. Input was gauged using the rate of ED visits with Emergency Severity Index 1, while throughput and output efficiency were assessed via the ED's occupancy rate. This comprehensive framework ensured a robust evaluation of the CHEC policy's impact while accounting for potential confounding variables and contextual factors.

Statistical Analysis

Patients' characteristics, process quality, and outcomes were presented using descriptive statistics. Continuous data were described using mean (SD), and categorical data were presented using numbers and percentages. To enhance the robustness of the outcomes, we calculated the propensity score using a multivariable logistic regression that included all baseline covariates. The standardized mean difference was calculated to confirm the balance of potential confounders at baseline between groups before and after matching. A standardized mean difference of <0.1 was considered to represent a negligible difference [23].

We evaluated the impact of the CHEC intervention on each outcome, including overall differences, the differences within individual diseases, and between-disease differences in changes from baseline (ie, group-by-disease interaction effects), using a DID framework integrated with generalized estimating equation (GEE) models. The DID approach allowed us to compare changes in outcomes between the before and after CHEC policy periods across diseases, enabling the estimation of differential effects of the intervention while controlling for time-invariant unobserved confounders. This method is particularly suitable for evaluating policy interventions by focusing on within-group changes relative to a reference group over time. The GEE model is specified as follows:

$$Y_{ij} = \beta_0 + \beta_1 (\text{CHEC policy})_j + \beta_2 \text{ disease } + \beta_3 (\text{CHEC policy} \times \text{disease})_{ij} + \varepsilon_{ij,}$$

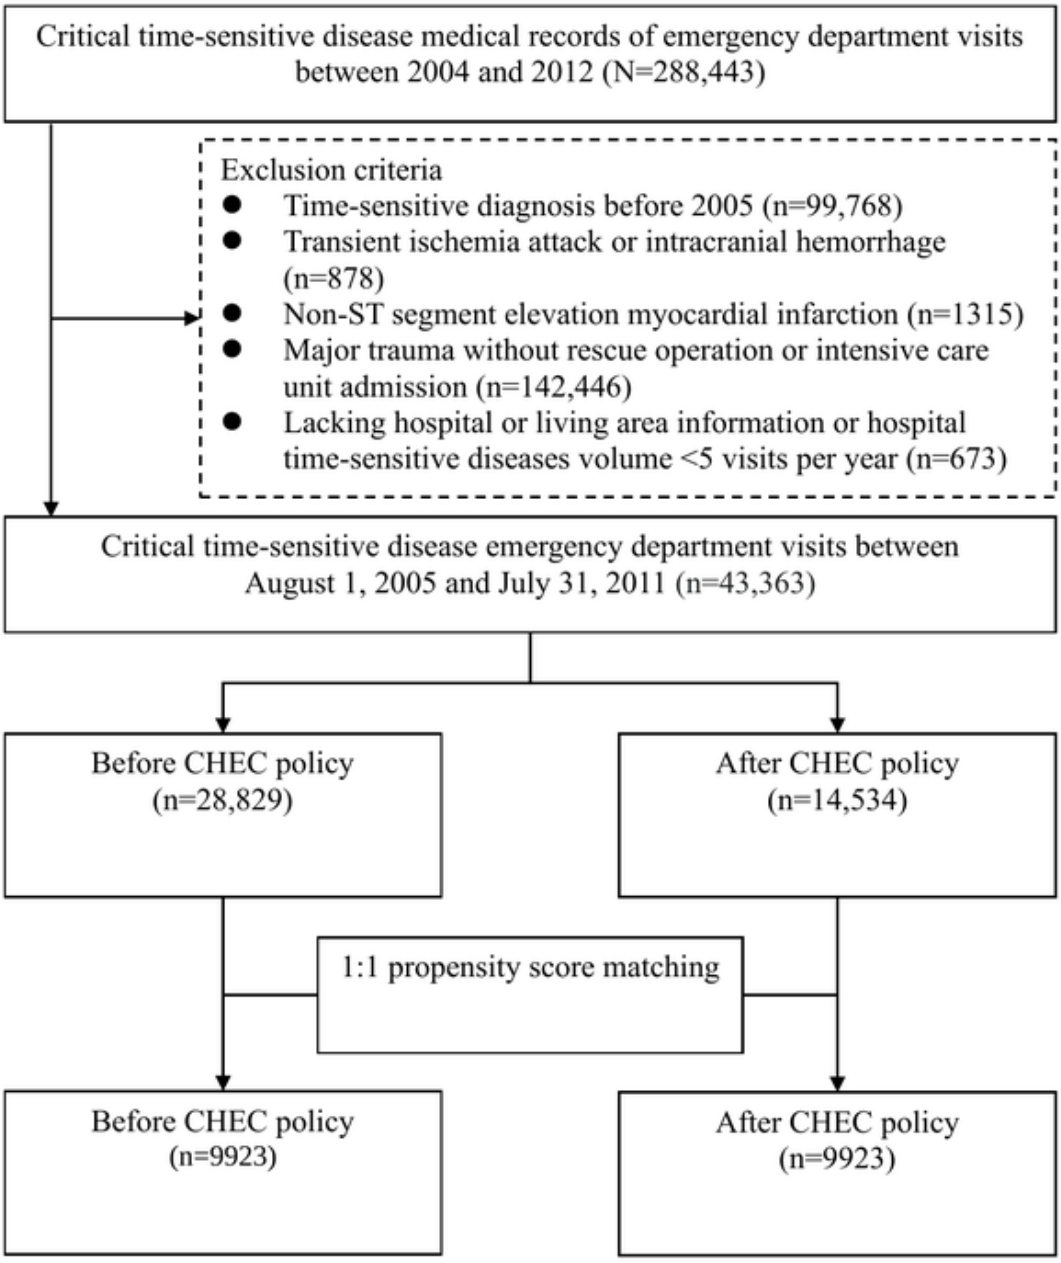
where Y_{ij} represents the outcome variable (eg, diagnosis indicator, treatment indicator, mortality, or medical use) for individual i at time j. β_0 is the intercept, capturing the baseline level of the outcome for the reference disease (ie, major trauma) in the pre-CHEC period. CHEC policy$_j$ is a binary variable (0=before CHEC, 1=after CHEC), and its coefficient β_1 captures the overall impact of the CHEC policy across all diseases. Disease$_i$ is a categorical variable representing the 4 diseases (ie, AIS, STEMI, septic shock, and major trauma), with β_2 estimating disease-specific differences at baseline. The interaction term (CHEC policy × disease)$_{ij}$, with coefficient β_3, reflects the differential impact of the CHEC policy for each disease compared to the reference group (ie, major trauma). A positive β_3 value indicates a greater change in the outcome for the respective disease relative to major trauma. All statistical analyses were performed using SAS (version 9.4; SAS Institute), and statistical significance was defined as value of <.05.

Ethical Considerations

This study used secondary data from the NIH LHID2005, which are fully anonymized and deidentified to protect participant privacy. The dataset contained no personal identifiers, such as names, addresses, or social security numbers, so individual informed consent was not required. The original consent provided for primary data collection, and the institutional review board approval covered secondary analyses without requiring additional consent. All analyses were conducted in compliance with relevant regulations to safeguard confidentiality, and data access was restricted to authorized researchers under institutional guidelines. The study received ethics approval from the Taiwan National Yang-Ming University Institutional Review Board (YM107035E).

Results

Participants' Characteristics



During the study period, we analyzed emergency presentations related to 4 CTSDs, originally encompassing 288,443 patients. Exclusion criteria included the diagnosis of CTSDs before 2005 (n=99,768, 34.59%), patients with transient ischemic attack or intracranial hemorrhage (n=878, 0.3%), non-STEMI cases (n=1315, 0.45%), individuals with major traumas defined by *ICD-9-CM* codes that did not necessitate a rescue operation or intensive care unit admission (n=142,446, 49.38%), and cases lacking hospital or living area information or where the hospital's volume of CTSDs was <5 visits per year (n=673, 0.23%). These criteria refined the total sample size to 43,363 (15.03%) patients. Considering the extended period before the policy intervention, this research adopted a 1:1 PSM technique, resulting in a final matched sample of 9923 patients. The flowchart and baseline table (Figure 1) display the initial count of emergency patients with CTSDs and the numbers after PSM, broken down by each of the 4 diseases. Table 2 presents the

XSL•FO
RenderX

PSM of participants with CTSDs before and after the PSM. After the matching process, each variable baseline characteristic demonstrated almost complete congruity. In addition, uniformity was achieved within each disease subgroup after matching (Table S1 in Multimedia Appendix 1). In 9923 patients, the distribution for each disease before and after PSM was as follows: AIS (n=2895, 29.17%), STEMI (n=723, 7.29%), septic shock (n=5441, 54.83%), and major trauma (n=864, 8.71%).

Septic shock was the most prevalent condition, accounting for 54.83% (5441/9923) of all cases. The patient population was male-dominated (5566/9923, 56.09%), with the majority (6084/9923, 61.31%) aged ≥65 years. Nearly three-fourths of the CTSD cases (7563/9923, 76.12%) were managed in hospitals categorized as moderate or severe levels. Care provided by specialty consultants accounted for 67.9% (6738/9923) of the cases.

Impact of CHEC Policy Overall and on the Processes and Outcomes of the 4 Individual CTSDs Before and After Implementation

In examining individual diseases, primary diagnostic indicators for AIS, septic shock, and major trauma decreased after intervention, while only those for STEMI increased (Table 3).

Diagnostic fees increased for AIS, STEMI, and major trauma cases but decreased for septic shock cases. A similar trend was observed in the primary treatment indicators, which increased for AIS and STEMI cases and decreased for septic shock and major trauma cases. In contrast, medical orders showed a universal decline. Upward transfer rates increased for AIS and major trauma cases but decreased for STEMI and septic shock cases. Regarding outcome indicators, short-term and long-term mortality rates displayed a universal decline, except for AIS cases, which showed an increase. The medical expenses were higher for AIS and STEMI cases but lower for septic shock and major trauma cases.

In assessing the overall policy effects on 4 CTSD cohorts, the primary diagnosis indicator significantly decreased by 0.21% points (95% CI –0.29% to –0.13%; $P<.001$) and medical orders per case dropped by an average of 7.29 items (95% CI –10.09 to –4.48; $P<.001$). In comparison, diagnostic fees demonstrated an average increase of 376.37 points (95% CI 92.42-660.33; $P=.01$). The 30-day mortality rate saw a notable reduction of 0.09% points (95% CI –0.17% to –0.02%; $P=.01$), 1-year mortality significantly decreased by 0.09% points (95% CI –0.15% to –0.04%; $P=.001$), and medical expense per case significantly decreased by 5328.35 points (95% CI –10,387.10 to –269.60; $P=.04$).

[a]Overall impact of the CHEC policy across all diseases.

[b]Acute ischemic stroke major diagnosis indicator: head image and major treatment indicator: intravenous tissue plasminogen activator thrombolysis.

[c]STEMI: ST-elevation myocardial infarction major diagnosis indicator: electrocardiography and major treatment indicator: percutaneous coronary intervention.

[d]Septic shock major diagnosis indicator: culture and major treatment indicator: antipathogen medication.

[e]Major trauma major diagnosis indicator: computed tomography, magnetic resonance imaging, or sonography study and major treatment indicator: rescue operation.

[f]Diagnostic fees: since Taiwan's National Health Insurance system operates on a global budget with reimbursement based on a point system, the actual monetary value of each point fluctuates. Currently, 1 National Health Insurance point is reimbursed at <NT $0.90 (US $0.0275) per point based on the latest exchange rate (1 NT $=US $0.03057 as of February 16, 2025).

Association of CHEC Policy With Processes and Outcome Quality in the 4 CTSDs

As presented in Table 4, model 1 examined the changes in indicators for individual diseases before and after the implementation of the CHEC policy, and the results show significant improvements in process quality measures. For AIS cases, following the implementation of the CHEC policy, there was a significant decrease in major diagnosis indicators by 0.23% points (95% CI –0.36% to –0.10%; *P*<.001). Conversely, the major treatment indicator experienced a significant increase of 0.57% points (95% CI 0.07%-1.07%; *P*=.03), and the upward transfer rate also significantly increased by 0.52% points (95% CI 0.02%-1.03%; *P*=.04). Moreover, there was a trend of increasing diagnostic fees, with a rise of 460.66 points (95% CI –3.44 to 924.76; *P*=.05). For STEMI cases, the diagnostic fees significantly increased by 2746.59 points (95% CI 1141.67-4351.51; *P*<.001). When examining septic shock, the major diagnosis indicator saw a significant decrease of 0.25% points (95% CI –0.37% to –0.12%; *P*<.001) following the introduction of the CHEC policy. Thirty-day mortality decreased by 0.11% (95% CI –0.20% to –0.02%; *P*=.02), and one-year mortality decreased by 0.15% (95% CI –0.22% to –0.07%; *P*<.001). In addition, medical orders significantly dropped by 9.67 items (95% CI –13.99 to –5.35; *P*<.001), and average medical expenses significantly decreased by 11,059.10 points (95% CI –18,603.60 to –3514.55; *P*=.004). Finally, regarding major trauma cases, after CHEC policy implementation, the average medical orders significantly decreased by 16.13 items (95% CI –25.32 to –6.94; *P*<.001).

Critical time-sensitive disease	Change between before and after CHEC policy	Model 1[a]		Model 2[b]	
		β_2 (95% CI)	*P* value	β_3 (95% CI)	*P* value
Total medical expense per case	−13,056.54	–13,056.50 (–32,010.60 to 5897.53)	.18	N/A	N/A

[a]Model 1 compares the specific disease differences between before and after CHEC policy implementation.

[b]Model 2: model-adjusted estimates for an interaction between a binary measure of CHEC policy (ie, postimplementation vs preimplementation) and critical time-sensitive diseases compared with major trauma (eg, acute ischemic stroke vs major trauma, ST-segment elevation myocardial infarction vs major trauma, and septic shock vs major trauma).

[c]Acute ischemic stroke major diagnosis indicator: head image and major treatment indicator: intravenous tissue plasminogen activator thrombolysis.

[d]Diagnostic fees: since Taiwan's National Health Insurance system operates on a global budget with reimbursement based on a point system, the actual monetary value of each point fluctuates. Currently, 1 National Health Insurance point is reimbursed at <NT $0.90 (US $0.0275) per point based on the latest exchange rate (NT $1=US $0.03057 as of February 16, 2025).

[e]STEMI: ST-segment elevation myocardial infarction major diagnosis indicator: electrocardiography and major treatment indicator: percutaneous coronary intervention.

[f]Septic shock major diagnosis indicator: culture and major treatment indicator: antipathogen medication.

[g]Major trauma major diagnosis indicator: computed tomography, magnetic resonance imaging, or sonography study and major treatment indicator: rescue operation.

[h]N/A: data not applicable as major trauma cases were the reference group.

In model 2, results from the GEE model highlighted the CHEC policy's varied effects across different diseases. A positive group-by-disease interaction β_3 coefficient indicated that the outcome changes for that disease was greater than the reference group (Table 4). Compared to major trauma cases, AIS cases exhibited a significant increase in the major treatment indicator (interaction β coefficient=0.77; 95% CI 0.21-1.33; *P*=.007) and medical orders (interaction β coefficient=15.20; 95% CI 5.28-25.11; *P*=.003) between before and after CHEC policy implementation. Meanwhile, STEMI cases demonstrated a significant increase in diagnostic fees (interaction β coefficient=1983.75; 95% CI 84.28-3883.21; *P*=.04) and a significant decrease in upward transfer rate (interaction β coefficient=−0.59; 95% CI –1.18 to –0.001; *P*=.049) than the major trauma cases. Moreover, there were trends toward increasing major treatment indicators (interaction β coefficient=0.30; 95% CI –0.03 to 0.62; *P*=.07), medical orders (interaction β coefficient=11.92; 95% CI –0.90 to 24.73; *P*=.07), and medical expense (interaction β coefficient=24,275.54; 95% CI –640.71 to 4,991,991.78; *P*=.06), although these were not statistically significant. Compared to major trauma cases, no significant change was observed in either process or outcome quality indicators for septic shock cases.

Discussion

Principal Findings

The CHEC policy was universally implemented across Taiwan's emergency medical service systems. Evaluating the impact of such a policy on a nationwide population presents significant challenges, primarily due to the absence of a control group. This limitation restricts the analysis to pre- and postimplementation comparisons, complicating the understanding of how the policy may influence shifts in various diseases. Despite these challenges, our study aimed to analyze the policy's differential effects on time-sensitive conditions thoroughly. By examining disease-specific guidelines, we identified the groups most affected by the policy and those serving as relatively unaffected counterfactuals, offering valuable insights into the policy's impact. To address these challenges, we used a DID design combined with PSM, using major trauma cases as a reference group. This approach ensured that baseline covariates were balanced between before and after policy periods, allowing us to investigate the policy's effects while controlling for preexisting differences in participant and hospital characteristics. Our analysis revealed 2 major findings. First, the CHEC policy effectively improved system efficiency and patient outcomes, resulting in significant reductions in medical orders (ie, –7.29 items per case), short- and long-term mortality rates (ie, –0.09% each), and total medical expenses (ie, –5328.35 points per case), despite a modest increase in diagnostic fees (ie, 376.37 points). Second, we observed unintended "policy spotlight effects," where conditions with time-based surveillance indicators, such as AIS and STEMI, showed disproportionately greater improvements than conditions without such indicators. Specifically, AIS cases experienced significant increases in major treatments (β=0.77) and medical orders (β=15.20), while STEMI cases demonstrated increased diagnostic fees (β=1983.75) and decreased upward transfer rates (β=–0.59) relative to major trauma cases. These findings highlight the varied impacts of the policy based on the presence or absence of time-based monitoring indicators. Thus, the effectiveness and efficiency of the CHEC policy underscore its dual ability to lower costs while improving patient outcomes. However, why has the CHEC policy significantly reduced medical costs and mortality rates, even though the major diagnosis indicator has declined, and no substantial changes have been observed in treatment indicators? The subsequent sections will delve further into diseases' individual and interactive effects to provide analysis.

Distinction Between the Hawthorne and Policy Spotlight Effects

To distinguish health care providers' behaviors influenced by the Hawthorne effect or policy spotlight effects, we selected AIS and STEMI, which have well-established guidelines and

XSL•FO
RenderX

time-based quality indicators under the CHEC policy. In contrast, septic shock, a disease with well-established guidelines but no specific time-based quality indicators, and major trauma, lacking both well-established guidelines and time-based quality indicators, were chosen as reference groups (Table S2 in Multimedia Appendix 1).

After implementing the CHEC policy, we hypothesized that the observed responses might indicate varying levels of awareness among emergency care providers [24]. The Hawthorne effect highlights that individuals' productivity in experimental settings may increase due to the simple fact that they are being observed. This phenomenon underscores the influence of human attention and intervention on behavior [25]. The policy spotlight effects may be intensified by factors such as time constraints, ambiguous symptom patterns, and time-based quality surveillance indicators, prompting emergency care providers to unconsciously adopt selective behaviors concentrating on specific diseases according to policy targets [25]. Consequently, diseases not prioritized by the policy, such as septic shock and major trauma in this study, may experience a significant decline in process quality and a reduction in medical orders on an individual disease basis (Table 3). When using major trauma as the reference group, both AIS and STEMI group showed increases in major treatments, medical orders, diagnostic fees, and medical expenses. In contrast, no significant changes were observed in the septic shock group (Table 4).

When examining the effects of the policy on individual diseases, we observed distinct patterns. A decrease in diagnostic indicators was noted for AIS cases, likely due to increased upward transfer rates, as hospital physicians appeared more inclined to transfer patients with AIS to higher-level hospitals to enhance access to thrombolytic treatment [26]. This aligns with a significant increase in primary treatment indicators. For STEMI cases, there was an increase in diagnostic fees and a notable rise in diagnostic and treatment indicators, coupled with decreased transfer rates, suggesting a more intensive treatment approach that correlates with reduced mortality rates. These findings highlight the differential impacts of the policy, with AIS and STEMI cases benefiting from improvements in process and treatment quality due to the presence of time-based indicators and targeted monitoring. In contrast, septic shock and major trauma cases, which lack such indicators, showed either no significant changes or potential deterioration in quality metrics. These contrasting trends between diseases with and without time-based monitoring suggest the influence of policy spotlight effects. Under the CHEC policy, AIS and STEMI cases have demonstrated marked improvements, while septic shock and major trauma cases remain relatively unaffected, underscoring the importance of targeted policy monitoring in driving quality improvements.

While the Hawthorne effect typically manifests as generalized behavioral improvements across most observed conditions due to the awareness of being monitored, the implementation of the CHEC policy was explicitly designed to optimize emergency medical capacity through enhanced adherence to evidence-based guidelines, with a particular emphasis on reducing unnecessary medical orders and improving emergency care efficiency. The observed outcomes demonstrated significant improvements, including reductions in medical orders and per-case expenses, concurrent with decreased short- and long-term mortality rates, which are the overall impact of CHEC policy effects on the 4 CTSDs. These observed improvements may be attributed to the Hawthorne effect, wherein the awareness of being observed leads to enhanced performance among health care providers.

Both AIS and STEMI cases appeared to be influenced by the policy spotlight effect, and they showed opposite results in diagnostic indicators and upward transfer rates. These could potentially be attributed to the inherent differences between AIS and STEMI cases. For instance, only about 1% to 2% of all patients with AIS underwent primary treatment with intravenous thrombolytic agents, which is far lower than the STEMI major treatment rate. Unexpectedly, in less policy spotlight affected groups, such as septic shock and major trauma, despite significant decreases in primary diagnostic indicators, medical orders, and diagnostic fees, there were unexpected reductions in 30-day and 1-year mortality rates and medical expenses per event. These unintended consequences might resonate with the "less is more" initiative [27], suggesting that curbing excessive diagnoses and avoiding unnecessary procedures could improve patient outcomes and decrease costs [28,29].

Policy Implications

Many emergency care policies implement time-based criteria [30-32], such as Australia's 4-hour rule [30] and the United Kingdom's 4-hour standard [32]. Australia's experience showed that an emergency care policy using time-based criteria could improve emergency congestion without increasing the rate of ED revisits. However, in New Zealand, a policy in effect from 2006 to 2012 dictated that emergency patients must be hospitalized, transferred, or discharged within 6 hours of visiting the ED. After emergency care policy intervention, the length of ED stay decreased while the treatment outcomes of acute myocardial infarction, severe septic shock, and acute appendicitis did not improve significantly [31]. Similarly, after the Canadian Emergency Observation Reduction Program implementation, the length of ED stay decreased, while the treatment quality indicators for acute myocardial infarction, asthma, and upper limb fractures could only be treated in time for the abovementioned time-sensitive diseases during the noncongested emergency period [33].

Emergency care quality is closely related to the practices of medical care providers [12]. Policy makers must reconsider the conventional emphasis on time-based process indicators. This approach may have unintended consequences for diseases that are outside the "spotlight" of rigid time-sensitive evaluation. Instead, a broader and more nuanced evaluation of emergency care quality is needed to incorporate the complexity and ambiguity of various time-sensitive diseases that emergency care providers often manage [12]. We propose replacing time-based indicators with a broader set of multidimensional performance-based indicators, such as those exemplified in the National Health Service Best Practice Tariff policy [34]. This shift toward "best practice" can create a more flexible approach that goes beyond merely relying on time-based or diagnosis-based practices [34]. Such a transition is crucial, as an excessive reliance on diagnostic tests may lead to ED

XSL•FO
RenderX

crowding, a decline in emergency care quality, and increased safety issues [28].

Strengths

This study used a robust DID method within a GEE framework to evaluate the impact of the CHEC policy. The analysis compared pre- and postintervention periods and distinguished treatment and control groups using a categorical disease variable. Interaction terms captured differential policy effects across disease groups, while GEE accounted for correlated data from repeated measures, ensuring robust variance estimation. The estimated coefficients quantified both overall and disease-specific policy impacts, providing a reliable and nuanced evaluation of the CHEC policy. Our study also examined the behaviors of emergency care providers under time constraints and their interactions with strict time-based quality surveillance indicators and adherence to "get with the guidelines" protocols, revealing policy spotlight effects.

Limitations

This study has several limitations. First, the data were derived from a secondary dataset of insurance claims rather than a randomized controlled trial, which may limit causal inferences. Second, the analysis lacked detailed information on time-related quality indicators, such as door-to-evaluation and door-to-treatment times, and critical emergency care metrics. Third, the effectiveness of emergency medical care often depends on collaboration between emergency and consulting physicians; however, this study did not explicitly evaluate the dynamics of their interaction. Future research should examine the coordination and teamwork between these physician groups to understand their impact on care quality better.

Conclusions

Our study reveals that CHEC policy implementation demonstrates a dual capability to reduce costs and improve patient outcomes. The policy spotlight effects result in a disproportional improvement in disease guideline adherence and process quality of CTSDs with time-based surveillance indicators. In contrast, disease entities not fully encompassed in the surveillance indicators may be jeopardized by decreasing diagnosis and treatment process quality.

Acknowledgments

The authors would like to acknowledge the Taiwan National Health Insurance Research Database, provided by the National Health Insurance Administration and managed by the National Health Research Institutes. They would also like to thank the Center for Public Health, Department of Education and Research, Taipei City Hospital, for providing administrative and research grant support. The authors extend their deepest gratitude to the esteemed members of the dissertation committee for their invaluable guidance and support throughout their research journey. The concept of this paper, titled "The Structure, Process, and Outcome Quality Impacts of the Categorization of Hospital Emergency Capability Policy," was significantly shaped by their insightful feedback and thoughtful encouragement, for which they are profoundly grateful.

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. Generative AI tools (eg, ChatGPT by OpenAI) were used to assist with language refinement and reformatting text for clarity. All AI-generated content was thoroughly reviewed, validated, and edited by the authors to ensure accuracy, scientific rigor, and adherence to academic standards. No content was directly incorporated without author verification, ensuring the integrity of the manuscript remains uncompromised.

Data Availability

The data that support the findings of this study are available from the Taiwan National Health Insurance Research Database, but restrictions apply to the availability of these data, which were used under license for this study, and so are not publicly available. Data are, however, available at the academic request and with the permission of the Taiwan National Health Insurance Administration.

Authors' Contributions

CYL took the lead in conceptualizing the study, drafting the original manuscript, and conducting the formal data analysis. In addition, CYL verified the underlying data presented in the paper. CCL contributed to the study design, data curation, and formal data analysis and oversaw the data collection process. Both CCL and YTH ensured the accuracy of the data analysis and interpretation, as well as verified the paper's underlying data. YCL supervised the study, validated the findings, and played a significant role in reviewing and editing the manuscript. All authors contributed to the development of the study concept and design, as well as the analysis and interpretation of data and the preparation of the manuscript. All authors have approved the final version of the manuscript and take collective responsibility for all aspects of the work, pledging to investigate and resolve any concerns related to the accuracy or integrity of the work.

Abstract

Background: The growing administrative burden on clinicians, particularly in medical documentation, contributes to burnout and may compromise patient safety. Recent advancements in generative artificial intelligence (AI) offer a promising solution to improve documentation processes and address these challenges.

Objective: This study aims to evaluate the feasibility of using a fine-tuned OpenAI Curie model to automate the generation of medical report summaries (epicrises) in ophthalmology. By assessing the model's performance through human and automated evaluations, this study seeks to determine its potential for reducing clinician workload while ensuring accuracy, usefulness, and compliance with regulatory requirements.

Methods: A data set of around 60,000 anonymized medical letters was created using a custom algorithm to comply with General Data Protection Regulation guidelines. The Curie model was fine-tuned on this data set to generate epicrises from medical histories, diagnoses, and findings. The performance evaluation involved various human assessments and automated evaluations from 2 large language models (LLMs).

Results: In the clinical context, 49.9% (384/769) of epicrises were evaluated as helpful or excellent, whereas only 25% (194/769) were considered disturbing. In a human (manual) evaluation, formal correctness was rated significantly higher than the neutral midpoint of 2.5 on the 4-point rating scale, as determined by a 1-sample Wilcoxon signed-rank test (mean 3.59, SD 0.85; W=1686; P<.001). Using paired t tests, we found a significant reduction in time, as correcting an AI epicrisis was faster than manually writing one (mean 109.52, SD 53.30 vs mean 54.25, SD 63.34 s; t_{68}=3.39; P<.01). While medical accuracy and usefulness showed positive trends, these did not reach statistical significance when compared to the neutral midpoint (for medical accuracy, W=7456; P=.08), for usefulness, W=7652.5; P=.18). Epicrises generated or corrected with AI were significantly shorter than manually written ones (mean 330.43, SD 115.42 vs mean 501.07, SD 243.50 characters; t_{68}=–6.10; P<.001). Automated LLM assessments showed alignment with human ratings, with over 52% (356/679) and 66% (489/743) of responses in the top agreement categories, respectively. This supports overall consistency, though the comparison remains a proof of concept given methodological limitations.

Conclusions: Our study demonstrates the technical and practical feasibility of introducing fine-tuned commercial LLMs into clinical practice. The AI-generated epicrises were formally and clinically correct in many cases and showed time-saving potential. While medical accuracy and usefulness varied across cases and should be focused on in further developments, a significant workload reduction is likely. Our anonymization process showed that regulatory challenges in the context of AI with patient data can effectively be dealt with. In summary, this study highlights the promise of transformer-based LLMs in reducing administrative tasks in health care. It outlines a pipeline for integrating LLMs into European Union clinical practice, emphasizing the need for careful implementation to ensure efficiency and patient safety.

KEYWORDS

artificial intelligence; large language models; medical reports; epicrisis generation; documentation automation

Introduction

In modern health care, administrative tasks have seen a sharp rise, escalating clinician workloads and increasing the risk of burnout and potential patient hazards due to an overload of work. [1,2] This trend has led to a critical demand within the medical community for effective and reliable assistance with documentation tasks. In parallel, the world of artificial intelligence (AI) has witnessed the development of large language models (LLMs) by organizations such as OpenAI and Anthropic and big tech companies like Google. These models have demonstrated their capability for generating coherent, human-like text that closely resembles professionally written content. However, out-of-the-box solutions like ChatGPT and similar models are, in many cases, not viable for immediate implementation in medical settings. This is due to several factors, including "refusal" due to built-in safety checks, the lack of alignment with local treatment guidelines, and the absence of detailed domain-specific knowledge [3,4].

To address these limitations, the concept of fine-tuning LLMs has emerged. Fine-tuning involves training existing language models on specialized data sets to enhance their performance in specific domains. Haghigi et al [5] demonstrated that training LLMs with specialized ophthalmic data improves their effectiveness in clinical decision-making and patient education. Their EYE-Llama models, pretrained on ophthalmology-specific data sets and fine-tuned on diverse question-answering data sets, outperformed baseline Llama 2 and ChatDoctor models, achieving results comparable to ChatGPT.

Van Veen et al [6] demonstrated that LLMs can outperform medical experts in summarizing clinical text across tasks like radiology reports, patient questions, and progress notes. Their study found that in most cases, summaries generated by adapted LLMs were equivalent or superior to those produced by human experts. This suggests that integrating LLMs into clinical workflows could significantly reduce the documentation burden on clinicians, thus allowing them to dedicate more time to patient care.

This study examines the feasibility of using adapted LLMs to automate medical report writing, specifically focusing on generating epicrises, or summaries. In our ophthalmology reports, there are three main sections: (1) patient history and diagnosis, (2) clinical findings, and (3) the epicrisis, which synthesizes the key information. We identified the epicrisis as the most suitable target for LLM-based assistance, as it synthesizes and consolidates information from the earlier sections. This reduces the risk of hallucinations by the model since the content is already documented and can be cross-referenced. In contrast, sections such as history and findings present more uncertainty and are more prone to variability or missing data, making them vulnerable to confabulation [7].

Epicrises are the most promising targets for automating the generation of medical reports. Heilmeyer et al [8] already provided valuable insights into fine-tuning LLM on premises for epicrisis generation to fulfill a similar task. To achieve this, different LLMs were fine-tuned on local servers to generate parts of medical reports, with varying degrees of success. We hypothesized that large commercial LLMs, such as OpenAI, hosted on capable infrastructure could outperform the local LLMs with limited resources and may be more accessible to sites with lower local resources. To our knowledge, OpenAI does not fully disclose the infrastructure on which the models are hosted, but it is known to use the Microsoft Azure Cloud and have access to a state-of-the-art graphics processing unit (GPU), such as NVIDIA H100, and server infrastructure [9].

Transferring medical reports to the United States for the purpose of improving medical report writing using an LLM poses significant challenges due to stringent legal and regulatory requirements. The General Data Protection Regulation (GDPR) in the European Union (EU) sets high standards for the protection of personal data, including medical information. According to the GDPR, the transfer of personal data to a third country, such as the United States, is only legal under certain conditions. Two primary approaches can be taken to make this transfer feasible: anonymizing the data beforehand or using Standard Contractual Clauses (SCCs) in combination with obtaining individual consent [8,10-12].

First, fully anonymizing the text under the legal basis of "legitimate interest" and validating the results as part of a Data Protection Impact Assessment (DPIA) is one approach. Once the data are anonymized, they no longer fall under the stringent regulations governing personal data, thus facilitating the transfer.

Alternatively, the use of SCCs or Binding Corporate Rules (BCRs), coupled with obtaining individual consent, can provide a lawful basis for the transfer. The invalidation of the Privacy Shield framework by the European Court of Justice (Schrems II decision) necessitates these legal mechanisms, along with additional safeguards, to ensure an adequate level of data protection [12]. Furthermore, ensuring compliance with the Health Insurance Portability and Accountability Act (HIPAA) is essential for any US entity handling health information. These regulations require comprehensive risk assessments, stringent data protection measures, and maintaining transparency with data subjects [13,14].

By either fully anonymizing the data before transfer or utilizing SCCs in combination with individual consent, the process of leveraging LLMs for enhancing medical report writing can be successfully navigated within the regulatory framework.

Other groups have already investigated approaches to anonymize clinical report data. Wiest et al [15] presented an LLM-based anonymization pipeline that can effectively deidentify medical free-text data, facilitating secure data sharing for medical research. This approach used a different locally installed LLM to anonymize clinical text data.

Therefore, the primary aim of this feasibility study was to evaluate the potential of a fine-tuned LLM, specifically

XSL•FO
RenderX

OpenAI's Curie model, to automate the generation of ophthalmic epicrises. We hypothesized that such a model, when fine-tuned on a large, anonymized data set of clinical reports, could generate accurate and clinically useful summaries, thereby demonstrating the potential to reduce clinician documentation workload. This study specifically sought to assess the feasibility of this approach, the quality of the generated epicrises through both human and automated evaluations, and potential time savings, all while ensuring compliance with data protection regulations like GDPR.

Methods

Overview

Our approach involved obtaining quality training data from a large pool of consecutive medical letters available in our electronic database, which numbered close to 60,000. The data had no inclusion criteria to avoid introducing bias and to reflect real-world medical letters. Only high-quality medical letters that were reviewed by both a resident and an attending physician were included. Incomplete letters with missing fields were excluded.

Anonymization Process

The following custom anonymization algorithm was developed and applied to all letters. In the first step, we extracted the data using an SQL query that selectively recalled the content of the letters but not any identifying data, such as names and addresses. The patient ID, however, was kept alongside the textual data for the second step. Here, we handled the rare cases where identifying information had been placed within the letters' contents, such as a reference to the patient's name and/or precise temporal information. This was done by explicitly replacing the patient's first name and surname with specific placeholders, using the patient ID to look up all identifying words to be eliminated from the document. The third step involved applying several regular expressions to capture date/time values, third-party names, and postal addresses. All occurrences were substituted with specific constant placeholders to preserve the semantic context and grammar.

This approach ensured that there was only a comparably small remaining text corpus containing only the information needed for the individual visit and not the whole patient history. This makes the anonymization process more consistent. Deanonymization in this case can only be assumed to be possible for highly individual cases and rare diseases. To ensure the robustness of our anonymization process during a DPIA, we conducted a rigorous evaluation. A randomly selected sample of 300 anonymized letters was independently reviewed by 2 expert investigators who were blinded to the original content. Neither reviewer was able to identify any residual personal data, demonstrating the algorithm's effectiveness in protecting patient privacy. Following this successful validation, our data protection officer approved the transfer of the anonymized data set to OpenAI.

We opted for this custom-made approach because it offers excellent reproducibility and explainability, giving us a high level of control over the anonymization process to ensure its quality. While other anonymization methods, including those using LLMs, exist, they do not provide the same degree of control, making our approach more reliable for our needs [15].

Training and Fine-Tuning Process

OpenAI offers self-service fine-tuning for selected models from the GPT-3 family. We opted for the second powerful base model named "Curie" at the time of training since we wanted to assess the feasibility of our approach and not get a false-negative outcome due to selecting a base model with insufficient capabilities [16]. The training data set comprised a total of 90 million tokens, which were derived from approximately 60,000 medical letters.

We conducted a simple completion training in which the full medical letter, excluding the epicrisis, served as the prompt and the epicrisis as the corresponding completion. We did not use any instructions during training.

The fine-tuning of our model was achieved by using the OpenAI fine-tuning API via the official command line tools. The fine-tuning methodology of OpenAI is not publicly disclosed to the best of our knowledge. However, the low pricing and 24/7 availability of the fine-tuned model make it likely that some kind of adaptor technology is used instead of fully fine-tuning the base model. Hyperparameters, such as learning rate and batch size, are chosen automatically by the OpenAI command line tools.

The overall cost of fine-tuning totaled approximately 500 € (US $581). The fine-tuned model was hosted by OpenAI and accessed via a private key using the official API during the study period. At the time of publishing this article, the model has now been deactivated because its base model was depreciated by OpenAI, although the API remains operational [16].

Integration Into a Testing Environment for a Global Assessment

We built a custom evaluation software tool. In this step, the physicians were prompted to evaluate the quality of sequential model-generated epicrises for anonymized data from real patients that had not been used to train the model. The testing physicians' personal data were not collected, ensuring maximal data privacy without creating conflicts with employee rights. This study was performed during the period between calendar weeks 11 and 35 in 2023. The evaluation was based on a single Likert scale question ranging from "disturbing" to "excellent."

Structured, Multi-Item Human Evaluation in a Holdout Set of the Training Data

To evaluate the model's performance and potential for real-world application, we conducted a comprehensive study involving a systematic clinician rating of epicrises generated from a set of random, anonymized historical report prompts. This seemed to be the best approach to evaluate the model's performance and to estimate its potential benefits.

The human evaluation was performed using another custom intranet-based Python-programmed web application. Four experienced physicians, with professional experience ranging

XSL•FO
RenderX

from 1 to 20 years, used the evaluation tool to rate the output of the generated epicrises in different metrics that are described later in the study. The physicians were given a guideline on how to evaluate each aspect.

Estimating the Time-Saving Potential

We also developed a method to estimate the time savings for physicians when using AI-generated epicrises. In our multidimensional evaluation tool, we included a section where users copied and pasted the AI-generated epicrisis and revised it to match the quality of a gold-standard human-written version. We measured the time taken for this task. Prior to this, users completed a test to assess their writing speed. These results were then used to calculate the estimated time savings per epicrisis. This approach was intended to account for the possibility that there are mistakes of any kind in the AI-generated text, but just adapting the text would still be a benefit in terms of time consumption compared to writing a completely new epicrisis.

Structured Multi-Item Automated Evaluation Using 2 LLMs

We implemented an automated evaluation technique where the outputs from LLMs were assessed based on several parameters. This evaluation was conducted using the commercially available OpenAI GPT-3.5 Turbo model, alongside Google's open-source Gemma2 model (27B), to provide more nuanced and unbiased results [17,18]. We chose 2 different models to avoid potential bias, as the epicrises being evaluated were generated by an OpenAI model, and using only models from the same ecosystem could introduce bias.

The OpenAI model was accessed through the official API, with the total cost for evaluating all 86 letters amounting to approximately $0.20 USD. These costs were privately funded, and there were no conflicts of interest. The Gemma2 model was accessed via Ollama and installed locally on an Apple MacBook Pro (M3 Processor, 24GB RAM; Apple Inc).

For each evaluation, the medical report, human-written epicrisis (as the gold standard), and AI-generated epicrisis were provided as inputs. The models were prompted to assess whether the AI-generated text was medically accurate, formally correct, provided a time-saving advantage for clinicians, and was overall useful. Responses were requested on a 5-point scale ranging from "I disagree" to "I completely agree," aligning closely with the human evaluation to ensure consistency.

Prompt engineering played a crucial role in obtaining meaningful results. The prompting was achieved using state-of-the-art techniques and libraries, such as LangChain. A total of 86 randomly selected reports were evaluated by both the OpenAI and Gemma2 models, using the same reports as in the human evaluation to enhance repeatability and consistency. Our evaluation prompt was carefully designed to align with the other evaluation metrics, ensuring coherence across all assessments.

Ethical Considerations

The Ethics Committee of the University of Freiburg (24-1370-Anfrage) confirmed that formal ethical approval was not required for this project, as it exclusively involved the use of fully anonymized data. The committee clarified that research using anonymized text data does not constitute human participant research under the current ethical guidelines. All research was conducted in adherence to relevant ethical guidelines and regulations, ensuring compliance with institutional and international standards.

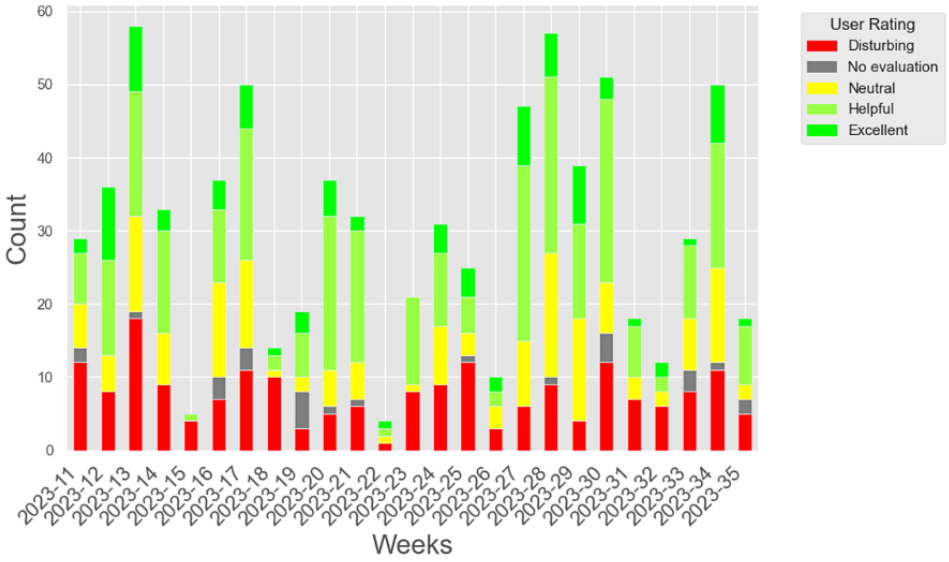
Individual informed consent was not required as this study used only fully anonymized data, with no possibility of identifying individual patients. This approach was validated through a DPIA and approved by our institutional data protection officer.

Data Analysis

Statistical analyses were conducted using Python (SciPy, NumPy, and Pandas). A 1-sample Wilcoxon signed-rank test was used to compare subjective ratings (eg, formal correctness, medical accuracy, and usefulness) against a hypothesized neutral midpoint of 2.5. Paired *t* tests were employed to compare time and length measurements (eg, manual vs AI-corrected writing durations, and character counts). As each AI-corrected epicrisis was compared against the original human-written version for the same medical report, these data were inherently paired. Agreements between human and automated assessments were evaluated descriptively, based on the percentage of categorical rating alignment.

Results

Results Of the 1-Dimensional Clinical Rating



In the real-world evaluation (n=769), the AI-generated epicrises received a mean rating of 1.08 (SD 1.38, coding for helpful) on a scale from –1 (disturbing) to 3 (excellent). Most ratings were positive, with 290 of 769 (37.7%) marked as helpful and 94 of 769 (12.2%) as excellent, while 194 of 769 (25.2%) were rated disturbing, indicating some polarization (Table 1). The results of the real-life clinical rating are shown in Figure 1. Although a 1-sample Wilcoxon signed-rank test did not show a statistically significant deviation from the neutral benchmark of 1 (W=83,038; P=.87), this may be attributable to the broad rating scale and inherent variability in real-world clinical presentations. Given the favorable distribution and positive trend in responses, the results still suggest that the model's output was generally perceived as useful and well-accepted in everyday practice.

XSL•FO
RenderX

Table 1. Distribution of the 1-dimensional human evaluation. The largest percentage was evaluated to be useful.

Rating	Count (N=769), n (%)
Disturbing	194 (25.2)
No evaluation	30 (3.9)
Neutral	161 (20.9)
Helpful	290 (37.7)
Excellent	94 (12.2)

Figure 1. One-dimensional human evaluation recorded during the calendar weeks 11 to 35. The data were obtained over several weeks. Bad ratings are colored in red tones and good ratings in green tones .

Results of the Manual Evaluation

The physician rating was performed by 4 different physicians with clinical experience ranging from 1 year to more than 20 years. The ratings were performed as explained earlier in the Methods section. Table 2 shows the summarized numerical results of the evaluation.

Table 2. Overall physician rating of the AI[a]-generated epicrises. The ratings of all 4 physicians are summarized.

Evaluation metric	1: I disagree (n=107), n (%)	2: I partly agree (n=147), n (%)	3: I mostly agree (n=235), n (%)	4: I completely agree (n=254), n (%)
Formally correct	12 (11.2)	8 (5.2)	48 (20.4)	118 (46.5)
Medically correct	32 (29.9)	48 (32.7)	63 (26.8)	43 (16.9)
Useful	33 (30.8)	47 (32)	67 (28.5)	38 (15)
Advantage in time	30 (28)	44 (29.9)	57 (24.3)	55 (21.7)

[a]AI: artificial intelligence.

The proportion of evaluations representing a helpful AI written epicrisis was in all cases bigger than the proportion representing a rather disturbing or useless one. Figure 2 shows a different approach to visualizing the results grouped for the different metrics to experience a more nuanced view. The evaluations are very balanced for most metrics. In the case of the metric *formally correct*, there was a bigger tendency toward positive evaluations. Wilcoxon signed-rank tests were used to evaluate whether physician ratings differed significantly from a neutral midpoint of 2.5 on the 4-point rating scale. The neutral midpoint of the scale was 2.5, representing a neutral evaluation. The 1-sample Wilcoxon signed-rank test was used to assess if ratings significantly deviated from this midpoint. *Formally correct* was rated significantly higher than neutral (W=1686; P<.001), reflecting strong agreement on structural quality. *Advantage in time* was also rated significantly above the midpoint (W=6564; P<.01), indicating that clinicians perceived a clear time-saving benefit. In contrast, ratings for *medically correct* (W=7456;P=.08) and *usefulness* (W=7652.5; P=.18 did not significantly differ from neutral, suggesting more variable impressions regarding clinical accuracy and usefulness while still showing a quantitative tendency. All statistical results can be found in Table 3.

XSL•FO
RenderX

Figure 2. Physician rating of artificial intelligence (AI)-generated epicrises .

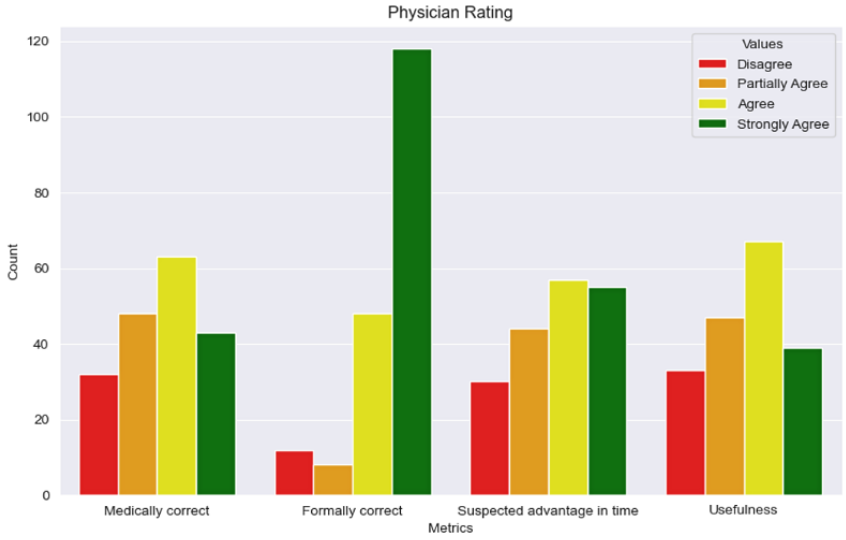


Table 3. Statistical results for the physician ratings.

Metric	Median	*W* statistic	*P* value	Significant (*P*<.05)
Medically correct	3	7456	.08	No
Formally correct	3	1686	<.001	Yes
Useful	3	7652.5	.18	No
Advantage in time	3	6564	.003	Yes

Calculation of Possible Time Advantage

As previously described, we added a way of estimating a possible benefit in time consumption for our study. The time the tester needed to correct the computer-generated epicrisis was measured. The time to write the human-written epicrisis was calculated by dividing the length of the human-written epicrisis by the user's individual writing speed. The average time to rewrite the human epicrisis was 109.52 seconds, while the average time to correct the AI-generated epicrisis was 54.25 seconds, suggesting a time advantage of 56 seconds per epicrisis. The exact results are shown in Table 4.

Table 4. Times and lengths of the epicrises evaluated by 4 different physicians (N=69).

Statistic	Real epicrisis time (seconds)	Corrected epicrisis time (seconds)	AI[a]-generated length (characters)	Real length (characters)	Corrected length (characters)
Mean	109.52	54.25	330.43	501.07	352.22
SD	53.3	63.34	115.42	243.5	135.78
Min	11.35	0.77	125	52	118
25th percentile	73.14	21.94	261	335	255
Median	98.47	44.46	315	451	342
75th percentile	131.86	65.12	400	604	445
Max	261.4	499.86	689	1192	691

[a]AI: artificial intelligence.

What must be considered in this context is that there were significant differences in epicrisis length. To assess whether differences in documentation time were influenced by the length of the epicrises, we compared character counts across versions. AI-generated epicrises were significantly shorter than human-written ones (t_{68}=–6.10; *P*<.001), and the corrected AI versions also remained significantly more concise (t_{68}=–6.65; *P*<.001). These results suggest that the AI system may support more efficient and focused documentation by generating concise summaries of relevant information. This may be particularly beneficial for nonnative speakers, as it helps reduce linguistic complexity while preserving clinical content. The differences are portrayed in a boxplot that can be found in Multimedia Appendix 1. Additionally, this may be due to a person's information advantage when writing, since not all information can be inferred from the letter above. A paired *t* test comparing the time required for generating human-written epicrises versus correcting AI-generated ones revealed a statistically significant

XSL•FO
RenderX

reduction in time with AI assistance (t_{68}=3.39; P=.001). On average, correcting the AI-generated epicrises was notably faster, suggesting a potential efficiency gain in documentation workflows. This result supports the hypothesis that AI-assisted documentation can meaningfully reduce the time burden for clinicians. All exact statistical results are shown in Table 5.

Table 5. Statistical results for time and length comparisons.

Comparison	Mean (SD)	Test type	*t* test (df)	*P* value
Time: human-written vs corrected AI[a]	109.52 (53.3) vs 54.25 (63.3) s	Paired *t* test	3.39 (68)	<.001
Length: human-written vs AI-generated	501 (243.5) vs 330.43 (115.42) characters	Paired *t* test	–6.10 (68)	<.001
Length: human-written vs corrected AI version	501 (243.5) vs 352.22 (135.78) characters	Paired *t* test	–6.65 (68)	<.001

[a]AI: artificial intelligence.

Results of the Automated Evaluation

The automated evaluation showed a tendency for medium values but demonstrated an overall good correspondence with the human evaluation from earlier. Notably, the automated AI evaluation was more hesitant to assign extreme values. The exact results of the evaluations can be seen in Table 6, and they show good overall correspondence. Automated LLM assessments generally aligned with human ratings, with over 52% (356/679) of LLM responses and 66% (489/743) of human ratings falling into the top 2 agreement categories. While this supports overall consistency, direct statistical comparisons (eg, interrater reliability) are not appropriate, as LLMs are not human raters. The evaluation serves as proof of concept for future refinement.

Table 6. AI[a]-generated evaluation of the epicrises. The evaluation was conducted using 2 LLMs[b]. The first was OpenAI's GPT-3.5 Turbo model, accessed through the OpenAI API. The second was a locally run Gemma2 (Google LLC), accessed through Ollama.

Metric	Disagree	Partially agree	Agree	Strongly agree
OpenAI ChatGPT 3.5 Turbo				
Medically correct	0	62	22	1
Formally correct	2	18	64	1
Suspected advantage in time	4	28	44	8
Usefulness	0	63	22	0
Google Gemma2				
Medically correct	0	48	37	0
Formally correct	1	9	74	1
Suspected advantage in time	3	18	53	11
Usefulness	1	66	18	0

[b]LLM: large language model.

Discussion

Principal Findings

Our study had 2 primary objectives. First, we aimed to develop a proof of principle for medical report writing assistance under optimal conditions, providing valuable insights for future developments that could be implemented within EU regulatory frameworks. Second, we sought to assess the potential degree of workload reduction for clinicians.

To achieve the goal of exploring the full potential of current LLM technology in medical report writing, we deliberately chose to use OpenAI's high-resource data centers and powerful models. Although this approach may have limitations for routine usage in the EU due to GDPR constraints, our work may also be directly useful for sites outside the EU without the infrastructure to fine-tune and host LLMs on premises.

By using OpenAI resources, we were able to demonstrate a best-case scenario for LLM-assisted medical report writing. Our results show that under these conditions, there was a significant potential for reducing the administrative burden on clinicians. The real-life clinical ratings, where more than 50% of evaluations found the AI-generated epicrises helpful or excellent, suggest that such a system could substantially decrease the time and effort required for documentation tasks.

The physician ratings and automated evaluations further support this potential for workload reduction. The high scores in categories such as *advantage in time* and *useful* indicate that AI-generated epicrises could save valuable clinician time, allowing for more focus on direct patient care.

The estimation for writing time revealed a potential savings of approximately 56 seconds (nearly 50%) per medical report. Given that physicians typically handle about 20 reports daily, this could lead to a significant reduction in workload. Our study

XSL•FO
RenderX

successfully demonstrated that our approach is a viable solution to achieve these goals, showcasing the potential of LLMs in medical documentation. Additionally, we developed an effective anonymization algorithm that complies with the stringent data protection standards of European law for data transfer to non-EU countries. This accomplishment is significant, as it facilitates collaboration on sensitive patient data while maintaining compliance with GDPR. Our anonymization process, replacing sensitive patient data with placeholders, was crucial in providing the LLM with a high-quality text corpus to work with.

Comparison With Prior Work

Our findings align with and build upon several key studies in this field. There are now several studies that show that the use of LLMs can be helpful in reducing physician workload [6,19].

Van Veen et al [6] demonstrated that adapted LLMs could outperform medical experts in summarizing clinical texts, with their generated summaries often rated as equivalent or superior to human-written ones. This study adopted a broader approach across various medical fields. Heilmeyer et al [8] explored the use of open-source LLMs hosted on premises for a similar task, focusing on the viability of local, privacy-preserving solutions. Other approaches that could also be combined with our work in a helpful context include that of Kernberg et al [20], who used LLMs to create medical notes from audio files. Singh et al [21] successfully used LLMs to create discharge summaries and operative notes. We believe this demonstration suggests that our approach could potentially be applied in a broader context while working with the same techniques.

Limitations

We recognize that the time-saving potential is merely an estimate, and actual results may vary in practice, which we could not evaluate at this stage. A standardized assessment of the time-saving potential is methodically challenging to quantify.

In addition, it is crucial to note that these results represent an ideal scenario, while real-world implementation may present additional challenges. This might include retraining the fine-tuned models or developing models that are capable of online training to adapt to changing guidelines and state-of-the-art medical treatment. The development of models with reinforcement learning may be a good approach and should be considered in further research.

While our anonymization process was conducted to fulfill the high data privacy standards according to the laws in Germany and Europe, it must still be considered that complete anonymization is difficult to achieve. There are cases of very rare diseases, such as corneal or retinal dystrophies, or other individual conditions that could potentially be identified if supplementary data were available.

Our training corpus has limitations in terms of size and domain diversity, which may affect the model's adaptability. We observed that the model performs best on very common, standardized cases in our daily clinical routine, such as pterygium, keratoconus, and age-related macular degeneration. On the other hand, the model sometimes struggles with more complex cases involving individualized treatment plans. This has motivated us to continue in-house model development to improve the training corpus and retrain a new model in the future. It is also worth noting that the model may perform differently when applied to other medical disciplines. Ophthalmology, as a specialized field, may present challenges for generally trained models, while areas like internal medicine, which benefit from more extensive training data, may see better results.

While our approach is relatively straightforward to implement, significant challenges remain. Many hospitals do not have structured access to medical reports and still use unstructured formats like Microsoft Word, complicating automated data processing. Although our model setup is simple, delivering data to APIs such as OpenAI in a structured JSON format is crucial. For clinics that can achieve this, the training process becomes easier compared to developing in-house hardware and software for model fine-tuning. However, considerable domain knowledge is still required for effective implementation, which may be lacking in many hospitals.

Evaluating the performance of language models in medical contexts is inherently challenging, which is why we implemented a variety of metrics to assess our model's performance. We aimed to create a set of possibilities that can be used to evaluate the performance of LLMs. This mainly relied on human ratings in different contexts. We also included an AI auto-evaluation as a proof of concept that could be applied in other contexts with bigger sample sizes that are difficult to evaluate manually. Since the human and the AI auto evaluation showed good alignment, we believe this approach can be used for similar tasks in the future.

Several factors must be considered when evaluating our project and identifying areas for future research. The rapid advancement of generative AI requires ongoing reevaluation.

One limitation in this context is the fact that this study was conducted using the OpenAI Curie model, which has since been deprecated. While the specific model is no longer state-of-the-art, the primary contribution of our work lies in the demonstration of a feasible end-to-end pipeline. The methodologies and principles established here are directly transferable to newer, more powerful models, and we are actively conducting ongoing research with these models.

Additionally, other groups within our hospital have achieved success using on-premises solutions for this task. However, the training and fine-tuning processes remain challenging because of the demand for highly qualified personnel as well as hardware requirements. Our study did not perform a direct head-to-head comparison, and the hypothesis that commercial models outperform local ones remains a topic for future empirical validation.

Conclusion

In conclusion, our study demonstrates the significant potential of LLMs in medical report generation under optimal conditions, provides a quantitative assessment of possible workload reduction for clinicians, and highlights the challenges of implementing such systems within the EU's regulatory framework. The proof of principle established here sets a

XSL•FO
RenderX

benchmark for what is achievable with the current LLM technology. Future research should focus on developing equally powerful solutions that can be deployed on premises or within EU-based cloud services, ensuring both high performance and full compliance with the GDPR. We hope that this study will guide the development of EU-compliant solutions capable of matching or exceeding this performance level while significantly reducing the administrative burden on health care professionals—allowing physicians to focus rather on patient care than on medical documentation. Our work represents one step toward achieving this goal [3].

Acknowledgments

We would like to thank all physicians who participated in the evaluation process for their time and insights. We are grateful to the Department of Ophthalmology of the University Hospital Freiburg for providing the necessary infrastructure. We appreciate the help of the data protection team as well as the local ethics committee for their assistance in ensuring that our study was GDPR-compliant. This study received no additional funding from external sources. The costs for the fine-tuning process and all hardware requirements were paid by the institution. Generative AI and AI-assisted technologies (DeepL, GPT-4o, and Gemini) were used to make linguistic improvements during the writing process. The authors carefully checked the text suggestions for accuracy and made corrections where necessary. They take full responsibility for the publication's content. We acknowledge support by the Open Access Publication Fund of the University of Freiburg.

Data Availability

The data sets used and/or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

SA and DB were responsible for data acquisition, training, fine-tuning, and implementation of the model. SA and DB also created the evaluation software. DB and SA were responsible for integrating the model into clinical production. AR, QVN, LS, and SA performed the model evaluation manually. TR and FH were responsible for overseeing the project. SA was the main manuscript author. Extensive proofreading was performed by LS and FH. All authors approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Ferroptosis, as a novel modality of cell death, holds significant potential in elucidating the pathogenesis and advancing therapeutic strategies for breast cancer.

Objective: This study aims to comprehensively analyze current ferroptosis research and future trends, guiding breast cancer research advancements and innovative treatment strategies.

Methods: This research used the R package Bibliometrix (Department of Economic and Statistical Sciences at the University of Naples Federico II), VOSviewer (Centre for Science and Technology Studies at Leiden University), and CiteSpace (Drexel University's College of Information Science and Technology), to conduct a bibliometric analysis of 387 papers on breast cancer and ferroptosis from the Web of Science Core Collection. The analysis covers authors, institutions, journals, countries or regions, publication volumes, citations, and keywords.

Results: The number of publications related to this field has surged annually, with China and the United States collaborating closely and leading in output. Sun Yat-sen University stands out among the institutions, while the journal *Frontiers in Oncology* and the author Efferth T contribute significantly to the field. Highly cited papers within the domain primarily focus on the induction of ferroptosis, protein regulation, and comparisons with other modes of cell death, providing a foundation for breast cancer treatment. Keyword analysis highlights the maturity of glutathione peroxidase 4-related research, with breast cancer subtypes emerging as motor themes and the tumor microenvironment, immunotherapy, and prognostic models identified as basic themes. Furthermore, the application of nanoparticles serves as an additional complement to the basic themes.

Conclusions: The current research status in the field of ferroptosis and breast cancer primarily focuses on the exploration of relevant theoretical mechanisms, whereas future trends and mechanisms emphasize the investigation of therapeutic strategies, particularly the clinical application of immunotherapy related to the tumor microenvironment. Nanotherapy has demonstrated significant clinical potential in this domain. Future research directions should deepen the exploration in this field and accelerate the clinical translation of research findings to provide new insights and directions for the innovation and development of breast cancer treatment strategies.

KEYWORDS

breast cancer; ferroptosis; bibliometric; malignancy; cancer studies; treatment; bibliometric analysis; VOSviewer; China; United States; breast carcinoma; mammary cancer; strategy; trends; bibliography; review; disparities; forecast; treatment strategies; advancements

Introduction

Based on 2022 International Agency for Research on Cancer data, the global burden of breast cancer is alarming, with 2.3 million new cases, and over 665,000 deaths annually. Breast cancer constitutes 11.6% of new cancers and 6.9% of cancer deaths, underscoring the need for urgent research and intervention [1]. It has been projected that by 2040, due to global population growth and aging, the cancer burden will further increase, with breast cancer experiencing particularly notable growth. The number of new cases and deaths are expected to rise to over three million and one million, respectively [2]. As the most prevalent cancer worldwide, surpassing lung cancer, breast cancer poses a significant threat to human health. Despite the considerable progress achieved through sustained research in breast cancer diagnosis, treatment, and prevention, the intricate etiology of this malignancy remains widely undeciphered. Consequently, there is an urgent need to delve deeper into the complex mechanisms that underlie its development, with the aim of developing more precise and efficacious strategies for its management [3]. There is considerable variation in treatment response among individuals with this disease, and the prognosis and treatment outcomes for individuals diagnosed with advanced breast cancer are notably unfavorable [4]. Exploring new mechanisms can enhance our understanding of the biological behavior of breast cancer and improve treatment sensitivity.

Ferroptosis has added a new theoretical basis to the study of the molecular mechanisms underlying breast cancer. Since the introduction of this concept, the popularity of research in this field has rapidly increased, showing an exponential growth trend [5]. Ferroptosis is a recently discovered cell death mechanism mediated by iron-dependent phospholipid peroxidation and is tightly regulated by various cellular metabolic networks, including redox balance, iron handling, mitochondrial function, and amino acid, lipid, and glucose metabolism. This intricate regulation highlights its significance in breast cancer research [6]. Studies on breast cancer have revealed that the regulatory network of ferroptosis is sophisticated and complex, involving the synergistic effects of multiple signaling pathways and transcription factors. This regulatory network may modulate the malignant biological behavior of breast cancer cells via autophagy [7], metabolism [8], immune regulation [9], and other procedures, opening novel strategic directions for breast cancer treatment [5,6,10]. However, the literature concerning breast cancer and ferroptosis currently appears highly fragmented, and a systematic bibliometric analysis to consolidate this information is lacking, making it difficult to accurately summarize the research status and future direction of this field.

In response, this study aims to use bibliometric methods to conduct a comprehensive and objective analysis of the current status and future trends in breast cancer and ferroptosis research. This will entail a rigorous examination of pertinent indicators, including author distribution, research institutions, journals, country or region contributions, scientific publication output, highly cited papers, and keyword analysis. The ultimate objective of this study is to provide an in-depth revelation of the research hotspots and potential development trends in this field, thereby offering guidance for future research endeavors in exploring the mechanisms and therapeutic strategies related to ferroptosis in breast cancer.

Methods

Data Sources and Search Strategy

This study used data from two core collections within the Web of Science Core Collection (WOSCC): the Social Sciences Citation Index and the Science Citation Index Expanded. An advanced search was conducted using the search query (TS=(“Breast Tumor*” OR “Breast Cancer” OR “Mammary Cancer” OR “Breast Carcinoma” OR “Carcinomas, Breast”) AND TS = (“Ferroptosis”)), yielding a total of 624 papers. The search was further refined to include papers published between January 1, 2016, and February 1, 2024. Paper types were limited to original research papers, excluding reviews, conference abstracts, news items, advertisements, and non-English literature that did not meet the inclusion criteria. All data records in this study consisted of complete records and cited references and were exported in plain text format. To avoid errors and ambiguities due to database updates, all searches and data exports were completed on February 18, 2024. Additionally, all data in this study were obtained from open-source public databases; thus, no ethical issues were involved. The search and screening processes were independently conducted by JYL and YLD. In the case of any disagreements during the screening process, the final decision was reached after a discussion with the corresponding authors WP and XY.

Inclusion and Exclusion Criteria

The inclusion criteria were (1) published journal papers; (2) papers with “breast cancer” and “ferroptosis” in the title, indicating a primary focus on breast cancer and ferroptosis; (3) papers not mentioning “ferroptosis” in the title but including ferroptosis-related research on breast cancer in the abstract; and (4) papers containing actual research on the relationship between breast cancer and ferroptosis within the full text.

The exclusion criteria were (1) nonliterature records, such as reviews, conference reports, briefings, news articles, editorial materials, letters, and advertisements; (2) non-English literature, (3) duplicate or data-deficient papers; and (4) withdrawn papers.

Data Standardization and Visualization Methods in Bibliometrics

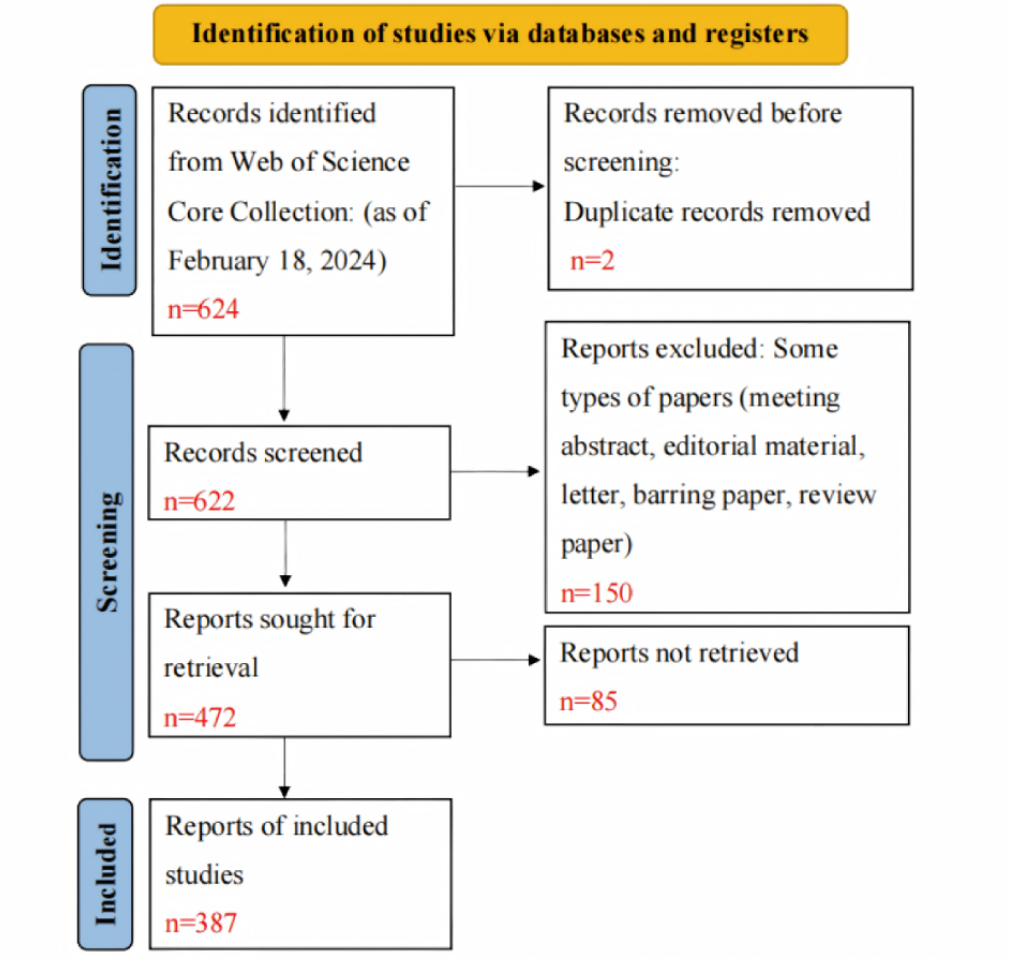
To ensure data accuracy and consistency, rigorous data standardization processing was applied to the raw data in this study. First, the study uniformly standardized the names of

XSL•FO
RenderX

authors and institutions. Second, controversies over the attribution of country or region names were carefully resolved to ensure that the geographical attributes of the data were clear and unambiguous. In addition, synonymous keywords with the same meaning were merged, and keywords that were not directly related to the specific research content were deleted.

The study used the following tools for visualization and bibliometric analysis: the R package Bibliometrix (version 4.3.2; Department of Economic and Statistical Sciences at the University of Naples Federico II), VOSviewer (version 1.6.19; Centre for Science and Technology Studies [CWTS] at Leiden University), and CiteSpace (version 6.1.R6; Drexel University's College of Information Science and Technology). The specific content included visual analyses of annual scientific publication output and citation trends, authors, institutions, journals, countries or regions, highly cited papers, and keywords. Notably, in VOSviewer, we applied "full counting" for normalized data processing. For cluster analysis of authors, institutions, and countries or regions, a minimum threshold of three publications and citations was set, and the clustering map of the top 100 keywords was further presented. Additionally, the Walktrap method was used in thematic map analysis for more precise topic delineation, while other analyses adhered to default software thresholds. By using these visualization methods, this study provided researchers in related fields with an intuitive and clear understanding of the research landscape.

Ethical Considerations



No animal or human studies were carried out by the authors for this paper.

Results

Key Information

This study included a total of 387 academic papers published by 2494 authors in 192 academic journals as the data source (the detailed data collection process is illustrated in Figure 1). On average, each paper had 8.26 coauthors, with only two papers authored by a single individual. The proportion of international collaborations was 16.54%. A total of 840 keywords and 15,107 cited references were identified. It is noteworthy that the average publication age of papers in this field was only 2.02 years, while the average number of citations per paper was as high as 27.22. These data demonstrate that this topic is rapidly emerging as a new research focus (Multimedia Appendix 1).

Figure 1. Flowchart of literature data included in this study.

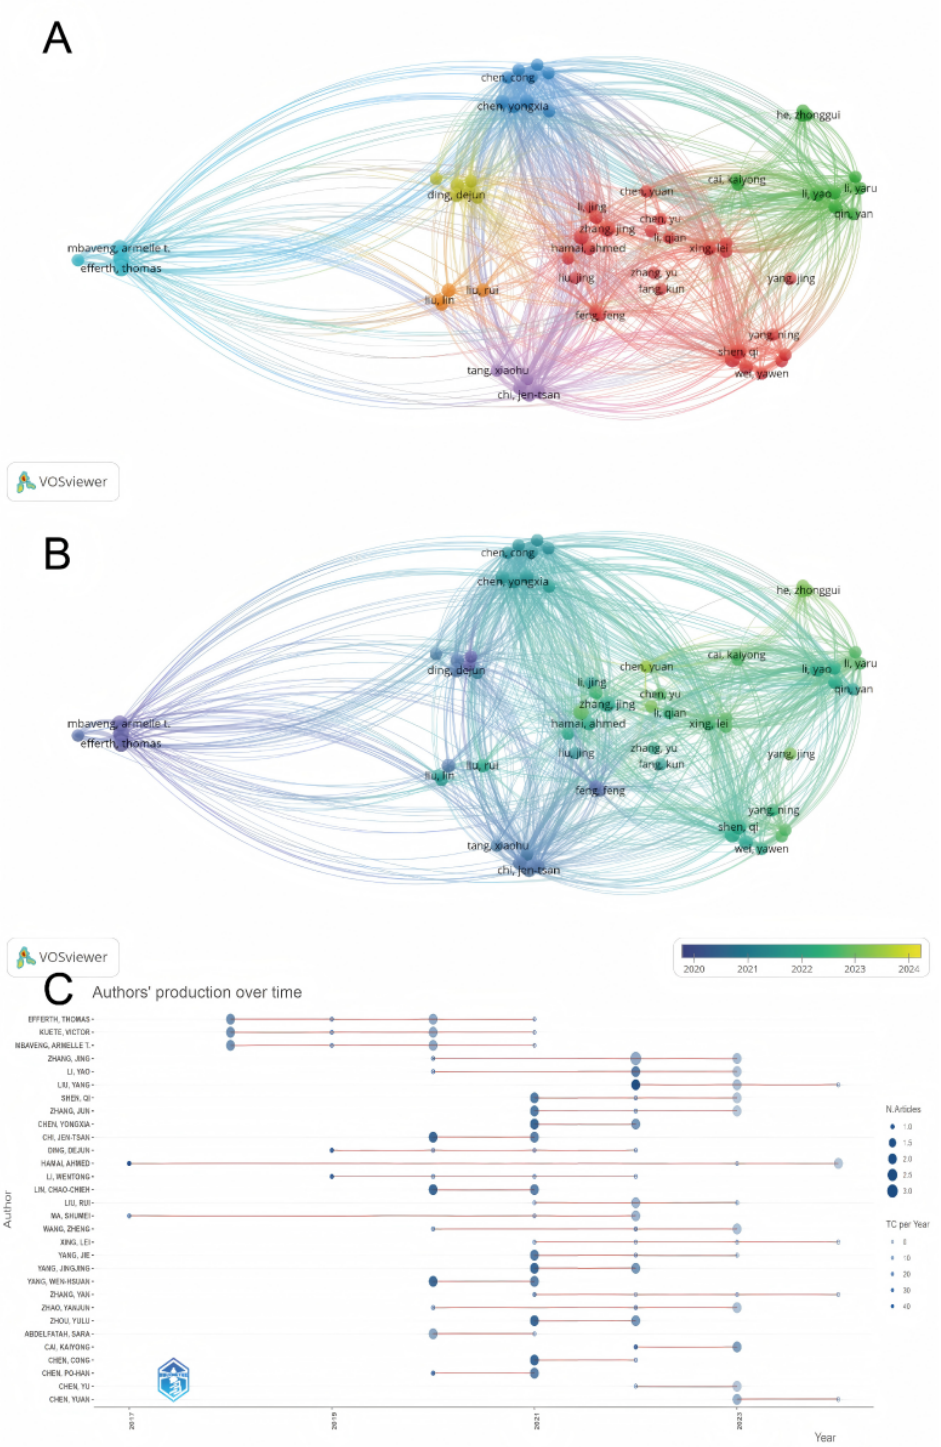
RenderX

Analysis of Scientific Output in Breast Cancer– and Ferroptosis-Related Research

Annual Analysis of Scientific Publications

Due to the limited availability of relevant literature data published in 2024 up to the retrieval cutoff date of February 1, this study collected complete annual data spanning from 2016 to 2023 (n=364) from a total of 387 papers. A cubic function was fitted to the data to analyze the trend in publication volume (R^2= 0.9972; Figure 2). Specifically, the bar chart indicates that the first paper in this field was published in 2016 (n=1), with 2023 marking the peak year of annual publications (n=154). The line graph represents the average annual citation frequency of relevant literature from 2016 to 2023, revealing a peak of 599 citations in 2017, followed by an overall decreasing trend in subsequent years.

Figure 2. Visualization of annual publication and citation trends of papers (2016-2023). Note that the literature data for 2024 is only counted up to February 1, 2024, with 23 publications and 0 citations.

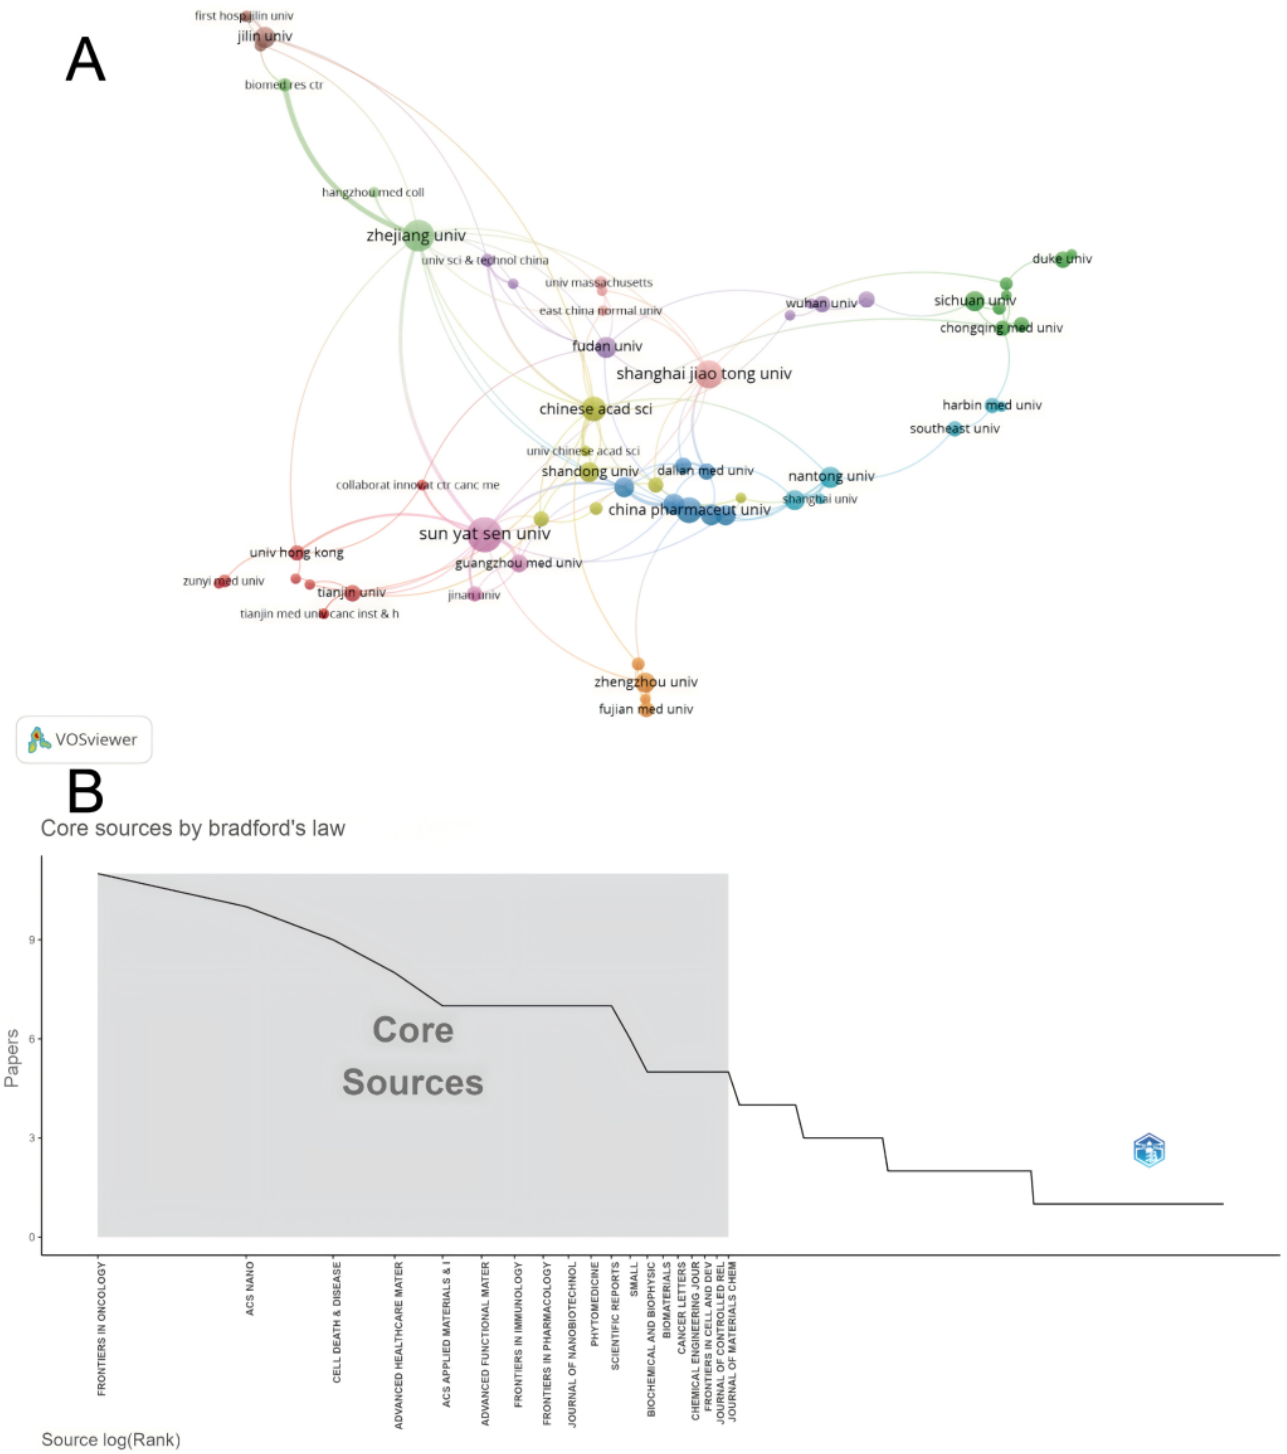


Analysis of Scientific Publications by Prolific Authors

Through an analysis of the scientific publication output of prolific authors, the study found that 22 distinguished authors had published more than two papers in this research field, with no significant differences in the publication volume among the author groups in the field of ferroptosis and breast cancer. Notably, a minority of authors, represented by Efferth et al, had a significantly higher publication output, reaching six papers. Closely following them were authors from the Shen and Zhang groups, who have also contributed significantly to the lactoferrin research landscape, with a noteworthy publication count of five papers each, occupying important positions in the field of breast cancer and ferroptosis research (Figure 3A). It is noteworthy that, excluding the incomplete data from 2024, as shown in Figures 3B and 3C, an increasing number of new distinguished authors have emerged in recent years, with their publications mainly concentrated after 2020.

XSL•FO
RenderX

Figure 3. Visualization charts of authors' publication volume and publication trends. (A) Network visualization map of authors' publication volume. (B) Stacked visualization map of authors' publication volume. (C) Heatmap of authors' publication volume.

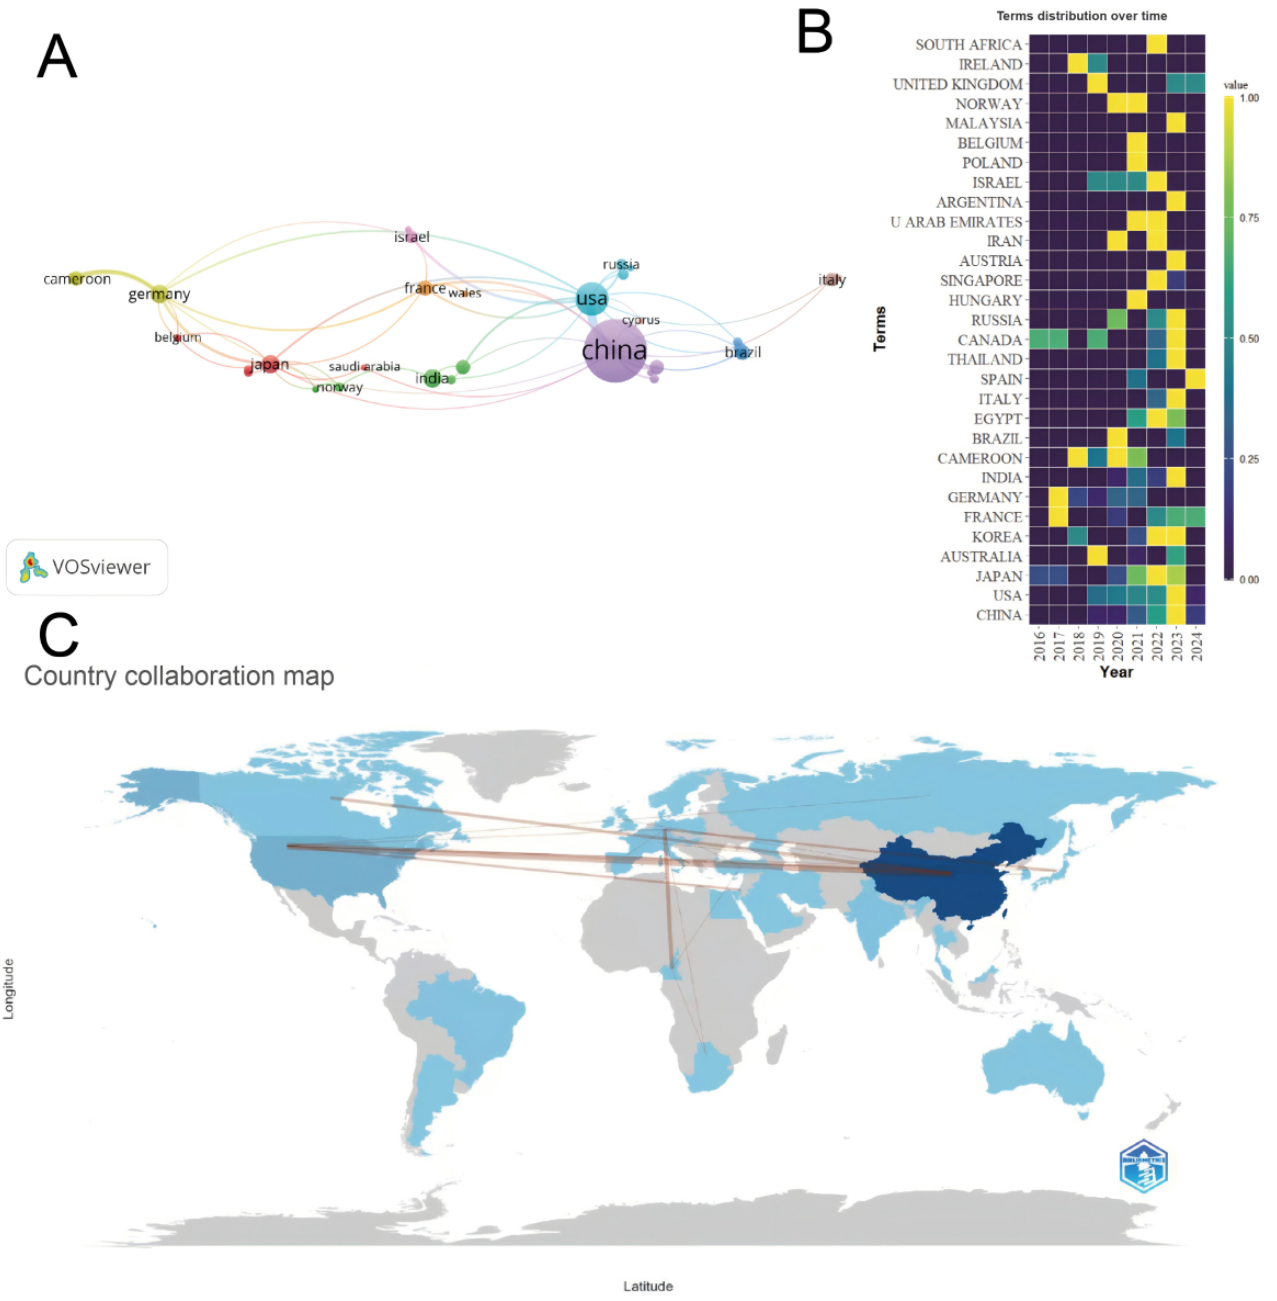


Analysis of Scientific Publications by Prolific Institutions

By analyzing the bibliometric data related to the research fields of breast cancer and ferroptosis, this study identified a group of institutions with significant scientific output in this area (Figure 4A). Among them, Sun Yat-sen University (n=23 publications) and Zhejiang University (n=19 publications) lead the list of institutions with publications related to breast cancer and ferroptosis. Apart from these two universities, other renowned domestic institutions, such as Shanghai Jiao Tong University (n=15 publications), China Pharmaceutical University (n=13 publications), and the Chinese Academy of Sciences (n=12 publications) have also performed exceptionally well in this field. It is also worth mentioning that non-Chinese institutions, such as Duke University (n=6 publications) and Stanford University (n=3 publications), also possess research capabilities in this area.

XSL•FO
RenderX

Figure 4. Visualization maps of institutions' publication volume and identification of core journals. (A) Network visualization map of scientific institutions' publication volume. (B) Identification of journals that have made significant contributions to the field, based on Bradford's Law.



Analysis of Scientific Publications by Prolific Countries

The study found that China (n=287) and the United States (n=52) occupy a dominant position in terms of paper output. Furthermore, countries such as Germany (n=11), India (n=11), Japan (n=11), France (n=7), Brazil (n=7), and Cameroon (n=6) have achieved certain research outcomes in the study of breast cancer and ferroptosis (Figure 5A). Furthermore, as depicted in Figure 5B, China experienced a pronounced acceleration in the volume of scientific publications focused on this research area around 2023, exhibiting a remarkable growth pattern. Moreover, the establishment of a close collaborative partnership between China and the United States emphasizes the inherently global nature of research endeavors in this domain (Figure 5C).

Analysis of Citation Volume in Breast Cancer– and Ferroptosis-Related Research

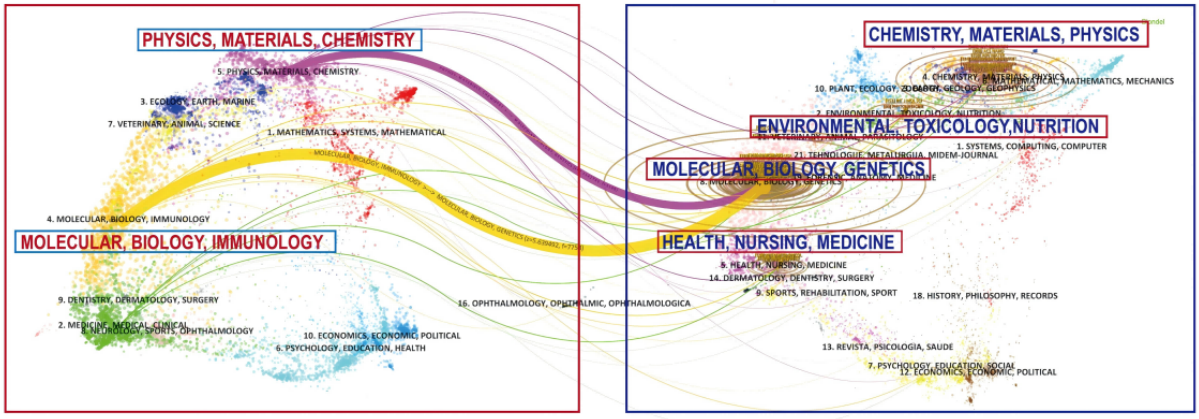
Analysis of Frequently Cited Papers

As shown in the data presented in Multimedia Appendix 2, this study found that the highest citation count was from the paper "Ferroptosis is induced following siramesine and lapatinib treatment of breast cancer cells," published in the journal *Cell Death & Disease*, with 38 citations. From the perspective of research focus and content, these citations primarily concentrate on the following aspects: first, the mechanisms and impacts of ferroptosis induction in breast cancer cells by distinctive drugs or therapeutic methods, as exemplified by papers 1, 2, 3, 4, 6, and 10; second, the exploration of the web-based mechanisms between related protein modulation and ferroptosis variations in breast cancer, as demonstrated in papers 2, 5, 7, 8, and 9; and third, the contrasts and interrelationships between ferroptosis and other modes of cell death in breast cancer cells, as discussed in paper 9.

Analysis of Frequently Cited Authors

The contributions and recognition of different authors can be reflected by the total citation count of their papers. According to the author citation analysis in Multimedia Appendix 3, Chen Y ranks at the top among all authors, with a total citation count of 64. Following closely is Gibson SB, with a total citation count of 51. Additionally, papers by Ding DJ, Li WT, Gai CC, Henson EE, Li ZHR, and Ma S have all been cited 38 times or more.

XSL•FO
RenderX



Analysis of Frequently Cited Countries

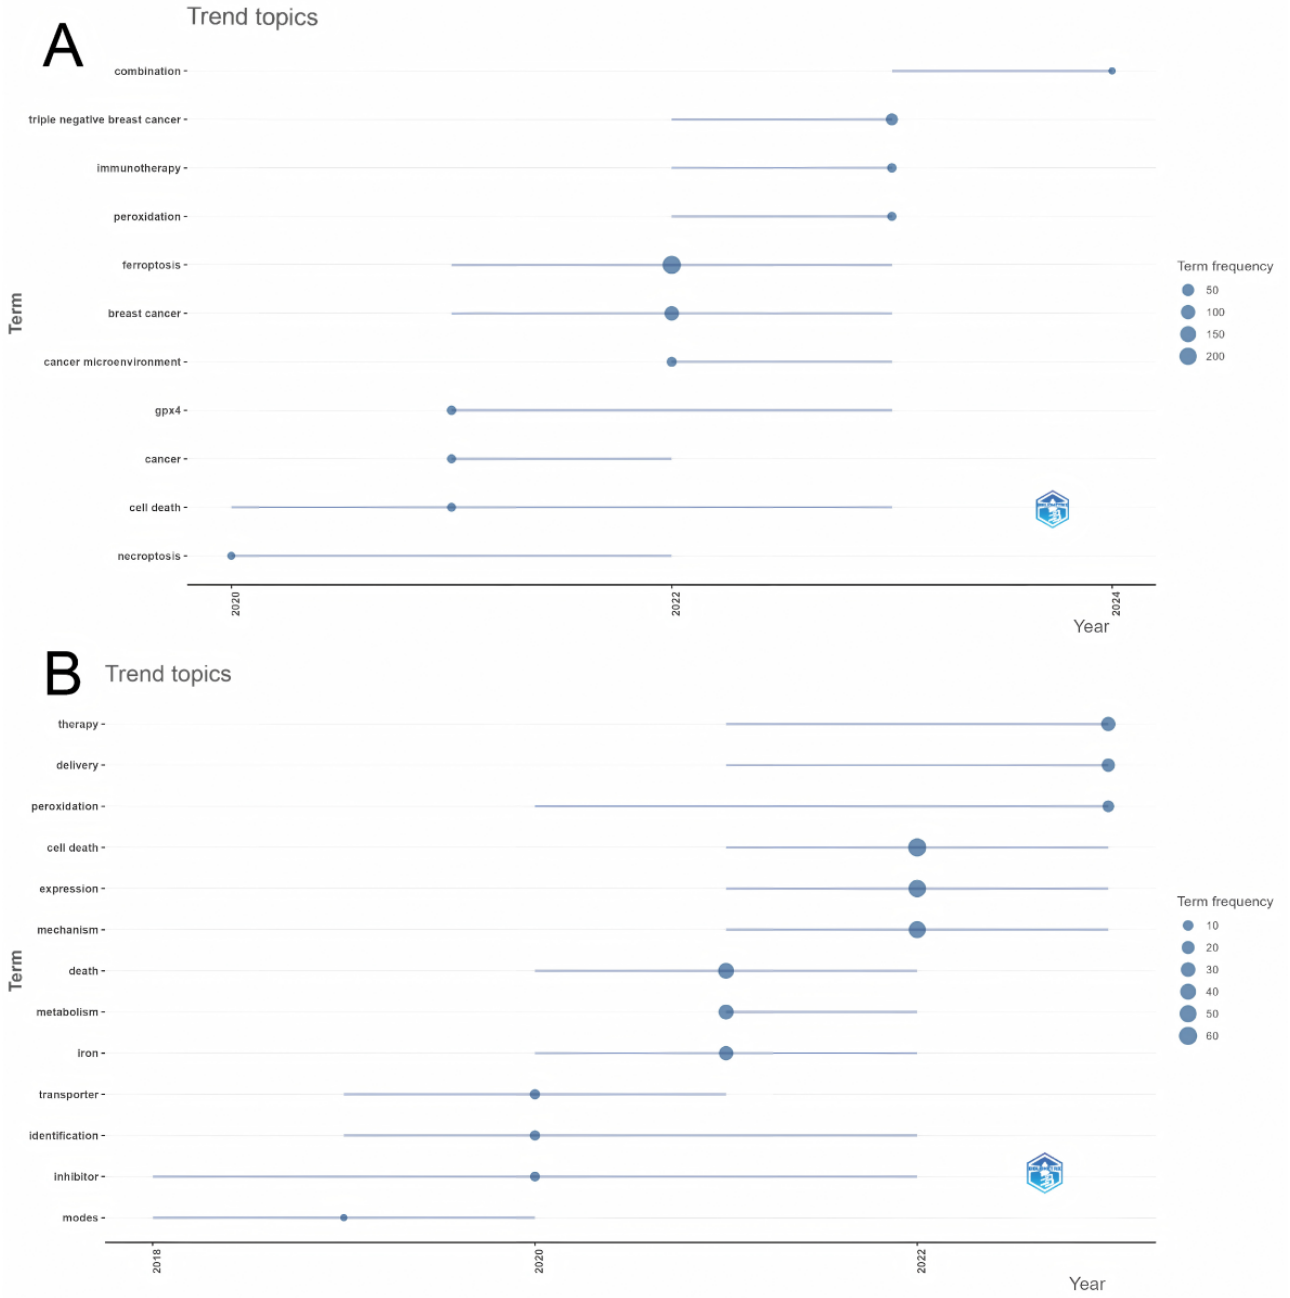
There are notable differences in the citations of research outcomes from different countries. According to the results shown in Multimedia Appendix 4, China ranks at the top in terms of total citations, with 4877, but the average number of citations per paper is 17.40. Conversely, Germany boasts the highest average citations per paper, reaching an impressive 489.20 citations. The United Kingdom, France, and Canada follow closely with average citations of 187.00, 118.70, and 108.80 per paper, respectively. It is noteworthy that the United States while ranking third after China and Germany in total citations with 1658, records an average of 50.20 citations per paper.

Overlay Analysis of High-Frequency Citing and Cited Journals

In this study, CiteSpace software was used to construct a dual-layer overlay map of journals, visually representing the intricate relationships between citing journals (located on the left) and cited journals (located on the right) within the research domain of breast cancer and ferroptosis (Figure 6). The analysis results revealed that the group of citing journals represented by "Molecular, Biology, Immunology" and the core group of cited journals centered around "Molecular, Biology, Genetics" constitute the pivotal nodes in the knowledge flow path at the journal level (*z* score=5.639492; *f*=7758). Closely following this, there is a strong connection between the citing journal group of "Physics, Materials, Chemistry" and the cited journal group of "Molecular, Biology, Genetics" (*z* score= 2.1142766; *f*=3189).

Figure 6. Dual-map overlay of journals illustrating the citation relationships between citing journals on the left and cited journals on the right. The width of the connecting lines represents the strength of the citation relationships.

Cluster Analysis of High-Frequency Keywords and Main Evolution Directions in Breast Cancer– and Ferroptosis-Related Research



Cluster Analysis of Author Keywords and Analysis of Main Evolution Trends

After eliminating the core terms "breast cancer" and "ferroptosis," along with their synonyms, this study conducted a clustering analysis of the top 100 most frequent author keywords. The results indicate that these keywords can be categorized into four primary clusters (Multimedia Appendix 5). Specifically, Cluster 1 (in red) predominantly focuses on research topics such as "triple-negative breast cancer" (n=56), "prognosis model" (n=18), and "cancer microenvironment" (n=17). Cluster 2 (in green) centers its research around concepts such as "peroxidation" (n=13), "photothermal therapy" (n=12), and the general term "cancer" (n=11). Cluster 3 (in blue) revolves around high-frequency keywords, such as "reactive oxygen species" (n=17), "gpx4" (n=14), and "stress" (n=13). Finally, Cluster 4 (in orange) concentrates on areas related to "cell death" (n=10), "anticancer" (n=6), and "drug delivery" (n=5).

A deeper analysis was undertaken to examine the evolutionary patterns of high-frequency keywords over recent years, as presented in Multimedia Appendix 6A and Figure 7A. These trends reveal a progressive intensification of research focused on the concepts of cell death and glutathione peroxidase 4 (GPX4), indicating a growing interest and emphasis within the scientific community. It is noteworthy that from 2022 onwards, the frequency of keywords related to "cancer microenvironment," "triple-negative breast cancer," "immunotherapy," "combination therapy," and "peroxidation" increased significantly. Additionally, as witnessed from the time heatmap of the top 30 author keywords, keywords such as "erastin" and "autophagy" have maintained stable popularity in recent years (Multimedia Appendix 6; left panel).

XSL•FO
RenderX

Figure 7. Trend charts of keywords. (A) Trend chart of author keywords. (B) Trend chart of Keywords Plus.

Through a deep analysis of the thematic map data derived from the author keywords (Figure 8A), this study gained insights into the potential evolutionary directions in the research field of breast cancer and ferroptosis. The upper right quadrant of the map features motor themes, which incorporate the pivotal thematic terms including ferroptosis, breast cancer, and its subtype, triple-negative breast cancer (TNBC), underscoring their interconnectedness and centrality in the research landscape. The niche themes in the upper left corner encompass thematic keyword clusters such as anticancer and gene signatures. The emerging or declining themes in the lower left corner include topics such as chemodynamic therapy and photothermal therapy (PTT). Finally, in the lower right corner, the basic themes include thematic keywords such as cancer microenvironment, immunotherapy, and prognosis model.

XSL•FO
RenderX

Figure 8. Thematic maps of keywords. (A) Thematic map of author keywords. (B) Thematic map of Keywords Plus.

Cluster Analysis of Keywords Plus and Analysis of the Main Evolution Trends in Research

The statistical data revealed that some papers had missing keywords, with an omission rate of 19.64%. By increasing the likelihood of yielding more precise outcomes, keywords derived using the Keywords Plus feature can enhance the rigor and reliability of research findings. Therefore, the following section presents a detailed analysis of Keywords Plus.

During the clustering analysis of Keywords Plus, this study excluded the core terms “breast cancer” and “ferroptosis,” along with their synonyms, focusing instead on the analysis of the top 100 most frequent terms. The analysis revealed that these terms could be grouped into five clusters (Multimedia Appendix 7). Among these clusters, the keyword “cell death” stands out as a focal point, with a high frequency of 99 occurrences. Additionally, “expression” (n=53), “mechanism” (n=49),

XSL•FO
RenderX

"transporter" (n=19), and "stress" (n=9) were identified as core terms within their respective clusters.

This paper further analyses the evolution trends of keywords in the past and future. As shown in Multimedia Appendix 6 (right panel) and Figure 7B, the results indicate that researchers in the field of breast cancer and ferroptosis have consistently maintained a certain level of interest in the study of cell death in recent years. Additionally, newly emerged keywords such as "mechanism," "expression," and "nanoparticle" have been frequently observed in recent years.

Through the visualization presented in the thematic map (Figure 8B), the results indicate that the motor themes in the upper right quadrant consist of keywords such as "migration," "epithelial-mesenchymal transition (EMT)," and "negative breast cancer." The niche themes in the upper left quadrant encompass two core themes: "radiotherapy" and "progression." Within the radiotherapy category, keywords such as "alpha" emerge, while in the progression category, keywords such as "discovery" and "hallmarks" appear. The emerging or declining themes in the lower left quadrant reveal keywords such as "transporter," "flavonoids," and "modes." The basic themes in the lower right quadrant exhibit two main themes: "expression" and "cell death." Within the expression category, keywords such as "apoptosis" and "ferroptosis" are present, while in the cell death category, keywords such as "mechanism" and "nanoparticle" emerge.

Discussion

Principal Findings

Breast cancer, as a malignancy with a high mortality rate, still faces significant limitations in early diagnosis and late-stage treatment. In recent years, ferroptosis, a unique form of cell death triggered by cellular metabolic imbalance, has attracted widespread attention [11], underscoring the importance and potential of research in this area. This study systematically reviewed 387 papers related to breast cancer and ferroptosis, retrieved from the WOSCC database, published between 2016 and February 1, 2024. The analysis revealed that the number of publications in this field peaked in 2023, showing a significant growth trend. However, the annual citation frequency of related publications exhibited fluctuations, with the highest citation rate observed in 2017, followed by a gradual decline. Further analysis highlighted the prominent contribution of scholars such as Efferth T, with Chen Y having the highest citation frequency. In terms of institutions, Sun Yat-sen University led in the number of publications. Research output from China and the United States dominated this field, with increasing collaborative efforts between the two countries. While China had the highest total citation count, Germany recorded the highest average citation frequency per paper. The journal *Frontiers in Oncology* published the highest number of papers. Citation network analysis indicated that journals in "Molecular, Biology, Genetics" were central to the citation network. High-impact papers focused on the induction mechanisms of ferroptosis in breast cancer and the regulatory role of related proteins. Keyword analysis identified GPX4 as a central research trend. Additionally, breast cancer subtypes emerged as key drivers of ferroptosis research. Fundamental research themes pointed to the tumor immune microenvironment, prognostic models, and nanotherapy as future research priorities.

In-Depth Analysis of Publication Volume and Citation Counts in Breast Cancer and Ferroptosis Research

A comprehensive analysis of breast cancer and ferroptosis research reveals that publication volume and citation counts serve as crucial indicators for assessing the impact and development of this field. These metrics not only reflect the significance of research outcomes but also highlight emerging trends. An examination of frequently cited papers shows that key studies focus on the induction mechanisms of ferroptosis in breast cancer cells, protein regulation, and comparisons with other forms of cell death, aiming to discover novel therapeutic strategies. Specifically, the first study in this field published in 2016 demonstrated the effectiveness of siramesine and lapatinib in inducing ferroptosis in breast cancer cells [12], leading to high citation rates. Since then, exploration of the relationship between breast cancer and ferroptosis has deepened, with research becoming increasingly refined. TNBC, notable research by Yu et al [13] revealed that exosome-encapsulated erastin elevates ferritin levels, suggesting a new therapeutic approach. Hasegawa et al [14] further elucidated the intricate interplay between the cystine/glutamate antiporter, CD44v, and the MUC1-C oncoprotein in TNBC, enhancing our understanding of this subtype. Additionally, studies on the glutathione (GSH)-degrading enzyme CHAC1 have uncovered a novel mechanism of ferroptosis in TNBC via the GCN2-eIF2α axis [15].

The analysis of influential authors highlights those with high publication volumes and citation impacts. A distinguished team led by Efferth T has investigated the cytotoxicity of natural products, such as alkaloids and saponins, against multidrug-resistant cancers, focusing on their ability to induce various forms of cell death, including ferroptosis [16-21]. Their work provides important insights into overcoming drug resistance and developing novel anticancer therapies. High-impact authors, such as Chen Y and Gibson SB, have explored the therapeutic potential of ferroptosis in breast cancer, particularly through nanotechnology and drug design, contributing new perspectives to the field [22,23].

Institutional analysis reveals that Sun Yat-sen University and Zhejiang University lead in publication output in this area, reflecting their strong research foundations. Journals such as *Frontiers in Oncology*, *ACS Nano*, and *Cell Death & Disease* play pivotal roles in disseminating key findings and shaping the breast cancer and ferroptosis research landscape. By understanding the complex relationships between citing and cited journals, we uncover the distribution characteristics of core journals and knowledge flow paths within this interdisciplinary field, highlighting the contributions of journals from molecular biology, immunology, genetics, physics, materials science, and chemistry.

At the national level, China and the United States dominate in publications related to breast cancer and ferroptosis. China has made significant contributions to exploring the application of ferroptosis in cancer treatment, particularly through drugs, gene

XSL•FO
RenderX

regulation, and nanotechnology. The United States, on the other hand, focuses on the mechanisms and regulation of ferroptosis in cancer, including its impact on lipid composition, iron metabolism, and key genes influencing ferroptosis sensitivity [23-27]. Despite limited resources, research teams from resource-poor countries like India and Brazil have leveraged nanotechnology to propose novel therapeutic strategies [28,29]. While China ranks first in total citations, Germany and the United States have higher citation rates per paper, indicating greater research impact and quality, possibly due to higher research investment and international collaboration.

The publication trend shows robust development in this field, with 28 publications by February 1, 2024, suggesting that 2024 may surpass 2023 in research output. The slight decline in citation rates reflects the surge in publications and underscores the growing interest in exploring the interplay between breast cancer and ferroptosis.

This growing research body highlights ferroptosis in breast cancer as an emerging frontier in biomedical science. Leading scholars in the field continue to make significant contributions, and institutions and countries demonstrate high levels of cooperation and investment. These positive factors predict that the field of breast cancer and ferroptosis research will achieve major breakthroughs in the near future, opening up new avenues for the diagnosis and treatment of breast cancer with profound implications.

A Systematic Summary of Ferroptosis Mechanisms

Ferroptosis, characterized by its unique mechanism involving iron-dependent regulation through multiple pathways, plays a pivotal role in the onset and progression of various diseases. The core mechanism of ferroptosis lies in the imbalance between phospholipid peroxidation triggered by the oxidation of polyunsaturated fatty acids and the antioxidant system mediated by GPX4. When GPX4 activity decreases or GSH levels, as a cofactor, decline, phospholipid peroxidation products accumulate, leading to ferroptosis [5]. Methods to induce ferroptosis include the use of ferroptosis inducers (such as erastin and RSL3), inhibition of the system Xc-/GSH-GPX4 axis, and increased iron accumulation. Conversely, strategies to inhibit ferroptosis involve upregulating GPX4 expression, using ferroptosis inhibitors (such as ferrostatin-1), and enhancing the antioxidant system [7].

The signaling pathways and defense mechanisms of ferroptosis are complex and diverse. The initiation of iron toxicity involves multiple sources of reactive oxygen species (ROS), including iron-mediated Fenton reactions, mitochondrial ROS, and membrane-associated ROS driven by the NADPH oxidase (NOX) protein family. Cells defend against ferroptosis by upregulating antioxidant gene expression, repairing membrane damage, and clearing damaged organelles [30]. There is also a crosstalk between the mitochondrial dynamic regulatory network and ferroptosis, with mitochondrial dysfunction and damage potentially promoting ferroptosis [31]. By regulating lipid metabolism pathways, ferroptosis can affect cellular sensitivity to ferroptosis, thereby modulating its occurrence and development [32]. Furthermore, mechanisms such as epigenetic modifications and posttranslational modifications also play crucial roles in the regulation of ferroptosis [33].

Given that iron accumulation, oxidative stress, and lipid peroxidation are common features of various diseases, ferroptosis, as a unique cell death mechanism, may be a key link in the pathological processes of diverse diseases [34]. In neurodegenerative diseases, such as Parkinson disease and ischemic stroke, ferroptosis also plays a significant role [35]. In the field of cancer, ferroptosis is considered a potential antitumor strategy. For example, ferroptosis interacts with the tumor immune microenvironment, influencing tumor growth and metastasis [36]. Inhibiting ubiquitin-specific protease 8 can destabilize GPX4, thereby enhancing cancer cell sensitivity to ferroptosis, inhibiting tumor growth, and enhancing the efficacy of immunotherapy [37]. Additionally, ferroptosis is closely related to the death of plaque cells (such as vascular endothelial cells, macrophages, and vascular smooth muscle cells) and the development of atherosclerotic plaques in cardiovascular diseases [38]. Therefore, the application of ferroptosis in the treatment of various diseases, including cancer immunotherapy and neurodegenerative diseases, is gaining increasing attention.

Research on the regulatory mechanisms of ferroptosis in breast cancer indicates that its regulation involves multiple aspects, such as lipid metabolism and the immune microenvironment [39-42], and that ferroptosis plays a crucial role in the sensitivity and drug resistance of breast cancer to therapy [43-45]. With a deeper understanding of ferroptosis mechanisms, the methods for its detection are continuously evolving, including fluorescence probes, positron emission tomography imaging, and others, providing multiscale perspectives for ferroptosis research [46].

Future research should further elucidate the specific mechanisms of ferroptosis in the onset and progression of diseases, as well as its specific roles in the regulatory pathways, sensitivity, and resistance of breast cancer, providing new targets and strategies for breast cancer treatment.

Keyword Analysis: Key Hotspot GPX4 and Ferroptosis Regulation in Breast Cancer

An analysis of evolutionary trends has revealed the increasingly prominent importance of GPX4 in relevant academic research fields. Previous studies have illustrated that GPX4, as a core regulatory factor of ferroptosis, plays a crucial role in organisms by catalyzing the reduction of phospholipid peroxides to inhibit iron ion degeneration, thereby affecting the ferroptosis process [47,48]. It has been reported that RUNX1 intron transcript 1 (RUNX1-it1) is significantly overexpressed in breast cancer tissues, and it can block the impact of ferroptosis by increasing GPX4 expression, thereby promoting the occurrence of breast cancer [49].

On the other hand, Tubastatin A, as an efficient and selective Histone Deacetylase 6 inhibitor, has been confirmed by relevant studies as a novel ferroptosis inducer. It promotes ferroptosis by inhibiting the activity of GPX4, thereby enhancing the effect of cancer radiotherapy [50]. Chloramine T has also been found to inhibit the cell growth of breast cancer and induce ferroptosis

XSL•FO
RenderX

by targeting the GPX4 axis, indicating that it may become a potential new strategy for breast cancer treatment [51].

In addition, recent research has provided new insights into the regulatory mechanism of GPX4. As a crucial selenoprotein, the function of GPX4 in resisting ferroptosis depends greatly on the presence of its unique selenocysteine residue, which provides an important basis for understanding the mechanism of GPX4 [52]. The process of selenocysteine uptake mediated by low-density lipoprotein receptor-related protein 8 has been elucidated as a core mechanism in promoting GPX4 protein synthesis and effectively inhibiting ferroptosis [53,54].

Another study found that phospholipid-modifying enzymes MBOAT1 and MBOAT2, as ferroptosis inhibitors, regulate ferroptosis by remodeling the cellular phospholipid profile through the sex hormone signaling pathway [55]. These findings indicate that research on GPX4 and its related regulatory mechanisms is gradually deepening from phenotypic description to molecular mechanism analysis, offering unprecedented opportunities for the treatment of breast cancer.

Motor Themes Analysis in Author Keywords: Differential Sensitivity of Ferroptosis in Various Breast Cancer Subtypes Driving the Field's Development

Breast cancer is a highly heterogeneous disease, with different breast cancer cell types, characterized by the expression of estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor 2 (HER2), and the proliferation marker Ki67, all exhibiting marked differences in sensitivity to ferroptosis. In the analysis of motor themes, findings related to ferroptosis sensitivity across breast cancer subtypes, including TNBC, have become well-established, closely interconnected with other emerging themes, and serve as a major driving force in the development of this field.

In ER-positive breast cancer, studies have shown that a combination of ferroptosis inducers, such as erastin and etoposide, can significantly enhance cellular sensitivity to ferroptosis by regulating IREB2/FPN1 expression and thus affecting iron metabolism, ultimately inducing ferroptosis [56]. Furthermore, ACSL4, a key regulator of ferroptosis, is upregulated in ER-positive breast cancer, promoting the accumulation of lipid peroxidation products and thereby enhancing cellular sensitivity to ferroptosis [57].

In contrast, sensitivity to ferroptosis in HER2-positive breast cancer may be regulated by multiple factors. For instance, inhibiting crVDAC3 can induce ferroptosis in breast cancer cells by reducing HSPB1 expression, thereby mediating resistance to deruxtecan in HER2-low breast cancer [58]. Additionally, m6A methylation modification of FGFR4 can inhibit ferroptosis, enhancing the resistance of HER2-positive breast cancer cells to anti-HER2 therapy [10]. Additionally, research has found that the inhibition of FGFR4 affects the expression of β-catenin/TCF4-SLC7A11 and FPN1, which has a significant impact on ferroptosis in HER2-positive breast cancer cells, thereby enhancing treatment sensitivity [10]. These studies suggest that the regulatory mechanisms of ferroptosis in HER2-positive breast cancer are more complex, involving the interaction of multiple signaling pathways.

In PR-positive breast cancer, although direct research on ferroptosis sensitivity is scarce, some indirect evidence suggests that PR may regulate the sensitivity of breast cancer cells to ferroptosis. Specifically, studies have reported that PR may indirectly regulate the sensitivity of TNBC to ferroptosis through metabolic pathways mediated by PR membrane component 1; however, these hypotheses await further experimental validation to establish their accuracy [59].

Relatively speaking, breast cancers that are negative for ER, PR, and HER2, especially TNBC, exhibit higher sensitivity to ferroptosis inducers. This characteristic may be closely related to the abnormal disruptions in iron and lipid metabolism in TNBC, which make TNBC cells more susceptible to ferroptosis inducers [60,61]. For example, the high expression level of ACSL4 in TNBC promotes the generation of lipid peroxides, a core step in the execution of ferroptosis [62]. Studies have also found that ferroptosis is enhanced through the combined action of GSH depletion and dihydroorotate dehydrogenase inhibitors [61]. Furthermore, the functions of key regulatory factors, such as the Xc-/GSH/GPX4 axis, ACSL4/LPCAT3 pathway, and nuclear factor erythroid 2-related factor 2 (NRF2) in ferroptosis, as well as their potential dysregulation mechanisms related to cancer cell survival and drug resistance, have been thoroughly explored [60]. Additionally, some natural compounds, such as artemisinin derivatives and traditional Chinese medicine extracts, have been found to inhibit the growth of TNBC cells by inducing ferroptosis [63].

Ki67, a commonly used proliferation marker, is often associated with higher proliferative activity and malignancy in breast cancer. Interestingly, breast cancer cells with high Ki67 expression also exhibit higher sensitivity to ferroptosis inducers [64]. However, research on the direct relationship between Ki67 expression and ferroptosis sensitivity is still limited. Future studies should further explore the role of Ki67 in the regulation of ferroptosis and whether it can serve as a biomarker for predicting the therapeutic effect of ferroptosis induction.

The motor themes analysis has provided a solid foundation for research in the area of breast cancer and ferroptosis. Continued investigation into the interactions between differential ferroptosis sensitivity across breast cancer subtypes holds the potential to uncover new therapeutic targets and biomarkers, ultimately driving the development of precision medicine and improving treatment outcomes and prognoses for patients with different breast cancer subtypes.

Analysis of Basic Themes in Breast Cancer and Ferroptosis Research: Immune Microenvironment and Prognostic Models Reveals Future Directions

The basic themes of immune microenvironment and prognostic models in breast cancer and ferroptosis research are closely interrelated and have led to several significant findings. For instance, in an insightful review by Shen et al [65], the authors explicitly point out the central role of iron in innate and adaptive immune responses, further emphasizing the potential positive influence of targeted regulation of iron metabolism on antitumor immunity and cancer treatment. Recent studies have demonstrated that T-cell–mediated immune responses [65] and

XSL•FO
RenderX

short-term acidosis-induced M1 macrophage polarization can effectively promote ferroptosis [66], thereby playing an active role in antitumor immunotherapy.

Research undertaken by Xu et al [67] has elegantly demonstrated that the development of ferroptosis-related gene (FRG) signatures holds significant promise as robust prognostic indicators for the immune microenvironment and therapeutic responsiveness. This approach shows great potential to inform and guide the design of future individualized treatment strategies, thereby enhancing precision medicine in breast cancer management.

A new lncRNA signal closely related to ferroptosis has been discovered, with its immune-related pathways significantly enriched in high-risk patients with breast cancer, demonstrating great potential for predicting the prognosis of patients with breast cancer [68]. Knocking down the hub gene SLC39A7, combined with TME scoring, can significantly affect the apoptosis and ferroptosis of cancer cells, with higher prognostic efficacy.

Meanwhile, epithelial cells and B cells exhibit higher ferroptosis scores, which are respectively related to the immune checkpoint blockade response and immune checkpoint blockade-independent gene expression, suggesting a connection between ferroptosis and the immune microenvironment [69]. It is noteworthy that research has accurately predicted the survival of patients with breast cancer through a novel prognostic model composed of nine FRGs [70].

Chen et al [71] used the Cancer Genome Atlas to identify 11 ferroptosis genes related to breast cancer prognosis, established a precise prognostic model, and analyzed therapeutic targets, thereby enhancing prognosis management. In TNBC, the subtype of breast cancer with the worst prognosis, research by Wu et al [72] evaluated the role of FRGs and found that they may affect prognostic models by regulating the tumor microenvironment, thus providing a solid theoretical basis for a clinically accurate prediction of TNBC prognosis. Furthermore, studies have evaluated the FRG AKR1C1, revealing its potential related to the immune-microenvironment, which may further affect the progress and prognosis of patients with breast cancer, making it a novel biomarker for the immune microenvironment and prognosis determination of breast cancer [73].

In conclusion, although significant progress has been made in the areas of immune microenvironment and prognostic models within the context of breast cancer and ferroptosis research, these fields remain underexplored and offer considerable potential for future investigation. These themes provide valuable directions for further research and offer essential guidance for researchers aiming to deepen their work in this area.

Innovative Applications and Strategies of Nanoparticles: Further Supplementing Future Research Directions in Breast Cancer and Ferroptosis

Through an in-depth analysis of the Keywords Plus basic themes, we further explore the future development directions of nanoparticles in the context of breast cancer and ferroptosis research. The application of nanoparticles in breast cancer treatment relies heavily on their unique physical and chemical properties to achieve the targeted delivery and controlled release of drugs, thereby enhancing therapeutic efficacy and reducing side effects [74]. Nanoparticles can exert their effects through various mechanisms that promote cell death, including ferroptosis [75]. Recent research has reported the use of a novel Fenton-independent pathway using photothermal nanozymes to overcome the limitations of the Fenton reaction. By using iron-containing hollow mesoporous Prussian blue (HMPB) nanocubes as an iron source to prepare HMPB@Lip, which combines PTT with nanozyme action, the induced ferroptosis through a non-Fenton reaction effectively ablates tumors, demonstrating the therapeutic potential of HMPB@Lip as a multifunctional nanozyme for ferroptosis. Furthermore, the development of Her2-DSG NPs nanostructures, which combine chemo-PTT with tumor microenvironment remodeling and immune activation, holds great promise for HER2-positive breast cancer [76].

Another study constructed nFeAPG nano-complex synergizing Fe^{3} with apigenin to enhance immune response through PTT, effectively controlling TNBC [71]. Additionally, the ICG@SANPs-cRGD nanomaterial-mediated combination of PTT/photodynamic therapy and immunotherapy has demonstrated its potential as a multifunctional platform for breast cancer treatment [77].

Furthermore, a search conducted on the Clinical Trials website revealed that there is only one clinical trial project related to breast cancer and ferroptosis, and that it is associated with nanocarriers (Multimedia Appendix 8). As of the search date, November 12, 2024, this project is still in the recruiting phase. Its focus is on the application of carbon nanoparticle-loaded iron (CNSI-Fe (II)) in the treatment of patients with advanced solid tumors, particularly those who have experienced treatment failure (including disease progression or intolerance) or lack of available standard therapeutic options (trial identifier: NCT06048367). The primary end point of this study is to assess the safety and tolerability of CNSI-Fe (II) throughout the study duration. The secondary end point, meanwhile, focuses on evaluating the pharmacokinetic profile of CNSI-Fe (II) in patients with advanced solid tumors.

Nanotechnology, as a fundamental topic in the research fields of breast cancer and ferroptosis, is still in its relatively early stages of development. Nonetheless, these research achievements have not only significantly expanded the application scope of nanotechnology in breast cancer treatment but have also highlighted its close connection with breast cancer therapy and identified numerous promising therapeutic research directions that await further exploration. More importantly, they have pointed out new avenues for future research endeavors and provided invaluable guidance for investigative pursuits.

Limitations

This study represents the first comprehensive bibliometric analysis of 387 academic papers related to breast cancer and ferroptosis sourced from the WOSCC database. By applying multiple analytical approaches, it thoroughly investigates the research hotspots and future trends in this field, offering a

XSL•FO
RenderX

comprehensive and systematic overview of the latest developments in this area. These strengths significantly enhance the academic value and practical relevance of the study, providing essential guidance for future advancements in the field of breast cancer and ferroptosis.

However, several limitations of our methodology must be acknowledged. First, although the WOSCC database is vast, it was not specifically designed for bibliometric analysis and relies on a single data source, which may not capture all relevant literature present in other databases (such as PubMed, Scopus, and Google Scholar), potentially introducing bias. Future research should integrate multiple databases to mitigate this issue. Second, our focus on English-language publications limits the comprehensiveness of the study by excluding high-quality non-English research. To address this, future studies should adopt multilingual search strategies. Third, the exclusion of nonpaper publications (eg, reviews and conference papers) constrains the scope of research outputs considered. To obtain a more holistic view, future work should adopt more inclusive selection criteria. Finally, given the rapid updates in databases, there is a risk of overlooking recent advances in the field's literature. Periodic updates to bibliometric analyses are recommended to ensure timely and accurate capture of the latest trends and developments in breast cancer and ferroptosis research.

Conclusions

Ferroptosis holds significant value and potential in breast cancer research. Through bibliometric analysis, this study suggests that enhancing collaboration and communication among authors, institutions, and countries, while leveraging the interdisciplinary nature of journal citations, can facilitate advances in fundamental research on ferroptosis in breast cancer. Specifically, this paper reviews the progress in understanding the mechanisms of ferroptosis, providing guidance for breast cancer research. It emphasizes the sensitivity of different breast cancer subtypes to ferroptosis as a driving force in the current research landscape and highlights the pivotal role of GPX4 in the regulatory mechanisms of ferroptosis in breast cancer as a key focus. Additionally, the study identifies the importance of the tumor microenvironment, immunotherapy, and prognostic models for future development. Although the application of nanoparticles in breast cancer treatment is in its preliminary stages, it has already shown promising prospects and serves as a rich supplement to the future directions. By elucidating the current status and future trends of ferroptosis in breast cancer research, this study provides direction for future research endeavors and promotes innovation in breast cancer treatment strategies.

Abstract

Background: Gestational diabetes mellitus (GDM) is characterized by hyperglycemia in pregnancy and typically resolves after birth. Women with GDM have an increased risk of developing type 2 diabetes mellitus (T2DM) later in life compared to those with normoglycemic pregnancy. While diabetes prevention interventions (DPIs) have been developed to delay or prevent the onset of T2DM, few studies have provided process evaluation (PE) data to assess the mechanisms of impact, quality of implementation, or contextual factors that may influence the effectiveness of the intervention.

Objective: This study aims to identify and evaluate PE data and how these link to outcomes of randomized controlled trials (RCTs) of T2DM prevention interventions for women with GDM.

Methods: A systematic review was conducted to identify studies published from 2005 to 2020 aiming to capture the most recent DPIs. Five electronic bibliographic databases (Cochrane Library, Cochrane Collaboration Registry of Controlled Trials, Embase, PubMed, and MEDLINE) were searched to identify relevant studies. Inclusion criteria were published (peer-reviewed) RCTs of DPIs in women with a current diagnosis or history of GDM. Exclusion criteria were studies not published in English; studies where the target population was women who had a family history of T2D or women who were menopausal or postmenopausal; and gray literature, including abstracts in conference proceedings. The Medical Research Council’s PE framework of complex interventions was used to identify key PE components. The Mixed Method Appraisal Tool was used to assess the quality of included studies.

Results: A total of 24 studies were included; however, only 5 studies explicitly reported a PE theoretical framework. The studies involved 3 methods of intervention delivery, including in person (n=7), digital (n=7), and hybrid (n=9). Two of the studies conducted pilot RCTs assessing the feasibility and acceptability of their interventions, including recruitment, participation, retention, program implementation, adherence, and satisfaction, and 1 study assessed the efficacy of a questionnaire to promote food and vegetable intake. While most studies linked PE data with study outcomes, it was unclear which of the reported PE components were specifically linked to the positive outcomes.

XSL•FO
RenderX

Conclusions: While the Medical Research Council's framework is a valuable source for conducting systematic reviews on PEs, it has been criticized for lacking practical advice on how to conduct them. The lack of information on PE frameworks in our review also made it difficult to categorize individual PE components against the framework. We need clearer guidance and robust frameworks for conducting PEs for the development and reporting of DPIs for women with GDM.

KEYWORDS

gestational diabetes mellitus; randomized controlled trial; process evaluation; implementation; complex interventions

Introduction

Gestational diabetes mellitus (GDM) is characterized by hyperglycemia first recognized in pregnancy and currently impacts between 8% and 23% of pregnancies globally [1]. GDM typically resolves after birth but can have significant implications for both short- and long-term health of women and babies [2]. Women with prior GDM have a nearly 10-fold increased risk of developing type 2 diabetes mellitus (T2DM) than those with normoglycemic pregnancy [3]. Risk factors for T2DM after GDM include high BMI, increasing age, multiparity, poor glucose tolerance, and prepregnancy complications [4-6]. Lifestyle interventions that target both diet and exercise are associated with small but significant effects in reducing the risk of T2DM in women with GDM [7-10].

Process evaluation (PE) theoretical frameworks provide a systematic approach to planning the design of health behavior change interventions [11,12]. However, many of the randomized controlled trials (RCTs) reported not using these PE frameworks to plan the design of lifestyle interventions [11,13-17]. Several key PE theoretical frameworks have been developed and widely used [13-17], and researchers have made progress in updating the methodologies and definitions of key PE components to construct more comprehensive frameworks to measure the success and effectiveness of interventions [13]. Knowledge of these processes can better inform future policy and practice [18] and provide opportunities to improve study design and methodologies of future diabetes prevention interventions (DPIs) [19].

The UK Medical Research Council (MRC) theoretical framework on PEs for complex interventions was chosen for this systematic review [15], as it is well regarded and recognizes the need for more formal guidance on how to conduct PEs. The framework considers processes along 3 interlinked dimensions: implementation, mechanisms of impact, and contextual factors. Table 1 presents a glossary of key PE components and methodologies [15].

The overarching aim of this review was to identify and evaluate any PE conducted and how these link to outcomes of RCTs of DPIs after GDM. Specific objectives were to identify the extent to which PE components were reported and described in RCTs of DPIs for women with previous or current GDM and to assess whether these components could contribute to explaining the intervention outcomes of the DPIs.

Table 1. Glossary of key process evaluation components and methodologies.

Key process evaluation components	Definitions	Quantitative methods	Qualitative methods
Implementation			
Content delivered	The content included in the intervention and the method in which the content is delivered to the participants.	• Structured observation	• Observational study
Method of content delivery	How the intervention content was delivered to the participants and the extent to which quantitative and qualitative methods were used.	• Structured observation	• Observational study
Fidelity	The extent to which the intervention was delivered as intended. Fidelity represents the quality and integrity of the intervention.	• Behavioral coding systems • Questionnaires • Protocol checklist • Structured observation	• Audiotapes of sessions • Observational study
Dosage delivered	The quantity or number of intended units delivered during the intervention including the component delivered and the extent of the participant's engagement.	• Checklist records of dose delivered • Structured observation	• Audiotapes of sessions
Dosage received	The quantity or number of intended units received during the intervention including the component received by the participants.	• Behavioral coding systems • Questionnaires • Structured observation • Digital monitoring (eg, digital feedback)	• Audiotapes of sessions • Focus groups • Interviews • Observational monitoring
Adaptations	The extent to which alterations were made to an intervention to achieve better contextual fit.	• Structured observation	• Observational study
Reach	The proportion of the intended target audience that comes into contact with and participated in the intervention.	• Attendance lists • Standardized protocols	Observational monitoring
Mechanisms of impact			
Participant responses toward the intervention	The responses of participants who interacted with and received the intervention, their satisfaction, and the degree to which they found the intervention acceptable.	• Questionnaires	• Interviews • Focus groups
Mediators	The extent to which intermediary processes inform subsequent changes in outcomes.	• Structured observations	• Observational study
Unexpected pathways or consequences	The extent to which identifying unexpected pathways and mechanisms during the intervention meets the research needs and leads to intervention outcomes.	• Structured observations	• Observational study
Contextual factors			
Barriers	Any external factors that may act as a barrier toward the intervention implementation or its effect on the outcomes.	• Statistical analysis • Questionnaires	• Interviews • Focus groups • Observational study
Facilitators	Any external factors that may act as a facilitator to the intervention implementation or its effect on the outcomes.	• Statistical analysis • Questionnaires	• Interviews • Focus groups • Observational study

Methods

Study Design

This review used the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and was registered on PROSPERO (CRD42020208212). Owing to limited guidance on conducting systematic reviews in this area, we used the UK MRC theoretical framework from which we derived a glossary of components to use as a checklist to extract and categorize qualitative and quantitative data (Table 1) [15]. This framework considers 3 linked dimensions in which to consider processes: implementation, mechanisms of impact, and contextual factors. Implementation involves an assessment of fidelity, dose delivered and received (ie, how often or effectively it was delivered), adaptations made, reach, content delivered, and method of content delivery [20,21]. Mechanisms of impact involve an assessment of participants' satisfaction with the intervention, "unexpected consequences," and "mediators" [18]. Contextual factors refer to the external barriers and facilitators, such as cultural or organizational factors, that may alter the implementation of an intervention [22].

Search Strategy

The timeframe for the search was limited to between December 1, 2005, and December 16, 2020. This timeframe was selected because of the rapid increase in DPIs in addition to the fast-moving space of digital technology. The review aimed to capture the most recent DPIs. Five electronic bibliographic databases were used: Cochrane Library; Cochrane Collaboration Registry of Controlled Trials; Embase; PubMed; and MEDLINE. The main key search terms were GDM, RCT, and PE (see Multimedia Appendix 1 for a detailed list of search terms and strings and Multimedia Appendix 2 for key definitions). Reference lists of the included studies were also searched for additional eligible studies. Boolean search was used to combine the keywords with operators such as AND, NOT, and OR to further produce more relevant results, for example: ((GDM OR gestational diabetes OR pregnancy-induced diabetes OR diabetes in pregnancy) AND ((RCT OR controlled clinical trial OR pragmatic control trial OR clinical trial) AND (process evaluation OR program evaluation OR process assessment OR process acceptance OR outcome measures)); ((GDMs OR gestational diabetes OR pregnancy-induced diabetes)) AND ((RCT OR controlled clinical trial OR pragmatic clinical trial OR clinical trial) OR (process evaluation OR program assessment OR process acceptance OR outcome measures).

Eligibility Criteria

Inclusion criteria were published (peer-reviewed) RCTs of DPIs in women with a current diagnosis or history of GDM. Exclusion criteria were studies not published in English; studies where the target population was women who had a family history of T2D or women who were menopausal or postmenopausal; and gray literature, including abstracts in conference proceedings. For further details about the eligibility criteria, please see the study protocol [23].

Study Selection

After initial deduplication of the extracted data using Endnote (Clarivate), studies were uploaded to the platform Rayyan for screening. The 2 reviewers (IIMS and MB) independently screened the titles and abstracts of the studies. Disagreements were resolved via consensus or decided by a third reviewer (IPN) when consensus could not be reached. The full texts of potentially relevant studies were retrieved for further screening and independently appraised by 2 reviewers (IIMS and MB) for final inclusion.

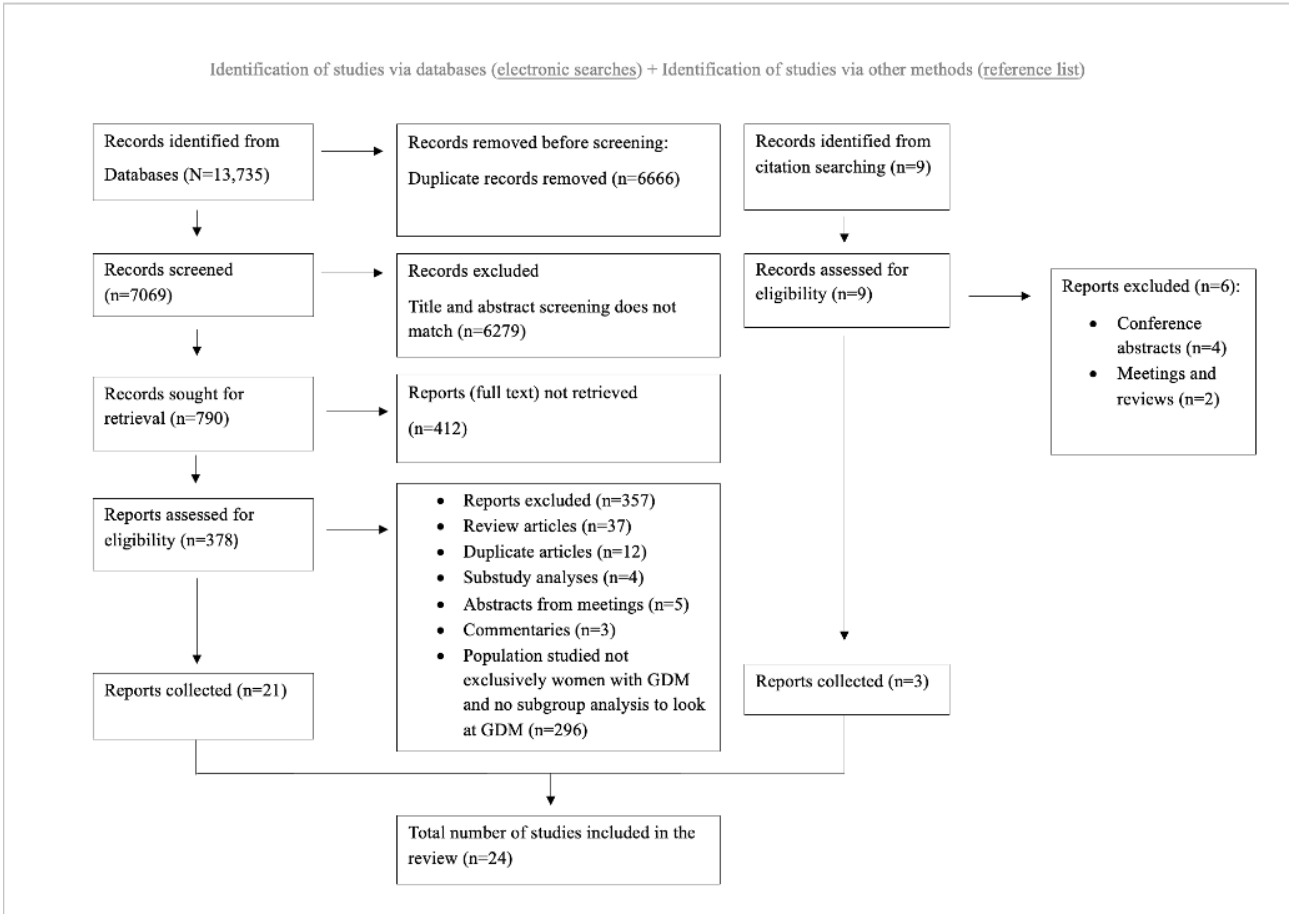
Data Extraction, Study Characteristics, and Analysis

Standardized data extraction forms were developed and piloted. Extracted data included a summary of study characteristics, evaluation of processes (if any), methods, and findings. Data were extracted by a single reviewer (IIMS) and verified by a second reviewer (NH); discrepancies were again resolved via consensus.

We conducted a narrative synthesis of the studies as we anticipated that the heterogeneity of the methods used to assess processes would preclude meta-analysis, as has been found previously [10].

Assessment of Quality

The Mixed Method Appraisal Tool was used to assess the quality of included studies by 2 independent reviewers (IIMS) and (NH). The discrepancies were again resolved via consensus.



Results

Study Selection

The PRISMA flow diagram for this review is shown in Figure 1. Of the 13,735 records initially identified, the full text of 378 full-text studies were screened for eligibility and 21 studies met the eligibility criteria. An additional 3 studies were added following citation searching. Therefore, 24 studies were included in this review. Most of these studies fulfilled at least 3 methodological quality criteria outlined by the Mixed Method Appraisal Tool for each study design (Multimedia Appendix 3 [3,24-46]).

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram of search. GDM: gestational diabetes mellitus.

Study Characteristics

The stated primary aims of all 24 DPI studies reviewed were to improve dietary and physical activity outcomes, increase self-efficacy levels and risk perception of T2DM, and decrease maternal postpartum weight and BMI. The 24 studies evaluated in-person (n=8), digital (n=7), and hybrid (n=9) interventions. Two of the studies were pilot studies of the feasibility and acceptability of DPIs. All studies were published between 2007 and 2020. Most studies (n=22, 92%) were conducted in high-income countries. Only 2 studies were conducted in low- to middle-income countries: Egypt (n=1) and Malaysia (n=1). The sample size ranged from 31 to 1180 participants. The intervention duration varied from 12 weeks to 6 years. See Multimedia Appendix 4 [3,24-46] for a description of study characteristics of the studies included in this review.

Number and Type of PE Components Reported

The most frequent PE components evaluated were content delivered and method of content delivery (n=24), dose delivered (n=20), reach (n=20), dose received (n=17), barriers (n=15), facilitators (n=8), and participants' responses toward the intervention (n=8). Relatively few studies reported process data relating to adaptations (n=7), mediators (n=7), fidelity (n=5), or unexpected pathways or consequences (n=2). All PE components outlined by the MRC framework and reported in the reviewed DPIs are summarized in Multimedia Appendices 5 and 6 [3,24-46].

PE Frameworks and Measures Reported

Five studies explicitly referred to a PE framework or PE quantitative or qualitative measures. Only 1 of these referred to process measures in the context of the MRC framework of complex interventions [24]. The others reported measures to ensure adherence to the study protocol [25], to measure "reach" (using the penetration, implementation, participation, and effectiveness metric) [26,27], or to assess participants' satisfaction to the program using a survey [47].

Implementation

Content Delivered and Method of Content Delivery

Eight studies evaluated in-person or group DPIs [3,28-34], 7 evaluated digital DPIs [35-40,48], and 9 delivered hybrid DPIs [24-27,41-44]. Most of the interventions were multicomponent that focused on diet and self-directed physical activity [24-27,33,35,40-46,49] or were facilitator led [29,30,43]. One intervention also included advice on breastfeeding [28].

Behavior Techniques and Theoretical Frameworks Used to Deliver Content

Behavior change techniques included motivational interviewing (MI) with individual goal setting [26,29]; enhancing healthy lifestyle change and self-management [24]; guided self-help [33]; nutritional and physical activity recommendations [30]; self-help guidance based on responses to a dietary food intake questionnaire [3]; and guideline-based nutritional strategies [44]. Five interventions were underpinned by established

XSL•FO
RenderX

theoretical frameworks—social cognitive theory and the transtheoretical model of behavior change [25]; the Health Action Process Approach supported by social cognitive and self-regulation theory [27] based on a Health Belief Model [50]; and messages on weight loss, diet, and physical activity based on a harm reduction model to promote healthy lifestyle changes [43].

The link between a process and outcome was reported in 2 studies. In the first, the use of behavior change strategies was reported to improve women's knowledge, beliefs, and self-reported practices as well as decrease postpartum weight gain in 1 study [33]. In the second study, there were no observed changes in weight, waist circumference, or blood glucose level and this was correlated with no changes in health perception or self-efficacy [3].

Fidelity

Five DPIs (digital: n=3 and hybrid: n=2) reported on the fidelity (quality) of intervention implementation [25,27,36,39,45]. Assessment of fidelity involved recording telephone calls or sessions [36,45], a qualitative [45] or quantitative [36,39] assessment of adherence, and sometimes also involved input from the participants [45]. Two of the studies attributed a high level of fidelity to effective weight loss and weight goals [27,36].

Dose Delivered

Nineteen studies reported on the quantity, frequency, and duration of the interventions [24-26,28-30,32,34,36,39-43,48]. Most studies delivered around 1 to 4 sessions lasting 2 hours. The shortest dose duration was 12 weeks and included 12-weekly sessions of 2.5 hours including group physical activity, health education, and an individualized lifestyle counseling session [29].

Further details in relation to dose delivery were generally limited. For instance, the frequency [24,40] or quantity of sessions or emails [43,45] were not reported. Similarly, 3 digital DPIs of web-based interventions involving health websites [40], internet telemedicine [37], or pedometer messaging [38] did not report the quantity of health content and messages sent by health care professionals. Borgen et al [35] reported the delivery of their mobile health app but did not mention how long it would take to peruse the app's content. Finally, another web-based intervention [44] did not report on how frequently participants should use the pedometer or step count goal target.

Dose Received

Sixteen of the studies reported data on the dose received by the participants [3,24-26,28-30,32,36-38,43,45]. The dose response included the average number of sessions attended by women [25-27,29,36,40,43-45]; those returning documents or questionnaires [51-53]; combined food intake and physical activity logbooks [38,54,55]; and log-ins to websites or systems [37,40,45].

Information on the dose received was used to highlight the willingness of participants to take part in the study and the subsequent success of the intervention. For example, in 1 hybrid study [44], it was reported that most women in the study attended all 4 lifestyle counseling sessions in their intervention, concluding that it was successful in reducing weight and increasing physical activity levels. Details on the dose received were also used to explain any lack of intervention effects. In another hybrid study [43], authors attributed their unsuccessful intervention outcomes to the limited number of women logging onto their website intervention and observed that engagement did not improve with fortnightly automated email reminders. One digital study observed that they did not collect data on user engagement for its mobile health app to protect women's privacy and questioned that this may have explained the nonsignificant effect of the intervention [35].

Adaptations

Adaptations were described in 7 DPIs, including 2 in-person [38,55], 2 digital [35,45], and 3 hybrid DPIs [24,25,32]. These adaptations were seen as important components for the success of the intervention and included providing a choice of intervention methods [28] and tailoring interventions to the characteristics of the target population [45] to specific ethnic or cultural backgrounds [24,34,35]. In 3 hybrid DPIs, MI techniques were used to tailor sessions for participants [24,25] and illustrations and simple messages were added to address low health literacy [41].

Reach

Twenty studies reported on the reach of its intervention in relation to the target population [24-26,28-32,34,36-41,43,45]. Loss to follow-up was a recognized challenge, perhaps reflecting the case mix of the target population. Two of the studies referred to pregnancy complications as a reason for dropout [31,33] with another attributing loss to follow-up to work or personal commitments, initiation of a weight loss diet, subsequent pregnancy, not being contactable, and finding intervention resources unhelpful [40]. One digital DPI reported a low participation rate of 17%, making inference to the broader target population difficult [39]; another reported that few women who received information about their intervention proceeded to enroll for participation [38]. Other studies that used PE methods to measure reach reported low rates [24,27,43] and 2 additional studies had 33% to 39% attrition rates [29,34].

Mechanisms of Impact

Participant Responses Toward the Intervention

Eight studies reported on participant feedback and responses toward the interventions including 4 digital [35,38-40], 3 hybrid [25,26,44], and 1 in-person DPI [29]. Overall, women expressed satisfaction with the interventions [25,29,38,39,44], reporting increased confidence in setting health goals [39,40] and more engagement with health management [35].

Some studies did not receive a positive response. Only a third of women reported being motivated by the website content in 1 digital intervention [40] and even fewer (22% and 31%) had a positive reaction to the text messaging component. Women also criticized the lack of information on optimal carbohydrates to consume when transitioning between pregnancy to postpartum diets and reported the need for more low-fat recipes [25,40].

XSL•FO
RenderX

Mediators

Mediators were described in the interventions in 2 in-person DPI studies [29,34], 4 digital DPIs [35,37,39,40], and 1 hybrid DPI [43], although not explicitly. O'Dea et al [29] found that women valued individual face-to-face sessions with health care professionals when setting health goals which improved their stress levels, diet self-efficacy, and quality of life. Social relationships also developed between the women due to regular attendance at the same lifestyle counseling groups [34]. Digital DPIs were also reported to increase women's engagement in their own health [35], enhance self-efficacy and confidence [37,40], and provide reassurance in developing and attaining health goals [39]. Further, 1 hybrid study [43] qualitatively linked the inclusion of partners in their intervention as a key mediator for women making them more likely to participate in and engage with the intervention.

Unexpected Pathways or Consequences

Only 2 studies [39,41] reported unexpected consequences in relation to their interventions. Carolan-Olah and Sayakhot [41] observed there was an unusually high percentage of women in the intervention group who had attended their postpartum oral glucose tolerance test (OGTT) appointment. Although not directly linked to the study, the intervention highlighted the importance of postpartum testing, which may have increased women's motivation to attend future follow-up appointments. Another digital study [39] experienced unexpected challenges with data retrieval from women and general practitioners, resulting in missing baseline blood tests and self-reported data at follow-up. However, this missing data did not appear to negatively influence the findings as women in the intervention group were found to significantly reduce their fat intake.

Contextual Factors

Barriers

Fifteen studies referred to barriers that women faced when participating in interventions [3,24-26,29,31,33-35,37-40,43,44]. Such barriers included lack of time due to family and work commitments, subsequent pregnancy, and changes to daily life due to the demands of motherhood [24,29,31,33,40,44] technology issues, and lack of internet access [24,38,43]. Similarly, unavailability due to childcare responsibilities and forgetting to attend study visits prevented mothers from engaging in in-person lifestyle counseling sessions in the nondigital interventions [3,24,29]. Another in-person DPI acknowledged how culture plays a role in hindering women from participating in and completing an intervention when they are placed under pressure to commit to family and social norms [34].

Facilitators

The 8 DPI studies including 4 in-person DPIs [28,29,31,34], 2 hybrid DPIs [43,44], and 2 digital DPIs [37,40] described facilitators as contextual factors which may have influenced the outcomes of their interventions. The most common facilitator identified in 1 hybrid and 1 in-person DPI was receiving support from a partner during the intervention [29,43] and having higher levels of income and personal education background [43]. Having access to healthy food, food vouchers, a babysitter, and an exercise buddy were also reported as facilitators to assist and support the uptake and maintenance of postpartum healthy behaviors [31,40]. The competency and skills of health care professionals delivering the interventions were acknowledged as facilitators to ensure the uptake of the intervention [28]. Having an accessible, central location for assessments and employers who allowed time for visits also facilitated participation [34,44].

Discussion

Overview

We identified and reviewed 24 RCTS of DPIs that evaluated at least 1 PE component for women with previous or current GDM. Only 10 studies explicitly reported individual processes, and only 5 explicitly referred to a PE framework or PE quantitative or qualitative measures to assess processes. Overall, few studies reported and evaluated processes in relation to study outcomes, and although most DPIs linked PE components and DPI outcomes in some capacity, it was challenging to attribute any 1 process component to the effectiveness and success of the intervention.

Summary of Key Findings

The most complete of the PE components reported across all 24 studies was the combined component of content delivered and method of content delivery. Clear narratives were provided on how the interventions were delivered and their content. Most of the interventions also referred to broad behavior change techniques such as goal setting and MI, which are known to be effective in promoting lifestyle behavior change [56,57]. However, few studies linked these theories with mechanisms of action by providing a detailed psychological or behavior change theoretical framework on which their intervention was underpinned. Such frameworks are important to make sense of "how," "why," and "under what circumstances" intervention components work together to achieve the desired outcomes. Moving forward, we recommend that all RCTs of DPIs publish an overview of the theories they have used to design and evaluate the intervention for greater transparency.

Although most DPIs reported information on the dose delivered, PE measures on the dose received were less complete. Generally, increased frequency and longer sessions resulted in more engagement with the intervention and better outcomes [26-28,30,31,36]. More frequent sessions may also be preferred by the participants: for a study on the use of MI and hemoglobin A_{1c} outcomes, women said that they would like more sessions to improve their engagement with the intervention [58]. The timing of the intervention is also a consideration. Most of the DPIs that we reviewed delivered interventions during either the antenatal or postpartum periods. However, systematic review evidence suggests that optimal pregnancy outcomes can be achieved by delivering the intervention during both periods since engagement with a healthy lifestyle poses tends to be poorer during the postpartum stage [5,51]. Moreover, there was little information in the studies reviewed on how the dose received impacted the success of the intervention. The challenges in assessing adherence to the dose received are well

XSL•FO
RenderX

recognized as people may have received a dose but choose not to take it [59]. This is also supported in the literature where a nurse-led psychological intervention for a T2D cluster RCT study identified a lower dose received than intended, but that this was not associated with the dose delivered [60]. Further research to explore how timing, frequency, and duration of the intervention affect outcomes among women with current or previous GDM is indicated.

Although all 24 studies included in this review sought to describe the reach of the intervention, few gave a detailed evaluation of this measure. Poor reach was attributed to generic reasons, most commonly low participation rates, loss to follow-up, and small sample sizes [26,27,29,36,39]. The increase in OGTT appointment attendance found in 1 study [41] is contrary to prior research linking loss to follow-up and withdrawal numbers to participants' reluctance to attend OGTT appointments [49,54], which highlights the influence that different contexts have on outcomes in this population. Moreover, the studies that made adaptations to tailor their DPIs to personal or cultural needs [24,25,28,34,35,41,45] are likely to have increased reach by making the interventions more relevant. A clear definition of the target population and consideration of how the DPI can be adapted to make it as inclusive as possible seems important for its success.

Most of the studies reported on barriers to intervention engagement. Similar to previous systematic reviews [10,61], the barriers primarily related to lack of time, childcare commitments, and challenges to maintaining healthy lifestyles [24,29]. Focus groups with women suggest that these inherent barriers can be mitigated by combining direct contact with health care professionals with web-based interventions [48]. Moreover, it is worth noting that, despite the many barriers to participation identified, women were still in favor of the DPIs, and many resulted in positive outcomes. This aligns with previous research in T2D [62] and supports a need and willingness among women with previous or current GDM to engage with DPIs.

A particular concern identified by this review was the lack of reporting or evaluation of fidelity. Only 5 studies reported on this process component. Ensuring fidelity is a key aspect of any DPI because it safeguards against nonadherence to the study protocols and inadequate implementation delivery [47,63]. Ideally, fidelity should be measured prior to conducting full-scale implementation to distinguish between outcomes that are related to ineffectiveness from those related to protocol deviation [64,65]. In our review, methods to assess fidelity included audiotaping and patient registers of attendance [27,36]. Such methods have been tried and tested in the T2D setting [47,63] and are likely to be more robust than relying on the expertise of health care professionals as a fidelity measure [66]. To minimize research waste, fidelity assessments should be commenced at the design stage of a trial and incorporate standardized measures where possible.

Finally, we welcome the use of both quantitative and qualitative methods to evaluate the PE components in our studies because this enables a more in-depth understanding of the relationship between individual components and outcomes [52,67]. We reemphasize the importance of mixed methods when conducting thorough PE.

Strengths and Limitations

To the best of our knowledge, this is the first and only systematic review of PEs of T2DM prevention interventions for women with GDM. We used robust methodology, an established framework of PE for complex interventions [15], and restricted the review to RCTs, which are known to be the best design for evaluating complex health care interventions [15]. The glossary list of standardized DPI content and PE terms developed during the review process can be used to guide future RCTs in this area. However, while the MRC framework [18] is a valuable source for conducting systematic reviews on PEs, it has been criticized for lacking practical advice on how to conduct them [68]. The lack of information on PE frameworks in our review also made it difficult to categorize individual PE components against the framework. Moreover, there is a lack of consensus on how PE components should be defined and interpreted by researchers, which is only partially addressed in the MRC guidelines [15], which facilitate understanding of PE constructs but provide little clarity on what should be measured and how.

Conclusions

This systematic review has highlighted that there are important gaps in the reporting of PE metrics for RCTs of T2DM in women with GDM. We recommend rigorous, systematic, and in-depth PE guidance to facilitate reporting of these studies. Future research should focus on reaching consensus on the reporting of PE measures using established frameworks and evaluating PE in real-world health care settings to optimize the interpretation of study outcomes.

Data Availability

All data generated or analyzed during this study are included in this published article (and its supplementary information files).

Authors' Contributions

IIMS developed the methodology, conducted the investigation and formal analysis, and cowrote and reviewed the original draft. MB conducted the investigation, cowrote the original draft, reviewed and edited subsequent drafts, supervised junior researchers, and contributed to project administration. IPN codeveloped the original concept, methodology, and investigation; curated data and cowrote the original draft; edited subsequent drafts; supervised junior researchers; and acquired funding. AB cowrote the original draft and reviewed subsequent drafts. MP developed the original methodology, contributed to the investigation, cowrote drafts, and supervised junior researchers. BNMY contributed to the writing of drafts and reviewing subsequent versions. SB contributed to writing, reviewed, and edited subsequent versions. CSM codeveloped the original concept, contributed to the writing and reviewing of subsequent versions, and supervised junior researchers. AF codeveloped the original concept, developed the methodology, cowrote and reviewed subsequent versions of the original draft, and supervised junior researchers. KI codeveloped the original concept; developed the methodology; conducted the formal analysis; contributed to the investigation, data curation, and inputting of data into the software; supervised junior researchers; contributed to project administration; and acquired funding. BHC codeveloped the original concept, developed the methodology, cowrote the original draft and reviewed subsequent versions, supervised junior researchers, and acquired funding. All authors reviewed the final manuscript.

Abstract

Background: Incorporating artificial intelligence (AI) into medical education has gained significant attention for its potential to enhance teaching and learning outcomes. However, it lacks a comprehensive study depicting the academic performance and status of AI in the medical education domain.

Objective: This study aims to analyze the social patterns, productive contributors, knowledge structure, and clusters since the 21st century.

Methods: Documents were retrieved from the Web of Science Core Collection database from 2000 to 2024. VOSviewer, Incites, and Citespace were used to analyze the bibliometric metrics, which were categorized by country, institution, authors, journals, and keywords. The variables analyzed encompassed counts, citations, H-index, impact factor, and collaboration metrics.

Results: Altogether, 7534 publications were initially retrieved and 2775 were included for analysis. The annual count and citation of papers exhibited exponential trends since 2018. The United States emerged as the lead contributor due to its high productivity and recognition levels. Stanford University, Johns Hopkins University, National University of Singapore, Mayo Clinic, University of Arizona, and University of Toronto were representative institutions in their respective fields. *Cureus*, *JMIR Medical Education*, *Medical Teacher*, and *BMC Medical Education* ranked as the top four most productive journals. The resulting heat map highlighted several high-frequency keywords, including performance, education, AI, and model. The citation burst time of terms revealed that AI technologies shifted from imaging processing (2000), augmented reality (2013), and virtual reality (2016) to decision-making (2020) and model (2021). Keywords such as mortality and robotic surgery persisted into 2023, suggesting the ongoing recognition and interest in these areas.

Conclusions: This study provides valuable insights and guidance for researchers who are interested in educational technology, as well as recommendations for pioneering institutions and journal submissions. Along with the rapid growth of AI, medical education is expected to gain much more benefits.

KEYWORDS

artificial intelligence; medical education; bibliometric; citation trends; academic pattern; VOSviewer; Citespace; AI

Introduction

Artificial intelligence (AI) seeks to develop innovative machines that are capable of responding in ways similar to human intelligence. Its scope encompasses robotics, language recognition, image recognition, natural language processing, and expert systems. In recent years, the integration of AI into medical education (AIME) has significantly transformed traditional teaching and learning methodologies [1,2]. It can enhance clinical reasoning training, facilitate adaptive learning,

XSL•FO
RenderX

construct innovative medical teaching platforms, and facilitate critical care simulation teaching. For instance, the AI-powered simulation mannequins called SimMan 3G PLUS allows medical students to practice their clinical skills and teamwork in a fully controlled and immersive environment. Augmented reality and virtual reality technologies enable students to gain valuable hands-on experience by recreating real-life situations, without compromising patient safety [3]. In other cases, AI helps tailor educational content based on individual students' needs and abilities, and it not only fosters academic success but also cultivates critical thinking [1,4]. AI applications have become an important tool and situation for both educators and students.

As AI continues to evolve and advance, its role in promoting medical education is expected to grow. Despite many publications that have explored AI's application in medical research, they are limited to specific clinical questions in cardiology, dentistry, oncology, etc [5,6]. No bibliometric analysis has ever been conducted to assess medical education, which is essential for medical talent reserve. Therefore, a comprehensive analysis of current scientific literature is imperative for the continued advancement of AIME.

Bibliometrics uses mathematical and statistical methodologies to evaluate scholarly productivity and publication patterns within a specific discipline. We used bibliometrics to analyze the contemporary academic landscape, research priorities, and emerging trends in AIME in the 21st century. We revealed the knowledge clusters, scientific social patterns, and evolutionary nuances from an objective standpoint. This work not only simplifies navigation for researchers across disciplines but also gives valuable guidance to newcomers in the field, directing them toward promising avenues for future research.

Methods

Study Design

The research adhered to the step-by-step guidelines of bibliometric analysis and followed the reporting guideline of bibliometric reviews in biomedical literature [7].

Data Collection

The Web of Science Core Collection database was selected as the primary tool to identify relevant publications for this study. This database is well-known for its exceptional bibliometric research capabilities across over 190 subject areas and offers manual-checked literature retrieval. A 2-step process was used to construct an effective retrieval strategy. First, we extracted search terms from relevant systematic reviews and meta-analyses. Second, these search terms were meticulously reviewed and refined by authors (TW and RL) to ensure adequate coverage of all relevant research topics. The final search strategy was formulated based on this collaborative assessment: TS=("artificial intelligence" or AI or "convolutional neural network" or "recurrent neural network" or "long short-term neural memory" or "machine learning" or "genetic algorithm" or "evolutionary algorithm" or "artificial neural network" or "support vector machine" or "fuzzy logic" or "random forest" or "deep learning" or "natural language processing" or "speech recognition" or "computer vision" or "smart robot" or "video recognition" or "image recognition") and TS=(medical education or medicine education). Data collection took place on October 1, 2024, with publication years restricted from 2000 to 2024. No language restrictions were applied during the search process. Full records of retrieved papers were exported in plain text format.

Selection of Eligible Studies

Since search engines may yield results that do not fully align with the intended criteria, it is necessary to perform a manual screening process to identify the final included literature. To address this, two authors (TW and RL) independently screened the titles and abstracts of available studies based on the following exclusion criteria: (1) publications unrelated to AI. For example, some topics are associated with artificial insemination. (2) Publications unrelated to medical education, such as engineering curriculum and patient education. Notably, a majority of these studies have applied AI technologies to clinical questions and research, and only a small number pertained to medical education. Any discrepancies between the studies selected by the authors were resolved through a consensus meeting to reach a binding decision.

Data Cleaning and Preprocessing

The records from the Web of Science Core Collection database undergo rigorous selection criteria adhere to meticulous curation standards, and it partly enhances our research quality [8]. To further ensure accuracy and consistency, we performed a thorough data cleaning process. This involved the elimination of duplicate papers, which were identified through digital objective identifiers and study titles. The biblioshiny package in RStudio was used to standardize the names of authors and institutions. Any variations in author names were consolidated. As an author usually affiliates with institutions at different times, only the institution of the author at the time of publication is retained. Synonyms, aliases, and singular or plural forms, such as "AR," "augmented reality," and "augmented realities" were cleaned using a thesaurus file. The data cleaning was conducted manually by two authors (TW and RL).

Data Analysis and Visualization

To present the knowledge structure and emerging research trends, VOSviewer (version 1.6.18; Leiden University), Incites (Clarivate), InteractiVenn (Universidade de São Paulo), and Citespace (Drexel University) were used. Incites is a research evaluation tool developed by Clarivate Analytics, and the scores of citation impact, H-index, journal impact factor, international collaborations, study influence, and immediacy index were directly obtained in Incites. The citation impact is calculated by dividing the citation impact by the number of years since publication. The H-index indicates that H papers published by an author have been cited at least H times, thereby serving as a gauge of both scholarly productivity and influence. The journal impact factor was used based on the 2023 Journal Citation Reports. International collaborations were assessed to reveal the extent of interdisciplinary cooperation among coauthors hailing from various nations, highlighting the global reach and collaborative nature of the research topic. The study's influence measures the mean influence of a study within the first 5 years

XSL•FO
RenderX

of post publication, providing a view of its long-term impact. Concurrently, the immediacy index represents the average frequency with which a study is cited in the year of its publication, offering insight into the immediate reception in the academic community. The VOSviewer software was used to cluster countries, institutions, journals, and keywords. The Citespace software was used to identify keyword clusters and citation burst time. The specific parameter settings for analysis in VOSviewer and Citespace are provided in Tables 1 and 2. The latent semantic indexing and log-likelihood ratio algorithms were used for literature clustering. The InteractiVenn tool was used to identify the specific and overlapping journals in 4 categories: count, citation, top 10% papers, and cooperative work. To compare the frequencies of keywords in the AI and medical education fields, the keywords were classified based on their basic definition, and lists of professional terms or vocabulary or terminology.

Table 1. Information for clustering using the VOSviewer.

Item	Type	Algorithm	Normalization method	Minimum document or occurrence[a]
Country	Coauthorship	Majorization	Full counting	12
Organization	Coauthorship	Majorization	Full counting	15
Journal	Citation	Majorization	—[b]	12
Keyword	Co-occurrence	Majorization	Full counting	33

[a]We set no limit on the minimum citation.

[b]Not applicable.

Table 2. Information for keyword cluster using the Citespace.

Setting	Value
Time slicing	From January 2000 to October 2024, one year per slice
Text processing	Title, abstract, author keywords, and keywords plus
Node type	Keywords
Links	Strength: cosinel Scope: within slices
Selection criteria	k=7

Ethical Considerations

The institutional review board of Tongji Hospital deemed ethical approval unnecessary for this study.

Results

Baseline Characteristics

This study initially retrieved a total of 7534 publications from the search. Figure 1 provides a detailed flowchart illustrating the publication retrieval and selection process. After title and abstract screening, 2775 publications remained for further bibliometric analysis. The academic publications underwent a relatively flat growth in publication numbers from 2000 to 2017 (Figure 2A). However, the number of annual papers exhibited exponential growth since 2018, indicating the flourished development in this field. The citation counts also demonstrated a consistent rise, surpassing 10,000 citations in 2024 (Figure 2B). These documents encompassed original studies (n=1769, 63.75%), proceeding papers (n=467, 16.83%), reviews (n=237, 8.54%), and meeting abstracts (n=67, 2.41%). Proceeding papers typically contain the latest research findings and methods, as well as techniques within a scientific field, and their high percentage indicates that AIME is receiving much attention and developing rapidly. The research areas are primarily focused on Education Scientific Disciplines (n=415), Medicine General Internal (n=334), Health Care Sciences Services (n=323), Engineering Biomedical (n=264), and Surgery (n=255). It suggested that AIME is an interdisciplinary topic that needs support from specialized educators, clinical doctors, hospital administrators, and engineers.

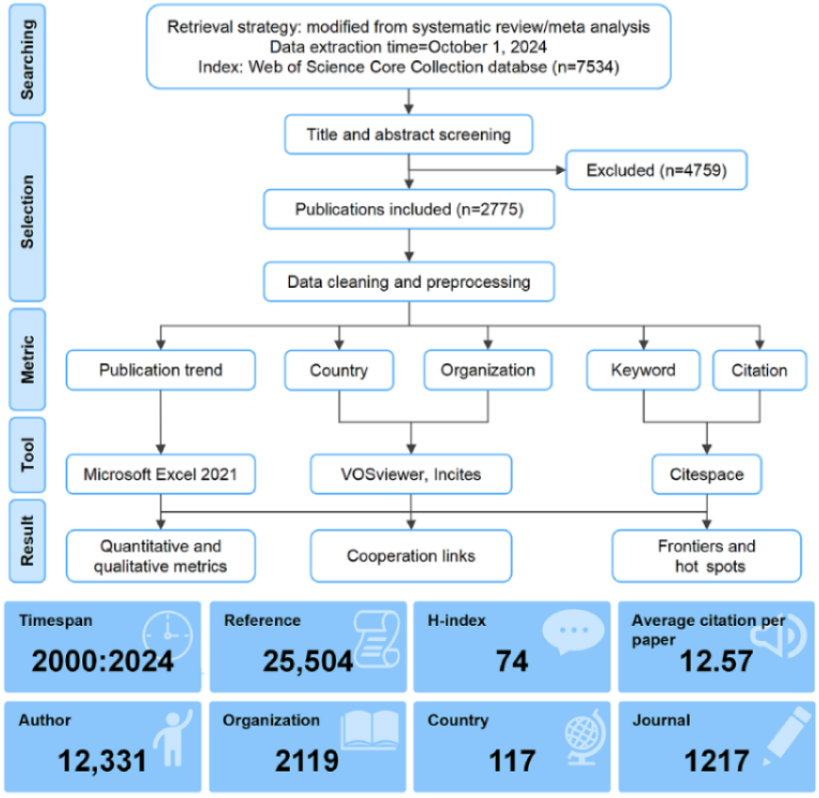
Figure 1. Flowchart and basic information of retrieval strategy, screen process, and analysis methods.



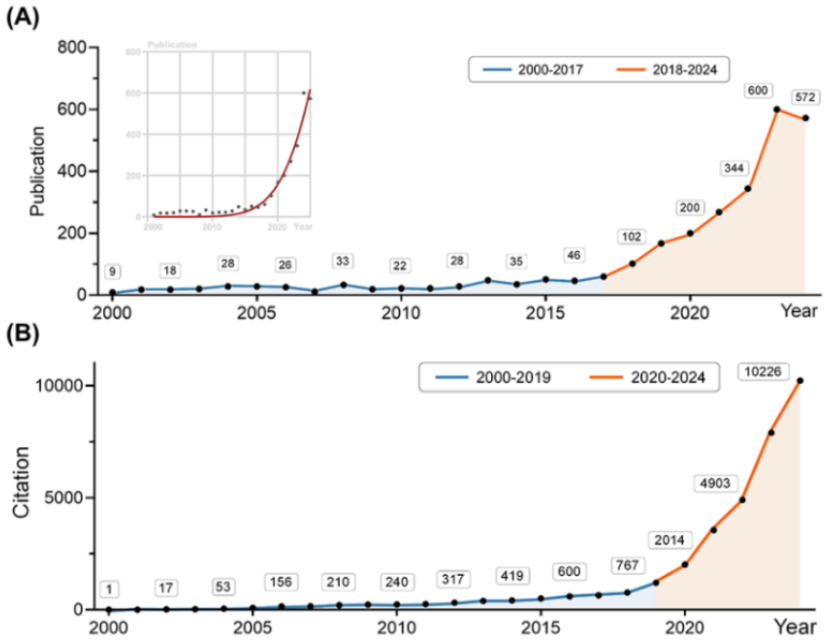


Figure 2. Baseline bibliometric characteristics of all eligible documents. (A,B) Line chart showing the annual number of documents and citations.

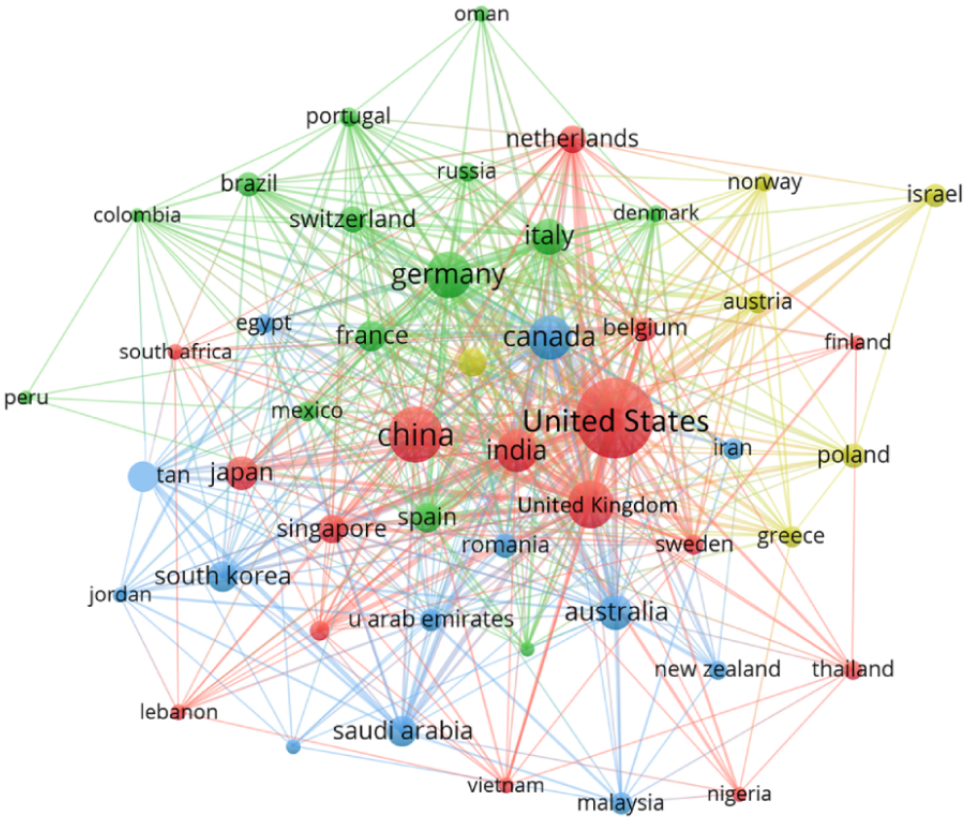


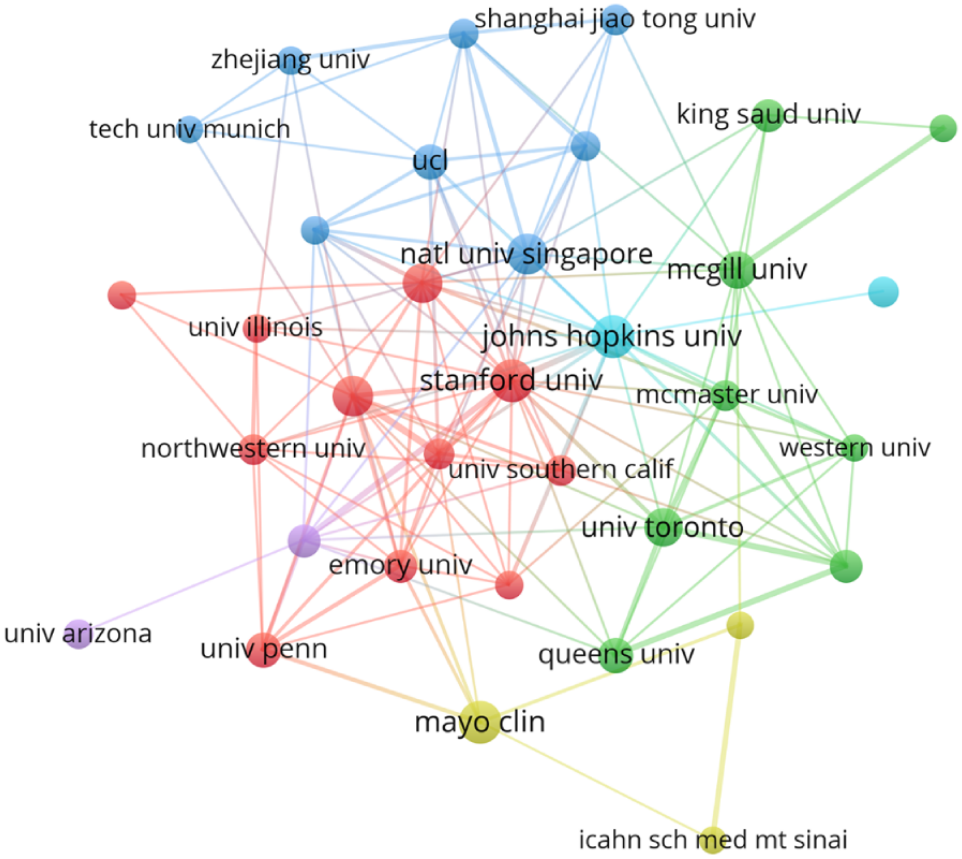
Productive and Influential Countries

In terms of national performance, 117 countries participated in the global discourse. The majority of research publications originated from Europe, North America, and Asia. The United States emerged as the primary contributor due to its high productivity (n=851 publications) and recognition levels (n=11,598 citations), exhibiting both the highest international and domestic collaborations. Although Chinese researchers published more papers than scholars from the United Kingdom (274 vs 227), their citations were relatively lower (3302 vs 3823). It may possibly be due to the limited innovation, restricted dissemination, and language barriers. The national cluster map revealed a diverse regional distribution pattern facilitated by these collaborative relationships (Figure 3). There was a strong collaboration among numerous countries, particularly close ties between the United States, China, the United Kingdom, and India.

XSL•FO
RenderX

Figure 3. Relationship and cluster of countries. Cooperative relationships networks among countries.

Institutional Performance



Altogether, 2119 institutions have participated in AIME studies. The top 10 institutions publishing the most papers are presented in Table 3. Among these, 4 institutions have published over 50 papers. Specifically, Harvard University emerged as the most prolific institution (n=70), and established the most international collaboration (n=35), while the University of London had the highest citation impact (n=27). The collaborative connections showed six clusters of countries publishing more than 40 papers (Figure 4). Stanford University, Johns Hopkins University, National University of Singapore, Mayo Clinic, University of Arizona, and University of Toronto were representative institutions in their respective cluster. Interestingly, regarding the impact relative to the world, the Alibaba Group had the highest score (value=61.43), followed by SUNY Downstate Health Sciences University (value=32.17), and Bukovinian State Medical University (value=25.14).

Table 3. Top 10 productive institutions of artificial intelligence in the medical education field.

Institution	Document	Citation	Citation Impact	International collaboration	H-Index	Impact relative to world
Harvard University	70	1085	15.50	35	17	1.25
University of California System	60	861	14.35	17	16	1.16
University of London	52	1211	23.29	27	17	1.88
Johns Hopkins University	51	1003	19.67	21	17	1.59
Stanford University	48	834	17.38	22	16	1.40
Harvard Medical School	47	588	12.51	25	13	1.01

University of Michigan	39	308	7.90	19	9	0.64

XSL•FO
RenderX

Figure 4. Visualization of institutional cooperation. Cooperative relationships networks.

Participants of the Source Journals

Cureus (n=78), *JMIR Medical Education* (n=72), *Medical Teacher* (n=54), and *BMC Medical Education* (n=54) ranked as the top 4 most productive journals among the 1217 involved journals (Figure 5A and Table 4). *JMIR Medical Education* published the most high-impact papers (n=48), and the second one, Cureus, only published 26. It is reasonable as *JMIR Medical Education* lies in the Q1 quartile, and likely receives more high-quality submissions, whereas Cureus is in the Q3 quartile. Cureus, *JMIR Medical Education*, *Medical Teacher*, and *International Journal of Computer Assisted Radiology and Surgery* were overlapped using a Venn diagram (Figure 5B). It was worth highlighting that Cureus and *JMIR Medical Education* had just begun to publish AIME-associated papers in 2020 (Figure 5C). Their open access characteristic helped them receive much attention in recent years. The publishers were diverse among the top 10 publication sources. More than half of these journals (7/10) published top 10% papers over 10. Notably, a significant proportion of the journals (n=1460, 52.61%) offered open access publishing, with gold access accounting for 33.26% (n=923) of this share.

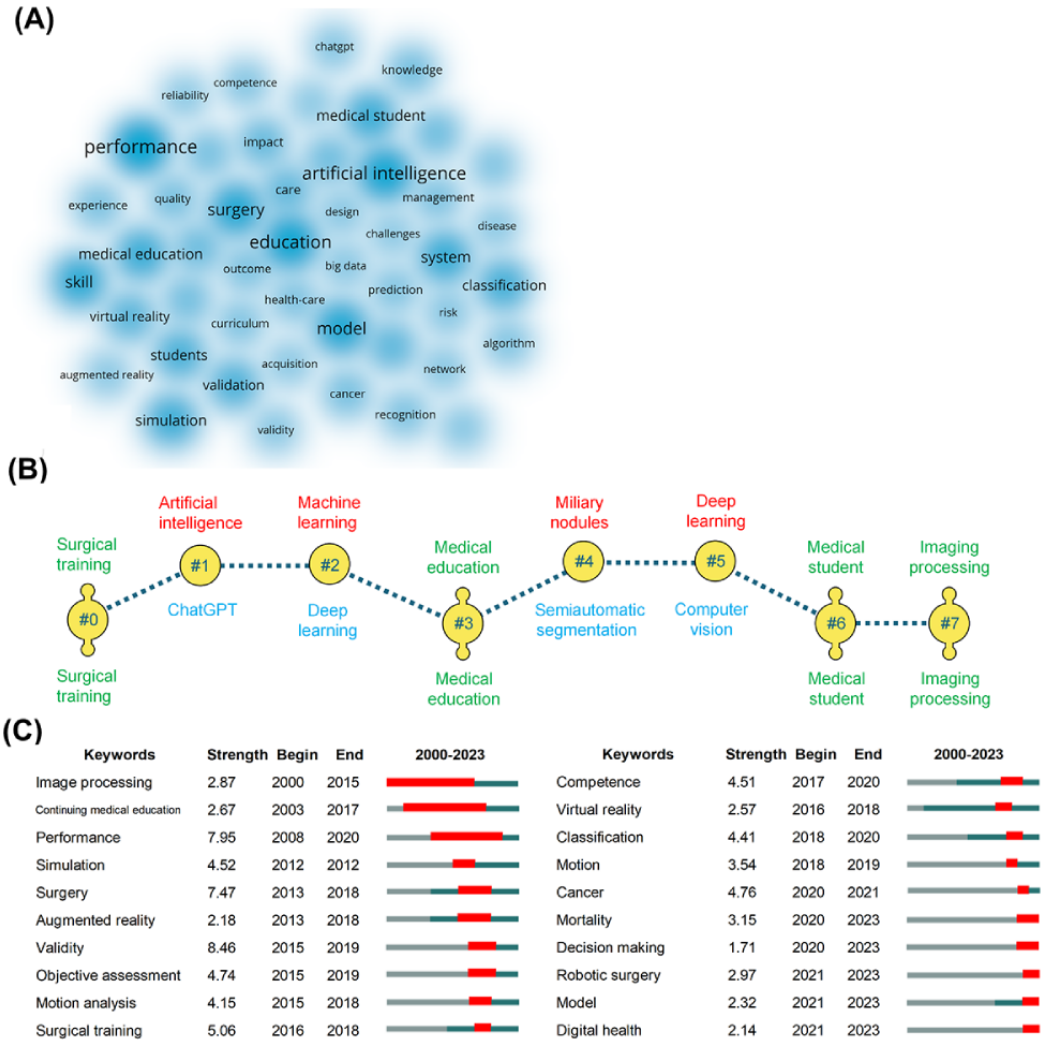
[a]Not applicable.



Keywords of Research Hot Spots

The study identified 7773 keywords from the titles and abstracts of the research materials, reflecting the central themes, areas of interest, and potential future developments within the discipline. The heat map highlighted high-frequency keywords, including performance (n=139), education (n=123), artificial intelligence (n=118), and model (n=103; Figure 6A). We next classified keywords according to the AI and medical education associated categories. The model (n=103), system (n=82), virtual reality (n=51), recognition (n=29), and algorithm (n=27) were popular topics, while most education focus was put on surgery (n=100), skill (n=90), simulation (n=75), classification (n=68), and diagnosis (n=47). The subsequent analysis produced eight distinct keyword clusters using log-likelihood ratio and latent semantic indexing algorithms (Figure 6B). Both algorithms

XSL•FO
RenderX

identified #0 surgical training, #3 medical education, #6 medical student, and #7 imaging processing as hub keywords. It suggested the critical role of AI applications in surgical operations and clinical image information. Citespace burst detection could reflect the research trends and innovative directions (Figure 6C). Notably, the citation burst time of terms revealed that AI technologies shifted from imaging processing (2000), augmented reality (2013), and virtual reality (2016) to decision-making (2020) and model (2021). Keywords such as mortality and robotic surgery persisted into 2023, suggesting the ongoing recognition and interest in these areas. Digital health involves the use of health apps, wearable equipment, and communication tools, which have been incorporated with AI. These devices not only provide personalized educational experiences and support mental health but also play a significant role in clinical teaching, disease prevention, and health promotion.

Figure 6. Keywords showing the hotspots and clusters. (A) Top keywords in the AIME field. (B) Eight clusters were obtained and unfolded using the latent semantic indexing (red), log-likelihood ratio (black) algorithms, or shared by both (green). (C) Keyword burstness panel showing the strength and duration. AIME: artificial intelligence into medical education.

Discussion

Principal Findings

AIME publication exhibits exponential growth these years, from approximately 50 counts in 2017 to 600 in 2023. This surge is further bolstered by the development of generative AI tools, and related national-level policies support. Here, we discuss the applications of AIME according to the keywords.

Machine Learning

Machine learning (ML), a subset of AI, is a technology that autonomously discerns inner patterns and relationships without explicit human instructions. For instance, after analyzing a large collection of cat and dog images, ML can identify distinguishing features, and subsequently differentiate between a cat and a dog in new photographs. The growing prominence of ML in medical education is evidenced by the surge in related topics, the approval of ML-based products, and the proliferation of entrepreneurial initiatives. ML-centric technologies have already been applied in clinical decision support systems, teaching tools, simulation, and training. An ML-based clinical decision support system could effectively integrate general information about HIV patients, including demographics, medical history, CD4+ lymphocyte count, viral load, genotypic data, and treatment history, to recommend an optimal combination antiretroviral

XSL•FO
RenderX

therapy [9]. More personalized advice on the appropriate dosage or duration of treatment will be provided with the help of other advanced ML algorithms [10]. In this context, it is vital to educate the next generation of medical professionals with adequate ML knowledge, enabling them to incorporate the outputs of ML tools into clinical decision-making, becoming part of this emerging data science revolution [11]. In the future, inexperienced medical students will use evidence-based learning models, like IBM's Watson Oncology system, as ordinary tools to interpret clinical data, make informed decisions, and recommend cancer treatments, in highly accordance with multidisciplinary teams [12].

Medical students require educational feedback to understand their performance and identify areas for improvement [13]. Traditional educational evaluation after surgical training falls short of providing timely, adequate, and objective assessment. A human rater is usually required to observe the video review to give a written or oral evaluation. The feedback is subjective and time-consuming, as well as limited to visual observation. With the help of automated ML-based AI assessments, the surgeon's performance can be objectively captured in a less resource-intensive way than human grading [14]. The motion, force, and vibration of robotic instruments are recorded according to the recognized structural metrics, like the Global Evaluative Assessment of Robotic Skill or the Objective Structured Assessment of Technical Skill [15].

Deep Learning

Deep learning (DL), a subset of ML, is often used to tackle complex tasks such as visual recognition, speech recognition, and natural language processing. This is achieved through the use of advanced architectures like convolutional neural networks, deep belief networks, and stacked auto-encoder networks. DL has been applied across medical undergraduate education, postgraduation education, and continuing education. A notable example is its use during medical retina rotations, where residents may not be fully trained due to limited time or access to complete their learning objectives. To address this, a DL-based model was developed to analyze a vast collection of retina images sourced from three public datasets, subsequently creating a comprehensive dataset for residents. These images were then distributed to each resident to aid in diagnosis, differential diagnosis, and therapeutic planning. The allocation system is tailored to each resident's case history, academic level, and performance, ensuring that those struggling with specific cases receive additional exposure to similar retinal conditions [16]. This approach enables AI models to identify the residents who will derive the most benefit from particular clinical cases, thereby significantly enhancing individualized ophthalmology education.

Additionally, DL technologies have been used to predict the difficulty of medical licensing examination questions, promoting more accurate assessments of examination difficulty. However, although DL models can effectively differentiate between cats and dogs, they do so by analyzing potentially hundreds or thousands of variables. The complexity and opacity of these variables often render them incomprehensible to humans. Consequently, there is an urgent need for improved interpretability methods in future DL applications to enhance understanding and transparency.

Natural Language Processing

Natural language processing plays a crucial role in smart health because of its ability to analyze and comprehend human language. The ChatGPT, developed by OpenAI Corporation, serves as a monumental tool for the natural language processing application. As for AIME, GPT-4 has been used for teaching cases, student analysis, creative writing, personalized learning guidance, and psychological support. ChatGPT is demonstrated to be effective in generating surgical procedure summaries, and its performance cannot be distinguished from a board-certified surgeon by less experienced residents [17]. In other cases, ChatGPT is used to teach the skills of breaking bad news [18], reasoning-based multiple-choice questions [19], and qualified examinations, including the Situational Judgement Test for final-year medical students in the United Kingdom [20]. These capabilities have revolutionized medical education and contributed to the overall improvement of health care delivery.

Segmentation

Image segmentation is a crucial AI technology in the radiology and pathology fields to accurately identify and delineate regions of interest, such as tumor lesions, ischemic tissues, and subcellular structures [21]. Traditional manual segmentation is not only time-consuming for physicians to learn and practice but also results in measurement variability that heavily depends on the observer's experience. In contrast, computer-assisted segmentation methods reduce the subjectivity and variability inherent in manual approaches, decrease processing time, and require minimal training. The use of image segmentation algorithms has led to significant improvements in the sensitivity and efficiency of detecting pulmonary nodules. Furthermore, these algorithms have been shown to enhance learning interest, bolster self-directed learning capabilities, sharpen problem-solving skills, and foster innovative thinking among medical trainees [22].

Effective surgical education for young surgeons presents significant challenges in practice. A segmentation-based system can identify key anatomical structures such as arteries, lymph nodes, and nerves during rectal cancer surgeries. Studies have shown the positive educational impact of AI-assisted videos in surgical training [23]. Some other AI technologies can facilitate surgical navigation and detect adverse events [24]. Taken together, real-time object segmentation is expected to play a major role in surgical education.

Comparison to Prior Work

AI has been increasingly used to enhance diagnostic accuracy, improve patient care, and facilitate the development of new treatments across various medical fields. In cardiology, for example, AI-powered algorithms are used to analyze electrocardiograms and detect arrhythmias, while in dentistry, AI-assisted diagnostic tools have been developed to identify oral pathologies [25,26]. Similarly, in oncology, AI-driven platforms are used to predict tumor growth and response to treatment [27]. Rather than concentrating on specific clinical questions, this study adopts a broader perspective to investigate

XSL•FO
RenderX

the role of AI in medical education as a whole. High-quality medical education is the key to improving the level of medical care. Through our bibliometric analysis, research trends and hot topics in this field were identified, offering insights into how AI is transforming medical education globally.

Future Direction

AIME has witnessed a remarkable evolution from the initial enthusiasm phase to the current acceptance situation [2]. Although the potential of AI technologies is expected to revolutionize medical education, related ethical considerations and challenges should be carefully examined. One major concern is whether AI might diminish the competence of medical students by increasing their reliance on external tools. Additionally, there is apprehension about the possibility of AI completely replacing medical educators. Issues such as bias, hallucinations, and uncertainties have further contributed to hesitancy in the acceptance and practical application of AI in the medical field [28]. It was necessary for a balanced approach to ensure sustainable implementation and find practical ways to incorporate AI into curricula. As deeper investigation is conducted, AI will be an integral part of medical education, highlighting a journey of personal and professional growth alongside technological adoption.

Since the release of ChatGPT, AI-generated content (AIGC) has emerged as an innovative educational tool with significant potential. AIGC technologies have the capability to reshape pedagogical practices through various applications, such as virtual patient construction, automated question bank generation, and 3D anatomical simulations [19,29]. These technologies may also help address the uneven distribution of educational resources and facilitate the updating of outdated knowledge. Exploring the application of AIGC in medical education represents both a transformation and expansion of existing teaching models, as well as a forward-looking exploration of future cultivation patterns.

AIME introduces new demands for educational accreditation systems and training models. While traditional medical education accreditation emphasizes faculty strength, physical facilities, and curriculum design, AI enriches these standards by incorporating digital classes, digital resources, and dynamic monitoring. In the context of postgraduate education, AIME necessitates a re-evaluation of training duration, content, and assessment methods. It is crucial for policy makers and practitioners to explore how AI can be reasonably integrated into residents' learning, ensuring a balance that prevents over-reliance on technology and maintains the importance of clinical practical experience.

Limitations

This study has several limitations. First, the bibliometric analysis was conducted exclusively using the Web of Science Core Collection database. This singular focus may introduce bias into the results, as it does not account for data from other significant sources. Future research should incorporate additional databases, such as Scopus and Google Scholar, to provide a more comprehensive analysis. Second, while citation frequency is often used as a measure of academic influence, it does not necessarily equate to positive evaluations. Citations can also be made for criticism or rebuttal. Therefore, supplementing bibliometric analysis with content analysis would offer a more accurate reflection of the literature's true impact. Finally, bibliometric analysis inherently concentrates on published research, which may not capture the most current research trends and developments.

Conclusions

This study delves into the current landscape of AI applications in medical education, encompassing the geographical distribution of research efforts, recognition of pivotal researchers, identification of key research trends, and exploration of emerging domains. There is a burgeoning interest in AIME and an expanding comprehension of its potential impact. The United States has emerged as a leader in this field, with many institutions standing out as prolific organizations. As the demand for more personalized and effective medical education grows, there is a pressing need for large-scale, rigorously designed studies to provide empirical evidence of AI's effectiveness and safety.

Acknowledgments

This work is financially supported by grants from the Teaching and Research Project of the Second Clinical College of Tongji Medical College (TJXYJ2023016 and TJSZ2024016). During the preparation of this work, the authors used Acadwrite [30] to improve readability, grammar, and language style. Abstract

Background: Peers are known to influence the health behaviors and attitudes of adolescents, yet recruitment of these networks is challenging. Previous studies have used web-based respondent-driven sampling methods to recruit this population, yet none have experimentally investigated the impact of financial reimbursements.

Objective: This study aimed to (1) compare the effectiveness of two financial reimbursement strategies for recruiting adolescents and their peer networks and (2) explore factors associated with successfully recruiting peers.

Methods: A parallel-design randomized controlled trial was conducted in which participants (seeds) were randomly allocated to a fixed cash reimbursement (control) or scaled reimbursement (experimental) group as a strategy to be recruited into a web-based peer network study. Seeds aged 16 to 18 years were recruited through social media advertisements and an online student panel. They completed a web-based survey, which assessed eligibility and included questions about their friends (peers). Allocation occurred through a survey platform using a simple randomization method. In the fixed group, all participants in a peer network received AUD $5 (US $3.29); in the scaled group, all participants in a peer network received an additional AUD $5 (US $3.29) per peer who successfully completed the survey (up to AUD $30 each [US $19.72]). Participants and researchers were not blinded to intervention groups. The primary outcome was recruitment of peers to complete the web-based survey (proportion of nominated peers). The number of peers recruited was a secondary outcome. In secondary analyses, we identified peer-, relationship-, and seed-level variables associated with successfully recruiting peers.

Results: Of 463 seeds allocated to an intervention (scaled n=221 and fixed n=242), 319 (68.9%) had complete data for analysis (scaled n=157, 71% and fixed n=162, 67%). A total of 11.9% of seeds successfully referred peers (18.5% scaled group and 5.6% fixed group). Those in the scaled reimbursement intervention were 3.80 times more likely to successfully recruit their peers than those in the fixed reimbursement intervention (proportion ratio 3.80, 95% CI 1.78 - 8.09). Similarly, the average number of peers recruited differed by 0.19 (95% CI 0.11 - 0.28) per seed between the scaled and fixed intervention groups. Peer recruitment success was similar regardless of the gender, age, education level, and network size of seeds or the gender, age, and closeness of peers. Seeds recruited through social media were more likely to successfully recruit their nominated peers than those recruited through a research panel (proportion ratio 2.20, 95% CI 1.06 - 4.55).

Conclusions: Scaled reimbursements resulted in significantly greater recruitment of peers than fixed reimbursements; however, the total number of peers recruited was low. Greater-value incentives and stronger initial recruitment through social media may be needed to recruit large numbers of friend networks.

Introduction

Background

The period from adolescence to adulthood is a significant period of transition during which key health risk behaviors emerge. This time is characterized by experimentation with alcohol and other drugs and sexual behaviors and the onset of mental health issues [1]. Researchers have consistently highlighted the importance of the social context in understanding the development of both positive and negative adolescent health behaviors [2,3]. As emphasized in social network theory, an individual's social network influences their attitudes and behaviors [3]. Peer influence is thought to occur through different mechanisms, including homophilic social selection—the selection of friends based on shared behaviors or attitudes—and social influence—the convergence of similar behaviors and attitudes within a network over time [4]. The presence of peers can increase adolescent susceptibility to risky behaviors, including sexual risk taking and alcohol use [5]. There is extensive evidence of high similarity in health behaviors among networks of young people [4,6-8]. By studying adolescents in the context of their peer networks, health interventions can be designed that utilize these social networks.

To date, studies investigating adolescent social networks have examined health behaviors such as smoking, alcohol and substance use, physical activity, and dieting [4]. However, these studies have predominantly taken place in school settings, using an existing dataset (1994 - 2002) from the United States [4]. While it is convenient and useful to sample adolescents and their friendships within schools, this approach does not reach those disengaged from mainstream education or capture the transitory period after completing school. Less is known about the influence of nonschool peer relationships, particularly relevant in the current social media era where relationship boundaries are less defined. On social media, data are inherently organized in a network and provide an opportunity to study these processes at a larger scale [9].

Respondent-driven sampling (RDS) is a recruitment method typically used for hard-to-reach populations, where *seeds* (primary participants) are recruited and then asked to recruit several *peers* (secondary participants) within their network [10]. In recent years, there has been an increase in the use of web-based RDS (WebRDS), an online version of RDS that allows participants to be recruited without the need for face-to-face contact [11]. This method confers significant advantages over traditional RDS, including ease of access, reductions in time and cost, and respondent privacy and anonymity [10,12]. Equally, researchers have identified drawbacks of the web-based approach, including the increased potential for fraudulent and duplicate responses, lower quality data, and key differences in the population recruited (eg, higher socioeconomic status, fewer Aboriginal and Torres Strait Islander participants, and more participants who speak a language other than English at home) [10,12]. Despite these challenges, the nature of WebRDS provides an opportunity to study the interactions between and within networks in an online format. Existing studies have recruited seeds through social media ads (eg, Facebook), through online research panels, or through the researcher's networks and often include some researcher contact (ie, via phone or email) to confirm eligibility or motivation to engage [11]. Seeds typically recruit their peers by sharing a link via direct messaging (Facebook or WhatsApp) or email (see Helms et al [11] for a review). Since young people's lives largely exist online, and those engaging in higher risk behaviors are difficult to reach through traditional recruitment methods, RDS is well suited to recruiting young people and their peer networks.

While recruitment of peer networks can be challenging, one factor typically associated with successful recruitment is financial reimbursement, whereby seeds receive additional reimbursement for each peer they recruit [11]. In WebRDS studies conducted with adolescent and youth samples, seed reimbursement has ranged from US $4 to 30, with an additional incentive of US $4 to 20 per peer successfully recruited (maximum 2-5 referrals) [12-16]. Many studies have shown that offering incentives significantly improves individual participation in research [17]. However, to our knowledge, no studies to date have compared the effectiveness of different incentives for recruiting peers among adolescents and young people. One study investigated the best way to use internet-based RDS to recruit friends into an existing research panel within the general population and found that the combination of higher incentives for each peer recruited and the inclusion of a sign-up bonus (for joining the research panel) was effective at increasing the number of friends recruited [18]. The preference for incremental incentives (ie, an additional reimbursement for each peer) over a fixed amount (regardless of the number of peers recruited) was also emphasized in an adult sample of men who have sex with men [19]. Notably, this study reported that monetary incentives were more important for younger participants [19]. It remains unclear how varying financial reimbursements affect a young person's willingness to refer peers.

Demographic, relational, and methodological factors may also have an impact on recruitment success. While often seeds are more likely to recruit peers with similar demographic characteristics due to homophilic selection, this does not always explain recruitment differences [20]. Some studies within the general population have shown that productive seeds (in terms of recruitment or referrals) are more likely to be younger, female, more highly educated, and with a larger peer network [21]. Online recruitment and a smaller number of initial seeds have also been identified as key factors [11]. Further research within a youth sample is needed to understand the characteristics of successful seeds and their referred peers.

Rationale

We conducted a randomized controlled trial that aimed to determine the effectiveness of using WebRDS to recruit adolescent peer networks. Importantly, this study addresses a gap in the literature by investigating the impact of two different reimbursement structures on recruitment success—a scaled reimbursement (experimental) group, in which all participants in a peer network received an additional AUD $5 (US $3.29) for each peer who was successfully recruited, to a maximum

XSL•FO
RenderX

value of AUD $30 each (US $19.72); and a fixed reimbursement (control) group, in which all participants were reimbursed AUD $5 (US $3.29) for completing the survey. In the context of ongoing challenges with recruiting peer networks, this study provides valuable information to determine the feasibility and cost of monetary incentives in future WebRDS studies.

Aims and Research Questions

The primary aim was to compare the effectiveness of two financial reimbursement strategies for recruiting peer networks, explored through the following research questions:

1. Does a scaled group financial reimbursement for peer referral increase the proportion of an individual's peer network who complete the survey compared to having no peer referral reimbursement?
2. Does a scaled group financial reimbursement for peer referral increase the number of peers per participant who complete the survey compared to having no peer referral reimbursement?

We hypothesized that a scaled group financial reimbursement for peer referral would result in a significantly higher proportion of participants' peer networks and a significantly higher number of peers per participant who complete the survey, compared to a fixed reimbursement rate for individuals.

A secondary aim was to determine what demographic, relational, and methodological factors were associated with successfully recruiting peers. As this was an exploratory analysis, no hypotheses were specified.

Methods

Study Design

To test the effectiveness of reimbursements for peer referral in a web-based cross-sectional peer network study, a 2-group parallel randomized controlled trial (RCT) design was used. Participants were then randomly allocated in a 1:1 ratio to the scaled group reimbursement (experimental) or the fixed group reimbursement (control). The study design was informed by qualitative interviews with young people [22]. This RCT was not registered as the primary outcome (recruitment of friends) was not a direct health or medical outcome. The trial is reported in accordance with the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines for web-based RCTs [23]. Further details can be found in the published protocol [22]. A deviation from this published protocol occurred due to lack of success recruiting participants via social media. Recruitment was slower than anticipated, and a greater number of participants were recruited from Student Edge instead of social media (see Recruitment section).

Participants

In this study, seeds were defined as individuals recruited directly through online recruitment platforms who had the opportunity to recruit their friends. Peers were defined as friends nominated by seeds to complete the survey. Seeds were eligible if they were aged between 16 and 18 years and currently living in Australia; peers were eligible if they were aged 16 years and older and currently living in Australia. A peer network encompassed a seed and their peers.

Recruitment

Recruitment initially targeted participants through three platforms: Instagram or Facebook, Snapchat, and Student Edge panel (detailed further in protocol [22]). Instagram and Facebook were treated as a single recruitment source, given that they are managed through the same advertising account and owned by the parent company Meta. Student Edge is a web-based organization that hosts online surveys targeted at young people in high school and technical and further education in Australia [24]. The survey was made available to Student Edge members on their website, while recruitment through social media comprised paid advertisements. Advertisements in still and video format were designed to appeal to young people, and they only briefly mentioned the study topic and the reimbursement. Recruitment initially took place from March 21 to April 2, 2022. Initial recruitment through social media platforms posed challenges, with no participants successfully recruited through Snapchat and only small numbers recruited through Instagram or Facebook. As such, in early 2023, the advertisements were revised into video format with brighter colors and more dynamic text and hosted on TikTok as well as Instagram or Facebook, with the goal of increasing recruitment through social media platforms. TikTok is a free hosting platform for short-form videos, primarily accessed via smartphone. As was the case with Snapchat, TikTok advertising proved unsuccessful, while a small additional sample of young people was recruited through Instagram or Facebook with the revised advertisements. Following this, the remainder of the target sample was recruited through the Student Edge platform. Student Edge participants who completed the survey in 2022 were unable to complete it a second time. This second phase of recruitment occurred between March 15 and May 12, 2023. In total, across both years, active recruitment took 10 days more than anticipated.

Intervention

First, seed participants answered questions about their own behaviors and then were asked to specify their number of "close friends" (peers), up to a maximum of 10. Seed participants were then asked to answer questions about each peer, including initials and a chosen codename, and advised of the reimbursement amount depending on their reimbursement group. At the completion of the survey, seeds had the opportunity to either personalize a message or use a suggested message inviting their peers to participate in the survey. Seeds received this information in an email immediately after completing the survey and again after 72 hours. Seed participants were provided with a unique link via email to share with their peers, which included their record ID. Peers were automatically recruited in the same reimbursement group as their seed. When commencing the survey, peers were asked to provide their given codename and their initials. Peer networks were linked using the seed's ID number and peer initials and codenames. Linkage required a match of seed ID and at least one of the peer's codename or initials. Peers were also asked questions about their own peer network, yet were not able to refer them to complete the survey.

All seeds and peers in the fixed reimbursement group received AUD $5 (US $3.29) for completing the survey, with no additional reimbursement for peers in their network who successfully completed the survey. In the scaled reimbursement group, seeds and peers within a peer network received AUD $5 (US $3.29) for completing the survey, plus an additional AUD $5 (US $3.29) for each peer who successfully completed the survey, up to a maximum of AUD $30 (US $19.72) per participant (detailed in [22]). At the completion of the recruitment phase, participants were reimbursed with online gift vouchers sent via SMS text messaging through a third-party service. Due to the existing platform features, participants recruited through Student Edge received the first AUD $5 (US $3.29) through the Student Edge platform and any additional value in the form of gift vouchers. Participants could contact the research team via an online form if they encountered any issues with the survey.

Outcomes

The primary outcome was defined as completion of the survey by a peer (yes/no). We estimated the difference in the proportion of seeds' nominated peers who completed the survey in the scaled group reimbursement compared to the fixed individual reimbursement group. Survey completion was recorded if the peer clicked the final survey submission button. This outcome measure indicates the level of complete data about each seed's peer network.

The secondary outcome was the number of a seed's peers who completed the survey. We estimated the difference in the number of peers who completed the survey per seed in the scaled group reimbursement compared to the fixed individual reimbursement group. This outcome measure assesses whether the reimbursement model results in an overall higher number of participants.

Randomization

Randomization (generation and allocation) occurred automatically through the REDCap survey platform [25]. This involved a simple randomization based on the final digit (seconds) of the main survey page timestamp. Those who commenced the survey with an even number of seconds were allocated to the scaled (experimental) group, and those with an odd number of seconds were allocated to the fixed (control) group. The intervention was identical, differing only in the amount of reimbursement offered. Randomization occurred after consent, yet participants were only advised of which intervention group they had been allocated to at the end of the main survey section, prior to answering questions about their peers. Researchers were not blinded to allocation on the survey platform yet did not interact with participants directly. Participants were unaware of the other experimental condition.

Data Collection

Participants completed an online survey through REDCap. Participants could not proceed with the survey if they did not meet the age criteria. The survey captured potential factors associated with successfully recruiting peers. This included seed-level factors such as demographic characteristics, recruitment setting, and network size. Peer-level variables included perceived closeness, age, and gender. To increase engagement, seeds could choose a codename and avatar to identify themselves and a codename and avatar to identify each peer. The survey also covered topics such as social media and media related to sexual health (ie, pornography, sexting, and dating apps), mental health, sexual health, alcohol and other drug use, and COVID-19 vaccination, which will be reported on elsewhere.

Sample Size and Statistical Analysis

We determined the required sample size of seeds to detect a difference in the proportion of an individual's peer network that completed the survey between each intervention group. In line with previous research, we predicted that seeds would refer an average of three peers [26,27] and that approximately half of participants in the scaled group would successfully recruit at least one peer (as indicated by the peer's completion of the survey) [12,15]. Assuming the probability of recruiting each peer is binomial and the probability of recruiting no peers being $(1-p)^n$ (where n is the total number of peers and p is the probability of any one nomination being recruited), the probability of any nomination completing the survey was 0.2. We assumed some variation between friendship groups, including an intracluster correlation of 0.5 and a mean cluster size of 3, with a coefficient of variation for cluster size of 0.83. On this basis, 153 seeds were required per intervention group (total of 306 participants). This estimate allowed us to detect a difference of 1.4 peers per seed completing the survey between intervention groups, with 80% power. Conservatively, we estimated a total of 92 peers across both groups. We intended to recruit equal numbers from each of the three recruitment settings [22], yet due to the limited success with social media advertising outlined above, a greater number of participants were recruited through the Student Edge platform.

To assess balance in demographic characteristics between seeds in the two intervention groups, descriptive statistics were reported by intervention group in table form, reporting mean and SD for continuous data and number of participants (n) and percentages for categorical data.

The primary outcome was evaluated in a modified intention-to-treat analysis where participants were excluded from analysis if they did not answer questions about their peers, as this was considered an incomplete response. The exception to this was if participants were identified as having zero close friends. To assess the effect of the reimbursement intervention on the proportion of a seed's peers who completed the survey, we used generalized estimating equations (GEE) with a log link, binomial family, and exchangeable correlation structure to account for within friendship group correlation. In this analysis, peer nominees were the unit of analysis, grouped by their seed. Each peer could either be successfully recruited or not recruited (binary outcome). This analyzed seeds who nominated at least one peer.

To determine the effect of the intervention on the number of peers per participant who completed the survey (secondary outcome), we estimated the expected difference in counts between groups using predictions from a Poisson regression

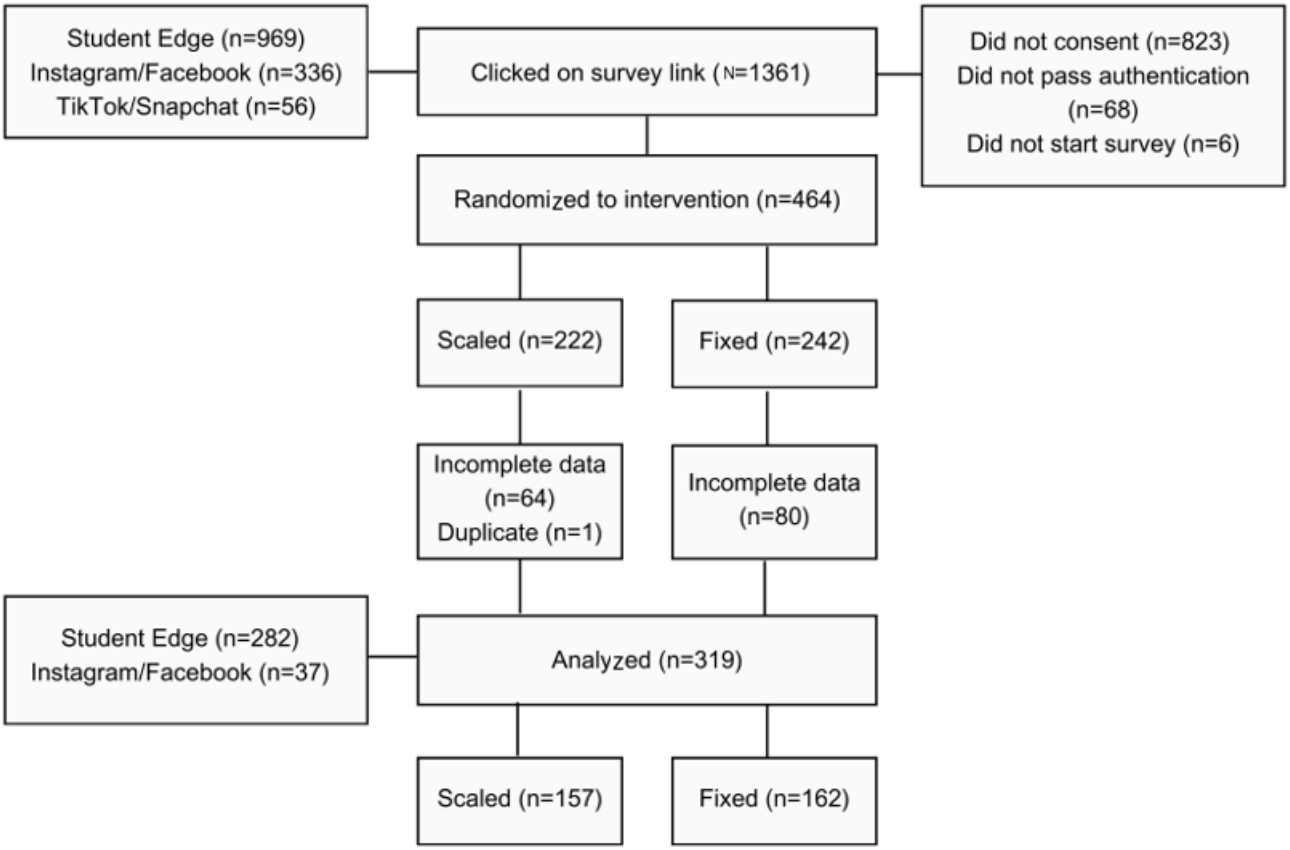
XSL•FO
RenderX

model. Poisson regression was chosen for analysis based on the distribution of the number of peers. In secondary analyses, we identified factors associated with successfully recruiting each peer, considering peer-, relationship-, and seed-level variables. Predictor selection was informed by prior studies investigating online survey recruitment [11,20,21]. We used bivariable log binomial GEE, where the outcome was the successful recruitment of a nominated peer. Potential predictors included recruitment setting, demographics, perceived closeness, and network size. Exchangeable correlation structures were used to account for clustering. In addition, we identified factors associated with recruiting a larger number of peers. We used bivariable Poisson regression models. Only seed-level variables were considered for the latter analysis. For simplicity in interpretation, demographic variables in secondary analyses were included in categorical form or converted into categories, and "I don't wish to say" responses were coded as missing.

Ethical Considerations

This study received approval from the Monash University Human Research Ethics Committee (project 23132). Participants were provided with information about the study in both video and written form. Informed consent was obtained through a series of checkboxes, indicating that participants had understood the information provided and were happy to take part and share their information for the study purpose. All data were deidentified for analysis. As described in detail earlier in the Intervention section, participants received between AUD $5 (US $3.29) and AUD $30 (US $19.72) in compensation. Details of relevant support services were provided at the completion of the survey.

Results



Overview

A total of 1361 seeds clicked on the survey link. Of these, a total of 897 did not provide consent, pass authentication (due to being identified as a duplicate), or commence the main survey following authentication (see Figure 1). The remaining 464 participants were randomized to the scaled intervention (n=222) or the fixed intervention (n=242). Of these, 144 only partially completed the survey, and 1 was identified as a duplicate. Thus, 319 participants were analyzed (n=157 in the scaled group and n=162 in the fixed group). Of those with partial completion, 127 stopped the survey post unblinding. Post-unblinding attrition was higher in the fixed group (n=74, 30.6%) than in the scaled group (n=53, 23.9%).

The demographic characteristics of seeds overall and separated by intervention group are shown in Table 1. Intervention groups were balanced in demographic characteristics. Overall, the sample had a mean age of 17.03 (SD 0.8) years, and 60.8% (n=194) identified as a woman. Most were from New South Wales (n=128, 40.1%) or Victoria (n=71, 22.3%), were currently studying (n=299, 66.2%), and spoke English at home (n=194, 60.8%). Most of the sample (n=282, 88.4%) were recruited through the Student Edge panel, and almost two-thirds (n=198, 62.1%) were recruited during the second wave of data collection in 2023, yet these characteristics were consistent across intervention groups. There were no missing data as participants were required to answer each question, with the option to select "I don't wish to say." Of variables included in secondary analyses, seed-level gender (n=4, 1.3%) and education level (n=9, 2.8%), and peer-level gender (n=7, 2.3%) and closeness (n=1, 0.5%), contained a small number of "I don't wish to say" responses, which were not included in the analysis.

Primary Analyses

Overview

Participants nominated an average of 3.47 (IQR 2 - 5, range 0 - 10) peers. Peers who were ineligible based on age were excluded (n=4). This left 298 (of 319) participants who had nominated at least one eligible peer. Of 1069 total peers nominated, 55 completed the survey, of which 48 (aged 16-21 y) were successfully linked with their seed. The remaining peers were unable to be linked via the ID number of their referring seed and peer initials or codename. In total, 11.9% (n=38) of seeds successfully recruited a peer (18.5% scaled and 5.6% fixed). Only participants in the scaled group recruited more than one peer (3.8% recruited two peers and 1.3% recruited three peers).

Primary Outcome

Those in the scaled reimbursement group were approximately 3.80 times more likely to successfully recruit their nominated peers than those in the fixed reimbursement group (proportion ratio 3.80, 95% CI 1.78 - 8.09).

Secondary Outcome

Results from the Poisson regression analysis showed an effect of intervention group on the number of peers recruited. Each participant in the scaled group recruited an average of 0.25 peers, while those in the fixed group recruited an average of 0.06 peers, resulting in a difference of 0.19 (95% CI 0.11 - 0.28) between groups.

Secondary Analyses

Primary Outcome

Results from exploratory bivariable log binomial GEE analyses can be found in Table 2. The proportion of nominated peers successfully recruited was similar regardless of the gender, age, education level, and network size of seeds, or the gender, age, and closeness of peers. On average, seeds recruited through Instagram or Facebook were approximately two times as likely to successfully recruit their nominated peers. However, the CI was wide, indicating the difference between seeds recruited through Instagram or Facebook and those recruited through Student Edge was relatively imprecise (proportion ratio 2.20, 95% CI 1.06 - 4.55).

Secondary Outcome

Results from bivariable Poisson regression analyses using seed-level variables can be found in Table 3. The number of nominated peers successfully recruited was similar regardless of the gender, age, education level, and network size of seeds. On average, seeds recruited through Instagram or Facebook were likely to recruit approximately two and a half times more peers. However, the wide CI indicates that the estimate of this difference between seeds recruited through Instagram or Facebook and those recruited through Student Edge was relatively imprecise (count ratio 2.54, 95% CI 1.32 - 4.88).

Reimbursement Costs

Excluding additional costs associated with using the student panel or advertising the study on social media, overall, the average reimbursement per participant was AUD $6.39 (US $4.20). Separated by group, average reimbursement per participant was AUD $5 (US $3.30) in the fixed intervention and AUD $7.60 (US $5.00) in the scaled condition. Specifically, an average seed received AUD $5.61 (US $3.68; fixed group AUD $5, US $3.29; scaled group AUD $6.24, US $4.10), and an average peer received AUD $11.56 (US $7.60; fixed group AUD $5, US $3.29; scaled group AUD $13.08, US $8.60).

Discussion

Principal Results

As predicted, a scaled reimbursement strategy that included additional incentives for each peer in a network was more effective than a fixed reimbursement strategy in recruiting adolescent peer networks. Those in the scaled reimbursement group recruited a greater proportion of nominated peers and recruited a greater average number of peers, compared to the fixed reimbursement group. Additionally, seeds recruited through Instagram and Facebook were more likely to recruit peers and each recruit a higher number of peers than those recruited through Student Edge. Other demographic and relational factors of seeds or peers were not found to have an impact on peer recruitment success.

Comparison With Prior Work

While we are not aware of any studies to date that have compared the relative effectiveness of different financial incentives for recruiting adolescent peers, our results are consistent with those from a WebRDS study with a sample of men who have sex with men, which identified a preference for scaled over fixed reimbursement for recruiting peers in their network [19]. More broadly, they also reflect the findings of a review that reported lower recruitment success among WebRDS studies with no monetary incentive [11]. The study by Schonlau et al [18] is also relevant, as it experimentally varied reimbursement amounts for each peer recruited (US $15 vs $30) and the inclusion of sign-up bonuses for peers (US $0 vs $20) to determine the most effective way to recruit adults into an internet panel. The combination of higher incentives and a sign-up bonus significantly increased peer recruitment compared to either one alone [18]. Despite key differences between that study and the current study, this highlights the importance of adequate monetary reimbursements for both seeds and peers. In our study, the additional cost for scaled reimbursements was AUD $2.60 (US $1.68) per participant, which is minimal when considered against the total expenses of conducting the study. Although peer recruitment in the scaled condition was improved compared to the fixed condition (18.5% vs 5.6%), overall peer recruitment in this study was low (11.9%). We conservatively estimated recruiting 92 peers, yet only obtained 55, not all of whom could be linked automatically to their seed due to ethical constraints. Despite allowing participants to recruit up to 10 peers each and incentives scaling up to the fifth peer for those in the scaled group, very few seeds recruited more than one

XSL•FO
RenderX

peer. Similar studies conducted with youth samples have reported peer recruitment rates by seeds of 61.8% and 66.7%, although these studies had fewer initial seeds, higher incentives, and capped referrals at three per participant. Helms et al [11] highlighted that more initial seeds tended to result in less successfully recruited peers, possibly due to fewer resources being allocated to engage seeds or seek out seeds with a larger social network. This may explain the low rates of recruitment in our study, where seeds were recruited online (via a research panel for students or social media advertisements) and informed of the study requirements at the beginning of the survey rather than directly through research staff. A drawback of offering monetary incentives to participants is the increased potential of recruiting those who are not inherently engaged with the topic and therefore not motivated to refer their peers [10]. Since most participants were recruited from an online panel of students (Student Edge) who are used to completing short surveys in exchange for small payments, reaching out to peers to complete the survey—without the guarantee that they would finish it and thus receive extra payment—might not have been very appealing. This may also explain the finding from exploratory analyses that seeds recruited through social media were more likely to recruit their peers than those recruited through Student Edge.

Although recruitment through Student Edge allowed us to quickly recruit the remainder of our sample, it did not result in effective peer recruitment. Few WebRDS studies in the literature have used research panels to recruit peers. Stein et al [28] sampled seeds from two internet participatory surveillance panels comprising a community of adult volunteers who regularly report on health symptoms. While those in the panel with the chance to win a gift card were more likely to recruit peers, overall, both samples successfully recruited peers [28]. Notably, participants from that study likely had different motivations for engaging in the research (ie, interest in assisting in health surveillance) than our participants recruited through the Student Edge panel.

Although social media recruitment was more effective for recruiting peers, no seeds were recruited through Snapchat or TikTok, and only a small number through Instagram and Facebook. Currently, WebRDS studies have largely recruited young people and adults using Facebook, and there are few examples of researchers using any platforms other than Meta (Instagram and Facebook) [12,14,29]. Considering the key differences between social media platforms, video content should be tailored to the platform. For instance, our advertisements comprised short videos with colorful and dynamic text, yet TikTok recruitment videos typically feature an individual (ie, health professional or peer) introducing the research [30]. There is no clear formula for success in social media recruitment. There are many factors that contribute to recruitment success, such as ad style and content, advertising budget, the account that distributes the ad, and interactions between users and the ads [31]. While many studies have reported on successful recruitment and made recommendations such as use of colorful images, pop-culture memes, or bold text, other studies attempting to duplicate these methods fall short [31-34].

Consistent with other WebRDS research, successful and nonsuccessful seeds did not differ in gender, age [35,36], or education level [36]. Although some general population studies have reported that successful seeds are more likely to be younger (19-24 y), our age range was quite narrow (16 - 18 y), suggesting that there may be no meaningful difference within these later teen years. Similarly, recruited peers did not differ in age, gender, or closeness of relationship with their referring seed, relative to nonrecruited peers. To our knowledge, no studies have directly examined this, although many have reported on homophily (the tendency for seeds to recruit peers with similar characteristics) present within samples [10]. Theoretically, it would be useful to understand relationship factors driving peers to engage in research (ie, if closeness of relationship was predictive of engagement, we could encourage seeds to only target these relationships). Nonetheless, most referred peers in our study had very (40.2%) or extremely (28.5%) close connections, suggesting that seeds are more inclined to recruit closer friends anyway. Overall, these findings emphasize the importance of focusing on financial reimbursement and recruitment source when attempting to recruit adolescent peer networks.

Strengths and Limitations

Our study compared the effectiveness of two reimbursement strategies in a WebRDS study with adolescents aged 16 to 18 years in an RCT. We experimented using social media advertisements and a student panel to recruit young people, expanding beyond school-based relationships. The use of two-factor authentication allowed us to largely address the issue of fraudulent responses commonly reported in the WebRDS literature [10]. Nonetheless, we encountered other methodological issues, namely around the effectiveness of recruitment sources and recruitment of peers. Issues recruiting young people through social media resulted in a delay in recruitment while advertisements were revised. As a result, recruitment took place in two phases over a 2-year period. This does not appear to have significantly impacted the nature of the sample, as there were no key demographic differences between the two recruitment phases. A further deviation from protocol occurred because we could not reach a sufficient sample size from each recruitment source, and most participants were recruited through a market research panel. We have previously found that participants recruited through survey panels demonstrated greater attrition in a longitudinal study compared to those recruited through social media [37]. Another study showed that a research panel was significantly more representative than a sample recruited via social media [38]. It is recommended that future studies invest sufficient resources into creating advertising content that is engaging and relevant for specific social media platforms.

We were able to recruit sufficient seeds into each group, but the peer sample was smaller than anticipated based on previous literature. While the sample was sufficient to answer the primary research question, showing that scaled incentives are more effective than fixed incentives for participant recruitment, the smaller than anticipated number of peers recruited in both study arms raises questions about whether further methodological adjustments are needed to maximize peer recruitment. We found

XSL•FO
RenderX

that those recruited through social media were more likely to refer peers than those recruited through the Student Edge panel. Further research is warranted to determine why that may be the case. As a result, the confidence intervals for exploratory analyses were wide. As such, results from secondary analyses should be interpreted with caution.

Notably, seven peers were unable to be linked with their seed using their codename, initials, and their seed's ID number, highlighting a limitation of relying on manual linking methods. Due to the higher attrition rate post unblinding in the fixed intervention group, it is possible that participants stopped the survey when advised of their intervention group, which may overestimate the effectiveness of the intervention.

Finally, this study was conducted with a specific population of adolescents obtained through convenience sampling; hence, the sample is not representative of the population, and findings may not translate to other age groups and samples. Compared to Australian census data, our sample included a higher proportion identifying as lesbian, gay, bisexual, transgender, queer, intersex, asexual, and other identities (34% vs 10%), speaking a language other than English at home (37% vs 23%), identifying as Aboriginal and Torres Strait Islander (3.2% vs 1.9%), and attending government schools (65% vs 59%) [39].

Conclusions

The present findings highlight important considerations for using WebRDS methodology to recruit adolescent peer networks. Specifically, adolescents are more motivated to recruit their peers to complete a survey when incentivized for each additional peer, although this does not guarantee a large peer network. Participants recruited through Instagram and Facebook were more likely to recruit their peers than those from the student panel, possibly due to different motivations for research involvement. However, peer networks remained small across both recruitment methods. Further research is warranted to understand how to best recruit adolescent peer networks outside of the school setting using financial reimbursements and different recruitment sources. With more time and cost-effective web-based approaches to recruiting peers, longitudinal studies can be conducted to investigate the influence of social networks on key health behaviors over time.

Abstract

Background: Participation and completion rates in questionnaire-based surveys are often low.

Objective: This study aims to assess participation and completion rates for a survey using paper and mixed mode questionnaires with patients recruited by research assistants in primary care waiting rooms.

Methods: This cluster-randomized study, conducted in 2023 in France, involved 974 patients from 39 practices randomized into 4 groups: “paper with incentive” (n=251), “paper without incentive” (n=368), “mixed mode with tablet” (n=187), and “mixed mode with QR code” (n=168). Analyses compared the combined paper group with the 2 mixed mode groups and the “paper with incentive” and “paper without incentive” groups. Logistic regressions were used to analyze participation and completion rates.

Results: Of the 974 patients recruited, 822 (women: 536/821, 65.3%; median age 52, IQR 37-68 years) agreed to participate (participation rate=84.4%), with no significant differences between groups. Overall, 806 patients (98.1%) answered all 48 questions. Completion rates were highest in the combined paper group (99.8%) compared to mixed mode groups (96.8% for paper or tablet, 93.3% for paper or QR code; P<.001). There was no significant difference in completion rates between the “paper with incentive” and “paper without incentive” groups (100% vs 99.7%).

Conclusions: Recruiting patients in waiting rooms with research assistants resulted in high participation and completion rates across all groups. Mixed mode options did not enhance participation or completion rates but may offer logistical advantages. Future research should explore incentives and mixed-mode strategies in diverse settings.

Introduction

Questionnaire-based surveys are valuable tools in a variety of research areas, including health care. For example, they allow data to be collected on patients’ experiences, opinions, and behaviors, which helps health care professionals to better understand their needs and improve the quality of care. Apart from the fact that they are generally inexpensive and take little time, 1 major advantage of questionnaire-based surveys lies in the flexibility they can offer in terms of the mode of administration (ie, face-to-face interviews, telephone interviews, and paper or web-based questionnaires completed at home or elsewhere).

However, to maintain a good level of representativeness and avoid selection bias, it is crucial to obtain high participation and completion rates. For surveys with postal, email, or telephone recruitment, several studies showed that participation rates (especially for web-based questionnaires) [1-4] and

XSL•FO
RenderX

completion rates (especially for paper questionnaires) [1,2] tended to be relatively low, whether the participants were individuals, patients, or physicians. Other studies showed that physicians' participation and completion rates were generally lower than those of the general population, probably mainly because of their workload in the practice and the increasing frequency with which they were asked to respond to surveys [5,6]. Although participation and completion rates are generally particularly low among physicians, these rates may also be suboptimal in studies with patients [7]. This means that the results of a large number of surveys conducted with patients may not be representative of the target population as a whole and may therefore lead to misleading conclusions.

Among the factors likely to influence participation and completion rates, the method chosen to collect data and the use of incentives are key elements [8-12]. Mixed modes, that is, the use of several methods in the same study, seem particularly useful for improving participation rates [9,13]. To our knowledge, QR codes have only been the subject of a few studies, focusing on specific populations and with limited sample sizes [11,14-16]. The usefulness of mixed modes including QR codes to improve participation and completion rates in a questionnaire has not yet been explored in general practice.

The aim of this study was to compare the participation and completion rates for a 48-question survey across 4 groups: a paper questionnaire group with incentive, a paper questionnaire group without incentive, and 2 mixed mode groups (ie, paper or web-based with tablet, and paper or web-based via QR code). Specifically, we analyzed differences between the combined paper group and the 2 mixed mode groups, as well as between the "paper with incentive" and "paper without incentive" groups. Patients were recruited into primary care waiting rooms by research assistants who were available to answer their questions if necessary. We hypothesized that both mixed mode options and incentives would improve participation and completion rates.

Methods

Design, Setting, and Study Population

This cluster-randomized study carried out in 2023 in the Rhône-Alpes region (France) was part of an environmental health project aimed at profiling different patterns of meat consumers in primary care, with a view to designing brief interventions to reduce meat consumption.

We used a professional register of primary care physicians from which we randomly extracted 200 physicians using computer-generated random numbers. Five research assistants contacted each randomly selected primary care physician by email until the required number of participating physicians (ie, n=40, Sample Size Determination section) was reached. If the primary care physician refused to participate or did not respond after 3 consecutive reminders, we contacted the next practice on the list.

The research assistants in this study were postgraduate residents in primary care medicine, conducting this work as part of their MD thesis. They had prior clinical experience, which enabled them to effectively interact with patients. To ensure consistency in patient recruitment and minimize variability, all research assistants underwent standardized training before the study began. This training included guidance on presenting the study, explaining the information sheet, and following ethical protocols. Although the study covered a large geographic area, requiring assistants to work autonomously during the recruitment phase, their approach was standardized and aligned with the study's protocols. Due to logistical constraints, the assistants were not randomly assigned to specific clinics.

We used simple randomization to allocate our sample of medical practices into 4 groups using computer-generated random numbers. Fifteen practices were randomized into the "paper without incentive" group, 10 into the "paper with incentive" group, 7 into the "paper or web-based with tablet" group (ie, patients were given the option of using either paper or a tablet provided by the researchers), and 7 into the "paper or web-based via QR code" group (ie, patients were given the option of using either paper or a QR code if they had their smartphones with them). We used computer-generated random numbers to determine the day of the week on which the study would be carried out in each practice.

Ethical Considerations

The study was approved by the Research Ethics Committee of the University College of General Practice, Claude Bernard Lyon 1 University (2023-01-03-01). The committee granted approval for the study protocol, including patient recruitment and data collection procedures. No additional ethical approvals were required beyond this institutional review. Participants were nonurgent, French-speaking, consecutive adult patients who were able to understand the study and provide written informed consent. They were informed about the study's objectives, data confidentiality, and their right to withdraw at any time without consequences. No personally identifiable information was collected, and all data were anonymized before analysis to ensure participant privacy and confidentiality. In line with the environmental health theme of the study, an origami paper containing a seed was provided as an unconditional incentive to all patients in the "paper with incentive" group, regardless of their willingness to complete the questionnaire. No financial compensation was offered to participants. No identifiable features of research participants are present in any images or supplementary materials included in the manuscript.

Data Collection

Participants were informed by a poster and recruited in the waiting room by a research assistant (20-25 patients per practice) between January 9, 2023, and June 16, 2023. The research assistant verified that the inclusion criteria were met and was available to answer any questions from the participants. The questionnaire (Multimedia Appendix 1) consisted of 48 questions: 4 sociodemographic questions (age, sex, postcode, and occupation), the French version of the feeling of the Sense of Coherence Scale (=17 questions), the French version of the Meat Attachment Questionnaire (=17 questions), and a questionnaire on intentionality adapted from previous studies (=10 questions) [17-19]. The questionnaire generally took about 10 minutes to complete. The paper and web-based questionnaires

XSL•FO
RenderX

were designed to be as similar as possible. In the 2 mixed modes (ie, with a tablet or QR code), we included an alert indicating that one or more questions were not answered. However, to be consistent with the paper version, participants did not have to answer all the questions before submitting the web-based questionnaire.

Statistical Analyses and Sample Size Determination

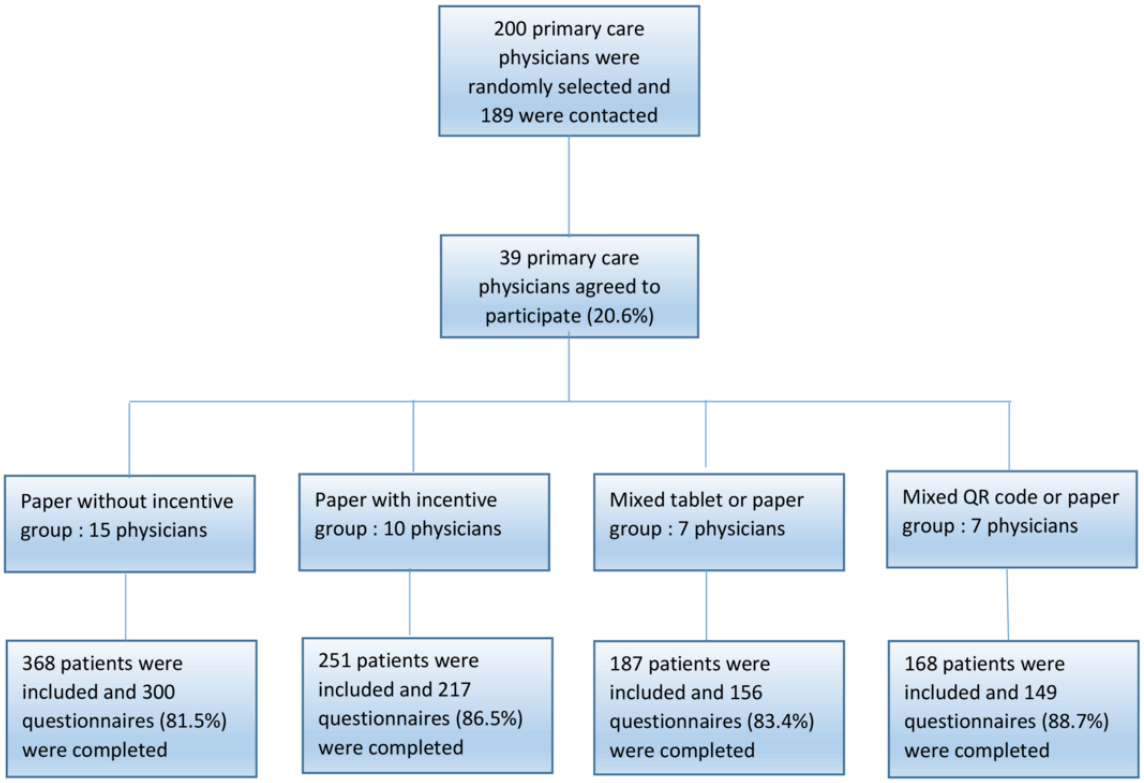
The sample size calculation was conducted to ensure sufficient power to detect differences in completion rates between groups. For simplification, the calculation was based on comparing proportions between 2 groups. Completion rates reported in the literature vary widely, ranging from 35% to 99%, depending on factors such as the study population, the theme of the study, and the format of the questionnaire [1,2,4]. We hypothesized that the completion rate in our study would be at least 80%, given the presence of a research assistant in the waiting room to assist participants if needed.

We calculated that 428 patients would be required in total to detect a 10-percentage-point difference between groups, with a power of 80% and a significance level of 5%, prior to accounting for clustering [20]. To adjust for clustering within practices, we assumed a conservative intraclass correlation coefficient of 0.02, based on findings from prior research in primary care settings [21], and an average cluster size of 20 patients per practice. This resulted in a design effect of 1.38, inflating the total adjusted sample size to 591 patients. With an average cluster size of 20 patients, this corresponded to 30 clusters in total. As 3 groups were compared, the sample size was increased to 40 clusters to ensure sufficient power.

We computed the proportion of patients who agreed to take part in the study (participation rate), the median number of questions answered with IQR, and the proportion of patients who answered all the questions (completion rate).

To assess whether the participation rate differed between groups, we used logistic regressions adjusted for intracluster correlation within practices. Comparisons were made between the combined paper group, the “paper or tablet” group, and the “paper or QR code” group as well as between the “paper with incentive” and “paper without incentive” groups. Multivariable analyses were not conducted for participation rates, as sociodemographic data were not collected for patients who refused to participate, in accordance with the ethics committee’s recommendations. This limitation prevented us from assessing variations in participation rates by sociodemographic factors.

For the completion rate, exact logistic regressions adjusted for intracluster correlation were used to address sparse data issues, where cells formed by the outcome and categorical predictor variables had few or no observations [22]. Comparisons were made for (1) the three groups based on initial randomization (ie, combined paper, “paper or tablet,” and “paper or QR code”); (2) groups based on the questionnaire format chosen (ie, paper, “web-based with tablet,” and “web-based with QR code”); (3) the “paper with incentive” and “paper without incentive” groups; and (4) sex and age group (<40, 40-60, and ≥60). Multivariable analyses were also carried out, adjusting for sex, age group, and occupation.



All analyses were carried out with STATA (version 15.1; StataCorp LLC).

Results

The flowchart for the study is shown in Figure 1. From the list of 200 primary care physicians, 189 were contacted, of whom 39 (20.6%) agreed to participate. The study included 15 primary care physicians in the “paper without incentive” group, 10 in the “paper with incentive” group, 7 in the “paper or web-based with tablet” group, and 7 in the “paper or web-based via QR code” group.

XSL•FO
RenderX

Figure 1. Flowchart of the study.

The study sample consisted of 974 consecutive nonurgent patients who were recruited from these 39 medical practices, representing an average of 25 patients per practice (min=16, max=37). There were 251 patients in the "paper with incentive" group, 368 in the "paper without incentive" group, 187 in the "mixed mode with tablet" group, and 168 in the "mixed mode with QR code" group (Figure 1). Of these patients, 822 agreed to participate in the study, resulting in a participation rate of 84.4% (woman: 536/821, 65.3%; median age of 52, IQR 37-68; min-max=20-93; aged less than 40 years=239/819, 29.2%; 40-60 years=267/819, 32.6%; and more than 60 years=313/819, 38.2%). The distribution of women and men and by age group was similar in all 4 groups (*P* value=0.91 for sex and 0.08 for age group). The majority of participants were retirees (264/822; 32.1%), employees (227/822, 27.6%), and executives or intellectual professionals (166/822, 20.2%). Smaller groups included those not currently active in the workforce (68/822, 8.3%), intermediate professions (41/822, 5%), workers (28/822, 3.4%), artisans or business owners (25/822, 3%), and farmers (3/822; 0.4%).

The main results of the study are presented in Tables 1 and 2. Table 1 shows the differences between the combined paper group, the "mixed mode with tablet" group, and the "mixed mode with QR code" group. The data are organized first by the initial randomization group and then by the chosen questionnaire format. Table 2 focuses on comparing the "paper with incentive" group to the "paper without incentive" group.

With incentives (n=217)	217/251 (86.5)	1.45 (0.84–2.49)		217/217 (100)	48 (48-48; 48-48)	1.74 (0-67.75)	

[a]The questionnaire consisted of 48 questions: 4 sociodemographic questions, the Sense of Coherence Scale (=17 questions), the Meat Attachment Questionnaire (=17 questions), and an intentionality questionnaire developed by our research team (=10 questions).

[b]OR: odds ratio.

[c]Univariable logistic regression (adjusted for intracluster correlation within practices).

[d]Univariable exact logistic regression (adjusted for intracluster correlation within practices).

[e]N/A: not applicable.

The participation rate ranged from 81.5% in the "paper without incentive" group to 88.7% in the "mixed mode with QR code" group, but the differences between the groups were not statistically significant. The incentive did not lead to a substantial increase in the participation rate. In this study, 51 patients (32.7%) in the "paper or web-based with tablet" group and 66 patients (44.3%) in the "paper or web-based via QR code" group preferred to complete the questionnaire using the paper version.

Overall, 806 patients (ie, 98.1% of patients) answered all 48 questions on the questionnaire. For the remaining 16 patients, the number of missing data ranged from 1 to 38. These patients were divided as follows: 1 patient belonged to the "paper without incentive" group, 5 to the "tablet" group, and 10 to the "QR code" group. The differences between groups based on the initial randomization and the questionnaire format chosen were small but statistically significant in both univariable and multivariable analyses. By contrast, the differences were not statistically significant for incentive, sex, and age group, but the number of patients with missing data was low.

Discussion

Main Findings

This study involved French primary care patients, recruited by research assistants and invited to complete a 48-question survey in the waiting room. We found that the participation rate was over 80% for all groups and that, when given the choice, a number of patients (n=117) preferred to complete the paper rather than the web-based questionnaire. We also found that the completion rate was 99.8% for the paper questionnaire and only slightly less for the web-based questionnaire. Finally, we found that the incentive had no influence on the participation rate or the number of questions answered.

Comparison With Existing Literature

Compared with other studies [12,23,24], we achieved excellent participation and completion rates in all groups (for participation rates, much higher than the 60% recommended in some publications [25]), despite a relatively lengthy self-administered questionnaire comprising 48 questions on a sensitive topic. The results of our study tend to reinforce the already known information that, among primary care patients, the response rate may not be affected by the length of the questionnaire, provided that the total duration is less than 15-20 minutes [26,27], which was the case in our study.

We found that the use of mixed options (paper or web-based), although intended to adapt more precisely to the preferences of each participant, did not appear to add value in terms of participation and completion rates. However, the web-based format (or mixed options) may be preferred for other reasons such as improved feasibility. Compared to paper questionnaires, the web-based format generally allows data to be obtained more cheaply (less printing, mailing, or typing costs), more quickly (real-time data tracking and less typing), and more accurately (the structured format minimizes incorrect entries and automatic data transfer minimizes data entry errors) [28]. Alongside the usual methods for collecting web-based data, QR codes have recently come into use in questionnaire surveys. They are simple and effective tools that are known to increase user engagement [29]. In a UK population-based maternity study, the inclusion of QR codes in the survey tended to lead to an increase in response rate, but this effect was limited and was probably also related to other factors (prior notification, short questionnaire, personalized study material, and additional reminder) [8]. In this English study, the initial response rate (30%) was considerably lower than ours.

The results of our study suggest that face-to-face recruitment with a research assistant achieves high participation and completion rates, providing support to participants. Previous studies have already highlighted that this strategy was associated with significantly higher participation rates [7,13,30]. Administering a face-to-face survey in the waiting room has the potential advantage of capturing patients' experiences when they are most accessible, with fewer competing demands than in other situations.

We found that, in the presence of a research assistant, neither the mixed mode, as discussed earlier, nor the unconditional nonmonetary incentive seemed to have any effect. Nonmonetary

XSL•FO
RenderX

incentives are recognized as important factors in improving the recruitment of participants to health-related surveys, with the impact being greater when the incentive is unconditional [31]. In our study, the high participation rate probably prevented us from observing a significant effect in the different methods tested. The presence of a research assistant seems to be the most powerful incentive, probably due to a desirability bias. This could be verified by carrying out the study using the incentives in the absence of a research assistant.

Significance and Recommendations for Future Research

This study makes a valuable contribution to the methodology of survey-based research in health care by underscoring the impact of recruitment strategies on both participation and completion rates. The notably high rates we observed across all groups suggest that face-to-face recruitment by a research assistant may be a critical factor for ensuring representativeness, especially in primary care settings where patient engagement can be challenging. Researchers conducting survey studies in similar environments may benefit from prioritizing in-person recruitment with trained personnel, as our findings indicate that this approach effectively mitigates common barriers to participation, such as lack of time. Additionally, while mixed mode survey options (including QR codes) did not significantly increase participation in this study, these tools still offer logistical advantages, such as ease of data collection, reduced error rates, and potential cost savings. For research teams looking to optimize both response rates and operational efficiency, mixed mode strategies may still be worthwhile. Future studies may benefit from investigating the impact of assistant-supported recruitment in different contexts or exploring alternative incentives, such as monetary incentives, that could further enhance response rates, particularly in larger or more geographically diverse samples.

Limitations

First, the results of our study cannot be generalized in all questionnaire-based surveys. Several studies showed that surveys carried out by recruiting participants by email, post, or telephone often led to mediocre participation rates for the web-based format [1-4] and mediocre completion rates for the paper format [1,2]. In this type of study, mixed mode options and incentives could be useful for positively influencing participation and completion rates. Second, selection bias is always possible in this type of survey, but in our opinion, it was reduced to a minimum by selecting physicians at random, including patients consecutively, and obtaining a high participation rate. In the context of our study, where patients were present in the waiting room, the selection biases usually described for electronic surveys in general practice do not apply [32]. Third, the study was carried out in only 1 region of France and only with primary care patients. The results obtained could have been different for other regions or countries, or for other study populations (physicians or patients visiting specialists). Finally, the use of simple randomization resulted in an unequal allocation of clusters across the study groups. While this does not affect the validity of randomization, it may have slightly reduced the power to detect differences between groups.

Conclusions

In conclusion, by recruiting patients in the waiting room with the help of a research assistant providing support to participants, we obtained a participation rate of over 80% in all groups. Neither the choice of response mode (ie, single or mixed, with or without a QR code) nor the use of incentives markedly influenced participation or completion rates. Future research would be useful to compare these rates with and without the presence of a research assistant in the waiting room to answer questions from participants. In terms of feasibility, the use of mixed options, including innovative methods such as QR codes, to offer participants the opportunity to choose, might be a relevant strategy, despite the results of our study showing no superiority in terms of participation and completion rates.

Acknowledgments

The authors of the study would like to sincerely thank all the primary care physicians and patients who collaborated on this project. The authors give special thanks to Amir Moussa for his involvement in this project. Patients or the public were not involved in the design, conduct, reporting, or dissemination plans of our research.

Abstract

Background: Sepsis is a life-threatening condition characterized by organ dysfunction resulting from dysregulated host response to infections. Approximately 48.9 million people worldwide are diagnosed with sepsis annually, leading to 11 million deaths and representing 19.7% of all global deaths. No specific, effective treatments for sepsis, which has a poor prognosis, are available.

Objective: The study aimed to systematically explore the association between genetically predicted modifiable risk factors and sepsis.

Methods: Univariable 2-sample Mendelian randomization (MR) analysis was performed to explore the association between 30 modifiable risk factors (12 lifestyle, 3 educational and psychological, and 15 metabolic factors) and sepsis. Heterogeneity was evaluated using the Cochran *Q* analysis. Sensitivity analyses were conducted using the MR-Egger regression intercept tests and leave-one-out analyses. Additionally, multivariable MR analyses were performed to adjust for genetic associations between the instruments and obesity.

Results: Genetically predicted smoking (odds ratio [OR] 1.20, 95% CI 1.06 - 1.36; *P*=.005), a higher number of cigarettes smoked daily (OR 1.70, 95% CI 1.29 - 2.23; *P*<.001), a higher overall health rating (OR 2.19, 95% CI 1.61 - 2.98; *P*<.001), BMI (OR 1.50, 95% CI 1.38 - 1.63; *P*<.001), waist circumference (OR 1.70, 95% CI 1.53 - 1.89; *P*<.001), whole body fat mass (OR 1.50, 95% CI 1.37 - 1.64; *P*<.001), trunk fat mass (OR 1.48, 95% CI 1.36 - 1.62; *P*<.001), arm fat mass (OR 1.57, 95% CI 1.43 - 1.71; *P*<.001), and leg fat mass (OR 1.69, 95% CI 1.51 - 1.90; *P*<.001) were associated with increased sepsis risk. However, light physical activity (OR 0.26, 95% CI 0.08 - 0.83; *P*=.03), higher education attainment (OR 0.52, 95% CI 0.40 - 0.67; *P*<.001), and high-density lipoprotein cholesterol (OR 0.91, 95% CI 0.84 - 0.98; *P*=.02) exhibited protective effects against sepsis. Using a multivariate analysis of obesity traits, the waist circumference (OR 2.16, 95% CI 1.18 - 3.96; *P*=.01) was an independent risk factor of sepsis.

Conclusions: Our study demonstrated that genetic predictors of lifestyle (smoking and physical activity), educational level, and metabolic factors (waist circumference and high-density lipoprotein cholesterol) exhibited a causal association with sepsis risk. Future research should further investigate the underlying mechanisms of these associations to inform more effective preventive strategies against sepsis.

Introduction

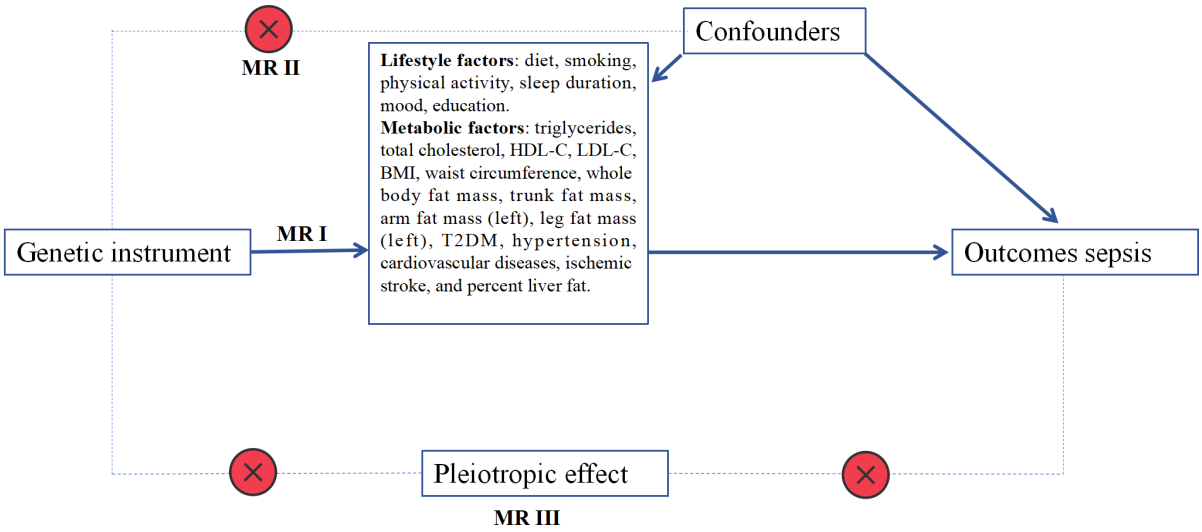
Sepsis is a life-threatening condition characterized by organ dysfunction resulting from a dysregulated host response to infections [1]. Epidemiological studies indicate that approximately 48.9 million people worldwide were diagnosed with sepsis annually, leading to 11 million deaths and representing 19.7% of all global deaths [2]. In China, sepsis affects 20% of patients in intensive care units, with a 90-day mortality rate of 35.5% [3]. The substantial epidemiological burden underscores the critical importance of sepsis as a public health issue [4]. Despite decades of research, current therapies remain limited to organ support and antimicrobial interventions, without any targeted treatment available [5-7]. These limited therapeutic options highlight the urgent need for shifting focus toward modifiable risk factors for prevention. The World Health Organization 2020 Sepsis Report specifically highlights vulnerable populations and health care seekers, while outlining future research directions and priorities in sepsis epidemiology. Although sepsis manifests diversely and can be life-threatening, it remains preventable and reversible [4].

Host risk factors for sepsis are multifaceted, encompassing extremes of age, immunosuppression, and comorbidities [8,9]. Emerging evidence suggests that socioeconomic determinants (eg, education level and occupation) and metabolic disorders (eg, obesity and diabetes) may influence susceptibility to sepsis [10-16]. However, the existing observational studies report inconsistent conclusions. For instance, although lower socioeconomic status is broadly linked to higher sepsis incidence [10,11], another study paradoxically found no association using adjusted models [17]. Metabolic comorbidities further illustrate this ambiguity. Although obesity is widely implicated in sepsis risk [18], some observational studies found that individuals with obesity showed a lower incidence and fatality than did those with underweight among patients with sepsis. These discrepancies may stem from methodological limitations in observational research, such as residual confounding and reverse causality. For instance, sepsis-induced systemic inflammation could transiently alter metabolic markers, obscuring true causal directions.

The core idea of Mendelian randomization (MR) is to use genetic variants (typically single-nucleotide polymorphisms [SNPs]) as instrumental variables to infer whether a potential causal association exists between an exposure and a health outcome. Recent MR studies have explored individual factors such as obesity, diabetes mellitus, and lipid profiles in patients with sepsis [19-23]; however, critical gaps persist. First, lifestyle factors (eg, smoking and diet) remain understudied despite their clinical relevance. Second, the existing MR analyses of sepsis predominantly examine isolated risk factors, neglecting potential synergies between socioeconomic, metabolic, and behavioral determinants [8,9,24-28]. Third, the interaction between modifiable factors and genetic predisposition remains unexplored, limiting personalized preventive strategies.

To address these gaps, we conducted a comprehensive 2-sample MR analysis of 30 modifiable factors spanning lifestyle, socioeconomic status, and metabolic health. This approach not only circumvents confounding biases but also systematically evaluates multifactorial contributions to sepsis pathogenesis. Our findings aimed to clarify controversial associations in prior literature and prioritize actionable targets for intervention.

Methods



MR Design

MR is based on three key assumptions: genetic variants are (1) linked to risk factors, (2) independent of confounding factors, and (3) influence outcomes solely through risk factors (Figure 1). A total of 30 prominent modifiable risk factors were included and grouped into lifestyle and metabolic factors. This study adhered to the Strengthening the Reporting of Observational Studies in Epidemiology using Mendelian Randomization (STROBE-MR) guidelines. Initially, we screened instrumental variables for MR analysis using lifestyle factors and metabolic comorbidities as “exposures” and sepsis as “outcomes.” Subsequently, we conducted a reverse MR analysis, with sepsis as the “exposure” and lifestyle and metabolic factors as the “outcomes.”

Data Sources

Genome-wide association study (GWAS) data of sepsis were obtained from the OpenGWAS database, a dataset published by the UK Biobank in 2021, comprising a sample of 486,484 participants from European populations. Additionally, we used 30 parameters from the Integrative Epidemiology Unit OpenGWAS Project as our lifestyle, education and psychology, and metabolic traits. Data are listed in Table 1.

Selection of Genetic Variants

In this MR analysis, instrumental variables were used to investigate the association between potentially modifiable risk factors and sepsis. These risk traits were categorized into three main parts: (1) lifestyle factors encompassing 4 dietary traits, 3 smoking-related traits, 2 pertaining to physical activity, and 3 regarding sleep habits; (2) educational and psychological factors, including physical and mental well-being and education level; and (3) metabolic factors comprising 4 traits linked to blood lipid parameters, 6 associated with obesity traits, and 5 related to metabolic comorbidities. SNPs were selected as independent genetic predictors based on the following criteria: first, a genome-wide significance threshold of $P<5\times10^{-8}$ was applied. If there were insufficient significant SNPs under this threshold, a threshold of $P<1\times10^{-5}$ was used. Second, the clump function was used to test for linkage disequilibrium with a threshold of $R^2<0.001$ and a distance of 10,000 kb. Third, SNPs related to outcomes were excluded using the linkage disequilibrium link database to avoid confounding factors. Fourth, SNPs with an *F* statistic <10 were excluded to avoid bias from weak instruments. The proportion of exposure variance explained by genetic instruments (R^2) was calculated to quantify the strength of the genetic tools. The *F* statistic for each SNP was calculated to assess the strength of the selected instruments.

Ethical Considerations

This study is a secondary analysis of publicly available GWAS summary statistics obtained from the Integrative Epidemiology Unit OpenGWAS database [29] as shown in Table 1. These datasets consist of deidentified data from participant studies approved by an ethics committee concerning human experimentation, comply with the ethical principles of the Declaration of Helsinki, and were approved by the Ethics Committee of the First Affiliated Hospital of Zhejiang University (2025B-1097).

Statistical Analysis

In this study, all analyses were performed using the *TwoSampleMR* package in R (version 4.2.1; R Foundation for Statistical Computing). The random-effects inverse variance weighted (IVW) method was used as the primary outcome; this method assumed that all instrumental variables (SNPs) were valid instruments (ie, satisfying the exclusion restriction assumption) and estimated the causal effect between exposure and outcome by calculating the weighted regression slope of the SNP-outcome associations on the SNP-exposure associations. Although the IVW approach offered the highest statistical power among MR methods, it was sensitive to directional pleiotropy, which might have biased causal estimates if invalid SNPs were present. Therefore, the MR-Egger and weighted median methods were used to refine the IVW estimation. These alternative methods offered more dependable estimates across a broader spectrum of scenarios, albeit with a trade-off of reduced efficiency, resulting in wider CIs. MR-Egger permitted all genetic variants to exhibit pleiotropy; however, pleiotropy must be independent of variant exposure associations. Meanwhile, the weighted median method allowed the incorporation of potentially invalid instrumental variables under the assumption that at least half of the instruments used in the MR analysis were valid. We performed reverse MR analyses by swapping the roles of the original exposure and outcome variables; IVW analysis tests were conducted using the same set of SNPs.

Heterogeneity was evaluated using the Cochran *Q* analysis. Sensitivity analyses were conducted using MR-Egger regression intercept tests and leave-one-out analyses, with statistical significance set at $P<.05$. Additionally, multivariable MR analyses were performed to adjust for the genetic association of the instruments with the BMI.

Results

Baseline Characteristics

We assessed 30 potentially modifiable risk factors to investigate their causal associations with sepsis and categorized them into 3 groups (Table 1): lifestyle, educational and psychological, and metabolic factors. The number of SNPs ranged between 7,892,037 and 15,533,528 (Table 1). Notably, the *F* statistics for all considered traits exceeded 10, indicating the absence of a potential weak instrumental bias.

Lifestyle Factors

Regarding the investigation of lifestyle factors, our findings revealed that genetically predicted smoking initiation (odds ratio [OR] 1.20, 95% CI 1.06 - 1.36; $P=.005$) and a higher number of cigarettes smoked daily (OR 1.70, 95% CI 1.29 - 2.23; $P<.001$) were associated with an increased risk of sepsis. Conversely, genetically predicted light physical activity (OR 0.26, 95% CI 0.08 - 0.83; $P=.02$) was associated with a decreased risk of sepsis. These results remained consistent across the random-effects IVW and weighted median analyses (Table 2). Notably, no significant causal association was detected between genetically predicted alcohol, coffee, milk, and sweet consumptions; age at smoking; moderate to vigorous physical activity; insomnia; daytime napping; sleep duration; and sepsis (all $P>.05$). We did not find statistically significant results when investigating reverse causality validation ($P>.05$).

[a]SNP: single-nucleotide polymorphism.

[b]IVW: inverse variance weighted.

[c]OR: odds ratio.

[d]WM: weighted median.

[e]HDL - c: high - density lipoprotein cholesterol.

[f]LDL - c: low-density lipoprotein cholesterol.

[g]T2DM: type 2 diabetes mellitus.

Educational and Psychological Factors

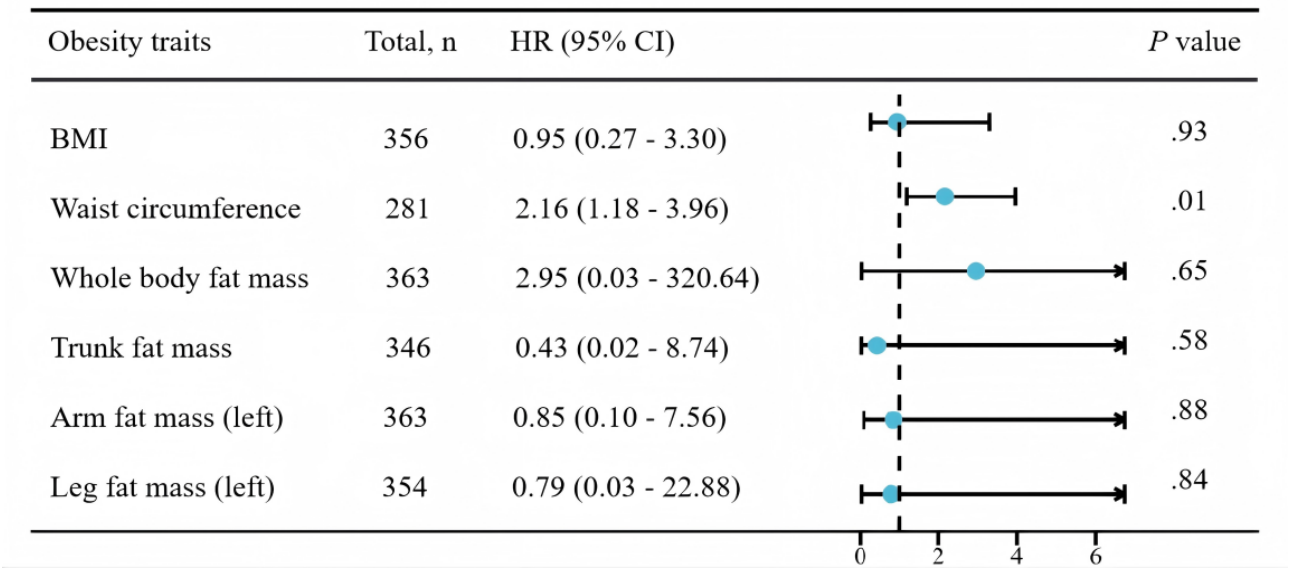
Considering the investigation of educational and psychological factors, we found that genetically predicted higher overall health rating (OR 2.19, 95% CI 1.61 - 2.98; *P*<.001) was associated with an increased risk of sepsis (Table 2). Conversely, genetically predicted higher education attainment (individuals with a college or university degree; OR 0.52, 95% CI 0.40 - 0.67; *P*<.001) was associated with decreased risk of sepsis. Notably, no significant causal association was found between genetically driven unhealthy emotions and sepsis (*P*=.40). We did not find statistically significant results when investigating reverse causality validation (*P*>.05).

Metabolic Factors

We found an increased risk of sepsis associated with genetically predicted obesity. All fat mass–related traits were significantly associated with an increased risk of sepsis. The odds of developing sepsis increased with every 1 - SD increment in the BMI (OR 1.50, 95% CI 1.38 - 1.63; *P*<.001), waist circumference (OR 1.70, 95% CI 1.53 - 1.89; *P*<.001), whole body fat mass (OR 1.50, 95% CI 1.37 - 1.64; *P*<.001), trunk fat mass (OR 1.48, 95% CI 1.36 - 1.62; *P*<.001), arm fat mass (left; OR 1.57, 95% CI 1.43 - 1.71; *P*<.001), and leg fat mass (left; OR 1.69, 95% CI 1.51 - 1.90; *P*<.001; Table 2). However, high-density lipoprotein cholesterol (HDL-C; OR 0.91, 95% CI 0.84 - 0.98; *P*=.02) exhibited a protective effect against sepsis. In contrast, no significant causal association was observed between genetically predicted triglycerides, total cholesterol, low-density lipoprotein cholesterol, type 2 diabetes mellitus, hypertension, cardiovascular diseases, ischemic stroke, percent liver fat, and sepsis (all *P*>.05).

Reverse MR Analysis

To validate the reliability of the exposure-outcome causal direction, we performed reverse MR analysis by swapping the roles of the original exposure and outcome variables, and IVW analysis tests were conducted using the same set of SNPs. We did not find statistically significant results when investigating reverse causality validation (*P*>.05).



Multivariable MR Analysis

Considering the mutual influence of various obesity indicators, we conducted a multivariate MR analysis of BMI, waist

XSL•FO
RenderX

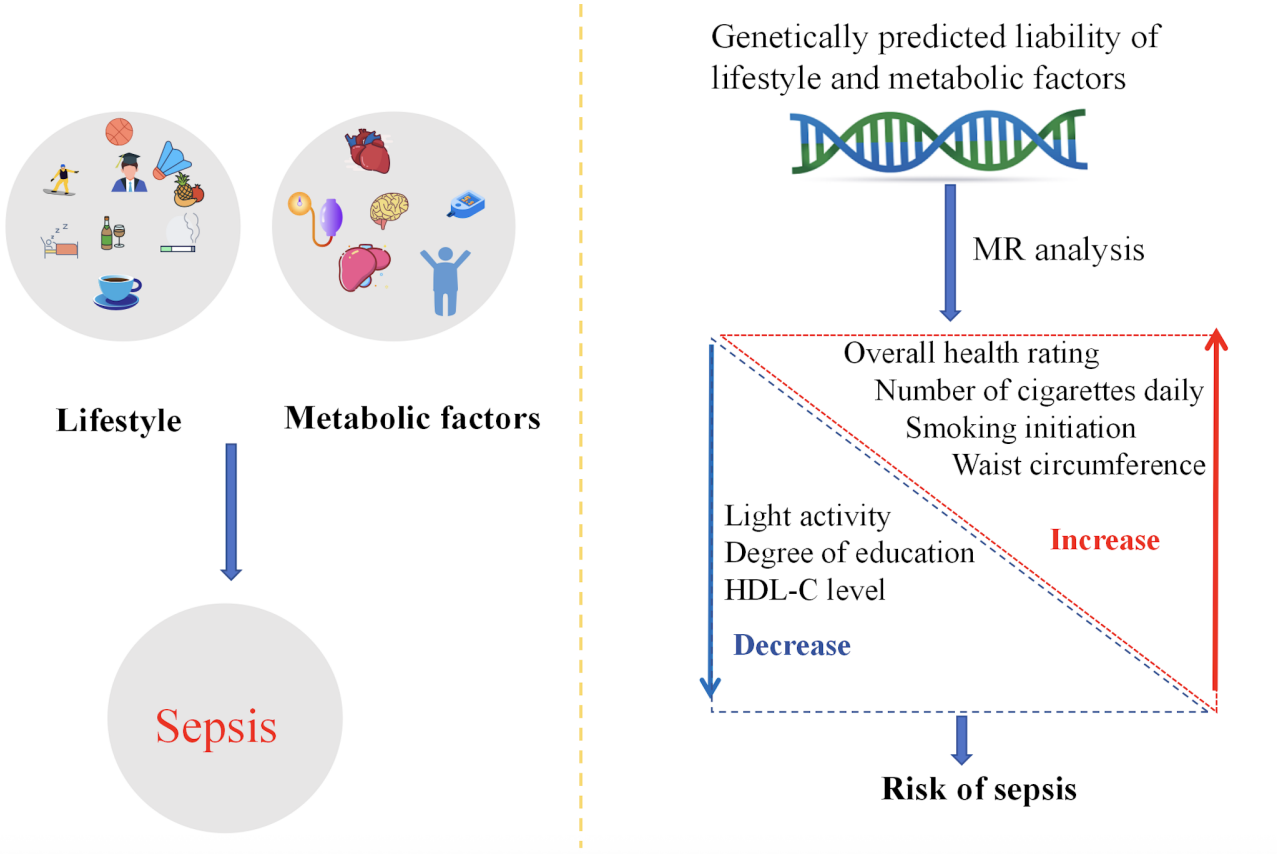
circumference, whole body fat mass, trunk fat mass, arm fat mass (left), and leg fat mass (left). The results revealed that the waist circumference (OR 2.16, 95% CI 1.18 - 3.96; *P*=.01) was an independent risk factor of sepsis (Figure 2).

Figure 2. The association between obesity traits (BMI, waist circumference, whole body fat mass, trunk fat mass, arm fat mass, and leg fat mass) and sepsis by multivariable Mendelian randomization. Odds ratios (ORs) represent the associations with sepsis.

Heterogeneity and Pleiotropy Test

Although some results displayed heterogeneity based on the Cochran *Q* test (*P*>.05), the use of random-effects IVW as the primary outcome rendered this heterogeneity acceptable and did not undermine the validity of the MR estimates in this study (Table 2). In addition, the results were subjected to pleiotropy testing, demonstrating that those with significance did not exhibit pleiotropy. Therefore, assuming the absence of horizontal pleiotropy in this study is reasonable.

Sensitivity Analysis



We conducted a sensitivity analysis using the MR-Egger intercept tests and the leave-one-out method. MR-Egger intercept tests showed no evidence of pleiotropy (Table 2). Using leave-one-out analysis, it is evident that nearly all lines align on one side of the y-axis, with minimal deviation beyond the axis. This consistency indicated the robustness of the results. The stable results shown in the MR visualization further corroborate the reliability of our study findings.

Discussion

In this bidirectional MR study, we investigated the association of lifestyle, educational and psychological, and metabolic factors with the risk of sepsis. Genetic variants such as smoking initiation, smoking frequency, and waist circumference were associated with an increased risk of sepsis, whereas light physical activity, higher education, and high levels of HDL-c were causally associated with a lower risk of sepsis (Figure 3).

XSL•FO
RenderX

Figure 3. Association of modifiable lifestyle and metabolic factors with the risk of developing sepsis. HDL-C: high-density lipoprotein cholesterol; MR: Mendelian randomization.

Genetic variants such as smoking initiation, smoking frequency, and waist circumference were associated with an increased risk of sepsis, whereas light physical activity, higher education, and high levels of HDL-c were causally associated with a lower risk of sepsis.

Owing to the modifiable nature of lifestyle, the impact of lifestyle on diseases with high mortality, such as sepsis, has received increasing attention. Numerous observational studies have described an association between smoking, alcohol consumption, and the risk of various infectious diseases [22,30-35]. However, establishing a causal link between lifestyle and sepsis remains challenging. This study aimed to explore the potential causal relationships between lifestyle factors and sepsis. The results showed that smoking initiation and a high frequency of smoking were associated with an increased risk of sepsis. Previous immunologic experiments reported that smoking has been associated with impaired phagocytic function and cytokine expression of T lymphocytes and macrophages in the respiratory tract or peripheral blood [36-38]. These studies collectively underscore the detrimental impact of smoking on the immune system. These findings provide a better understanding of the role of smoking in patients with sepsis. Therefore, healthy lifestyle modification is a preventive measure against sepsis; individuals should be advised to reduce smoking to reduce the risk of developing sepsis.

Physical exercise is a planned, purposeful action to maintain a healthy lifestyle and improve physical fitness (World Health Organization, 2010) [39]. Furthermore, the evidence suggests that physical exercise affects multiple organ systems under various conditions [40]. It has been found that inadequate exercise is associated with a doubled risk of sepsis-related mortality [40]. Given that the incidence of sepsis is increasing, these results suggest that exercising could be immediately effective in reducing disease incidence. Currently, no MR analyses of the association between physical activity and sepsis are available. Our analysis confirmed that light physical activity is associated with a lower risk of sepsis.

The socioeconomic status affects health through environmental exposure, health behaviors, and lifestyle and has been shown to be positively related to health [10,41]. Education stands as the most potent indicator of socioeconomic status, exerting influence over lifestyle choices and access to health resources [42]. Observational studies suggest an inverse association between educational attainment and sepsis risk. Wang et al [43] reported significantly higher sepsis risk among individuals with lower education (hazard ratio 1.88, 95% CI 1.54 - 2.29), though without controlling for comorbidities and other confounders. Another cohort study adjusting for socioeconomic factors still demonstrated a higher risk of sepsis-related intensive care unit admission in moderately educated versus highly educated individuals [44]. It should be noted that these observational findings may be influenced by residual confounding and do not establish causality. This study found a negative correlation between genetically predicted educational levels and sepsis risk. Higher education may reduce sepsis risk through multiple pathways, including enhanced health literacy (eg, earlier recognition of infections), greater access to health care resources, and adoption of healthier behaviors (eg, smoking

XSL•FO
RenderX

cessation and improved diet). These mechanisms could collectively mitigate exposure to risk factors and improve timely medical intervention.

In recent years, an increasing number of studies have focused on the impact of metabolic factors such as blood glucose, blood lipids, and obesity on various infectious diseases [45-49]. Previous studies have reported that high HDL-c levels are significantly associated with reduced sepsis risk and other sepsis-related outcomes [50,51]. Extremely low serum HDL-c levels (≤20 mg/dL) are associated with an increased risk of death, sepsis, and malignancy [52]. However, observational clinical and epidemiologic studies have potential problems such as confounding, reverse causation, and unaccounted comorbidities. An MR study found that lower HDL-c levels were significantly associated with an increased risk of sepsis and related outcomes in infected patients [53]. This is consistent with our findings. Our study found a genetic relationship between high HDL-c levels and low risk of sepsis. HDL-c might exert protective effects against sepsis via its anti-inflammatory and antioxidant properties, as well as its role in modulating endothelial function and neutralizing bacterial endotoxins [54-56].

In observational studies on the general population, a higher BMI has been associated with an increased incidence of mortality from bloodstream infections and sepsis [57-59]. This finding is confirmed in this study. We also found that BMI, arm fat mass, leg fat mass, whole body fat mass, waist circumference, and trunk fat mass were significantly associated with sepsis. However, using the multivariate factor analysis, only increased waist circumference was an independent risk factor for sepsis, which might be because other factors included the causes of increased waist circumference, suggesting that these factors might influence sepsis risk as a consequence of shared risk factor profiles.

This study had several limitations. First, the population limited to the European ancestry hampered the generalization of the findings to individuals of other ancestries, as genetic and environmental factors influencing sepsis risk may vary across ethnic groups (eg, differences in inflammatory responses or health care access). Further studies are required to assess the modifiable risk of sepsis in other races. Second, as with all MR studies, pleiotropy in an MR setting is challenging. Additionally, gene-environment interactions (eg, how lifestyle modifies genetic risk) and potential measurement errors in exposure variables were not fully addressed, which might have introduced bias. We performed various sensitivity analyses that made different assumptions regarding the underlying nature of pleiotropy. Most tests showed stable results. Future studies should incorporate multi-ancestry cohorts and explore gene-environment interplay to strengthen causal inference.

In conclusion, our combined MR analysis supports the causal roles of smoking, educational level, HDL-c level, physical condition, obesity, and physical activity in patients with sepsis. The findings of this study highlight actionable targets for sepsis prevention. For instance, smoking cessation programs, public health initiatives to promote physical activity, and interventions to improve HDL-c levels (eg, dietary modifications or pharmacotherapy) could be integrated into personalized preventive strategies for managing high-risk populations. Furthermore, educational campaigns targeting health literacy and early symptom recognition might reduce delays in seeking care, particularly among socioeconomically disadvantaged groups. Future research should prioritize replication in diverse populations, mechanistic studies to elucidate pathways (eg, HDL-c's immunomodulatory effects), and translational interventions targeting high-risk subgroups.

Acknowledgments

The authors would like to acknowledge the participants and investigators of the Integrative Epidemiology Unit OpenGWAS project used in this paper.

Data Availability

Publicly available datasets were analyzed in this Mendelian randomization study. Genome-wide association study summary-level datasets were downloaded from the Integrative Epidemiology Unit OpenGWAS Project [29]. Full details are provided in Table 1.

Abstract

Background: Medication adherence, or how patients take their medication as prescribed, is suboptimal worldwide. Improving medication-taking habit might be an effective way to improve medication adherence. However, habit is difficult to quantify, and conventional habit metrics are self-reported, with recognized limitations. Recently, several objective habit metrics have been proposed, based on objective medication-taking data.

Objective: We aim to explore the correlation between objective habit metrics and objective medication adherence on a large dataset.

Methods: The Medication Event Monitoring System Adherence Knowledge Center, a database of anonymized electronic medication intake data from ambulant participants enrolled in past clinical studies, was used as the data source. Electronic medication intake data from participants following a once-daily regimen and monitored for 14 days or more were used. Further, two objective habit metrics were computed from each participant's medication intake history: (1) SD of the hour of intake, representing daily variability in the timing of medication intakes, and (2) weekly cross-correlation, representing weekly consistency in the timing of medication intakes. The implementation component of medication adherence was quantified using (1) the proportion of doses taken and (2) the proportion of correct days.

Results: A total of 15,818 participants met the criteria. These participants took part in 108 clinical studies mainly focused on treatments for hypertension (n=4737, 30%) and osteoporosis (n=3353, 21%). The SD of the hour of intake was significantly negatively correlated with the 2 objective adherence metrics: proportion of correct days (Spearman correlation coefficient, ρ_S=–0.62, P<.001) and proportion of doses taken (ρ_S=–0.09, P<.001). The weekly cross-correlation was significantly positively correlated with the 2 objective adherence metrics: proportion of correct days (ρ_S=0.55, P<.001) and proportion of doses taken (ρ_S=0.32, P<.001). A lower daily or weekly variability in the timing of medication intakes is thus associated with better medication adherence. However, no variability is not the norm, as only 3.6% of participants have 95% of their intakes in a 1-hour window. Among the numerous factors influencing medication adherence, habit strength is an important one as it explains over 30% of the variance in medication adherence.

Conclusions: Objective habit metrics are correlated to objective medication adherence. Such objective habit metrics can be used to monitor patients and identify those who may benefit from habit-building support.

Introduction

Medication adherence is "the process by which patients take their medication as prescribed" [1]. It comprises 3 components: initiation of the treatment, correct implementation of the prescribed regimen, and persistence to the treatment [1]. Poor medication adherence is a global public health issue [2,3] and has important negative consequences on the personal level [3-6], but also at the societal level [3-5]. Interventions aiming at improving medication adherence are abundant in the literature, but few have been shown to be effective across a population [5,6]. Most medication adherence interventions have focused on structural factors outside of the individual (simplification of the regimen, refill reminders, etc) or on behavior change interventions that target reflective or deliberative factors, such as patient education [7]. As at least half of our daily behaviors are nonreflective, but rather habitual [8], interventions that target these habitual processes may be more successful than education or persuasion-based interventions.

Habits are defined as automatic behaviors responding to recurring environmental cues [9]. As stronger medication-taking habit has been shown to be associated with better medication adherence [4,10-13], in particular its implementation component, some successful interventions have focused on improving habit [5,14]. However, medication-taking habit, and habit in general, is difficult to quantify [8]. Conventional habit metrics are self-reported [12], with an important example being the Self-Reported Habit Index [15], a 12-item questionnaire. Another example is the Self-Reported Behavioral Automaticity Index [16], a 4-item subset of the Self-Reported Habit Index. These and other self-reported indices endure common limitations associated with self-reported metrics, such as social desirability bias and poor patient recall [13].

Medication-taking habit can also be assessed using objective medication-taking data [17]. Such data is collected using smart medication packages, which can take several forms: an electronic cap fitted on a medication bottle [17], an inhaler with a chip embedded [13], a blister that detects when a pill is expressed out of a cavity, etc. The common feature of smart medication packages is that they passively timestamp each time a patient accesses their medication, thus providing objective data on when a patient takes their medication. This detailed information can be used to derive habit metrics quantifying the consistency of medication intake behavior over time [11,17]—the validity of which rests on the fact that habits are context-stable responses to conditioned cues. Such habit metrics are objective and do not endure the limitations associated with self-reported habit.

Day-to-day consistency of the timing of medication intake is frequently used as an objective habit metric. It has been operationalized as the variance of the hour of intake [17], its SD [13,18], or the proportion of medication intakes occurring in a fixed-size window, for instance, 2 [4,19,20], 3 [21,22], or 4 hours [23].

These day-to-day consistency measures will penalize someone for having different routines on different days of the week (for instance, systematically taking their medication at 6 PM on weekdays and 10 PM on weekends). However, this feature might not be desirable if the cue for medication-taking (eg, breakfast) is the same throughout the week, reflecting a good medication-taking habit. To overcome this limitation, Phillips et al [11] recently introduced another metric, called the weekly cross-correlation, based on the weekly consistency of intake timing. In this metric, the medication intake timing of each day of a given week is compared to the corresponding day of the next week.

Recently also, Hoo et al [13] introduced a "pragmatic habit index" empirically defined as the product of 2 variables: stability, measured as the SD of the hour of intake and frequency, measured as the proportion of prescribed doses taken. Introducing behavioral frequency in a habit index has been criticized [16], as it incorporates the dependent variable of interest (behavior frequency) in the predictors.

In a recent study on 79 patients with type 2 diabetes, objective habit metrics were found to correlate with objective medication adherence [11]. The goal of this paper is to reinvestigate this correlation on a 200-fold larger dataset covering multiple pathologies, introduced in the next section.

The main hypothesis is that a more consistent medication-taking habit is correlated to better medication adherence.

Methods

Data

This study was a retrospective cohort study. AARDEX Group's database, the Medication Event Monitoring System (MEMS; AARDEX Group) Adherence Knowledge Center was used as the data source. This database contains anonymized electronic medication adherence data from ambulant participants enrolled in clinical studies that ran between 1989 and 2016. These participants' medication adherence was electronically monitored using the MEMS. The following selection criteria were used: (1) once-daily medication with (2) a follow-up longer than 14 days. This second criterion was required because 14 days is the minimum duration needed to compute the weekly cross-correlation. These selection criteria matched data from 15,818 participants totaling 3,053,779 medication intakes.

Ethical Considerations

Human Participants' Ethics Review Approval or Exemptions

Approval from an institutional review board was not required for the present analysis, as it consists of secondary research for which the identity of the participants is unknown, per Title 45 of the Code of Federal Regulations Part 46, Subpart A, Section 46.104, Paragraph (d)(4)(ii) [24]. The original data collection for all studies included in this analysis was approved by institutional review boards.

Informed Consent

Data were obtained from participants enrolled in clinical studies. As such, the participants provided informed consent for the procedures of the original studies. These procedures required participants to store their medication in electronic medication

XSL•FO
RenderX

packages. Participants were informed that these electronic medication packages recorded their medication intakes. The original study procedures also included using the generated data to monitor the participants' dosing history and analyze their medication intake behavior. As a consequence, informed consent was not sought for this secondary analysis, because it corresponds to the use of the data that was originally presented to participants.

Privacy and Confidentiality

The data in AARDEX Group's database, the Adherence Knowledge Center, is anonymized.

Compensation Details:

Participants were compensated for their participation in the original clinical studies. Compensation modalities varied between studies and countries, and the authors do not possess information about the compensation process, which was managed by the sponsors of the original studies.

Objective Habit Metrics

For each participant, 2 objective habit metrics were computed. The first objective habit metric is the SD of the day-to-day hour of intake. The hours and minutes are extracted for each medication intake timestamp, irrespective of the date of intake, and the SD of the resulting list of hours and minutes is computed. The lower the SD, the more consistent a person is in the timing of their medication intakes. In the extreme case, when SD equals 0 h, all intakes occur at exactly the same time of the day.

The second objective habit metric is the "weekly cross-correlation" introduced by Phillips et al [11]. This metric compares each day of a given week with the corresponding day of the next week and quantifies whether intakes occurred around the same time on these 2 days. To do so, medication intakes are represented in a 2D matrix, denoted A, of dimensions $24 \times N_{days}$, with N_{days} being the number of follow-up days. The matrix is initially filled with zeros. Each medication intake occurring on day l at hour k is translated as a value of 1 for element $A[k,l]$. Then, each element $A[k,l]$ of the matrix is multiplied by its matching element from the previous week, $A[k,l-7]$. If intakes occur at the same time from week to week, the product will be close to 1. Otherwise, it will be close to zero. Finally, the weekly cross-correlation is equal to the sum of all element-wise products divided by the Euclidean norm of A. More details and code explaining how to compute these metrics are presented in Multimedia Appendix 1. As the pragmatic habit index incorporates adherence, it was not included in the present analysis.

Implementation Adherence Metrics

Medication adherence, more precisely its implementation component [1], was quantified as the proportion of correct days, that is, the proportion of days with exactly 1 intake. A second implementation metric was used: the proportion of doses taken. The proportion of doses taken was computed as the ratio between the total number of doses taken and the prescribed number of doses. In this work, since participants were on a once-daily regimen, the prescribed number of doses was equal to the number of follow-up days. If a participant discontinued treatment too early, the analysis was limited to the period during which the participant was on treatment.

The hypotheses were that (1) SD of the day-to-day hour of intake would be negatively correlated to objective adherence (the more variable the hour of intake, the worse the adherence); (2) the weekly cross-correlation would be positively correlated to objective adherence (the more consistent the pattern of intakes, the better the adherence); and (3) the weekly cross-correlation would be more strongly correlated to objective adherence than the SD of the hour of intake.

All dosing history data were compiled while patients were engaged with the monitored medication in the trial. Therefore, noninitiation and nonpersistence are not part of the adherence evaluation in this research.

Statistical Analyses

Continuous variables were reported using medians and first and third quartiles. Categorical variables were reported using counts and proportions. Pairwise correlations between continuous variables were assessed using the Spearman rank correlation coefficient. Correlation coefficients were converted using Fisher Z-transformation to obtain CIs [25,26]. Correlation coefficients were compared by performing a z-test on the difference between their Fisher Z-transformations [26,27]. The proportion of variance in adherence explained by habit was quantified using the Pearson correlation coefficient, squared [26]. Analyses were performed using Python 3 (Python Software Foundation) [28].

Results

The 15,818 participants whose data was extracted from the MEMS Adherence Knowledge Center took part in 108 clinical studies. These studies enrolled a median of 59 (IQR 22-169) participants. Table 1 presents the characteristics of the population.

Figure 1 presents the distributions and pairwise plots for the 4 variables of interest: proportion of correct days and proportion of doses taken as 2 objective measures of adherence, and SD of the hour of intake and weekly cross-correlation as 2 objective habit metrics. According to the 2 top-left diagonal panels, the proportion of correct days ranges between 0 and 1 by definition, while the proportion of doses taken ranges between 0 and 1.5 indicating that some participants took more doses than prescribed. The scatter plots also show that the proportion of doses taken is correlated to the proportion of correct days. In addition, the first is always superior to the second, which is a consequence of their definition.

According to the 2 bottom-right diagonal panels of Figure 1, the SD of the hour of intake ranges between 0 and 12 hours, while the weekly cross-correlation ranges between 0 and 1. These two findings are direct consequences of the definitions of these variables. According to the scatter plots, these 2 variables are negatively correlated, indicating that a larger consistency in day-to-day timing (low SD hour of intake) is associated with a larger consistency in week-to-week timing (high weekly cross-correlation).

XSL•FO
RenderX

Table 2 presents the associated correlation coefficients. All 4 Spearman correlation coefficients were significantly different from zero (T scores for the significance of the coefficients, from left to right and top to bottom: –61.48, –10.70, 104.11, and 48.59 with a df of 15,816, all P<.001).

According to Figure 1 and Table 2, the correlation between the SD of the hour of intake and objective adherence (measured using the proportion of correct days or proportion of doses taken) has a negative sign, indicating that, as hypothesized, the more day-to-day consistency in timing the higher the adherence. Figure 1 and Table 2 also show that the weekly cross-correlation is positively correlated to objective adherence, meaning that the more consistent a person's medication intake pattern is from week to week, the higher their medication adherence, which is also in line with the hypotheses.

The comparison of the Spearman correlation coefficients presented in Table 2 shows that the SD of the hour of intake is more strongly correlated to the proportion of correct days than the weekly cross-correlation is (95% CI for the difference between absolute values of Spearman coefficients: 0.05 to 0.09, z score for this difference=21.46, P<.001), conversely to what was hypothesized. On the other hand, the weekly cross-correlation is more strongly correlated to the proportion of doses taken than the SD hour of intake is (CI for the difference between absolute values of Spearman coefficients: 0.25 to 0.21, z score for this difference=9.45, P<.001), as hypothesized.

Habit accounts for about 30% of the variance in medication adherence, measured using the proportion of correct days: 29.18% for SD of the hour of intake (95% CI 29.17% to 29.19%) and 31.25% for the weekly cross-correlation (95% CI 31.24% to 31.26%). When medication adherence is measured using the proportion of doses taken, the proportion of variance explained by habit is smaller: 4.91% for the SD of the hour of intake (95% CI 4.91% to 4.92%) and 15.74% for the weekly cross-correlation (95% CI 15.73% to 15.75%).

Figure 1. Pairwise relationships between the four variables of interest: 2 objective adherence metrics: proportion of correct days (number 1) and proportion of doses taken (number 2) and 2 objective habit metrics (numbers 3 and 4). Off-diagonal panels contain scatter plots for each pair of variables; on-diagonal panels show a histogram of the distribution of single variables.

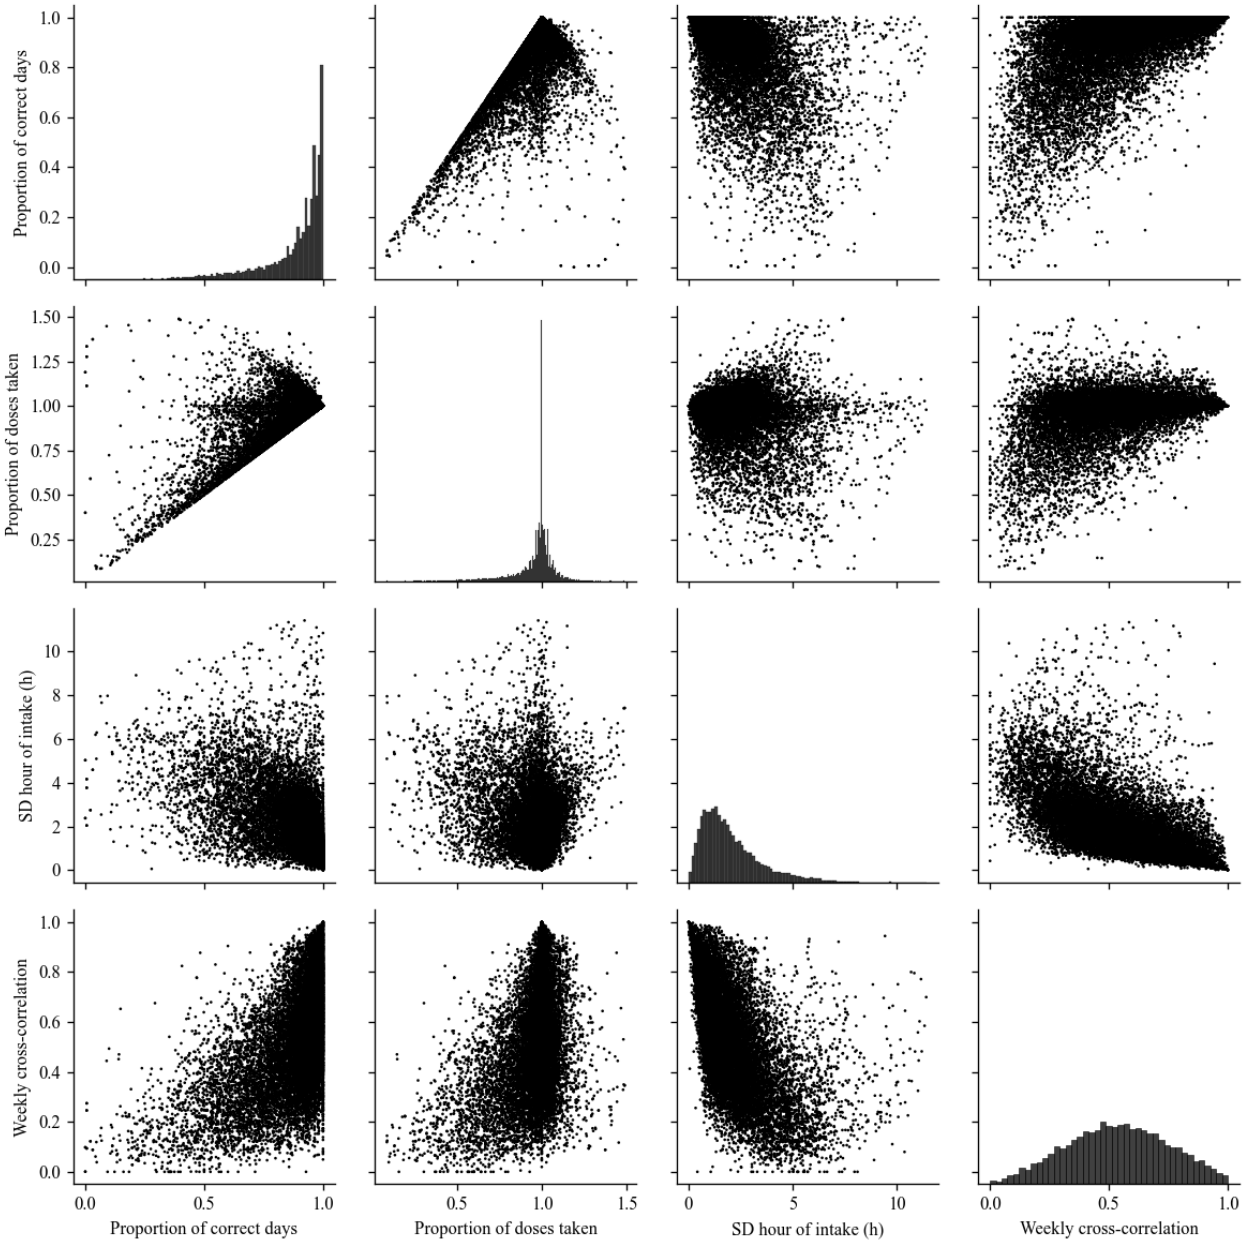

Table 2. Spearman correlation coefficients with 95% CI between 2 objective habit metrics (rows) and 2 objective adherence metrics (columns).

Objective habit	Objective adherence	
	Proportion of correct days	Proportion of doses taken
SD hour of intake	–0.62 (–0.63 to –0.61)	–0.09 (–0.1 to –0.07)
Weekly cross-correlation	0.55 (0.54 to 0.56)	0.32 (0.3 to 0.33)

Discussion

Principal Findings

This work showed that medication-taking habit is positively correlated to medication adherence in a very large, cross-pathology population of participants enrolled in clinical studies. Medication-taking habit was quantified using 2 measures of the consistency in the timing of medication intakes: day-to-day and week-to-week. The implementation component of medication adherence was quantified using 2 measures: the proportion of correct days and the proportion of doses taken. The conclusion was the same irrespective of the habit or adherence measure: the stronger the habit, the better the medication adherence.

XSL•FO
RenderX

The results showed no clear superiority of any of the 2 objective habit metrics per the strength of their correlation with adherence. The correlation of objective habit metrics with self-reported habit metrics, which are the most frequently used habit metrics, might be used to differentiate the 2 objective habit metrics. Previous studies exploring this correlation are discussed in the next section.

Comparison to Prior Work

The link between objective habit metrics and medication adherence has been investigated in very few other studies. The first one [11], performed by the authors on a much smaller dataset, reported very similar results: (1) a negative correlation between a measure of day-to-day variability and the proportion of correct days and (2) a positive correlation between the weekly cross-correlation and the proportion of correct days. The second one [13], previously discussed, used a habit metric incorporating adherence and reported an expected correlation between these 2 quantities.

Over 700 determinants of adherence have been reported [29]. Among all these determinants, objective habit strength seems to be an important one, as it explained over 30% of the variance in medication adherence in this work. This observation empirically justifies studying objective medication-taking habit.

A question related to the present work is whether people use time-based cues for taking their medications [10]. To answer this question, the proportion of participants having 95% of their intakes in a 1-hour window was computed. Only 3.6% of participants met this criterion. In a previous study [10], 21.7% of participants reported taking their medication at a specific time of the day. These numbers mean that a minority of patients rely on cues triggered by the clock and take medication at the same time every day. This finding might explain why reminders for medication adherence sent at a specific time of the day can be ineffective [30].

Few studies have studied how well objective habit metrics for medication adherence correlate with conventional self-reported habit metrics. SD or other metrics of day-to-day consistency were found to correlate with self-reported habit in 2 studies [17,18], but not in a third one [11]. Weekly cross-correlation was found to correlate with self-reported habits in 1 study [11].

Strengths and Limitations

First, the 2 objective habit metrics used in this study are measures of consistency in timing, day-to-day, or week-to-week. However, not all habits translate into consistency in timing, and consistency in timing can originate from other factors than habit [9]. In such cases, the objective habit metrics will not reliably quantify the presence or absence of habit. On the other hand, the objective consistency metrics have the advantage that they do not endure biases associated with self-reported habit metrics, such as recall bias.

Second, the dataset used in this paper was very large, so the findings are likely to be generalizable to the whole population of participants enrolled in clinical trials. On the other hand, no conclusion about a specific disease, population, or time can be drawn, because there would be a large confounding influence of the underlying study design and specific medication characteristics. The main result is that, in general, adherence is related to objective habit.

Third, in this study, habit and medication adherence were computed over a participant's whole follow-up, until treatment discontinuation. However, for a single participant, habit strength may have changed throughout the duration of this study, for instance, because of the introduction of a new device for medication adherence monitoring. The evidence on the effects that electronic adherence monitoring causes on adherence itself is unclear [22,31]. The effects of electronic adherence monitoring on medication-taking habit have never been studied, to the best of the authors' knowledge.

Another reason that may have caused individual changes in habit strength is that some of the studies analyzed were testing habit-building interventions. In such settings, the objective habit metrics used in this paper can be computed over shorter periods to capture the dynamics of habit formation and maintenance. For instance, in the case of a specific habit-building intervention, Pironet et al [32] observed that habit strength increased after a 6-month intervention and remained stable 6 months after the intervention was stopped.

Future Directions

If a patient's implementation adherence is measured electronically, their habit can be computed continuously from the recorded data and serve as a support for an intervention, in-person or through a mobile app. The intervention could focus on providing support to build a better medication-taking habit. An example of such a mobile intervention is presented in the study by Stawarz et al [33].

This work investigated the relationship between habit and the implementation component of medication adherence. Other, evenly important questions are whether objective habit indices predict the quality of implementation over the longer term, and if objective habit indices predict early treatment discontinuation.

Conclusion

In this study, the correlation between objective habit metrics, computed from electronic medication intake data, and objective medication adherence was assessed in a large database of participants enrolled in past clinical trials. The 2 objective habit metrics tested in this work were correlated to the 2 objective adherence metrics. These 4 pairwise correlations all imply that a lower variability in the pattern of medication intakes, be it day-to-day or week-to-week, is correlated with higher medication adherence. However, no variability is not the norm.

Objective habit metrics allow us to better identify patients who might benefit from habit-building support. If a patient uses electronic monitoring, the habit metrics can even be automated and computed in real time, directly reflecting habit changes and allowing for timely intervention. In addition, some effective interventions for medication adherence are based on developing or improving habits [5]. In such settings, electronic monitoring can be used to assess the effect of the habit-building intervention in real time [32].

Abstract

Background: Nutritional inadequacy and consequent diminished immunity among school-age children is a public health problem in India. Nutrition interventional studies using a cluster randomized controlled trial (RCT) design can avoid ethical issues inherent in double-blind individual RCTs in children involving daily administration of an empty-calorie placebo.

Objective: We tested the hypothesis that daily administration of a fortified malt-based food (FMBF), a multinutrient supplement, would improve immunity outcomes against common infectious diseases, nutritional status, and gut health in Indian school-age children by using a cluster RCT design. This report presents the study design attributes and the baseline characteristics of the study population.

Methods: This was an open-label, 2-arm, parallel-group, matched-pair cluster RCT, stratified by gender, in children aged ≥7 to ≤10 years old with height-for-age *z* scores (HAZ) of ≥−3 to ≤−1 and good general health. Four schools located in Pune city in India participated in the study. Each school was deemed as a cluster and was randomized to the test group (FMBF and dietary counseling) or control group (dietary counseling alone). A total of 924 participants from the 4 randomized schools were enrolled in the study.

Results: Observed mean age (SD) was 8.0 (SD 0.81; range: 7-10) years. There was no significant difference in mean age (*P*=.06), gender (*P*=.55), race (*P*>.99), HAZ category (*P*=.051), HAZ (*P*=.17), and BMI (*P*=.03). A very large proportion of children had micronutrient inadequacies in terms of vitamin D (97.5%), folate (79.2%), zinc (66%), and vitamin A (34.3%) at baseline. The study design meant that administration of the study intervention at a cluster level was easy. Mean compliance with the test product was 99.99% and retention in the study was 98%.

Conclusions: The findings highlight the extent of nutritional inadequacies in Indian school-age children, reaffirming the need for nutritional strategies to optimize the nutritional status among these children. A cluster RCT design can be effectively used in nutritional intervention trials with children by maintaining high compliance and retention.

KEYWORDS

multinutrient supplement; study design; Indian children; immunity; fortified malt-based food; school-based

Introduction

Nutritional inadequacy has been the major and long-standing cause of nutritional and health concerns and developmental shortcomings in Indian children [1]. Despite numerous health care advances, the burden of major communicable diseases in children continues to be high in India compared to other countries [2,3]. As per the 2021 Global Burden of Disease study, diarrheal diseases and respiratory infections among children (5 - 14 y) were 2 of the 5 leading infectious causes of disability-adjusted life-years in the country [3]. Furthermore, child and maternal malnutrition (nutritional deficiencies, diarrhea, lower respiratory infections, and other common infectious diseases) were among the top 5 leading risk factors for disability-adjusted life-years [3].

In terms of nutritional status, approximately 60% of the Indian pediatric population has protein-energy malnutrition [4-8]. A recent nationwide survey further reported a deficiency in zinc, iron, and folate, as well as vitamins A, B12, and D in

XSL•FO
RenderX

14% - 32% of preschool children (aged 1-4 y), 17% - 28% of school-age children (aged 5 - 9 y), and 16% - 37% of adolescents (aged 10 - 19 y) [9].

Nutritional inadequacy hampers the overall development of children as it adversely affects their immunity, normal physiological functions, physical growth, and cognitive development [10-14]. Such inadequacies often coexist with infectious diseases and exhibit complex interactions, leading to a vicious cycle of malnutrition and infections [15-18]. This is evidenced by the fact that child undernutrition is responsible for 22% of the country's burden of disease [19].

As per the recent Global Nutrition Report, India performs poorly across standard child nutritional measures, accounting for nearly 39% of stunting and 15% of wasting worldwide [20]. On the national level for children under 5 years of age, data from the 2015 - 2016 National Family Health Survey showed a reduced prevalence of child stunting and underweight (38% and 36%) since 1992 - 1993 (52% and 53%) [21], however, it is still alarmingly high considering the multisectoral nutritional policies and initiatives that have been implemented [22]. Although there is sufficient anthropometry-related nutritional data for the under-5 age group, there is a dearth of national-level anthropometric data for school-age children. The Comprehensive National Nutrition Survey (CNNS) was the first national survey to measure anthropometry in children aged 5 to 14 years. According to the CNNS 2016 - 2019, the prevalence of stunting and underweight for children in the age group of 5 - 9 years was nearly 22% and 35%, respectively. However, the prevalence of stunting and underweight varied with school status, with a higher percentage of both among children who were out of school compared to school-going children (stunting: 38% vs 20%; underweight: 45% vs 34%) [9].

Evidently, at the individual level, appropriate nutrition actions in children can help bridge the nutritional gap, reduce the morbidity burden through improved immunity, and contribute to their overall health during the crucial formative and learning years [13,23-31]. Nutritional supplementation is one of the widely accepted approaches out of several effective nutritional strategies available worldwide [32,33]. Of note, in the Indian scenario, nutritional supplements have mainly been studied for their effect on the nutritional status and immunity of children <5 years of age. However, since school-age children represent about one-fifth of the total Indian population [34], understanding the effect of nutritional supplements in this cohort is equally essential. In addition, of the existing literature, none of the studies have comprehensively evaluated any nutritional supplement for its overall effect on the growth and immunity/health outcomes of Indian school-age children [35-38].

Thus, we conducted a study to provide a comprehensive overview of one such supplement, a multinutrient fortified malt-based food (FMBF), for its effect on immunity as well as other health aspects, in combination with dietary counseling, in a large group (>900) of Indian school-age children (>7 and <10 y). This paper gives an overview of the study design and baseline characteristics of the study population.

Methods

Study Design

This was a single-center, multiple-site, open-label, parallel-group, school-based, matched-pair cluster randomized controlled trial (RCT) conducted with Indian school-age children aged ≥7 to ≤10 years (ClinicalTrials.gov registration number NCT02542865). The study was conducted over 10 visits that consisted of screening (visit 1), baseline assessment (visit 2), dietary counseling (visit 3 to 9), and an end-of-study visit (visit 10). Nutritional intervention with an FMBF for the test group was done every day from visit 3 to 9 over a period of 9 months.

After obtaining written permission from management boards, 4 nongovernment schools from Pune, India, with a coeducation system and no history of outbreaks/clusters of infectious disease cases in the prior month consented to participate in the study. Schools were matched for size (with respect to the number of children aged 7 to 10 y), socioeconomic profile of the students, and type of school (government-subsidized or private) and 2 matched pairs were formed. Each school was deemed a cluster and assigned a randomization number in ascending numerical order. A randomization schedule with details on treatment assignment was prepared by an independent statistician from the Biostatistics Department, GlaxoSmithKline Consumer Healthcare, using validated internal software. The researchers involved in the study did not know the details of the schedule. The schedule was stored and concealed in an internal electronic document management system. Based on the randomization schedule and school list, each school within the matched pairs was randomized to receive either the multinutrient FMBF along with dietary counseling (test group) or dietary counseling alone (control group) during the intervention phase. The study assessed the effect of the FMBF on the overall development of these school-age children (immunity, nutritional status, gut health, anthropometry, dietary status), along with the FMBF's safety profile.

For quality control, all equipment and instruments were regularly calibrated, an accredited lab was used, and tools were validated. Staff were trained and retrained at regular intervals. To maintain the quality standards of data collection as per protocol and regulatory standards, data monitoring and data collection and analysis were done by a contract research organization. In addition, the study was audited by the Clinical Data Quality Assurance team at GlaxoSmithKline US and received an audit certificate.

Ethical Considerations

The study was conducted in accordance with the International Council on Harmonization Guidelines for Good Clinical Practice and the Declaration of Helsinki. The protocol and all the amendments were approved by Ethics Committee Jehangir Clinical Development Centre Pvt Ltd (ECR/352/Inst/MW2013) prior to study initiation. Written informed consent was obtained from one of the parents or a legally acceptable representative (LAR) of each participant and written assent was obtained from all participants before any study-specific procedures were performed. Participants didnot receive any compensation for participating in the clinical study but all participants travel cost

XSL•FO
RenderX

for study visit was reimbursed as per approved amount by Ethics Committee and same was mentioned in Informed Consent. The data collected for clinical study was stored by protecting privacy and maintaining confidentiality.

Study Inclusion and Exclusion Criteria

The key study inclusion and exclusion criteria are summarized in Textbox 1.

Textbox 1. Key study eligibility criteria.

Inclusion criteria

- Children of either gender
- Children aged 7 to 10 years (inclusive) with height-for-age *z* scores (HAZ) between −3 and -1 (inclusive)
- Children with good general and mental health in the opinion of the investigator or a medically qualified designee, defined as: (1) no clinically significant/relevant abnormalities in medical history or upon physical examination and (2) absence of any condition that could affect the child's safety/well-being or their ability to understand the study aspects

Exclusion criteria

- Children in care
- Children with an allergy or intolerance to any ingredient of the fortified malt-based food
- Children with severe anemia (hemoglobin <8 g/dL)
- Children with a history of use of immunosuppressive therapy (eg, oral corticosteroids or chemotherapy) in the 6 months prior to the screening visit
- Children with a recent history (2 months) of serious infections, injuries, and/or surgeries
- Children with a current or relevant history of any serious, severe, or unstable physical or psychiatric illness or any medical disorder that could have made them unlikely to complete the study
- Children who have consumed nutritional supplements and/or health food drinks on a regular basis (≥3 times a week) in the last 3 months
- Children with any other condition that presented an undue risk to them from the study interventions or procedures, in the opinion of the investigator or medically qualified designee

Study Interventions

The FMBF was prepackaged in sachets, each containing 27 g of multinutrient beverage powder. The nutrition profile of this supplement is presented in Table S1 in Multimedia Appendix 1. Participants from the test group consumed 27 g of this powder mixed in 150 mL of lukewarm water twice per day for 9 months. To avoid stomach fullness as a deterrent against compliance, the interval between the 2 doses was maximized. One dose was administered as soon as the participants entered the school and the second dose was given just prior to school dismissal. When a child was absent from school (eg, due to holidays or sickness), parents/LARS administered the 2 doses at home (one in the morning, one in the evening).

Nutritional inadequacy and the resulting immunity outcomes could be influenced by dietetic interventions implemented to improve nutritional intake. Background diet is a major confounder and it is imperative to track dietary quality throughout the study. Thus, to keep the background diets comparable between the 2 groups, the test group was administered the test product, while both the test and control group received dietary counseling. All study participants, their teachers, and their parents/LARs received age-specific dietary counseling to optimize the nutritional intake of the participants, which was based on the dietary guidelines for Indians established by the Indian Council of Medical Research–National Institute of Nutrition [39]. A total of 7 separate sessions of dietary counseling were administered to study participants and parents/LARs in both groups. The first 2 sessions involved the delivery of content and were mandatory to attend. The remaining 5 sessions were for follow-up, reinforcement, and problem-solving of content delivered in the first 2 sessions and these sessions were not mandatory to attend. The quality, content, and duration of the dietary counseling were equivalent in both the study groups.

Study End Points

The primary efficacy end point assessed the total number of ill days due to gastrointestinal (GI) and respiratory illness episodes in the participants over 9 months. GI illness was defined as an acute illness that included any of following symptoms: 3 or more loose, liquid, or watery stools or any vomiting in 24 hours [40]. Diarrhea or vomiting arising from noninfectious causes, such as irritable bowel syndrome or medications, were excluded. Respiratory illness was defined as an acute illness that included ≥1 of the following symptoms: runny nose, stuffy or blocked nose, cough, fever or chills, sore throat, or sneezing [41]. Symptoms arising due to noninfectious causes (eg, allergy) were excluded from the diagnosis. The secondary efficacy end points evaluated over 9 months included assessment of frequency and severity of the GI and respiratory illness episodes, school absenteeism due to these episodes, change from baseline in serum micronutrient levels (vitamins A, B12, D, and E, folate, and trace elements zinc, iron, copper, and selenium), change from baseline in macronutrient status, change from baseline in dietary diversity assessed using 24-hour individual dietary diversity score (IDDS), change from baseline in gut integrity as measured by a lactulose:mannitol test and urinary neopterin test, and change from baseline in BMI. Details of the evaluation

XSL•FO
RenderX

of secondary end points are presented in Table 1. Safety assessments included an evaluation of adverse events (AEs), treatment-emergent AEs, and serious AEs throughout the study. The laboratory assessments, vital signs, physical examinations, and hemoglobin measurements in these participants were conducted at baseline and at the end of the study.

XSL•FO
RenderX

Table . Secondary end point evaluation methods and tools.

Secondary efficacy end point	Frequency of assessment	Evaluation tool	Evaluation/test method
Frequency (number of episodes) of gastrointestinal and respiratory illnesses	Weekly basis during scheduled SPWR[a] visits	Diagnosis form	Calculated as total number of gastrointestinal and respiratory illness episodes, divided by the duration of the intervention, where each episode is defined as each instance of illness followed by at least 3 symptom-free days [40,42,43].
Severity of an illness episode	Weekly basis during scheduled SPWR visits	Diagnosis form	Assessed as per severity grading of mild, moderate, and severe as outlined, evaluated, and classified by a study physician [44].
School absenteeism due to gastrointestinal and respiratory illnesses	Weekly basis during scheduled SPWR visits	Diagnosis form	Calculated as number of days when a child failed to attend school because of gastrointestinal and/or respiratory illnesses.
Change from baseline in BMI	Twice in the study (at screening and at the end of the study visit)	• Portable stadiometer (SECA 213) for measuring a participant's height. • Standardized weighing scale (SECA 874) for measuring a participant's weight.	Calculated using the formula BMI=weight [kg]/(height[m])^2. All anthropometric measurements were performed using the guidelines adopted at the National Institute of Health–sponsored Arlie Conference [45].
Change from baseline in gut integrity/health	Twice in the study (at baseline and at the end of the study visit)	Urine testing	Urine lactulose:mannitol assessment by HPLC[b]. Urinary neopterin assessment by ELISA[c].
Change from baseline in mucosal immunity	Twice in the study (at baseline and at the end of the study visit)	Saliva testing	Salivary IgA[d] assessment by ELISA
Change from baseline in levels of the micronutrients vitamins A, B12, D (25-hydroxycholecalciferol), and E, folate, and trace elements selenium, zinc, copper, and iron	Twice in the study (at baseline and at the end of the study visit)	Blood testing	• Serum vitamin A, B12, D, and E, and folate assessment by ELISA • Serum copper assessment by 3, 5-Dibromo-PAESA • Serum zinc assessment by 5-Br-PAPS • Serum iron assessment by TPTZ[e] • Serum ferritin assessment by turbidimetry • Serum selenium assessment by ICP[f]
Change from baseline levels of ferritin, sTfR[g], CRP[h], and AGP[i]	Twice in the study (at baseline and at the end of the study visit)	Blood testing	• Serum sTfR and CRP assessment by immunoturbidimetry • Serum AGP assessment by turbidimetry
Change from baseline in dietary diversity score	Twice in the study (at baseline and at the end of the study visit)	• 24-hour dietary recall survey • Dietary diversity questionnaire [46]	Based on data of the foods and beverages consumed in the last 24 hours as captured by a 24-hour dietary survey, the appropriate food groups in the questionnaire were selected. Dietary diversity scores were calculated by adding the number of food groups consumed by the child over the 24-hour recall period.
Change from baseline in energy, protein, carbohydrates, and fat consumption	Twice in the study (at baseline and at the end of the study visit)	24-hour dietary recall survey [47]	24-hour dietary recall survey

[a]Study Physician Weekly Review was initiated 1 week (+ up to 2 days) post first dietary counselling visit of the participant and was continued on a weekly basis (+ up to 2 days) until end of study visit.

XSL•FO
RenderX

[b]Visit 1: screening visit.

[c]Visit 2: baseline visit (+1 to 21 days post–screening visit).

[d]Sessions number 3, 4, 5, 6, and 7 could be postponed in view of long school holidays and exams. Session number 7 was not to be conducted any later than the last day of month 8 of the intervention period. A minimum of a 4-week gap was maintained between sessions number 2, 3, 4, 5, 6, and 7.

[e]Visit 3/session 1: day 1 to 3 of week 1 from baseline visit; visit 4/session 2: week 2 from baseline visit and up to 3 days; visit 5/session 3: week 6 from baseline visit and up to 3 days; visit 6/session 4: week 10 from baseline visit and up to 3 days; visit 7/session 5: week 14 from baseline visit and up to 3 days; visit 8/session 6: week 18 from baseline visit and up to 3 days; visit 9/session 7: week 22 from baseline visit and up to 3 days.

[f]Visit 10: end of study visit (+1 to 7 days after the end of 9 months from the baseline visit).

[g]Obtaining informed consent and assent and performing screening activities could be on different dates but informed consent and assent were obtained prior to performing and applying any screening criteria or procedures. Screening activities were done within 60 days of obtaining consent and assent.

[h]Could be done any time after obtaining consent and assent but prior to baseline visit.

[i]Parent/legally acceptable representative symptom checklist and product compliance report forms were collected and reviewed for each weekly review with the physician.

[j]Saliva samples were collected for the assessment of salivary immunoglobulin A at visit 2 and visit 10.

[k]Intervention began +1 to 3 days from the baseline visit and continued for 9 months. Compliance checks (test product empty sachets were collected) and AEs were recorded throughout the intervention period.

To evaluate primary and secondary immunity outcomes, the parents/LARs of the participants regularly updated the symptom checklist and compliance report forms for study interventions, which were collected and analyzed during each study physician weekly review (SPWR) throughout the study. During the SPWR, the start/end date of GI and respiratory illness episodes along with the frequency, severity (mild, moderate, severe), and school absenteeism due to these episodes were noted in the diagnosis form by the study physicians based on details obtained from the following:

- Symptom checklist completed by parents/LARs
- External clinical record if treated by an external physician
- Direct information from participants or parents/LARs
- Clinical history and examination by study physician

Details of the evaluation methods and tools used for assessment of secondary immunity outcome end points, anthropometry, serum biochemistry, and dietary assessment are provided in Table 1.

During the study, the AEs and serious AEs were monitored in addition to those reported by participants or parents/LARs to the study physicians as and when observed or through the weekly symptom checklists. The AEs were regarded as treatment-emergent AEs if they occurred on or after the first administration of the FMBF in the test group or on or after the first dietary counseling session in the control group.

A compliance check of the study interventions was conducted as per the schedule presented in Table 2. Concomitant medications were recorded at each study visit. Except for immunosuppressive therapies (which were never used in the study), there were no restrictions on medications and medical treatments. However, the use of medications (eg, antibiotics, antipyretics) was standardized across all study sites.

A noninvasive, spot-check monitoring device (Masimo Corporation's Pronto Pulse CO-Oximeter) was used to screen study participants in school settings based on their hemoglobin (Hb). This device uses transcutaneous spectrophotometry to measure Hb concentration in the blood, and the result is comparable to invasive laboratory-based Hb estimations in children [48]. Anthropometric measurements included the assessment of height, weight, BMI, and HAZ. HAZ was obtained using the World Health Organization Anthroplus software [49].

Sample Size

The sample size was based on the primary efficacy end point, the total number of ill days due to GI and respiratory illnesses. Based on the data from the Global Burden of Disease by the World Health Organization [50], the Institute for Health Metrics and Evaluation [51], and the Census of India [34], approximately 7 ill days due to GI and respiratory illnesses per 9 months was assumed in this study population. Thus, the sample size was calculated based on the assumption of an average of 7 ill days in the control group with a difference of 10% (0.7 d) between the study groups.

No sample size considerations were taken into account for secondary objectives. The simulated data were also used based upon the assumption of a Poisson distribution per study treatment. On observation of these simulated data, it was considered that these Poisson distributions were not heavily skewed and, as a result, normal distributions could be assumed. Consequently, a normality assumption was adopted for both the generation of sample size and the intended approach to the statistical analysis. Because of the assumption of Poisson distribution, estimates of variability were calculated as the square root of the mean. The mean of the control was assumed to be 7.0 (SD 2.65), while the mean of the test group was 6.3 (SD 2.51). In order to achieve 80% power, 215 participants per treatment arm (total=430) were required to complete the study in case of individual randomization. This assumed a 5% level of significance (2-tailed *t* test). As this study used cluster randomization, to retain equivalent power to an individually randomized trial, design effect (DE), which is a function of the intracluster correlation coefficient (ICC), was considered for sample size calculations. The scientific literature suggested that DE due to a cluster sampling strategy should be assumed to be 1.5 [52]. A similar assumption was made in a study that used 3-stage systematic cluster sampling [53]. The following formula was used [54]:

$$N* = N \times DE$$

XSL•FO
RenderX

Where N* is the number of participants required for a cluster RCT, N is the number of participants required for an individual RCT, and DE is the design effect.

Since DE was assumed to be 1.5, the number of evaluable participants required to complete the study was determined to be 323 per arm (total=646). To allow for a 30% dropout rate, a total of 924 participants were to be randomized. Approximately 1300 participants were to be screened to randomize approximately 924 participants in order to obtain 646 participants completing the study.

Statistical Analysis

Analysis Population

Safety population was defined as participants who received ≥1 dose of the study interventions (only dietary counseling [control group] or both FMBF and dietary counseling [test group]) during the study. The intention-to-treat (ITT) population comprised all participants in the safety population with any postinterventional assessment (ie, SPWR), according to the study group assigned. The modified intention-to-treat (mITT) population was defined as all participants in the safety population with any postinterventional assessment (SPWR) who completed the entire intervention phase and attended the end-of-study visit.

Analysis Methods

Access to the treatment code was appropriately restricted during the process of blinded data review involving clinical research scientists and statisticians. The database with potentially unblinded information was separately reviewed for study population inclusion/exclusion by unblinded clinical research scientists. The database was later validated by a blinded reviewer prior to its release for analysis.

Analysis of the primary efficacy end point was done on the mITT population and the analysis of secondary and exploratory efficacy end points was done on both the mITT and ITT population. They were analyzed using the analysis of covariance (ANCOVA) model (SAS Studio version 9.4 or higher; SAS Institute Inc). The ANCOVA had cluster (school) as a random effect; study group and gender as fixed effects; and baseline assessments, baseline serum levels, and baseline IDDS as covariates. Unlike other study end points, frequencies for severity (mild, moderate, severe) of GI/respiratory illness episodes as well as IDDS categories (low, moderate, high) were compared using the χ^2 test (if frequencies were >5%). If frequencies were ≤5% in any study group, then these were compared using the Fisher exact test. Adjusted means for each study group, 95% confidence intervals, within-group *P* values, difference between the study groups, 95% confidence intervals of the difference, and the between-group *P* values were also presented based on the above statistical model. All statistical tests of hypotheses were 2-sided and used a level of significance of α=.05.

Demographics, baseline characteristics, and safety assessment (including laboratory tests) summaries were produced for the safety, ITT, and mITT populations. Descriptive statistics including n (%), mean (SD), minimum, and maximum (as applicable) were provided. Baseline characteristics were compared between the treatment groups using an independent *t* test for continuous variables and χ^2 test for categorical variables. A 2-sided significance level of 5% was used for the comparisons.

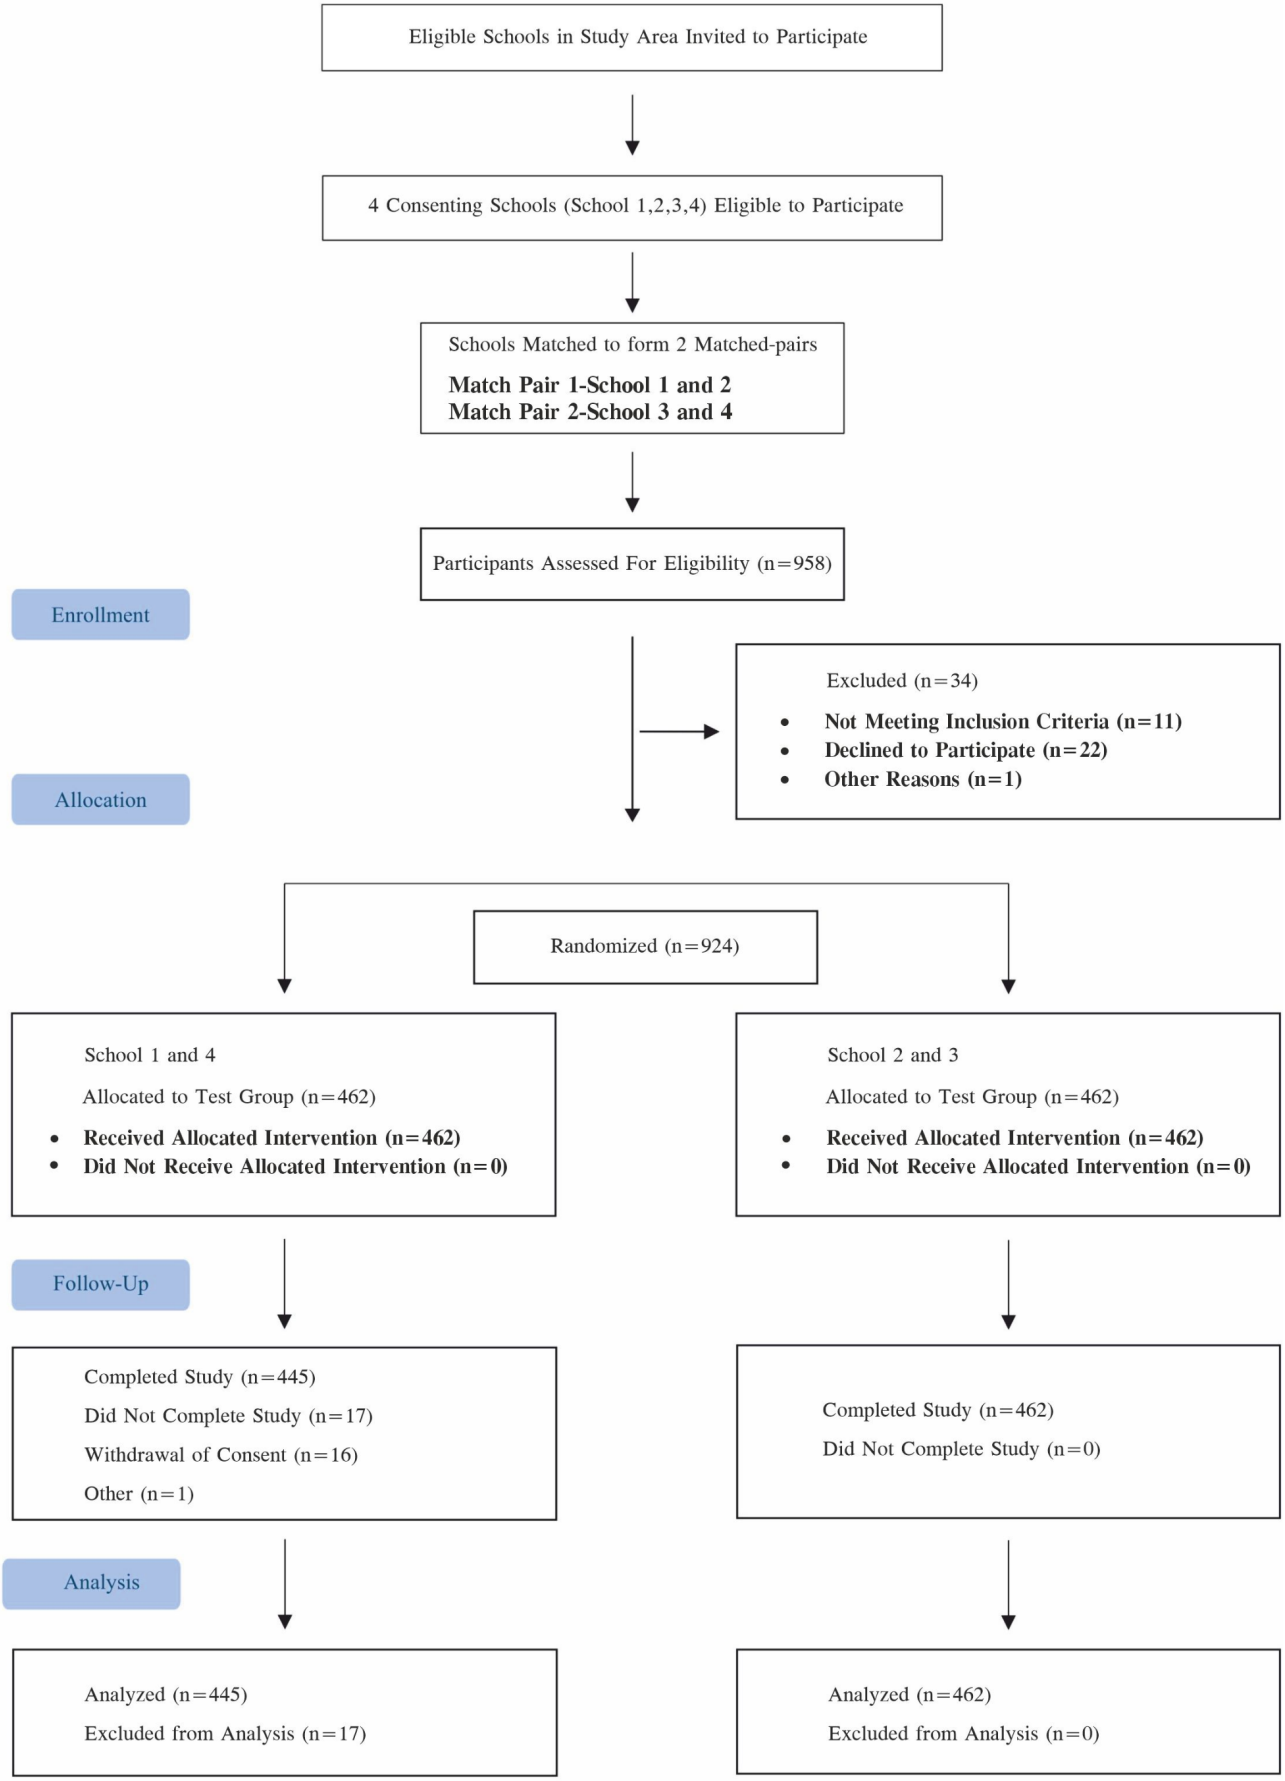
The intervention was targeted at the cluster level; however, outcomes were measured at the individual level. Thus, all ANCOVA analyses included cluster as a random effect to introduce correlation between children from the same school, which was estimated by the ICC. The assumptions of normality and homogeneity of variance were investigated. Violations of these assumptions were overcome using suitable transformation (eg, log).

Results

Overview

The study was conducted between July 2017 and July 2018. Recruitment of all participants was completed in a 4-month period. After screening and baseline assessment, each recruited participant remained in the study for 9 months to receive the interventions and undergo assessments.

The mean product compliance in the test group was 99.99% (SD 0.02, minimum 99.69% and maximum 100%). Mean compliance with both mandatory and follow-up sessions of dietary counseling for participants as well as parents/LARs was 100% in both the test and control groups.



Demographic and Baseline Characteristics of Study Participants

Figure 1 depicts the study design and disposition of the study participants. Of 958 screened participants, 924 participants were randomized to the test group and the control group in a 1:1 proportion (n=462 each). A total of 907 participants (98.2%) completed the study (test: n=445; control: n=462), whereas 17 (3.7%) participants did not complete the study, either due to withdrawal of consent (test: n=16, 3.5%) or other unspecified reasons (test: n=1, 0.2%).

The demographic and baseline characteristics of the study participants are summarized in Table 3. All the participants had Central/South Asian heritage. Both the study groups (test vs control) were comparable in terms of mean age of the participants (8.0 y vs 7.9 y), gender distribution (male: 57.4% vs 55.4%), mean HAZ (−1.52 vs −1.48), and mean BMI (15.47 kg/m^2 vs 15.12 kg/m^2).

Baseline Nutrient Status of Study Participants

Tables 4 and 5 summarize the baseline micronutrient status of the study participants. The findings indicate a considerable burden of micronutrient inadequacy in these participants. The most frequently observed inadequacy was vitamin D (97.5%), followed by folate (79.2%), zinc (66%), and vitamin A (34.3%; Table 6). An overview of the 24-hour macronutrient intake status is depicted in Table 7. The nutritional intake status was similar between both the study groups (Tables 4 and 5).

Table . Summary of micronutrient status of the study participants at baseline (mITT[a] population).

Parameters	Reference range[b]	Test group (n=445), mean (SD)	Control group (n=462), mean (SD)	Total (n=907), mean (SD)	*P* value
Serum vitamin A	26.00 - 49.00 µg/dL	29.52 (6.30)	28.14 (5.41)	28.82 (5.89)	<.001

[a]mITT: modified intention-to-treat.

[b]RDA: recommended dietary allowance.

[c]N/A: not applicable.

Since nutritional status is usually influenced by gut health, the study participants were also evaluated for their gut integrity through the lactulose:mannitol test and urinary neopterin test. A total of 111 (12%) participants demonstrated an abnormal lactulose:mannitol ratio (reference level: <0.035; test: n=66, 14.3%; control: n=45, 9.7%), indicating malabsorption in these participants (Table 8). On the other hand, the urinary neopterin test was normal for all the study participants across both groups (reference range: 0.10 - 5.00 mmol/mol creatinine).

Table . Summary of baseline gut integrity/health using the lactulose:mannitol test and urinary neopterin test (mITT[a] population).

Parameter	Test group	Control group	*P* value
Lactulose mannitol test			.002

Discussion

Principal Findings

This study revealed concerning facts about nutritional and growth parameters in the apparently healthy school-age children. The biochemical statuses of many micronutrients, namely vitamin A (34%), vitamin B12 (29%), vitamin D (97%), folate (79%), zinc (66%), and iron (28%) were observed to be inadequate in the children. In this study, we also assessed the gut health of the study participants. There is a paucity of prevalence data on this parameter in apparently healthy children, particularly those without diarrhea. We observed an abnormal lactulose:mannitol ratio in a substantial percentage (111/922, 12%) of the study population. This indicates compromised intestinal permeability, thus affecting their nutrient absorption.

This study found high compliance with the test product (99.99%), with a high retention rate of 98% (907/924). Maintaining similar influence and motivation among children and parents, particularly in an open-label individual RCT, could have been very challenging. However, this being a cluster/school-level intervention, peer influence could have helped improve compliance and adherence. Strategical measures used in the study to improve retention included weekly compliance monitoring, regular meetings and briefings with parents at the school, random home visits, and telephonic follow-up with nonresponders or during out-of-station travels.

Statistical implications of this study's cluster RCT design necessitated inflating the sample size by 1.5 times the number needed for an individual RCT. Despite a relatively large sample size and a 9-month duration, the study was administratively more efficient because of the greater logistical convenience resulting from the operational ease of administration of the study intervention at the cluster level.

The magnitudes of nutritional inadequacies observed in this study were in line with most of the previously published literature (Table 8), reaffirming the presence of nutritional concerns in Indian school-age children [9,37,55-65]. However, when compared with CNNS estimates, the observed magnitudes of vitamin D, folate, and zinc deficiencies were relatively high. This may be due to higher cutoffs for serum vitamin D, folate, and zinc used in this study compared to the CNNS. Cutoffs in this study versus the CNNS are as follows: 30 ng/mL versus 12 ng/mL for vitamin D, 5 ng/mL versus 4 ng/mL for folate (equivalent to the cutoff of 151 ng/mL of red blood cell folate used in the CNNS), and 78 mcg/mL versus 65 mcg/mL for zinc. As a result, a greater number of children were included in the

XSL•FO
RenderX

nutrient-deficient group in this study. Moreover, due to sedentary and indoor lifestyles, vitamin D deficiency is known to occur more commonly among children in urban settings [66,67], as in this study conducted with participants residing in the urban setting of Pune city.

This was one of the largest nutritional intervention trials conducted with a matched-pair cluster RCT design on Indian school-age children. Cluster trials are conceptually able to improve acceptability and adherence to an assigned intervention, but these qualities are rarely assessed and reported in cluster trial publications [68,69]. In a long nutritional intervention trial, consumption fatigue or boredom can set in, resulting in poor compliance and subsequent attrition from the study. This study recorded high compliance with the test product, with a high retention rate. Maintaining similar influence and motivation among children and parents, particularly in an open-label individual RCT, could have been very challenging. However, this being a cluster/school-level intervention, peer influence could have helped improve compliance and adherence. Besides, strategic measures used in the study including weekly compliance monitoring; regular meetings and briefings with parents at the school; random home visits; and telephonic follow-up with nonresponders or during out-of-station travels had an impact on retention.

Limitations

The open-label design used in the study had great potential to pose a threat to the validity by introducing potential biases associated with such a design, but this was curtailed significantly by using specific and objective criteria for the diagnosing and recording of morbidities by physicians. Besides, results based on biochemistry were also objective by nature. Additionally, access to the treatment code was appropriately restricted during the process of blinded data review involving clinical research scientists and statisticians. The study involved the random allocation of clusters (ie, schools); however, participants' selection within a school was not random due to the cluster RCT design. Prior knowledge of treatment could still have led to recruitment bias, which cluster RCTs are usually vulnerable to [70]. However, the study did not seem to have been impacted by this bias, as shown by the high screening to enrollment ratio, with a low proportion of participants refusing consent during screening in both the control group (16/482, 1.3%) and test group (6/476, 3.3%).

Although study groups were matched for overall socioeconomic status, the extent to which individual participants were matched was not ascertained. There was always a chance that potential socioeconomic status differences and associated factors (eg, access to health care, use of medications, hygiene, and sanitation practices) had the potential to confound the results. This was minimized by harmonizing the treatment of all morbidities by similarly trained study physicians in schools as a part of adverse event management. It was known that the use of medications could impact study outcomes, particularly ill days, school absenteeism, and illness severity. Thus, the medications (eg, antibiotics, antipyretics) were standardized across all study sites, and were thus eventually similar across both study groups. Since there were different study physicians at all 4 sites, an interobserver bias cannot be excluded. This was mitigated by making objective study end points and the physician's discretion was used only while ruling out the allergic etiology of the illnesses. In addition, the training of the study physicians was harmonized with respect to quality, content, and duration.

Cluster randomization has statistical implications. The sample size was adjusted and planned to be increased 1.5 times compared to that needed for an individual RCT. In the primary analysis, the observed ICC, which measures the relatedness of clustered responses, was higher than anticipated, corresponding to a design effect more than 10 times higher than the protocol assumption. It is, however, comparable with estimates from the literature [71]. A higher number of clusters, with the same overall number of participants, could have increased statistical power. However, fewer clusters were used in the study due to practical reasons.

Conclusions

The study findings highlight the extent of nutritional inadequacies in urban school-age children in India, reaffirming the need for nutritional strategies to optimize the nutritional status among these children.

This study suggested that a cluster RCT design can be effectively used in nutritional intervention trials. The design mitigates the ethical issues inherent in double-blind individual RCTs in children involving daily administration of an empty-calorie placebo. The strategies used to achieve high recruitment and retention rates are valuable for the conduct of future studies in a similar population.

Acknowledgments

We would like to acknowledge the contribution of the Jehangir Clinical Development Centre (JCDC) team for the smooth conduct of and data collection for this clinical study. Authors VR, DC, VG, and PV worked at GSK Consumer Healthcare (now Hindustan Unilever Limited) during the clinical study conduct phase and are currently working as Independent Researcher, Delhi, India; Senior Nutrition Scientist at Smarty Pants, California, United States; Global Medical Affairs Manager, Alliance Pharmaceuticals, Chippenham, United Kingdom; and Advisor, Hindustan Unilever Limited, India, respectively. This research was funded by HUL Nutrition (formerly GSK Consumer Healthcare).

Authors' Contributions

VR, PV, and VG were mainly involved in the design of the study. AK was involved in investigation, methodology, and review of the manuscript. JB was involved in the planning, quality check, and supervising clinical study conduct. DC drafted the original

XSL•FO
RenderX

manuscript. The final version of the manuscript was carefully reviewed and approved by all authors. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

All authors except AK were employed by the funder (GSK Consumer Healthcare, now Hindustan Unilever Limited) while this clinical study was conducted. AK was the principal investigator for this clinical study and part of the clinical study center.

Abstract

Background: Caregiver-employees (CEs) for older adults experience a high burden to fulfill their dual roles. Caregiver-friendly workplace policy (CFWP) has been used in many countries to balance employment and caregiving duties, but it is a relatively new concept in Hong Kong.

Objective: This study explored the views and experiences of CEs, employers, and health care professionals regarding CFWP (specifically for older adult caregivers) in Hong Kong.

Methods: This study explored the CFWP-related views and experiences in Hong Kong using 15 in-depth interviews with purposively sampled CEs for older adults, employers, and health care professionals.

Results: Two context-related themes ("lacking leadership" and "unfavorable culture") were identified with thematic analysis. They explain the absence of CFWP in Hong Kong due to the lack of governmental and organizational leadership, and the additional burden experienced by CEs because of the working culture that underpins work-life separation, overprizing business interest, and unsympathetic corporate attitude. Implicit voice theory was applicable in explaining CEs' nondisclosure about their status at work due to potential risks. In addition, the two facilitation-related themes ("role struggle" and "inadequate support") identified in this study exhibit how the dual role had positive and negative spillover effects on each other and the inadequacy of social welfare and health care support systems.

Conclusions: We strongly recommend exploring and adopting potential CFWP in Hong Kong, considering the complexity of factors identified in this study.

Introduction

Background

In 2020, one billion people globally were aged 60 years or older, which is expected to double by 2050 [1]. This unprecedented increase in the aging population poses numerous economic, political, social, and health care challenges [2]. One of the pressing issues has been providing daily care to older adults. However, the size of the professional and trained workforce has not increased proportionately to meet this demand [3], driving innovations in other fields, such as robotics, to relieve some of the unmet demands of older people care [4]. Even in countries where welfare systems are well established, family caregivers provide most of the care and support for older adults [5].

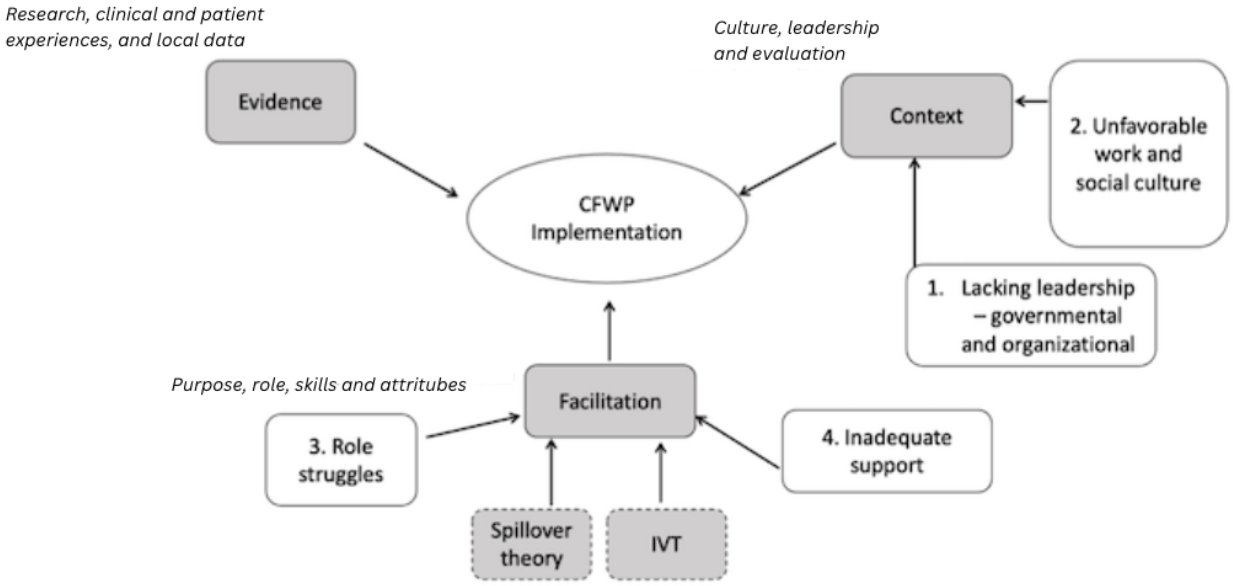
Consequently, caregivers experience high burdens, strain, and poor mental health outcomes such as burnout, anxiety, and depression, as noted by several studies [6,7]. Many caregivers may simultaneously engage in paid employment, referred to as caregiver-employees (CEs), who may experience additional burdens due to high professional and caregiving demands [8]. CEs experience significant impairments [7]; they are three times more vulnerable to adverse health issues than non-CEs [9]. The progressive decline in care recipients' functional capacity requires higher physical effort and caregiving time, resulting in poor health and depression among CEs [10].

Health care professionals (HPs) have traditionally provided psycho-educational support to promote caregivers' competency and well-being [11]. In addition, employers (ERs) are increasingly adopting caregiver-friendly workplace policies (CFWPs) to mitigate some of the caregivers' burden [7]. For instance, about 80% of ERs in the United States provide some CFWP [12]. CFWP typically includes flexible working arrangements, support services, and paid or unpaid leave [13] to help CEs manage their multiple roles and improve their work-life balance [7].

The growing international commitment to sustainable organizational behavior in which employee well-being is a significant determinant of their productivity, and therefore, organizational performance has accelerated the development and widespread adoption of CFWP [14-16]. For instance, studies have shown that in addition to employee well-being, CFWP may be critical for promoting the productivity of CEs [17] as they have been associated with improved overall health of CEs by reducing occupational and overall stress, minimizing work interruptions, and improving performance [18]. There are also direct economic benefits accruing from adopting CFWP. For example, educating CEs about their caregiving activities generates a net benefit ranging from US $48,010 to US $675,657 for CEs and ERs [19].

However, the three core stakeholders of CFWP may have different perspectives on the objectives, gaps, and limitations of the existing policies against the context of, for example, personal needs (for CEs), imparting caregiving competence (for HPs), or improving organizational performance (for ERs). Thus, exploring CFWP-related experiences and perceptions of CEs' and other stakeholders, especially HPs and ERs, is imperative. While several studies have reported the types and impact of CFWP [13,17], there is a paucity of studies reporting stakeholders' perspectives on CFWPs. Although we could not identify any study exploring the perspectives of CEs, one study explored the perspectives of managers working in the Canadian health care sector [20]. In addition, we could not identify any academic literature, public policy, or articulated organizational policy specifically devised for CEs caring for older adults.

Therefore, this study explored the CFWP-related views and experiences of CEs from Hong Kong caring for older adults, along with the views and experiences of local HPs and ERs with prior experience with formulating or implementing CFWP.



Conceptual Framework

Since CFWP is a relatively new idea in Hong Kong, we adopted the Promoting Action on Research Implementation in Health Services (PARIHS) framework for this explorative qualitative study. PARIHS was developed by the Royal College of Nursing in the United Kingdom as a conceptual framework of interacting elements to implement evidence-based practices [21]. The framework's key constructs, namely evidence, context, and facilitation, were used to guide the interview with participants regarding any future policy implementation.

To further add to the framework and explicate the facilitating factors, spillover theory [22] and implicit voice theory (IVT) [23] were used. The two theories orientate the questions from the point of view of the CEs, whereby spillover theory explores whether the interface between the microsystems of work and family is positive or negative [24], and IVT takes the gaze toward any perceived risks of inappropriateness of speaking up or disclosure of status in an organizational hierarchy [25]. These theories are fundamental in exploring the facilitation of CFWP, in other words, the expectation of and potential actions of stakeholders vis-a-vis the relatively new policy idea. Spillover theory aids the exploration of the interactions of the dual roles—work and caring—while IVT sheds light on whether CEs could or would disclose their CE status and advance their interests. Subsequently, the guiding theoretical framework adapted for this study effectively superimposes IVT and spillover theories on top of the PARIHS framework (Figure 1).

Methods

Study Setting

The economic and sociocultural factors in Hong Kong put carers in a particularly precarious position. Economically, laissez-faire has long been the foundation of Hong Kong's stability and prosperity [26,27]. However, free-market neoliberalism has failed Hong Kong in terms of increasing social inequality [28,29], leaving the economically and socially vulnerable even more susceptible to discrimination and unfair treatment. In our case, the CEs care for sick older people without their dual role being recognized in the workplace. Socioculturally, the experience of CEs is complicated by filial piety, the social value of reverence, which significantly constrains the attitudes and behaviors of the caregivers since Hong Kong households emphasize moral obligation in a strictly hierarchical sense based on the recognition of aid and care given to older adults [30].

The salient economic and sociocultural context of Hong Kong is further complicated by Hong Kong's aging population, which is expected to rise sharply from 17% in 2016 to 37% by 2066 [31]. Similarly, the older people dependency ratio is expected to increase from 5:1 in 2015 to 1.8:1 by 2064 [32]. The older people dependency ratio is attributed to the high prevalence of chronic disease in the older population; about 65% of the older adults in Hong Kong have a chronic condition, while one-third have at least two chronic conditions [33]. Furthermore, Hong Kong has the fourth highest cost of living among cities globally [34]. As a result, about 59.6% of the Hong Kong population is significantly engaged in the workforce [35]. These population trends indicate a high need for CFWP in Hong Kong and underscores the urgent need to scale up CFWP in Hong Kong. This need also emerged in our recent study in which 7% of CEs in Hong Kong caring for people with Alzheimer disease had signs of probable clinical depression and 10% possible mild depression [36]. Furthermore, the responses of this study's participants indicated that CFWPs can directly improve their mental well-being and organizational performance [36].

Study Design

This study was envisioned as theory-led research, considering both conventional theories in the field of CEs study and additional selected theories fitting into the context. Spillover theory and IVT were selected to guide and inform this study's design, perspectives, and interpretative lens.

Qualitative case studies are particularly appropriate when contextual conditions believed to be relevant to the phenomenon are under investigation and when boundaries between the phenomenon and context are unclear [37]. Given the absence of CFWP in Hong Kong, the contextual conditions the CEs are subjected to are relevant to CFWP because the potential construction of CFWP is firmly based on the context at hand. Therefore, a qualitative case study methodology involving the three core stakeholders of CFWP, that is, CEs, HPs, and ERs, was used in this study. Individual in-depth semistructured face-to-face interviews were conducted to explore CEs' experiences and needs while incorporating other stakeholders' perceptions, which is well served by a naturalistic, qualitative inquiry and triangulation of perspectives [38]. The data from the interviews were subsequently coded for thematic data analysis.

Hence, the study design adopted for this research allows the issues surrounding CFWP in Hong Kong to be explored via the lenses of multiple stakeholders who may harbor diverse and potentially contrasting perspectives. This method is valuable for health science research in developing interventions (ie, CFWPs) because of its flexibility and rigor in studying complex phenomena using several data sources [37].

Participants

The study participants included three groups: CEs caring for older adults, ERs such as company management personnel, and HPs providing ancillary services for CEs. The following inclusion criteria were used for recruiting CEs: residents of Hong Kong, employed full-time, concurrently taking up a

XSL•FO
RenderX

caregiver role for either their parents or spouses aged older than 60 years, able to provide consent, and that participation would not adversely affect their health or well-being. The eligibility criteria for ER were business owners or executives of a company with at least 10 employees and at least 5 years of management experience; for HP, licensed individuals who provided health care services and had at least 5 years of experience related to caregiver service were eligible.

As the time frame for data collection was limited, a purposive sample was used to select participants who already had some CFWPs-related background knowledge or experience. Potential participants were initially identified by referrals from a scholar in a local research institute specializing in caregiver welfare, followed by a review of participants' prior participation in policy forums and public campaign platforms. This process ensured that the participants were familiarized with the concepts of CE status and the relevant rights and burdens in Hong Kong. Additional participants were identified through the snowballing technique.

Study Instrument

The semistructured in-depth interviews were conducted using a discussion guide consisting of 17 questions (Multimedia Appendix 1) related to three aspects: (1) respondents' personal experience with CEs, (2) their attitudes and preferences for policies, and (3) their perceptions of a caregiver-friendly workplace. The discussion guide was developed based on (1) a thorough literature review, (2) the master's thesis of the first author [39], and (3) the recommendation of two expert panels of researchers specializing in the field of caregivers (ELW from the Chinese University of Hong Kong and XB from the Hong Kong Polytechnic University).

The interview guide was adapted for each participant type. Thus, three sets of interview guides directed the in-depth individual interviews for the three groups of participants. The interview guide for the CEs consisted of a checklist inquiring about the basic demographics of the CEs and their care recipients, followed by open-ended questions about their personal experience on the caregiving journey, encounters on their dual roles, and their interactions with regulatory frames and other actors within the workplace context. The interview guide for ERs started with a checklist to establish basic information about the company, followed by questions about their perspective on the current situation and potential for CFWP. For HPs, the guide outlined their observations and perspectives on CE's experience and CFWP.

Interview Process

The initial interviews were conducted face-to-face in informants' offices but later switched to videoconferencing due to the COVID-19 pandemic. All interviews were audio recorded. Interviews ranged from 20 to 70 minutes. The interviews were conducted in Cantonese (Hong Kong dialect) and then translated and transcribed into English verbatim.

The participant's written consent and demographic information comprising their age, sex, working position, and marital status were obtained before the interview. During the interview, conversation starters were used to open up the participants so they would feel more at ease and provide the most candid response. Prompts were used to elicit more specific and detailed responses to fully explore their experience and perception [40,41].

Thematic Framework Analysis

Thematic framework analysis based on the conceptual guiding framework was adopted. Data coding and analysis were independently conducted by two researchers (MML and XB) to ensure the consistency and reliability of the translation from Chinese to English.

The five stages of the analytical process comprised familiarization, identification of a thematic framework, indexing, charting, and mapping and interpretation [42]. The MAXQDA 2018 analysis tool (VERBI GmbH) was used to index all transcribed data. A total of 209 indexes were charted into 4 parent themes and 65 subthemes. The last stage, mapping and interpretation, was used to gauge the prominence of key themes and subthemes across the full list of participants. While the guiding framework informed the specification of questions and the main categories or themes of interest, the themes specified and explicated by this inquiry reflect participants' views. In other words, any strategy or recommendations emerging from this research echo the participants' attitudes, beliefs, and values [43]. Data credibility was established by obtaining validation from some participants on the accuracy of how their experiences were registered in the form of interview transcripts. Some participants were also invited to review the interpretations to ensure their beliefs were accurately represented, thereby minimizing bias.

Ethical Considerations

Research ethics approval was granted by the Imperial College Research Ethics Committee and The Hong Kong Polytechnic University Department of Applied Social Science Research Committee on June 6, 2018 (reference 18IC4581) and May 1, 2018 (reference HSEARS20180413002), respectively. Written consent was obtained from interview informants after the purpose of the study, and the plan for data confidentiality, analysis, storage, and dissemination was explained to them. All data were anonymized and kept in password-protected folders accessible only to the project supervisor and the research student. Participants were not provided monetary or material compensation for participating in this study.

Results

Participant Demographics

A total of 15 participants were interviewed between May and June 2018. The CEs (n=9; CE1-9) comprised 4 female and 5 male participants aged 20-70 years from four industries (banking or finance, technology, service, and education), with caregiving experience ranging from 0.5 to 13 years (Table 1). Three of the CEs had previously quit jobs because of caregiving roles. The major conditions leading to the caregiving roles were depression, dementia, physical disabilities, and tumors.

The HPs (n=3; HP10-12) comprised a geriatrician (HP10) who has been engaged in geriatric medicine for over 35 years in

XSL•FO
RenderX

private and public practice and two social workers (HP11 and HP12) with over 5 years of experience in different contexts, such as crisis intervention, end-of-life care management, and daily support services (Table 2).

The company personnel (n=3; ER13-15) were drawn from big, medium, and small enterprises engaging in retail, law, and technology, respectively (Table 3). Only ER15 works in a company with a Family-Friendly Employers Scheme by the Hong Kong Government [44].

Table 1. Characteristics of CEs[a] included in this study.

Informant code	Sex	Age group (years)	Industry (seniority)	Condition of the care recipients	Experience as a caregiver (years)	Ever quit a job because of the caregiving role
CE1	F[b]	21-30	Bank (junior)	Brain tumor	5	No
CE2	F	51-60	Retired; bank (senior)	Depression	6	No
CE3	F	21-30	Accounting (middle)	Lung cancer	2	Yes
CE4	F	41-50	Technology	Depression	10	No
CE5	F	31-40	Primary school teacher	Joint disorder	2	No
CE6	M[c]	51-60	Security guard	Physical disabilities	0.5	No
CE7	M	Older than 60	Retired; bank (senior)	Dementia	13	Yes
CE8	M	41-50	Servicing industry (middle)	Dementia	10	No
CE9	M	41-50	Secondary school teacher	Stroke	8	Yes

ER15	2000	Retails	Director, Human Resources	Yes

[a]ER: employer.

Current Overview

Interviews with all three CFWP stakeholder groups indicated the lack of formal workplace policy directly addressing CE issues. CEs further highlighted that any accommodation to their needs was made by management on a case-by-case, informal, and discretionary basis. Only two participants reported some form of formal workplace support for CEs. These family-friendly policies included a home office program and monthly 2-hour early leave for CE1 and CE4. These policies applied to all employees where CE1 and CE4 worked. Both CEs perceived these policies positively, exemplified by the remarks:

> *It makes a difference. It has reduced stress drastically. It is much easier to manage time, physical health (tiredness), and mental and emotional needs.* [CE4]

Thematic Analysis

Overview

The thematic analysis yielded 65 codes (Multimedia Appendix 2) categorized into four main themes: (1) lacking leadership, (2) cultural factors, (3) role struggles, and (4) inadequate support.

XSL•FO
RenderX

Lacking Leadership

A lack of guidance in laws or social policies for realizing CFWP in Hong Kong was evident during the interviews. All ER participants perceive that companies lack the resources, knowledge, and experience to support CEs. They consider government leadership essential, such as subsidies, guiding policy, and technical support. All three ER informants expressed willingness to adopt CFWP if the government takes the lead first. For example, one ER stated:

> *Government taking the lead is important. As long as there are some initiatives in the Employment Ordinance, corporates will initiate to follow...Citing paternal leave is a good example...How can he be part of the family throughout the journey? If considered, you could be surprised what the corporates would offer.* [ER15]

Within the organizational leadership, many operational factors and competing priorities influence ERs' decisions in adopting CFWP in Hong Kong, such as cost, fairness, potential uptake, and inadequate resources. ER13 reflected that caregiving roles and mental illnesses are stigmatized in Hong Kong, limiting potential service utilization. Smaller companies are hesitant to adopt CFWP officially for the potential cost implications and further responsibilities it might entail. ER14 remarked that formalization may unleash other obligations. ER14 and ER15 admitted they have other priorities, such as childcare, over CFWP. For example, ER15 highlighted, "Corporates might perceive not all older adults need help, but all children need care." HP10 confirmed that children-friendly work arrangements are common but not CFWP in Hong Kong.

Cultural Factors

CFWP aims to promote holistic integration of work and life by enabling CEs to balance their roles as employees and caregivers. However, some observations made by participants seem to suggest that the fundamental tenets of CFWP may be at odds with cultural and workplace values in the Hong Kong setting. The concept of work-life separation, rather than work-life balance, is highly prevalent in Hong Kong. A total of 6 (67%) out of 9 CEs indicated that it is an established norm in Hong Kong to separate personal or private concerns from work, if not altogether, rendering them secondary to work concerns. In other words, personal issues should not be imposed on workplaces. Failure to detach from personal stress at work could entail a reproach from management. For instance, CE7 recalled that his manager remarked, "Don't bring this burden to work. Once you clock in, you better not have this burden in your mind."

Four CE participants stated that the prevalent corporate attitude in Hong Kong prioritizes business interests over employees' well-being. The participants highlighted a culture of assumption of total work commitment from employees that leaves little room for considering CEs' concerns. They further intimated that this culture makes it difficult for CEs to raise the issue of caring for loved ones with their managers. HP10 shared this sentiment rather strongly while stating, "Employers expect slavery, working 10 hours, better not to go home, not taking leave, not getting sick, without seniors at home, no marriage, no relationship, and no children."

This attitude of management caused acute stress for employees and potential conflict with management when urgent health issues of the family care recipients need to be dealt with while the CE is at work. At these times, CEs find themselves in a dilemma of multiple roles and uncertainties. For example, one CE stated:

> *It was so stressful every time my mother called when I was at work...I was so nervous. Because of the long-term mental stress, I have hypertension.* [CE7]

All CEs lamented a general lack of compassion from their ERs and colleagues. CEs must take formal leave because "caregiving roles occur outside work hours." As a result of the unsympathetic attitude, 6 CEs chose not to disclose their CE status and remained silent, while others became more stressed or decided to quit. CE5 described her organization's management as so apathetic that she chose not to disclose her chronic condition as well. She regarded her role in the organization as "replaceable." Therefore, letting management know her caregiving role was not an option. She felt that she had no power or involvement in the decision-making process concerning her disease or her caregiving role because of the hierarchy of her organization. CE5 and HP11 attributed this passivity from the ERs to the assumption that the government should take full responsibility for supporting CEs.

CEs also spoke of colleagues' indifference to their circumstances. Fear of gossip limits CEs from disclosing their circumstances. Disclosing could be perceived as an excuse to do less work, as exemplified by a statement:

> *Trust is important, so information about me will not be spread around...I don't want people to see it as an excuse [weakness]. I don't want people to see me using my mother's condition as an excuse to do less work.* [CE3]

CE6, a security guard, believes that disclosure could dangerously affect his position in the organization. Conversely, CE4, a senior manager, expressed no hesitation or concerns regarding disclosure of his CE status. This indicates that seniority in the corporate hierarchy influences how empowered CEs may feel about disclosing their status.

The notion of the primacy of work over personal concerns is also reflected in CEs' behavior. Most CEs took it upon themselves to overcome additional burdens at work and were either not keen or could not seek help and share burdens with others. They expressed high expectations of themselves as employees and caregivers, compounding the stress. One HP noted:

> *They (CEs) will just impose the problems on themselves. They choose not to take absences but work until midnight to care for the older adults.* [HP10]

This work ethic exacerbates the stress experienced by the CEs.

Role Struggle

All CEs expressed experiencing struggles navigating the different roles as employees, caregivers, parents, partners, and friends. They felt the urge to reprioritize values in life as they

XSL•FO
RenderX

often take on a reverse role, from a child to a guardian for their frail parents. CEs reported that the caregiving role influenced their behaviors and decisions, like spending patterns or quitting a job. For instance, one CE stated:

> *I didn't want to abuse the system or the job and wanted to prioritize my students' learning experience, and that's why I decided to quit.* [CE9, teacher]

CEs sacrificed their time to undertake the caregiver role at the expense of self-care, potentially causing a loss of personal identity and difficulties connecting with themselves and others. As CE1 stressed, "The biggest change is the loss of friends and my personal time. All my time was devoted to family needs." In the case of CE7, he was abandoned by his wife after his full-time caregiving role forced him to quit his job. Thus, reprioritization of values could wreak havoc on family integrity. In addition, reprioritization may result in unmet psychological and emotional needs, introducing an identity struggle that further overwhelms the CEs. In this regard, CE7 remarked, "I need to look at myself as another person to live up to my caregiving role."

It is difficult to strike a balance between caregiver and employee roles. The intensity and stress of these roles are inseparable and nonexclusive, which may lead to a downward spiral if no support is available. New CEs may be more prone to this balancing problem because they lack institutional support and resources to prepare for these dual roles. For instance, one CE stated:

> *It was very difficult to adjust at the beginning...Letting go of work stress and switching to caregiver mode was very difficult.* [CE1]

Conversely, work could also be a protective factor for CEs to take on caregiving roles. Engagement at work can alleviate the caregivers' stress if balance can be attained. This was best exemplified by the statement:

> *If the caregiving role is 24/7, you will lose the meaning and make caregiving an obligation. It will become a burden. Especially in Hong Kong, where living space is so small. If you only take on the caregiving role, it can feel like being trapped in a cage.* [CE8]

The unavoidable familial tension—reported as "unresolved childhood emotions"—further rarifies the role struggle. HP12 spoke about how the inner child of the caregivers can be a vulnerability: "Since the care recipients are the parents who have shaped a large part of the caregivers' lives, a single gesture or action could trigger emotional stress from trauma as far [back] as those from childhood." CE5 exemplified inner child struggle as well. She reflected that she found it unfair that she had to care for her father, who had done little to support the family during her childhood. Even though she has become financially independent, CE5 would readily associate the overwhelming stress of the caregiving role with the powerlessness and lack of confidence in her child-self because of the wounds caused by her father. These emotions could intensify the present role struggle.

Inadequate Support

CEs exhibited a feeling of hopelessness mainly because of the uncertainties they faced. This hopelessness is exacerbated by the minimal assistance and support received, as explained by one HP:

> *Hopelessness...because chronic illnesses have no foreseeable end. The uncertainty of knowing how long the suffering will last causes hopelessness. The caregivers' task lists don't end either. It never ends. It is endless.* [HP11]

There is limited information to prepare and enable caregivers to live up to their roles. Besides limited information from doctors, there is a lack of reader-friendly, timely, and high-quality information. HP 10 remarked, "There is a serious need for information support...Hearsay is commonly found but useless." All CEs were frustrated in finding the quality information they needed to live up to their roles, including those related to social welfare support and handling the needs of care recipients. Most CEs had little idea about available social welfare support resources because of limited public awareness and promotion programs. In this context, one CE stated:

> *The hospital didn't actively promote them to us. And we didn't expect there is this kind of thing. It was difficult to find appropriate information. Doctors at public hospitals would not have the time to explain—only standard treatment procedures. But they didn't talk about the side effects or things about daily care to know. I was quite lost.* [CE3]

Most CEs perceived the information provided by social welfare support as inadequate. One of the social worker informants confirmed that due to potential conflicts of interest in recommending a specific service provider to caregivers, it is normal for caregivers to receive a long list of providers without recommendations, which can be confusing. The inadequate quality of information and the lack of promotional programs cause an information gap that makes CEs' caregiving journey challenging.

Accessing social welfare support is limited because of the high qualification threshold. Most cases are in the middle of the scale and ineligible for financial or physical support like respite care or home care services. In addition, the resources designated for caregivers are generally meager. One CE responded:

> *The social worker has only 1% of her work duties devoted to handling cases...she made decisions on my behalf without telling me about the rationale and the context.* [CE9]

Such negative experiences further discourage CEs from seeking social welfare support. ERs noted the need to match the services of providers with users, particular conditions they are facing, and the stage in the caring process. HP13 reported that CEs' characteristics influence service quality and satisfaction. Matching is crucial in the first stage to ensure good quality, according to ER9.

Health care providers agreed that social welfare support is inadequate because of fragmentation and lack of crisis

XSL•FO
RenderX

intervention. Crisis intervention services are available only to hospitalized cases. The chances of accessing them after discharge are minimal. The care system is fragmented and superficial because social workers have other challenging roles besides carer services. Social workers might chase the number of cases under their purview instead of going deeper individually by enhancing the caregivers' well-being or counseling them.

Besides limited resources and services, operations and priority matrix do not favor caregivers' referrals for social support, as exemplified by the following statement by HP10: "Relying exclusively on their doctors is not enough when these doctors are extremely busy." CE3 further reflected that health care providers' attitudes often lacked empathy and professionalism, resulting in disappointment and frustration. The lack of empathy or indifferent attitude of health care practitioners intensifies CEs' powerlessness. In this regard, CE3 stated, "Since time and resources are scarce in the public hospital, they wouldn't prepare you mentally for the situation. They would just tell me the symptoms and options and seek our consent for surgery immediately. There was no time allowed for our consideration. Everything was mechanical."

There are also substantial barriers to accessing professional mental health services for caregivers. For example, waiting time is considerably long, and according to HP12, "only serious cases, such as suicidal attempts, might be considered for the clinical mental health services."

Discussion

Principal Findings

This study explored the CFWP-related views and experiences of multiple stakeholders (CEs, ERs, and HPs) in Hong Kong, guided by a theoretical framework that oriented the interest toward exploring CE experiences in depth (IVT and spillover theory) and exploring the potentials of CWFP as new ideas within the broader context (PARIHS framework). Principal findings were broadly organized under two context-related ("lacking leadership" and "unfavorable culture") and two facilitation-related ("role struggle" and "inadequate support") themes.

Regarding CFWP, Hong Kong lags behind other aging Asian societies, such as Japan and Taiwan, which have already adopted 93 [45] and 21 [46] leave days for CEs, respectively. Lack of clear leadership and confusion in public policy roles and guidance was highlighted as one of the primary reasons why explicit CFWPs are absent in Hong Kong, despite the urgent need for CEs and the apparent willingness of ERs to adopt CFWP. The government taking the lead in establishing guiding frameworks for CFWP, both in law and administration, appears to be the critical missing link. Given that Hong Kong's health care system bears colonial inheritance [47], the United Kingdom's Care Act could prove instructional. The UK Care Act was implemented in 2014 to protect the rights of caregivers. The law provides provisions for the local authorities to identify CEs' needs by assessing private companies [48]. These provisions allow the UK government to strategically partner with private companies and provide support and services for ERs to achieve caregiver-friendly working environments [49]. Similar legal protection and policies adapted to the local context will be instrumental in widespread CFWP adoption among Hong Kong companies.

Regarding organizational leadership, welfare ideology and operational concerns are the two factors hindering the formulation and uptake of CFWP. Hong Kong's long-standing universal welfare ideology, described as distorted toward the government presumably providing for welfare in aging and antipoverty programs [50], fuels companies' denial of their corporate responsibility in addressing the needs of the CEs. This study also shows that operational factors, such as cost, potential uptake, and inadequate resources, prevent CFWP from gaining prominence in the organizational leadership agenda. However, the absence of CFWP is far more costly in the long run due to increased absenteeism, reduced work productivity, increased turnover, and work disruptions [51]. Sustainable long-term organizational growth would require well-considered organizational leadership that addresses this substantive issue.

In addition, local cultural factors were also identified as hindrances to CFWP adoption, such as issues concerning work-life separation, total work commitment, and lack of compassion from management. The Confucian work ethic of hard work, perseverance, and patience is also deeply embedded among Hong Kongers [52]. The sentiments and behavior reflected in our study affirm the prevalence of these values and further indicate that these may not always be compatible with the underlying principles of CFWP. The associated taboos and risks of speaking up, as perceived and experienced by CEs, further demonstrate the assertions of IVT that explain the risks and inappropriateness of speaking up.

Older adults may have diverse and unexpected health care needs that are not always associated with chronological age [53]. Thus, adopting a caregiver-friendly workplace culture conducive to compassion and acceptance of CE's circumstances is necessary. Such cultures include supportive management, a trusting environment, and establishing top-to-bottom leadership [54]. An empathic and caregiver-friendly culture would potentially encourage CEs to identify themselves (rather than implicit voice spaces), and incorporating flexibility and acceptance into business management and work culture enhances employee commitment [55].

Regarding role struggles, our findings indicate that there may be positive and negative spillovers between work and family, upholding the constructs of spillover theory. For some CEs, work can serve as a break from caregiving roles, and hence, be a protective factor, while the high burden of dual roles can force some CEs to quit work, sacrifice self-care, or even get abandoned by family members. For instance, a study focusing on the well-being of Hong Kong male caregivers reported that work has protective effects by improving caregivers' resilience and overall well-being [56]. Therefore, role-balancing is key because it rewards CEs with a sense of satisfaction and fulfillment and also avoids any ramifications by giving up paid employment for caregiving roles [57]. CFWP, which promotes and engages CEs to balance work and life, is critical for positively managing this spillover effect. These findings are

XSL•FO
RenderX

consistent with existing literature that CFWP reduces absenteeism and sick leave rates and increases employees' productivity, loyalty, engagement, and morale [58-60].

The inadequacy of support was amply reflected by CEs and HPs alike. Even though family caregiving has become more demanding, complicated, and longer-lasting than in the past, caregivers are often underprepared [61]. This study further highlights that CPWP is most needed by CEs who have just commenced the caregiving role and experience acute crisis because of little preparation and knowledge about their new role. This, in turn, emphasizes how support for new caregivers is critical for the short and long-term well-being of both CEs and their care recipients. Caregiver preparation and education are vital in reducing psychological stress and coping with the situation better [62-64]. Companies can bridge the information gap and facilitate matching according to their unique demographics and the needs of caregivers. CFWP is, therefore, imperative to help new CEs navigate their caregiving journey.

Previously, caregiving tasks in Hong Kong could be shared among siblings when family sizes were larger. However, nuclear families have become the norm in Hong Kong, with an average household size of 2.8 members [65]. Future generations are expected to have even fewer siblings sharing caregiving responsibilities, which is bound to compound and intensify the burden and sense of powerlessness. Therefore, effective CFWP is needed to ensure support for income earners to avoid the myriad adverse effects on individuals, society, and businesses.

Limitations

The major limitation of this study is that we predominantly recruited CEs engaged in full-time work, which may not fully reflect the views of CEs who are part-time or unemployed. In addition, CE participants in this study were well primed to reflect on these issues as they were already actively engaged in policy consultations for CFWP, limiting the generalizability of our findings.

Conclusions

This study is the first inquiry into the experiences of CEs and factors that may influence the adoption of CFWP in Hong Kong. The qualitative methodology and the purposively identified participants have provided a glimpse into the lives and tribulations of this otherwise invisible but growing population group. Our findings strongly indicate that Hong Kong's current workplace policy frameworks fall short of meeting the immediate needs of CEs and the long-term interests of companies and society. We urge actors to explore and adopt potential CWFP for Hong Kong, considering the complexity of factors explored in this study, including unique cultural dynamics and structural factors related to the aging population and ever-increasing health care burden. Future research should identify CEs who need the most support and pinning down the most optimal forms of regional law and organizational policy.

Abstract

Background: The COVID-19 pandemic had a substantial, negative impact on the world, and physicians played a crucial role in providing health care while facing the risk of contracting the virus themselves. While working on the frontlines, they also needed to protect themselves and their families from the virus. Unfortunately, their mental health was not given the attention it deserved. Many physicians experienced burnout due to the numerous challenges they faced, yet they received little support. Resource-limited countries such as Bangladesh were particularly affected due to a lack of resources. Although high-income countries have proposed a well-being model for physicians, this model is not directly applicable to resource-limited nations. However, redefining the model to suit the specific needs of physicians in resource-limited countries could provide sustainable support for their well-being.

Objective: We aimed to gain a deeper understanding of the mental and physical burdens faced by Bangladeshi physicians during the COVID-19 pandemic, and the contextual factors influencing their well-being. By understanding these aspects, we can recommend an adaptable, effective, and sustainable contextual model.

Methods: We conducted semistructured online interviews with 14 physicians in Chattogram, Bangladesh, during the COVID-19 pandemic. The physicians actively working in the COVID-19 unit were recruited from public and private hospitals through purposive sampling. Participants were aged between 25 and 35 years and had up to 8 years of working experience, including 43% (6/14) interns, 36% (5/14) medical officers, 14% (2/14) researchers, and 7% (1/14) surgeons. Each interview was conducted in Bengali, and we obtained consent to record the audio. Overall, 637 minutes of discussion were translated and transcribed. The results were analyzed using reflexive thematic analysis.

Results: We identified factors that impacted physicians' mental and physical health and well-being during the COVID-19 pandemic. They frequently dealt with undiagnosed patients, which put them at risk. Physicians often feared the potential danger their profession posed to their families, choosing to prioritize their family's safety over their own. In addition, heavy workloads, excessive duty hours, and a shortage of colleagues substantially affected their sleep patterns and disrupted their regular work schedules. Instead of receiving societal support, they often faced negative perceptions from the public. In addition, during times of mass patient deaths, many physicians struggled to cope with their emotions without any mental health support.

Conclusions: Our work shows physicians' mental and physical health burdens with various contextual difficulties. We understood these concerns and suggested a contextual (emphasizes understanding and addressing users' behavior within its specific context) intervention model inspired by the well-being framework. We emphasize the importance of integrating both contextual and

XSL•FO
RenderX

technological interventions. Through this model, our goal is to involve stakeholders in redesigning the work environment for physicians, ensuring it is sustainable in the long term and adaptable to different situations.

Introduction

Background

The COVID-19 pandemic has led to a significant loss of human life globally [1-5], with physicians serving as frontline warriors dedicated to the well-being of the population while trying to keep themselves and their families safe [6,7]. Tragically, many physicians lost their lives while performing their professional duties. In the United States, over 4500 physicians succumbed to SARS-CoV-2 [8], while approximately 6500 health care professionals died in England and Wales in the United Kingdom [9]. These tragic figures were not isolated to high-income nations. The crisis extended to India, with approximately 1800 deaths of health care workers [10], and China reported the loss of 64 health care workers [11], among many other countries. The situation was similarly dire in Bangladesh, a resource-limited country, which reported around 113 physicians' deaths within just a few months in 2020 [12]. With about 80,000 physicians caring [12] for a population of 180 million in Bangladesh, the high patient-to-physician ratio highlighted the immense pressure physicians face. This pandemic placed additional strain on physicians and the health care system, resulting in significant psychological distress [13].

While numerous studies have discussed the health effects of COVID-19 on patients, the impact on physicians has received less attention. Physician burnout became a prominent worldwide issue during the pandemic [14-16]. This burnout stemmed from several factors, including stress [17,18], workload [19,20], anxiety and depression [18,21], inadequate support [17,18,20], lack of protective gear [13,20], and many more. Research indicated that 32.9% of physicians experienced stress, 34.9% dealt with depression, and 39.5% faced anxiety [22]. In addition, a study by Emre et al [23] found that among 225 physicians, 17.8% exhibited symptoms of posttraumatic stress disorder, regardless of their gender, marital status, and other factors.

Factors contributing to this distress included a high risk of infection, inadequate protection from exposure, excessive workload, frustration, discrimination, isolation, negative emotions from patients, lack of family contact, and overall exhaustion [24,25]. Physicians often had to maintain social distance from their families to reduce the risk of transmitting the virus, further impacting their mental health [13,26]. In addition, during the pandemic, the extreme workload due to a surge in patients resulted in increased stress and depression [20,21]. Covering for colleagues [19,27] is a duty hour complexity [19] that also contributed to the increased workload. Because of these high work demands (mental, emotional, physical, and temporal), limited recovery experiences (such as relaxation and detachment from work) impact physicians' mental health [18]. Many physicians also experienced sleep disturbances, with more than two-thirds reporting insomnia (68.3%) and a majority (93.7%) experiencing stress as a result [15]. Despite risking their lives serving patients, physicians received inadequate support from hospitals, government agencies, and society at large [20,28]. A lack of logistics support, insufficient backing from peers and supervisors, and low feelings of occupational competence during COVID-19–related tasks contributed to the emotional toll on physicians [18].

Much of the existing research has focused on physicians' experiences in high-income countries, overlooking the burdens and well-being of physicians in resource-limited nations. Although some issues are similar, conditions are often worse in resource-limited countries, which struggle significantly with resource shortages and inadequate administrative support [20,29,30]. The pandemic has exacerbated the existing shortcomings within these health care systems, creating additional challenges for physicians. Therefore, there is an urgent need to explore the mental and physical health of physicians in the context of resource-limited countries and the unique problems they face.

Aims and Approach

This research aimed to understand the mental and physical burdens faced by Bangladeshi physicians during the COVID-19 pandemic, considering the specific contextual challenges they encountered. We sought to explore how they delivered care to patients while also managing their personal and professional lives, the sociocontextual problems they faced during the pandemic, and how these issues impacted their overall well-being. However, there is limited research on how physicians can sustain their well-being. Daniels et al [31] presented a well-being model for health care professionals during the pandemic, which identified several key factors necessary for maintaining well-being, including access to basic physical resources, communication, embedded support systems, and psychological interventions. This model inspired us, and a similar approach tailored to address the specific concerns and contextual problems faced by physicians in Bangladesh would enhance its effectiveness and sustainability. In this paper, we report the results of in-depth interviews conducted with physicians in Bangladesh.

Methods

We conducted in-depth qualitative interviews with 14 physicians in Bangladesh during the COVID-19 pandemic to understand

XSL•FO
RenderX

their well-being and stress indicators. The interviews were semistructured and held online.

Research Settings and Self-Disclosure

All participants were located in Chattogram, Bangladesh, which is the country's largest port city and second-major city, situated approximately 300 km southeast of the capital, Dhaka. During the pandemic, Chattogram experienced a high frequency of COVID-19 infections, prompting us to recruit physicians from this area.

It is important for the readers to understand the researchers' perspectives [32]. We chose this location because we are familiar with it. All researchers (2 men and 3 women) were born and raised in Bangladesh, making them well-acquainted with the local cultural norms. As native speakers, the researchers have conducted multidisciplinary research related to health and technology. These experiences allowed us to effectively facilitate this study.

Recruitment and Participants

We focused on recruiting physicians who worked in both public and private hospitals during the COVID-19 pandemic. We used a purposive sampling method [33] to recruit 14 participants to accomplish this. During recruitment, we used close connections, such as relatives, friends, and colleagues, to identify potential participants. We explained our inclusion criteria (physicians who worked as frontliners in hospitals during the intense period of the pandemic) to our contacts, who helped us connect with eligible individuals. Then, we contacted them by phone to explain our research objectives and interview techniques. Subsequently, we formally recruited interested participants.

The 14 recruited participants were aged between 25 and 35 years. They had between 1 and 8 years of work experience in public and private hospitals in Bangladesh. In total, 12 (86%) participants were unmarried, while the remaining 2 (14%) were married. The group included 6 (43%) intern physicians (who had recently completed their professional degrees), 5 (36%) medical officers (serving as junior physicians), 2 (14%) researchers (focused on medical topics), and 1 (7%) surgeon (a senior physician). A detailed description of the participants has been discussed in the Results section.

Although the sample size was small, we reached a saturation level within that sample because we conducted in-depth interviews. After each interview, we organized and analyzed the data to improve our approach for the next one. Regardless of the participants' gender, job positions, workplace, or years of experience, we found that they shared similar experiences during their duties throughout the pandemic, confirming the saturation of data.

Ethical Considerations

This research was approved by the ethics committee at North South University, Bangladesh (2021/OR-NSU/IRB/0303). Before the interviews, we provided participants with soft copies of consent forms that included the research objectives, aims, and methods in Bengali. We clearly explained that the interviews would be audio recorded and that we would collect demographic information, such as name, age, gender, designation, and workplace. We assured participants that all information would be anonymized to protect their identities. They returned the consent forms online to confirm their participation before the interviews began.

We avoided using participants' names, home addresses, and institutional affiliations as identifiers to maintain confidentiality. Instead, participants were assigned code names, such as participant 1, participant 2, ..., and participant 14. They were also informed that they had the complete right to withdraw from the interview at any time without losing their incentives. Only the researchers had access to the data, which was securely stored on a locked drive. These data will not be shared or transferred to any third-party entities. After the interviews, all participants received notebooks and stationery items sent via courier as a token of appreciation for their participation.

Procedure and Study Design

We conducted interviews between May and December 2021. The participants had busy schedules due to their duty hours; in addition, to maintain social distancing due to the emergence of COVID-19 during that time, we scheduled the interviews online based on preferences and availability. Three researchers were present at each interview to collect data, as the interviews were semistructured. We used the Google Meet platform for the interviews, and most lasted approximately 60 (mean 45, SD 16.26) minutes or more. Each of the 12 participants was interviewed individually, with only participants 5 and 6 attending together as acquaintances. The interviews were conducted in Bengali, audio recorded with the participant's consent, and we followed the same protocols for both individual and group interviews.

The interviews began with an introduction and a discussion about the participants' general work experiences during the first wave (March 2020-May 2020) and second wave (March 2021-May 2021) of the COVID-19 pandemic, as this was a new situation for them. We then explored their mental health and the factors that contributed to their stress during both normal and pandemic periods. In addition, we were interested in understanding how the pandemic impacted their social, family, and work lives, as well as what kind of support they received or felt was lacking, which could enhance their overall well-being. Finally, we inquired about any potential technology that could support their well-being. The participants were responsive and willingly shared their perceptions and suggestions.

Analysis

The sessions were conducted in Bengali and required transcription and translation of all the interviews. Being fluent in both English and Bengali, all authors transcribed and translated the audio carefully directly to English (forward translation). A total of 637 minutes of audio recordings resulted in a rich corpus of narrative data comprising 156 pages (approximately 71,700 words). All authors revised the translated version of the transcription that assured the validity of the data and analyzed it all without using generative artificial intelligence (AI). We created high-level summaries of narrative data for the following interviews. After completing all the interviews, we

XSL•FO
RenderX

used reflexive thematic analysis, both inductive and deductive [34,35]. While we had specific topics of interest, such as physicians' stress, work schedules, sleeping patterns, social problems, and lack of support, we used open inductive coding to identify broader trends [36,37]. We read and reread all the transcriptions multiple times to become thoroughly familiar with the data and subsequently identified 52 different codes across all the transcriptions. We then organized the codes using MIRO, mapping them out, and creating groups of similar codes. We kept in mind the specific topics, and lastly, during theme generation, we adopted a deductive approach that was guided by the model by Daniels et al [31], allowing us to structure our findings within an established theoretical framework. In total, 3 themes were generated.

Theme 1 focused on the risks and fears that physicians and their families faced regarding the SARS-CoV-2 virus as they worked on the front lines with patients who had undiagnosed infections, which ultimately led to their own infections. *Theme 2* highlighted the increased stress and workload that physicians experienced, indicating that the COVID-19 pandemic negatively impacted their overall well-being. In addition, the social isolation they faced contributed to their mental decline. *Theme 3* addressed the emotional connections that physicians formed with their patients while on duty during the pandemic, as well as the lack of mental support to help them cope with the emotional toll and potential mental breakdowns.

Results

Participants Demography

Table 1 shows participants demography, where among the 14 participants, 12 (86%) were female and 2 (14%) were male. We recruited more females for 2 reasons. One, the number of registered female physicians is more (52%) than the male physicians (48%) [38]. Second, women in Bangladesh in general face greater challenges in the workplace due to patriarchal social norms in Bangladesh, which was also the case during the COVID-19 pandemic [38,39]. However, we did not observe any gender-based differences regarding their work experiences during the COVID-19 pandemic (Table 1).

Table 1. Participants details (N=14).

Participant code	Marital status	Designation	Format	Unit and type of hospital
First round of individual interviews

Theme 1: COVID-19 Pandemic's Domino Effect: Undiagnosed Cases Impact Physicians and Their Families Health

The Risk From Undiagnosed COVID-19 Cases

During the peak period of the COVID-19 pandemic, the participant physicians primarily attended to undiagnosed patients in emergency zones of hospitals, often unaware of whether these patients were COVID-19 positive, putting the physicians at risk. The situation consisted of cases where patients were unaware of the conditions, and in a few cases, it was deliberate denial.

Many patients did not follow safety precautions while visiting hospitals and were not cautious about their own health conditions. This was due to the high physician-to-patient ratio along with a coping mechanism of handling fear, as a few

XSL•FO
RenderX

participants shared. The physicians diagnosed these patients by listening to their concerns and assessing their symptoms, often influenza-like and other respiratory disease symptoms. On the basis of their evaluations, they performed rapid antigen tests to obtain results in about 15 minutes, after which they transferred patients who were suspected to have COVID-19 to the COVID-19 unit for further care. Participant 10 expressed the following:

> *Most of the time, patients would come to us undiagnosed. They didn't even know their bodies were carrying the germs of COVID-19 and were unaware of it.*

All the physicians noted that patients often concealed their symptoms. This puts the physicians in a difficult position regarding the decision-making of whether to send patients to the COVID-19 pandemic unit. Once in the COVID-19 pandemic unit, patients were generally suspected of having the virus, and due to the lack of personal safety measures, there was a risk of further spread within the hospital. Consequently, physicians suggested that patients return home. As participant 13 explained the following,

> *We tell them that if they stay in the hospital during the COVID-19 period, they might get infected.*

Conversely, when physicians suspected COVID-19 pandemic symptoms—such as breathing difficulties, overlapping infections, or Omicron variant symptoms such as diarrhea and drops in oxygen levels—patients frequently denied they had COVID-19 and only accepted the diagnosis when test results came back positive. This situation increased the risk of physicians getting infected during the assessment period. Participant 6 expressed frustration about the patient's behavior:

> *People didn't admit they had COVID-19. They would say they had stomachaches and wouldn't mention a sore throat. After examining them, we noticed they had a fever and were coughing. After testing, we found them to be COVID-19 positive. Many of our doctors were affected by these patients.*

Some patients had clear signs of COVID-19 but yielded negative test results. As a precaution, physicians often tested themselves 2 to 3 times due to the potential risk of infection. Many physicians reported being infected with COVID-19, yet they continued to work for the well-being of their patients, often sacrificing their own health. Participant 13 shared her experience:

> *One night, I received seven patients, all suspected to have COVID-19. I also felt sick and distressed, but I didn't pay much attention and did my duty. It was nearly impossible to maintain proper sterilization and disinfection. I could feel something was happening to me, but I ignored it.*

It showed the major difficulty physicians faced, constantly battling the fear inside them.

Between Fear and Safety: Families Navigating the COVID-19 Pandemic Threat

The participant physicians often stayed away from families and did not share their concerns around getting infected with the SARS-CoV-2 virus. Several participants were infected with COVID-19 but chose to ignore their conditions due to concern for their families. If they suspected they had contracted the virus, they often refrained from sharing this information, especially with their parents, fearing it would cause unnecessary panic, as participant 1 expressed:

> *I can't share these feelings with my family, like telling them I suspect I could be affected. They panic easily. Indeed, people can't handle panic like a doctor can.*

Their primary concern was the fear of transmitting the virus to family members after returning home from work. Physicians who had previously contracted COVID-19 or whose loved ones had experienced it were particularly cautious while on duty, which heightened their tension and fear. Participant 9 noted the following:

> *Our colleagues who had COVID-19 or whose families suffered heavily due to it took extensive precautions when they returned to the ward. They struggled to breathe, wore N95 masks layered with double surgical masks, and worried about not wanting to be on duty for too long out of fear.*

These physicians felt an overwhelming burden regarding the risk their profession posed to their families, often prioritizing their families' safety over their own, as they shared during the interviews. When family members fell ill, they felt an added responsibility to secure the best medical care for them, which only increased their stress. Some physicians intentionally maintained isolation to minimize interaction with their families to keep them safe. Despite their families expressing concern about their health, these physicians tried alleviating fears. As participant 12 explained the following:

> *My family used to stress about it. But I wasn't as fearful because I didn't expose them to what I was going through. I felt like a carrier, so I lived in the hostel.*

This way, the physicians managed to safeguard their loved ones while managing their own health concerns.

Physicians' Struggles of Fighting COVID-19 Along With Families

During the COVID-19 pandemic, the families of physicians also faced significant challenges, as many were infected with the virus. Physicians struggled to balance their hospital duties with their responsibilities at home despite ensuring safety. For instance, participant 3 shared her experience of her baby, aged 14 months, contracting COVID-19 due to her exposure. At the same time, her husband was hospitalized for breathing issues, illustrating the helplessness, stress, and fear she felt regarding her family's situation, especially as she could not maintain proper isolation with a young child:

> *Despite maintaining precautions, I was affected by COVID-19 along with my 14-month-old baby; my*

XSL•FO
RenderX

> *baby has already suffered because of me. My husband also tested positive and was admitted to the hospital. We couldn't maintain proper isolation, as my baby was very young then. I wasn't seriously affected, but the baby was.* [Participant 3]

During the peak of the COVID-19 outbreak, the patient influx overwhelmed hospitals, pushing them beyond capacity. Therefore, all wards, cabins, emergency units, intensive care units, and critical care units were filled with susceptible patients with COVID-19. This created additional challenges for physicians trying to admit their sick relatives. Participant 6 recounted her struggle to admit her father to the hospital. Meanwhile, her sisters and mother were at home, infected with COVID-19, and their health was deteriorating, adding more to her stress:

> *I took my father to the hospital and asked for a cabin. There were no empty beds. I called my principal, who advised me to go to another hospital. It took me two hours as a doctor to find a space there; a random person would have needed much longer. My two sisters and my mother were also affected by COVID-19. They couldn't comprehend how my mother's oxygen saturation was falling. After three days, I went home, and there was no one else I could ask for help. I eventually took my mother to the cabin where my father was and provided her with oxygen. That night was incredibly stressful.* [Participant 6]

These experiences reflect a common theme among physicians, showcasing their declining mental and physical well-being as they navigated the dual responsibilities of caring for patients in the hospital and their families at home.

Theme 2: The Hidden Battles of COVID-19: Physicians' Burnout, Wellness, and Social Stigmatization

Navigating Physicians' Workload and Wellness

Physicians' pressures of their professional obligations profoundly impacted their personal lives, leading to multilayered experiences. During the COVID-19 pandemic, the work schedule for health care professionals was severely disrupted for 2 main reasons: an imbalance in the ratio of physicians to patients who were infected compared to normal times and the unavailability of coworkers due to COVID-19 infections. Participant 13 mentioned, "We, four doctors, are treating 50-60 patients simultaneously." Most patients with COVID-19 were admitted to the medicine unit, significantly increasing the workload. The physicians reported working closely with their senior colleagues to manage the high volume of patients, which led to behavioral changes and occasional outbursts among the staff. Participant 1 shared the following:

> *In the medicine unit, the mental pressure is greater than that of manual labor. Our seniors have to work even harder, which results in behavioral changes like bad tempers; some even misunderstand each other for no reason and shout.*

The rapidly deteriorating conditions of the patients added to the pressure, as physicians frequently had to revisit the same patients while simultaneously attending to new ones. Due to that, many experienced back-to-back morning and night shifts, which were more burdensome than usual. There were instances of 24-hour shifts, and after only a few hours of rest, the physicians had to return to work. This situation was exacerbated by the absence of many coworkers due to COVID-19 pandemic, forcing those present to take on additional responsibilities, negatively affecting their well-being. Participant 11 articulated the complexity of their duties and the resultant stress:

> *When co-workers skip their duty, we cannot skip ours. If they are assigned 12 patients, we ultimately have to manage their share, which adds pressure on us. It feels especially overwhelming to think about a week of consecutive night duties during that time. Compared to then, duty slots are better now.*

These demands greatly impacted their sleep quality. Many physicians experienced difficulties sleeping. Some developed insomnia during the pandemic, which took a long time to resolve. Participant 14 stated the following:

> *I suffered from insomnia for a while, but establishing a good routine helped me. During that time, I had to take sleeping pills.*

This indicates that when they desperately needed sleep, they found it difficult to rest without medication, further disrupting their sleep patterns. Participant 10 shared the following:

> *I sleep very little at night. I have developed insomnia, so I usually sleep around dawn.*

This lack of sleep adversely affected their physical health, leaving them feeling drowsy, with headaches and nausea, which in turn affected their ability to care for patients. Participant 13 remarked the following:

> *When I don't sleep enough, I feel drowsy. If my supervisor asks me about a patient's condition, I stare blankly because I didn't get adequate sleep; I feel nauseous and have a headache.*

This highlighted the lack of support toward the well-being of physicians during the intense period of the pandemic.

The Unseen Social Isolation and Stigmatization

Physicians experienced negative social perceptions during the pandemic due to their profession. Many people in their neighborhoods and relatives ignored them, seeing physicians as potential carriers of the virus because of their direct connection with hospitals. This perception took a toll on physicians' mental health, causing them to feel consistently down.

Many physicians struggled to manage their accommodation during this time because local residents were unwilling to live near them. Participant 3 mentioned that she had to secretly live in a place while hiding her medical laboratory coat:

> *We found a place through a relative, but we were required to take off our lab coats when returning home so that people wouldn't know we worked in a COVID-19 dedicated hospital.*

XSL•FO
RenderX

Therefore, physicians reported encountering negative attitudes from their neighbors, directly or indirectly. Participant 9 shared that no one in her building knew she was a physician:

> *Most people didn't know I am a doctor in my flat. If they knew, they might have treated me like others. I never wore my lab coat while going to work.*

Many physicians had to change their living arrangements multiple times. They initially stayed in hotels, but due to costs and safety concerns, they moved to a closed school where they had to sleep on the floor. However, the school committee eventually forced them to relocate. These challenges arose solely because of their work. In even worse situations, relatives refused to let them stay with them, and landlords denied rental applications from physicians. Participant 3 highlighted the mental pressure and uncertainty surrounding these issues:

> *No relatives would let us stay with them. We struggled to find rentals as landlords immediately refused to rent to us once they knew we were doctors.*

Consequently, during Ramadan in the COVID-19 period, the physicians did not have food facilities inside the hospital. So, they had to order food from outside, but they often faced negative attitudes from food delivery riders, who viewed hospitals as risky zones. Therefore, physicians frequently encountered rude behavior from these riders. Participant 6 stated this unhappily:

> *A rider asked me to come downstairs. I explained that I couldn't and asked him to come near the gate instead. He rudely replied, "We don't have any rules for that. COVID-19 is greater in the hospital." I responded, "Do we produce COVID-19 in medical facilities? If you or your family members were affected by COVID-19, wouldn't you come here? I have faced such dire situations several times."*

Physicians often faced harassment from traffic police while going out on duty. They had to show their identification to prove they were physicians, but frequently, the police did not believe them and prevented them from reaching their workplaces. The police prioritized enforcing nationwide lockdown restrictions over the physicians' essential roles in hospitals. Participant 2 expressed her frustration, saying:

> *When a doctor goes out and shows their ID, the police don't accept it. They say, "What's the guarantee that you have a duty now?" It's social harassment.*

This lack of support and social negligence was high during the initial period of the COVID-19 pandemic (March 2020-May 2020).

Theme 3: Emotional Toll and Lack of Mental Support on Physicians

Physicians often struggle to manage their emotions regarding their patients' conditions. They experience mixed feelings; they feel joy when patients recover but become stressed and emotionally exhausted when patients worsen. During the pandemic, however, many physicians found it increasingly difficult to cope with their emotions due to the rapid decline and mass deaths of patients. Constant sadness became a regular part of their experience, and some could not handle it. Participant 2 shared a painful memory:

> *She was 22 years old, with 90% lung problems, and I put her on high-flow oxygen. She had a 1-year-old child who was crying for milk beside her, but I couldn't stabilize his mother. I felt desperate to save her in any way possible. But eventually, she passed away. It was excruciating for me. Similarly, another patient was admitted two months ago with COVID-19 complications affecting his lungs. His wife was expecting their second baby. We tried desperately to save him, but suddenly, he passed away. These experiences affected us emotionally a lot.*

When physicians treat patients for an extended period, they often develop strong emotional attachments, especially to those older or similar in age. Patients can feel like family to them. The physicians invest a great deal of effort into trying to improve their patients' conditions, and when they are unable to do so, they experience significant emotional experiences. Participant 6 noted the following:

> *I stayed in a ward for so long that there was an attachment. It felt terrible seeing 28- to 30-year-old boys and girls come into the ward with COVID-19 and then witnessing their drastic decline. I couldn't do anything.*

Declaring a patient's death adds another layer of stress for physicians, as it involves both emotional and professional repercussions, particularly when informing the patient's family. Physicians experience immense psychological strain as they repeatedly witness their patients die. Participant 1 expressed her feelings:

> *The issue of declaring death causes my heart to race irregularly. One night shift, I was sad and had to declare four deaths in one night. I couldn't sleep that night; it was my most stressful night.*

Despite these overwhelming situations, many physicians reported a lack of mental support or counseling to help them manage the emotional toll. They often resort to self-counseling to cope, while in many Western countries, physicians' mental health is routinely prioritized. Participant 5 highlighted this gap in the Bangladeshi medical system, where taking a leave to focus on mental health is nearly impossible:

> *There is no counseling system. You have to continue your duties and manage everything on your own. Even if you must take leave for your mental well-being, you must find a replacement doctor to assume your duties. No matter what, you cannot leave the hospital ward empty. A co-worker of mine struggled greatly when her parents were hospitalized with COVID-19, but she couldn't take leave and had to fulfill her responsibilities.*

Physicians also encountered significant limitations in providing counseling services to patients' families during COVID-19. The sudden, tragic deaths of patients, who were often otherwise healthy, left families overwhelmed. Participant 2 commented the following:

XSL•FO
RenderX

> *Counseling services are limited in our country. When a patient passes away, their family members often don't want to hear anything. It's tough. Sometimes, one family member blames another for their own mental satisfaction.*

This underscores the need for counseling sessions to support mental health among all stakeholders within the health care system. Participant 14 suggested the following:

> *It would be very helpful if we had a group where doctors could share their problems and consult each other. Learning from others' experiences would help us mentally prepare for challenging cases and provide comfort in difficult situations.*

Discussion

Principal Findings

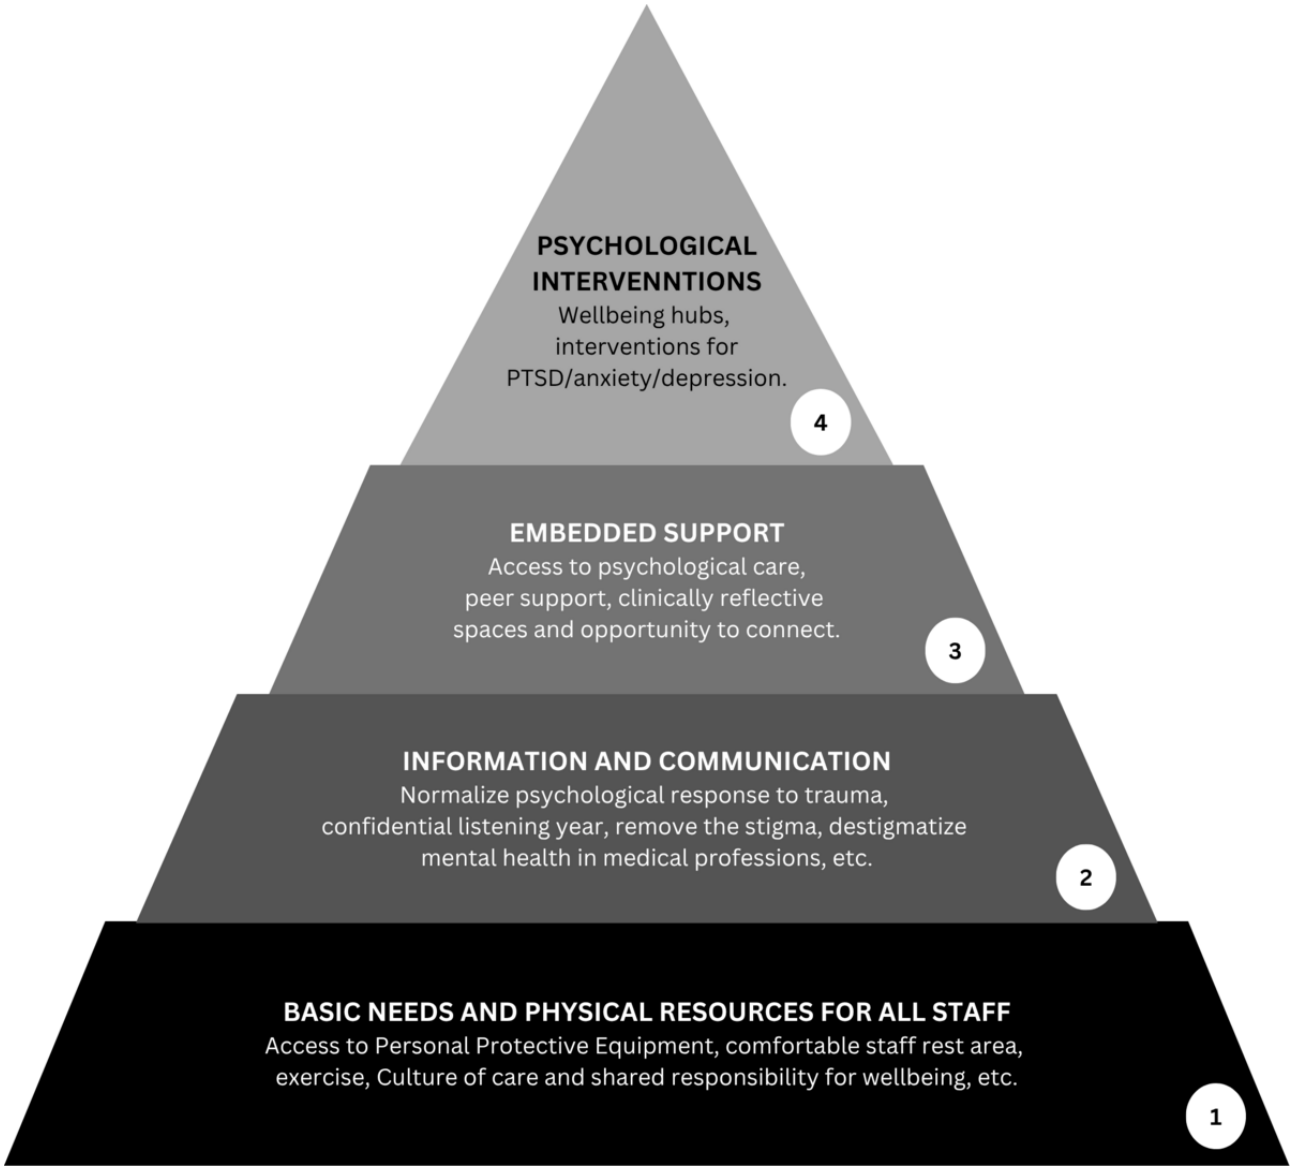
Our results highlighted the struggles faced by Bangladeshi physicians and the decline in their physical and mental well-being during the COVID-19 pandemic. These physicians had to attend to an excessive number of patients, often in close physical contact, exposing themselves to the risk of infection. This heightened their anxiety, especially with fears of transmitting the virus to their families. Many physicians, along with their family members, contracted COVID-19, which hindered their ability to provide adequate support at home due to the widespread crisis. In some cases, physicians chose not to reveal their COVID-19 symptoms to reduce fear and panic among their family members. As they worked tirelessly to manage a high volume of patients, they often could not take necessary breaks, even when unwell. This overwhelming workload compromised their physical health. Moreover, instead of receiving societal support, many physicians faced negative attitudes from the public, which further impacted their mental health. The loss of patients also took an emotional toll on these health care professionals. While counseling could help them cope with these challenges, the lack of a nationwide counseling system leaves many physicians feeling stressed and burned out.

To support physicians' mental and physical well-being, we need to consider well-accepted contextual support interventions that involve physicians and other stakeholders in society. During the pandemic, Daniels et al [31] proposed a grounded and coherent model based on the experiences and psychological care needs of frontline COVID-19 physicians in the United Kingdom, derived from ethnographic research. This credible model inspired us to develop our own contextual model, incorporating similar components while expanding to include available technological solutions for supporting physicians' health.

The Pyramid Model

The pyramid bottom-up model by Daniels et al [31] of well-being and psychological care for physicians consists of four layers: (1) basic needs and physiological resources, (2) information and communication, (3) embedded support, and (4) psychological interventions, as illustrated in Figure 1.

The first layer emphasized the importance of implementing local guidelines for proper nutrition, rest, and sleep. They suggested creating designated, quiet, confidential spaces for the physicians and the staff to reflect on and seek support. Fostering a culture of care and shared responsibility for staff well-being is essential, with senior leaders playing a key role in modeling positive behaviors related to well-being. In addition, they highlighted the need for personal safety measures.



The second layer focused on the fact that stressful and traumatic incidents require open discussions on their psychological effects and the promotion of mental health awareness in medical training. Staff should be educated on warning signs of mental health deterioration, such as emotional responses and absenteeism, and should have a safe space to discuss their well-being without fear of negative repercussions.

The third layer emphasized that all physicians should have access to integrated psychological support. This includes face-to-face or video call reflective sessions among peers and senior staff within clinical teams. In addition, structured peer-to-peer interventions, such as Trauma Risk Management or the "StartWell>EndWell" approach, should be readily available for enhanced support.

Finally, in the last layer, psychological interventions should be tailored to individual needs while considering team well-being and available in group, personal, and online formats. It should be able to manage the impact of fear, anxiety, panic, guilt, hopelessness, disconnection, and compassion fatigue among health care workers. Support should address issues such as moral injury, trauma, posttraumatic stress disorder, depression, and mental health stigma.

XSL•FO
RenderX

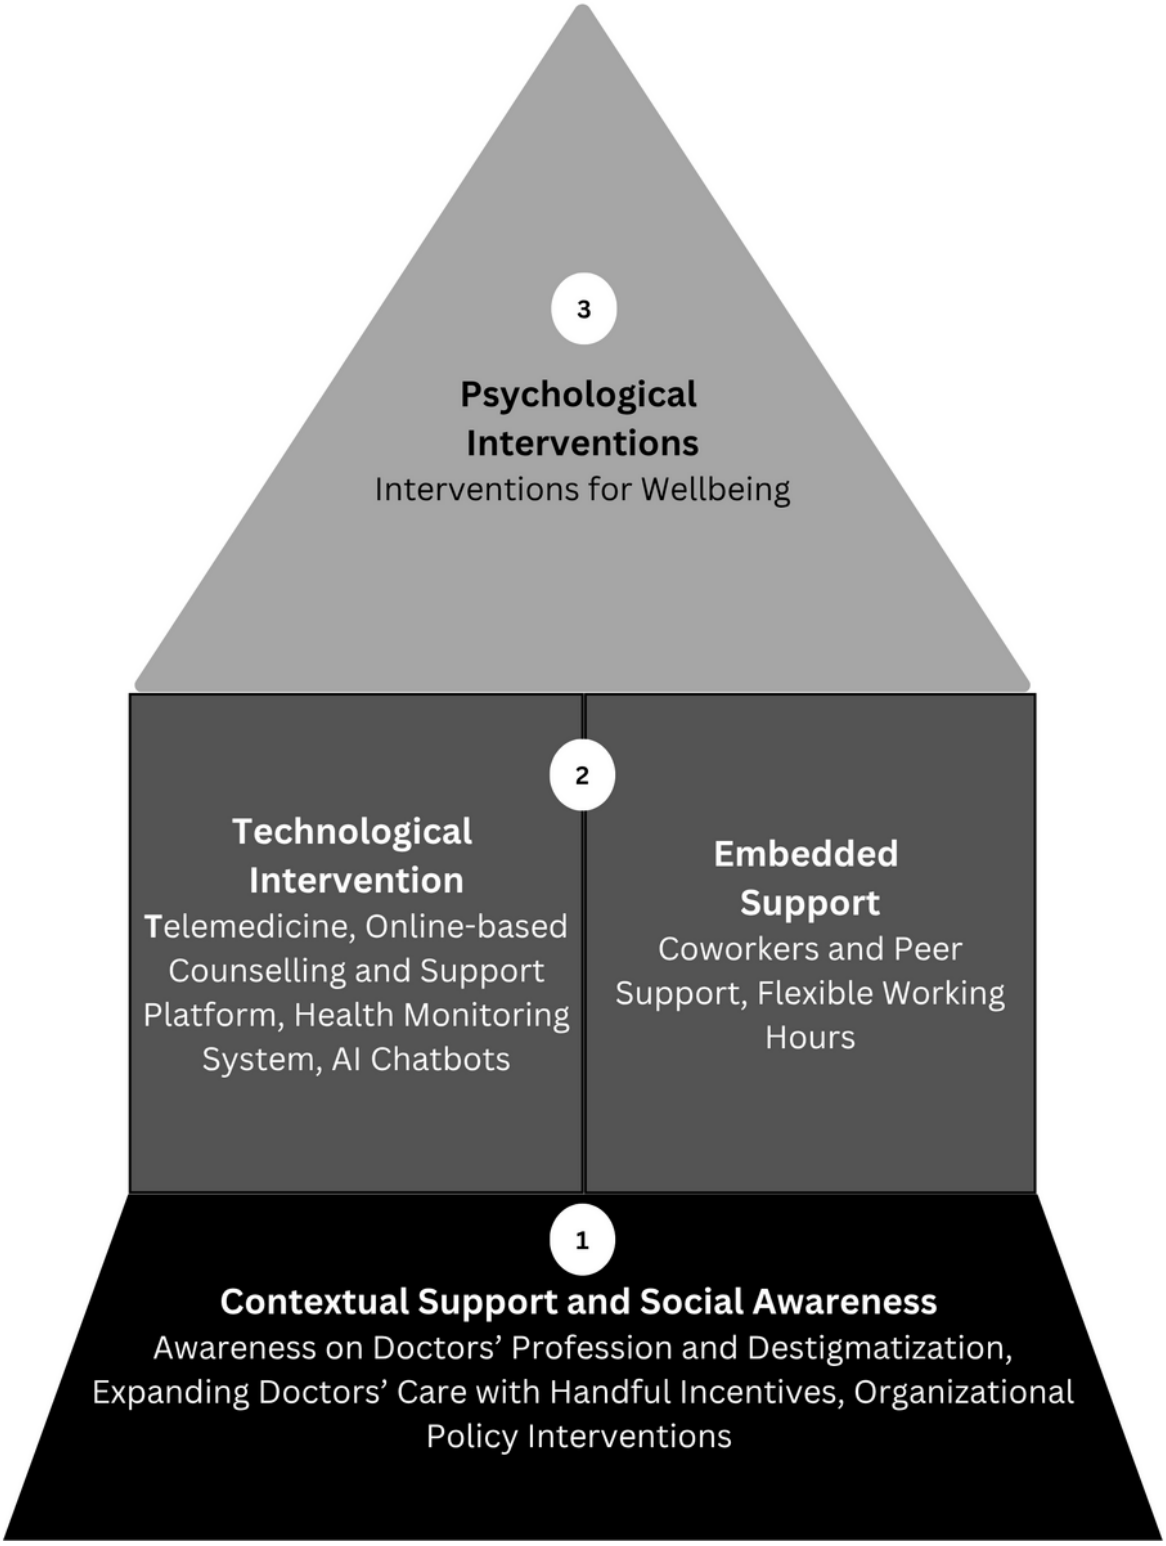
Comparison Analysis

The research by Daniels et al [31] shows physicians often cope with stress through various strategies, such as exercise, spending time outdoors, expressing their feelings, practicing mindfulness, and journaling, which is absent for Bangladeshi physicians. However, many reported storing emotions due to limited time to process events, leading to emotional disconnection, particularly when dealing with patients who are severely ill or dying. Bangladeshi physicians also cannot vent out their emotions. Physicians in the United Kingdom often prioritized others' needs over their own, setting aside personal well-being to support colleagues or patients, which a few physicians in Bangladesh also do. The research by Daniels et al [31] shows support systems included talking to coworkers, accessing embedded psychological services, formal therapy, mental health apps, phone support, and messaging groups, as well as relying on friends and family. Barriers to support included lack of time for discussions or attending sessions. Workplace wellness initiatives were mentioned, with small acts of kindness or environmental adjustments having a notable positive impact. Negative influences included poor communication, ineffective leadership, and government decisions. However, in Bangladesh, no support system exists for the physicians to assist them in their well-being. Hence, an improvement in the system is required along with a supportive network. This motivates us to work for the contextual support system, influenced by the research model by Daniels et al [31].

Proposed Trajectile Model for Physicians' Well-Being



Overview

Our trajectile bottom-up model for physicians' well-being is depicted in 3 layers, shown in Figure 2. We built upon our findings to develop this model and incorporated contextual and technological components, including AI interventions. The layers of our model include (1) contextual support and social awareness, (2) technological interventions and embedded support, and (3) psychological interventions. We aligned our findings with the proposed model by Daniels et al [31] (Figure 1) and then modified and integrated components to create our

XSL•FO
RenderX

proposed model (Figure 2). For example, the embedded support and psychological intervention layers are similar to the model by Daniels et al [31]. We recommend contextual support and social awareness, and the technological interventions components in the trajectile model differ from the model by Daniels et al [31], but that inspired us. The proposed model can be a sustainable model with effective implementation and can be adaptable in any situation and culture.

Figure 2. Proposed trajectile model for physicians' well-being. AI: artificial intelligence.

XSL•FO
RenderX

Layer 1: Contextual Support and Social Awareness

Overview

In the first layer of the trajectile models, we recommend enhancing contextual support and social awareness for physicians. This includes raising awareness about the medical profession, reducing stigma, expanding support for physicians through various incentives, and implementing policy interventions aimed at promoting both their mental and physical well-being.

Awareness of Physicians' Profession and Destigmatization

We found that physicians often faced negative attitudes and stigma from society during the COVID-19 pandemic, which can lead to feelings of stress. In addition, physicians tend to refrain from expressing their emotions in the workplace because they fear others might interpret their feelings as signs of fear or guilt rather than understanding that they genuinely care for their patients (referring to themes 2 and 3). In Bangladesh, for instance, many people blame physicians for patient losses due to perceived negligence [41]. Accordingly, Galbraith et al [13] highlighted methods for destigmatizing the workplace for physicians, such as fostering an open communication culture, organizing team-building activities, and providing peer support training during health crises and traumatic events, which can include nonmedical personnel [42,43].

However, in our context, most stigmatization occurs at the societal level. It is crucial for society to understand the challenges and hardships that physicians face and to offer expanded support accordingly. Key strategies for preventing blame and psychological trauma among physicians include raising public awareness, allowing physicians to maintain a sense of self-determination, and encouraging effective communication skills [28]. By implementing these strategies with the stakeholders around physicians, society can better appreciate physicians' dedication to their patient care.

Expanding Physicians' Care With Handful Incentives

Our physicians have mentioned that they often feel outnumbered by the increasing number of patients during the pandemic (referring to theme 2). This situation highlights the need to increase the number of physicians [44-47]. A significant reason is that rural patients tend to migrate to cities because there are fewer physicians in rural areas. In addition, many physicians are reluctant to work in these regions due to logistical challenges, such as low incentives, limited medical support, and inadequate accommodation options [48]. Previous research has also indicated that physicians do not receive sufficient recognition through incentives [21,28,44,47]. Bangladesh faces a similar issue, with only 5.26 physicians available for every 10,000 people [48]. Furthermore, their incentives are minimal, often no more than US $270, largely due to bureaucratic obstacles [49]. To address the shortage of physicians, the government should expand medical education and specialized training programs to ensure that more physicians are prepared to serve the rural population effectively. Establishing policies that provide adequate incentives in these areas is also essential. Many countries have already adopted performance-based incentive programs alongside salaries, and evidence shows that such incentives can significantly improve health care providers' performance [50-52]. By implementing these measures, we can develop a nationwide health care system that is more evenly distributed and sustainable. This system will help alleviate the patient overload in urban areas while extending vital medical support to rural regions.

Organizational Policy Interventions

Physicians often work irregular hours, which negatively impacts their well-being (referring to theme 2). To address this issue, hospital administration must revise policies to support physicians' health for the greater good. Certain measures, such as providing personal space for rest, protecting against occupational hazards, offering childcare opportunities, and implementing incentives and maternity and parental leave, can help prevent burnout among health care workers [31,53]. However, many public hospitals in Bangladesh lack these provisions, while some private hospitals offer them only to a limited number of physicians. Therefore, hospital administration should implement these measures within the health care system so the government can take the necessary steps to mandate these policies.

Layer 2: Technological Intervention and Embedded Support

In this second layer, we included 2 components: technological interventions (such as telemedicine, online support platforms, health monitoring systems, and AI chatbots) and embedded support (such as coworkers and peer support and flexible working hours), essential for improving physicians' health.

Technological Intervention

Telemedicine

Our physicians have expressed concerns about the risk of COVID-19 infection from undiagnosed patients and the necessity of physical contact (referring to theme 1). Telemedicine is crucial in reducing physical interactions between physicians and patients, thereby minimizing the risk of exposure to various viruses and diseases, including the SARS-CoV-2 [54]. Physicians can provide clinical care through telephone and video consultations, especially since COVID-19 significantly affects older populations [55].

Bangladesh offered several telemedicine services during the pandemic, such as "Tonic" and "ShebaGhor." However, these services struggled to sustain themselves due to inadequate regulations, patient trust, and limited resources [54]. In addition, many people in Bangladesh are not accustomed to telemedicine and face challenges related to access to information and communication technology, leading them to prefer in-person consultations. Nevertheless, we advocate for the adoption of telemedicine, as general practice in the United Kingdom has successfully transitioned to telephone or video consultations. This shift has reduced unnecessary face-to-face interactions and the associated risk of virus transmission, easing concerns about contracting illnesses [56].

The effectiveness of telemedicine is evident in high-income nations, where the system is regulated by the government. In contrast, telemedicine services in Bangladesh operate

XSL•FO
RenderX

independently, raising public trust issues. The Bangladesh Medical and Dental Council should establish proper regulations to create a sustainable telemedicine system. Hospitals could then operate toll-free telemedicine hotlines to broaden services and enhance accessibility. A single toll-free number could connect callers to local hospitals. Bangladesh already has emergency service numbers in place; using and expanding this existing infrastructure could help address the needs of a large patient population and benefit physicians' health.

Online Counseling and Support Platform

Physicians often seek counseling to express their emotions, but they face a lack of options, particularly in resource-limited countries such as Bangladesh, where hospitals do not have proper counseling units (referring to theme 3). Digital platforms can support physicians' mental health by providing easy access to counseling services, peer connections, and stress management tools. These resources can help them navigate the challenges of their profession and alleviate stress. Digital and technological platforms supplement traditional behavioral support [57]. Counseling delivered over the phone or through the internet can effectively manage physicians' mental health [58], but it should be easily available and accessible and timely [59,60]. To address this need, the Bangladesh Medical and Dental Council could establish an online counseling platform accessible only to physicians, enabling them to receive the support they require from anywhere.

Health Monitoring System

We additionally recommend technology-based health monitoring systems that can assist physicians in tracking their health and mental well-being. As participants are lacking in maintaining their personal well-being at this point, cost-effective wearable devices, such as Fitbit (Google LLC), offer valuable insights into various health metrics and self-assessment. For instance, Fitbit can monitor sleep patterns, physical activity, blood oxygen levels, heart rate variability, and exercise frequency, all of which can indicate a person's healthy lifestyle [61] and stress levels. This enables physicians to support their own health and pursue a healthier lifestyle. In addition, Anmella et al [62] developed 2 chatbots designed to screen, monitor, and mitigate anxiety and depressive symptoms as well as work-related burnout while also assessing suicide risk in physicians through conversational interactions. Such technology can help identify stress among physicians and alert relevant authorities or family members, enabling them to support the physicians' well-being. Meanwhile, physicians can use these tools to engage in self-care and self-medication therapies.

AI Chatbots

There is often a significant lack of resources in resource-limited countries, leading to accessibility issues for counseling tools and digital platforms. Participants also explicitly mentioned their lack of counseling support (referring to theme 3). AI chatbots can provide a cost-effective solution for resource-limited countries such as Bangladesh. Baek et al [63] suggested that AI chatbots can help improve states of anxiety, depression, and burnout. For instance, the Woebot chatbot has assisted young adults with depression and anxiety, resulting in a significant reduction in both conditions [64]. Similarly, the Vivibot chatbot contributed to reducing anxiety, although it did not have an effect on depression [65]. Today, AI technologies, such as ChatGPT by OpenAI, Gemini by Google LLC, Gork by X, and Meta from Meta are widely accessible and can offer open-ended well-being suggestions. However, these systems often lack personalization, making it difficult to address specific mental health issues effectively. Designing a mobile app that combines existing chatbots while incorporating personalized features is feasible. Therefore, AI chatbots could serve as a valuable tool to support the psychological well-being of physicians by providing personalized and accessible interventions, especially in resource-limited countries.

Embedded Support

Coworkers and Peer Support

We observed that when coworkers fall ill and request assistance, they must address those issues immediately, increasing pressure during the pandemic (referring to theme 2). On the other hand, coworkers also supported one another during their illnesses. This support is essential in the medical field to maintain workplace efficiency and the mental well-being of physicians. Having reliable, responsible, empathetic, accountable, and supportive coworkers during the pandemic was invaluable for navigating challenges. Senior coworkers provided clear guidelines, served as role models for junior physicians, and fostered a culture of learning and collaboration among peers [22]. This support is also considered peer support, which can be extended to social support with regular contact via phone call or video chat with colleagues, family, and friends [57]. Therefore, these supportive relationships can significantly enhance one another's well-being.

Flexible Working Hours

Physicians have said that they often work long hours without any breaks, leading to mental exhaustion (referring to theme 2). They should be given a flexible schedule with adequate breaks between shifts to address this issue. In Bangladesh, interns experience unstructured duty hours; most physicians work daily. Urooj et al [22] suggest that minimizing physicians' duty hours and limiting routine checkups can improve their health and reduce the number of staff working at any given time, allowing some to be reserved as backups. This approach would help achieve a better work-life balance [53]. Therefore, the administration needs to redefine and structure physicians' working hours, and the Bangladesh Medical and Dental Council should implement a policy to support these changes. This would ensure that the support provided is appropriately fixed and effective.

Layer 3: Psychological Interventions

We refer to psychological interventions similar to the model proposed by Daniels et al [31], which focuses on addressing individuals' needs while managing the effects of anxiety, hopelessness, and stress. The physicians involved in the study expressed a desire for regular monthly counseling sessions due to the significant loss of patients during every crisis. Therefore, counselors and volunteers could play a crucial role in not only addressing acute symptoms, such as depression, anxiety, and psychological distress, but also in supporting physicians during

the postpandemic phase and helping them cope with ongoing challenges. This support intervention should be available online and in hospitals with easy access.

Limitations and the Way Forward

We interviewed 14 participants online during the pandemic, all from the Chattogram region. This region is around 300 km southeast of the capital but is an overpopulated city. The medical support system was weaker than the capital's. We were able to access these physicians during this emergency period. Although we aimed to expand our interviews to different cities, such as the capital Dhaka, so that we could perform comparative analysis, many potential participants did not respond in Dhaka. This presents a limitation, as the findings may not be generalizable. However, they reflect physicians' overall experiences during the pandemic, which aligns with the situation of most physicians who worked during the COVID-19 pandemic in Bangladesh. In addition, the proposed model was not tested or validated. Testing the model with the stakeholders may give us valuable insight into its acceptability and usability.

Future research can be expanded by, including physicians and stakeholders from hospitals and the Bangladesh Medical and Dental Council, as many institutional issues are linked to hospital administration and policy makers within the council. Engaging these groups in further studies will provide insights into effective interventions for maintaining physicians' well-being. In addition, we plan to conduct longitudinal studies using wearable technologies, such as Fitbits, to gather real-time physiological data from physicians. Analyzing these data will help identify stress factors associated with their work, which may contribute to redesigning their work environment in the future.

Conclusions

A qualitative study involving 14 physicians explored their experiences and well-being during the COVID-19 pandemic. This study helped us identify their challenges in maintaining their well-being amid various contextual difficulties. We recognized the importance of addressing these concerns and set out to develop a contextual intervention model. Our model for promoting well-being was inspired by the well-being framework by Daniels et al [31], incorporating contextual and technological interventions. We proposed suggestions based on a bottom-up approach, highlighting interconnected concepts. By focusing on this model, we aim to engage stakeholders in rethinking and redesigning the work environment for physicians. This approach is designed to be sustainable over the long term and adaptable to any situation and culture.

Acknowledgments

The authors thank all their participants for their cooperation and support. This study was supported by the Design Inclusion and Access Lab at North South University, along with small seed funding (for buying equipment and participant incentives) from the University of British Columbia. The authors extend their special thanks to Md Sabbir Ahmed from the University of Virginia and Mohammad Hadi from the University of British Columbia for their contributions during this study's design and interview phases.

Authors' Contributions

RJR and NA designed and conducted the qualitative study, with NA supervising the overall process. RJR played a significant role in writing the manuscript from start to finish, as well as supervising the data analysis. SAA, LAT, and MM contributed to the data analysis, conducted the literature review, and worked on the introduction and discussion sections. All authors reviewed and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Bowel preparation compliance is an important intervenable factor that affects bowel preparation quality, and improving compliance is an important way to optimize bowel preparation outcomes. Despite its importance, the compliance rate and its influencing factors have not been thoroughly evaluated.

Objective: This study aimed to investigate the overall compliance with bowel preparation instructions in patients undergoing colonoscopy.

Methods: From September 2024 to March 2025, a cross-sectional questionnaire-based study was conducted at West China Hospital of Sichuan University, recruiting 740 participants via convenience sampling. We used an 8-item self-report scale to evaluate compliance with bowel preparation instructions. Items were rated on a 4-point Likert scale (0=completely noncompliant to 3=completely compliant), yielding a total score of 0‐24. Higher scores reflected greater compliance, with ≥95% of the maximum score considered adequate compliance. Univariate analysis and multivariate logistic regression analysis were used to assess factors (age, educational level, knowledge of bowel preparation, satisfaction with the taste of the laxative, physical discomfort during bowel preparation) influencing bowel preparation compliance.

Results: In this study, 42.0% (311/740) of patients demonstrated adequate compliance with bowel preparation instructions. In the univariate analysis, hypertension history, knowledge of bowel preparation, laxative type, satisfaction with the taste of the laxative, anxiety during bowel preparation, and physical discomfort during bowel preparation all had statistically significant influences. Multivariate analysis showed that older age (odds ratio [OR] 2.27, 95% CI 1.16-4.49), higher educational level (OR 3.29, 95% CI 1.41-8.33), adequate knowledge of bowel preparation (OR 1.59, 95% CI 1.14-2.24), satisfaction with the taste of the laxative (OR 2.11, 95% CI 1.48-3.02), and no physical discomfort during bowel preparation (OR 0.45, 95% CI 0.31-0.64) were key factors for adequate bowel preparation compliance.

Conclusions: Personalizing bowel preparation instructions according to patients' age and education level, and selecting a laxative that suits the patients' taste preferences when available, are feasible ways to improve compliance with bowel preparation.

Introduction

As the "gold standard" for the diagnosis of intestinal diseases such as colorectal cancer (CRC), colonoscopy provides direct and accurate visualization of the colonic mucosal surface, enabling early detection, accurate diagnosis, and timely intervention, thereby improving patient outcomes [1-3]. In 2021, the US Preventive Services Task Force recommended that people with risk factors such as a family history of CRC, obesity, inflammatory bowel disease, and smoking should undergo regular colonoscopies [4,5]. Even those without these risk factors should undergo CRC screening starting at the age of 45 years and have a colonoscopy every 10 years [4]. The effectiveness of colonoscopy largely depends on the quality of bowel preparation, with adequate cleanliness being essential for a safe, efficient examination and playing a critical role in clinical outcomes [6-8]. However, studies have reported that 20%‐40% of patients undergoing colonoscopy exhibit inadequate bowel preparation, which falls far below the European Society of Gastrointestinal Endoscopy–recommended adequacy standard of 90% [9-11]. Suboptimal bowel preparation may increase the risk of missed lesions, postprocedural complications, and prolonged procedural duration, and

XSL•FO
RenderX

necessitate repeat examinations, leading to additional patient discomfort and financial burden [12,13]. Thus, accurate identification of factors associated with bowel preparation holds significant clinical value for improving preparation quality. Numerous studies have identified multiple influencing factors that influence the quality of bowel preparation, including age, gender, BMI, anxiety level, and patient compliance with preparation protocols [14-20]. Strict compliance with bowel preparation instructions is recognized as a critical determinant of successful preparation. Poor compliance with prescribed requirements, including dietary restrictions, fluid intake limitations, and proper medication timing and dosage, may directly affect cleansing efficacy [19,20]. Current research predominantly evaluated compliance through single-dimensional metrics such as laxative consumption or dietary compliance, failing to holistically evaluate the full-process compliance, which includes dietary management, fluid intake restrictions, medication dosage, timing, and duration of medication use [21,22]. This study aims to evaluate the holistic compliance with bowel preparation instructions among patients undergoing colonoscopy and its multidimensional influencing factors in China. The findings will inform the optimization of personalized patient education strategies and the development of targeted preparation guidance, ultimately enhancing compliance to improve bowel preparation quality and subsequent colonoscopy outcomes.

Methods

Study Design

This cross-sectional study was conducted at West China Hospital from September 1, 2024, to March 1, 2025. Convenience sampling was used in this study.

Participants

The participants of this study were patients who underwent colonoscopy at the Endoscopy Center of West China Hospital, Sichuan University. At the time of scheduling a colonoscopy, standardized bowel preparation instructions were given verbally by the endoscopy unit receptionist, who was trained to provide these instructions as a daily routine. Patients and their relatives were also given a brochure as a reminder of bowel preparation instructions. The day before the colonoscopy, the patient began bowel preparation as instructed, including a low-fiber diet and the administration of a laxative, which was sodium phosphate or polyethylene glycol. Before undergoing the colonoscopy, patients waiting in the endoscopy center were invited to voluntarily and independently complete a mobile-based questionnaire by scanning a QR code. The questionnaire contained 32 single-choice items and required approximately 3 - 5 minutes to complete.

The following inclusion and exclusion criteria were used:

- Inclusion criteria: age ≥18 years, adequate understanding and communication abilities, and willingness to participate in the study and to sign the informed consent form
- Exclusion criteria: inability to understand the content of the informed consent form and the questionnaire, and failure to cooperate with the investigation or provide informed consent

Sample Size

The sample size was calculated using a single population proportion sample size–estimating formula. The formula can be given as $n = [(Z_{1-\alpha/2})^2 p (1-p)]/d^2$, where, n is the minimum sample size, $Z_{1-\alpha/2}$ is at a 99% CI of 2.58, *P* is the assumed adequate compliance with bowel preparation (50%), and d is the margin of error to be tolerated (5%). Using this formula, the estimated sample size is 666. Accounting for a 10% nonresponse rate, a total of 740 patients were needed. It should be noted that the 50% expected proportion was chosen as it provides the largest sample size estimate [23].

Questionnaire

General Information Questionnaire

The questionnaire was designed on the basis of a review of the literature and consultation with experts. It includes information on the following aspects: gender, age, educational level, residence, residency status, hypertension history, diabetes history, family history of CRC or polyps, know anyone with colorectal polyps or CRC other than a first-degree relative, and colonoscopy history.

Knowledge of Colonoscopy and Bowel Preparation

Patients' knowledge of colonoscopy and bowel preparation was measured using three and four questions, respectively. Each question has four response options: 0=no understanding at all, 1=a little understanding, 2=moderate understanding, and 3=complete understanding. Higher scores reflect better knowledge, with a score of 5 or above indicating adequate knowledge of colonoscopy and a score of 7 or above indicating adequate knowledge of bowel preparation.

Bowel Preparation Compliance

We designed a scale to assess patients' compliance with various aspects of bowel preparation instructions. The self-developed scale consists of 8 questions and is scored on a 4-point Likert scale, ranging from "completely noncompliant" to "completely compliant," with scores ranging from 0 to 3. The total score ranges from 0 to 24 points, with higher scores indicating greater bowel preparation compliance. A score greater than 95% of the total score was defined as adequate compliance and vice versa as inadequate compliance. Prior to the start of the formal study, we validated the questionnaire in a preexperiment that included 50 individuals, with a calculated Cronbach α coefficient of 0.877.

Current Bowel Preparation Experience Survey

In this section, we investigated the laxative type used by the patients for current bowel preparation, overall satisfaction with the taste of the laxative, anxiety during the bowel preparation, physical discomfort during the bowel preparation, and clarity of the bowel preparation instructions, with each variable classified as binary.

XSL•FO
RenderX

Study Variable Definitions

Dependent Variable

The dependent variable was the bowel preparation compliance (adequate or inadequate).

Independent Variables

The independent variables were gender; age; educational level (elementary school or no education, secondary school, university or higher); residence (urban, rural); residency status (living alone or with family); hypertension history; diabetes history; family history of CRC or polyps; know anyone with colorectal polyps or CRC other than a first-degree relative; colonoscopy history; knowledge of colonoscopy (adequate or inadequate); knowledge of bowel preparation (adequate or inadequate); and current bowel preparation experience, including overall satisfaction with the taste of the laxative (satisfactory or unsatisfactory), anxiety during the bowel preparation, physical discomfort during the bowel preparation, and clarity of the bowel preparation instructions.

Statistical Analysis

The data were analyzed using R version 4.3.2 (R Foundation for Statistical Computing). Continuous variables were presented as means and SDs, whereas categorical variables were expressed as numbers and percentages or frequencies. Intergroup differences with respect to continuous variables were assessed via Student *t* test, if the data met the normality assumption and variance homogeneity. Otherwise, the nonparametric Mann-Whitney *U* test was used. Intergroup differences with respect to categorical variables were assessed using Pearson χ^2 test or Fisher exact probability test, when appropriate.

Variables with $P<.10$ in the univariate analysis were included in the multivariate logistic regression analysis, and independent factors influencing patients' compliance with bowel preparation were identified through the "enter" selection method (ie, the totally adjusted model). The Hosmer-Lemeshow goodness-of-fit test was used to assess the fitness of the model, with $P>.05$ indicating an acceptable fit. The multivariate analysis results are expressed using odds ratios and 95% CIs only. A $P<.05$ was regarded as statistically significant.

Ethical Considerations

The research study received approval from the Ethics Committee of West China Hospital, Sichuan University (ChiCTR2400089364). Prior to conducting the questionnaire, written consent was obtained from all participants. The privacy of the participants was respected. All data in the manuscript were anonymized in accordance with ethical standards, ensuring no personally identifiable information could be discerned. No compensation was provided to participants in this study.

Results

Sample Characteristics

This study ultimately included 740 patients undergoing colonoscopy. Among the total sample, more than half (n=416, 56.2%) were female, 70% (n=518) had a university education or higher, and 90.5% (n=670) lived in urban areas. The majority (n=704, 95.1%) had no personal history of diabetes, and 86.5% (n=640) had no family history of CRC or polyps. More than half (n=385, 52.0%) of the patients had no prior colonoscopy. Other variables are listed in Table 1.

Knowledge of Bowel Preparation and Colonoscopy and Current Bowel Preparation Experience of Patients Undergoing Colonoscopy

Table 2 presents colonoscopy patients' knowledge of bowel preparation and colonoscopy, as well as their experience with the current bowel preparation. Of the 740 patients, a total of 56.4% (n=417) and 46.1% (n=341) had adequate knowledge of bowel preparation and colonoscopy, respectively. More than half (n=391, 52.8%) of the patients were unsatisfied with the taste of the laxative. Anxiety and physical discomfort during bowel preparation were experienced by 43.9% (n=325) and 59.3% (n=439) of patients, respectively.

Univariate Analysis of Factors Influencing Compliance With Bowel Preparation

Of the 740 patients, 311 (42.0%) showed adequate compliance with bowel preparation. Intergroup differences were compared between patients with and without adequate bowel preparation compliance (Table 3). The results indicate that hypertension history (P=.01), knowledge of bowel preparation (P=.004), laxative type (P=.008), satisfaction with the taste and flavor of the laxative (P<.001), anxiety during bowel preparation (P<.001), and physical discomfort during bowel preparation (P<.001) all have statistically significant impacts on patient compliance (Table 3).

Multivariate Analysis of Factors Influencing Bowel Preparation Compliance

Binary logistic regression analysis indicated that age, educational level, knowledge of bowel preparation, satisfaction with the taste of the laxative, and physical discomfort during bowel preparation are independent influencing factors for patient compliance (Table 4). The Hosmer-Lemeshow goodness-of-fit test was not significant, indicating that the model fits the data well (χ^2_8=5.09; *P*=.75).

Discussion

One of our study objectives is to evaluate the compliance rate with bowel preparation of Chinese patients undergoing colonoscopy. The survey results revealed that inadequate bowel preparation compliance among colonoscopy patients was up to 58.0% (429/740), which was significantly higher than the 23.6% previously reported in a study [24]. This may be related to the more multidimensional (including dietary management, fluid intake restrictions, medication dosage, timing, and duration of medication use) and demanding (a score greater than 95% of the total compliance score) assessment of bowel preparation compliance in our study.

Our results showed that patients' compliance with bowel preparation instructions was related to age, educational level, and knowledge of bowel preparation. Patients in the 65 - 74 years age group had higher compliance than younger patients in the 18 - 35 years age group. This may be related to the fact that the retired population has more time to read bowel preparation instructions, whereas the younger patients may ignore relevant details due to work pressure and busy routines. Moreover, the busy lifestyle and tendency of young people to eat out may also hinder their strict compliance with the long and complex food list for dietary restriction before colonoscopy [25]. Patients with a higher level of education and better knowledge of bowel preparation are more likely to understand the educational content provided by health care professionals

XSL•FO
RenderX

[26,27]. These patients may tend to recognize the importance and benefits of adequate bowel preparation for colonoscopy, thus improving their compliance [24]. In the future, personalized health education content can be developed for patients on the basis of their age and educational level to increase their knowledge and improve compliance. For example, customized instructions with concise content can be designed specifically for young people to address their unique challenges.

In this study, the type of laxative significantly influenced compliance in univariate analysis. However, in multivariate analysis, it no longer emerged as an independent factor, suggesting that the effect of laxative type may primarily influence compliance indirectly through associated experiential factors such as taste satisfaction and physical discomfort. Sodium phosphate and polyethylene glycol are two commonly used clinical laxatives that commonly cause adverse reactions such as bloating, nausea, vomiting, and dizziness [28]. These adverse reactions, as well as poor taste and flavor, may result in patients not being able to take adequate amounts of laxative, leading to poor compliance. Of the 740 patients in this study, more than half (n=391, 52.8%) were unsatisfied with the taste of the laxative used, and close to 60% (n=439) experienced physical discomfort during bowel preparation. A study by Hautefeuille et al [29] also showed that patients described nausea and vomiting as the main reasons for noncompliance with bowel preparation protocols. Therefore, for patients with prior experience of bowel preparation, it is important to inquire about their previous experiences with laxatives when they need to undergo bowel preparation again, and laxatives that are acceptable to the patient in terms of taste should be selected to minimize the occurrence of adverse reactions and improve patient compliance.

There are several limitations of this study. First, this study adopted a convenience sampling method and was conducted in a single tertiary hospital in an urban area, which may have introduced selection bias and led to an overestimation of certain indicators (eg, educational level and health awareness of patients). Future research could expand the study to multiple centers to gain a more comprehensive understanding of patient compliance in different settings. Second, bowel preparation compliance was self-reported, which may introduce recall bias, potentially leading to overestimation or underestimation of actual compliance. In addition, it was assessed using a newly developed scale that has only undergone preliminary validation, and its reliability and generalizability require further confirmation in larger and more diverse populations. Third, this study did not collect results on the quality of patients' bowel preparation, nor did it explore the correlation between compliance and bowel preparation quality. Lastly, due to the cross-sectional design, it is not possible to establish causal relationships. Overall, these limitations highlight critical areas for future research and improvement in understanding and bowel preparation compliance in patients undergoing colonoscopy.

This study revealed that patients had relatively low compliance with bowel preparation. Independent factors identified included age, educational level, knowledge of bowel preparation, satisfaction with the taste of the laxative, and physical discomfort during bowel preparation. Based on the data from this study, we recommend personalizing the educational content of bowel preparation according to the patients' age and literacy level, and selecting the type of laxative that the patient is satisfied with when available. Our study provides insights for improving bowel preparation compliance in patients undergoing colonoscopy.

Abstract

Background: The "Color of Drinking" is a study conducted at the University of Wisconsin-Madison. It examines the secondhand harms of high-risk drinking on college students of color and explores the connection between alcohol use and the campus racial climate. Since its findings were released in 2018, this study has received significant attention from other college settings around the country.

Objective: This study aims to describe the development of the most recent version of the Color of Drinking questionnaire and to assess its internal consistency, test-retest reliability, and construct validity in a sample of undergraduate students attending the University of Wisconsin-Madison.

Methods: This is an observational, analytic study. Questionnaire design experts revised the original instrument, and in-depth cognitive interviews with students were conducted to evaluate comprehensibility and acceptability. The revised questionnaire was administered 2 times, 3 to 4 weeks apart, in a sample of undergraduate students. The following properties were studied: internal consistency in 4 sets of items (Cronbach α), test-retest reliability among closed-ended questions (κ statistics and intraclass correlation coefficient), and construct validity (associations with other validated instruments, such as the Alcohol Use Disorders Identification Test). For a section of questions showing low reliability, the answers to open questions and other in-depth interviews were carried out, and online surveys were conducted with another sample of undergraduate students to evaluate reliability after changes.

Results: Eight students participated in the in-depth interviews, 177 responses from the online survey were included for the analysis of internal consistency, 115 for test-retest reliability, and 98 for construct validity. The 4 sets of items (sections) evaluated ("impact of alcohol consumption on academics," "impact of microaggressions," "witnessing microaggressions and alcohol intoxication," and "bystanders' interventions on alcohol intoxication") presented good internal consistency (Cronbach α between 0.723 and 0.898). Most items showed moderate to substantial test-retest reliability; agreement was from 68.1% to 95.2%, and κ coefficients ranged from 0.214 to 0.8. For construct validity, correlations between the number of drinking days, the maximum number of drinks in a day and the Alcohol Use Disorders Identification Test score were moderate to high, r=0.630 (95% CI 0.533-0.719) and r=0.647 (95% CI 0.548-0.741), respectively. Due to low reliability, a section regarding "health impacts" has been redesigned, including 8 items for the personal consumption of alcohol and the consumption of others (Cronbach α 0.735 and 0.855, respectively; agreement between the first and the second time the questionnaire was administered were 83.4% and 99.1%, and most of the items with κ coefficient from 0.476 to 0.877).

Conclusions: The revised version of the Color of Drinking questionnaire showed acceptable to adequate reliability and construct validity.

Introduction

The association between alcohol consumption and being a college student is broadly described in the literature. Students often understand drinking during college as part of their higher education experience and a way to socialize with peers [1]. The first years of college involve major transitions, including changes in family bonds, living arrangements, and peer socialization. That type of transition is often associated with risky behaviors, including high levels of alcohol consumption [2,3]. Environmental factors, such as the campus culture, can further [2,3] reinforce this behavior and contribute to its health consequences [4]. However, few studies have examined the potential impact of a high-risk drinking culture on the mental health and well-being of marginalized college students [5] The Color of Drinking study examines differences in narratives and perspectives related to alcohol culture, high-risk drinking, and the racial climate for students of color and White students at an American predominately White institution [6].

Results from the exploratory Color of Drinking Study (2017/2018) revealed key insights into the intersection of alcohol culture and student experiences. Safety concerns in high-risk drinking environments had a greater impact on students of color compared to their White peers. High-risk drinking was also positively associated with students' sense of connection and belonging. Students of color reported higher rates of abstaining from or avoiding alcohol than White students (15.3% vs 8.4%). Additionally, African American or Black students considered leaving the university at twice the rate of White students (43.6% vs 20.9%), and students of color were more likely to report financial struggles (14.5% vs 7%). White, problematic drinkers scored higher on the Diener Flourishing Scale than students of color (27.3% vs 10.2%). Campus alcohol culture also influenced academic routines, with 46% of students reporting the need to find alternative study spaces and 40% scheduling group meetings around alcohol consumption [6]. Furthermore, African American or Black was the racial group that most frequently witnessed (82.9%) and experienced microaggressions (79.8%). The likelihood of witnessing microaggressions increased with the year in school, from 49.3% among first-year students to 75.8% among fourth-year students. Among students of color, alcohol use in the last 30 days, feeling impacted by other's consumption of alcohol, and avoiding certain areas due to alcohol consumption were all significantly associated with experiencing microaggressions among students of color [7].

Since the release of its findings, the Color of Drinking has received significant attention from other college settings, media coverage, and numerous requests to replicate this study around the country [8]. As the instrument gained greater prominence as a research tool and a way for campuses to understand their student experiences, the decision was made to conduct a validation study of the Color of Drinking instrument. This validation effort enhances the University of Wisconsin-Madison's (UW-Madison's) ability to interpret survey results accurately and provides other institutions with a clearer understanding of the insights they can gain from administering the survey.

Thus, this study aims to describe the development of the last version of the Color of Drinking questionnaire and to evaluate its reliability and validity in a sample of undergraduate students attending UW-Madison.

Methods

Study Design

This observational, analytic study incorporated both qualitative and quantitative research components. Experts in questionnaire design reviewed the original version of the questionnaire and in-depth cognitive interviews were conducted with students to evaluate the comprehensibility and acceptability of the instrument. The revised version of the questionnaire was administered to a sample of undergraduate students at UW-Madison twice, with an interval of 3 to 4 weeks. This timeframe was selected to reduce the likelihood of participants remembering their previous responses while avoiding a gap long enough to span different semesters, which could impact the comparability of recall. Other validated instruments were administered alongside the first administration of the Color of Drinking questionnaire: (1) the Alcohol Use Disorders Identification Test (AUDIT), the microaggressions subscale from the Racial and Ethnic Microaggression Scale (REMS) [9], and the Sense of Belonging Index (SBI). The following properties were evaluated: internal consistency, test-retest reliability, and construct validity.

Participants

The study was conducted in a sample of undergraduate students aged ≥18 years at UW-Madison.For in-depth cognitive interviews, an opportunistic sample of students (n=8), ensuring variability in age, gender, and ethnicity or race among students with freshman, sophomore, junior, and senior standing, was selected. For the online survey the minimum sample size was estimated in 100 participants. This sample size was determined to assess the construct validity by applying a 2-sample *t* test, based on data previously published from the REMS subscale in a sample of undergraduate students, considering a mean difference of 0.5, an SD of 0.89, an error α of .05 and a statistical power (1-β) of .80 [10]. This sample size is also adequate for assessing test-retest reliability (n=63 participants completing the survey on 2 occasions), based on an anticipated intraclass correlation of 0.7 (with a minimum acceptably threshold of 0.5 [11]), a significance level (α) of .05 and β of .20 [12,13].

Student identity data was obtained from the UW-Madison Office of the Registrar and sampled self-identified White and censused self-identified undergraduate students of color or international students. Based on the recruitment rate from the study previously conducted in the same population [7], a random sample of 300 self-identified White undergraduate students and 200 self-identified undergraduate students of color or international students were invited to participate. Each student received an email with the invitation to participate, and 2 reminder emails were sent. It was explained that there were 2 opportunities to be part of the validation of the Color of Drinking Survey (a qualitative Zoom [Zoom Communications, Inc] interview or an online survey administered twice). Participation was voluntary,

XSL•FO
RenderX

and invitations were sent via listservs. Thus, students had the option not to respond to the task. Participants who had completed the first questionnaire were contacted by email with the invitation to complete the second questionnaire.

Color of Drinking Questionnaire

The original instrument was developed by the University Health Services at the UW-Madison [6]. The dimensions of interest were selected, and a list of questions was developed by an interdisciplinary team composed of a Subject Matter Expert on Alcohol (RW) and a Physician, Epidemiologist specialist in Public Health (AM), based on information gathered during interviews with students and a framework based on previous research [5]. The instrument explored the following dimensions: (1) personal alcohol consumption, (2) academics and alcohol drinking culture, (3) locations (avoiding areas at campus due to concerns of the alcohol use of others or where feeling unsafe), (4) the impact of others' alcohol use, (5) experiencing microaggressions (targeting students of color only), (6) bystander witnessing and intervention in situations of microaggressions or alcohol intoxications), (7) impact on personal health and well-being, and (8) overall experience and sense of belonging at the campus. The tool also included questions about sociodemographic characteristics such as age, gender, race or ethnicity, and financial situation. The questionnaire included both open-ended and closed-ended questions. Questions about experiencing microaggressions were asked only to students of color, under the definition of microaggressions used by the authors: "racial microaggressions are an everyday manifestation of oppression that brings psychological consequences to target groups" [14]. The well-being section included a validated scale, the Diener Flourishing Scale, consisting of 8 items [15]. The questionnaire was previously administered in 2015, 2017, and 2018 to more than 1100 students; thus, the research team has previously analyzed useful information from both closed-ended and open-ended questions.

During the first phase of the validation study, the original version was revised by a group of researchers with expertise in questionnaire design, obtaining a preliminary draft version. Later, a series of cognitive interviews were conducted with a sample of students. They consisted of the flexible administration of the draft questionnaire and relied heavily on verbal probing to improve the instrument [16,17]. An "inspect-and-repair" model was used to inspect the items, detect flaws, and repair them. If the interviewer identified any problem with 1 or more questions (about comprehension, recall, difficulty to answer, response, or other), they would rephrase the items to test a potential solution [18]. The interviews were focused on the questions developed for the questionnaire and did not include the already validated Diener Flourishing Scale or the section on sociodemographic characteristics. After the series of interviews, a new version of the questionnaire was produced.

Assessment of the Psychometric Properties

Internal Consistency

This property is a measure of the intercorrelation among items and hence the consistency in the measurement of the intended construct [19]. The internal consistency was evaluated in the following sets of items: (1) impact of alcohol consumption on academics (Q8. How often have you experienced the following during the current semester? items: 8.1 to 8.5), (2) impact of microaggressions (Q17. How much did the microaggressions impact your… items: 17.1 to 17.3?), (3) witnessed microaggressions (Q25. Have you witnessed any of the following? ...items: 25.1 to 25.8), and (4) bystander intervention (Q26. Would you intervene in the following situations? ...items: 26.1 to 26.4)

Test-Retest Reliability

Test-retest reliability, a measurement of reproducibility, was evaluated for closed-ended questions.

Construct Validity

To assess construct validity, participants also completed 3 validated scales: the AUDIT [20], the SBI [21], and the "Workplace and School Microaggressions" Scale from the REMS [9]. They also reported their Grade Point Average (GPA).

The AUDIT is a 10-item questionnaire with a range of possible scores from 0 to 40. Scores ≥7 and 8 have been proposed as "hazardous and harmful alcohol use" among women and men, respectively [20,22]. It was expected that (1) the median number of drinking days and the maximum number of drinks in a day during the last 2 weeks measured by the Color of Drinking questionnaire are greater among those scoring ≥7 than those scoring <7 in the AUDIT instrument, and (2) the number of drinking days and the maximum number of drinks per day during the last 2 weeks are correlated with the AUDIT score.

The validated "Workplace and School Microaggressions" subscale from the REMS, included 5 items describing experienced microaggressions in the last 6 months, with possible score ranges from 0 to 5. It was expected that those who answered that they had experienced a microaggression on campus or surrounding areas (Color of Drinking, Q14) score higher in the REMS subscale than those who did not have such experience [9].

The SBI is a validated 6-item questionnaire with possible scores ranging from 5 to 30 (the greater the score, the more the sense of belonging). It was hypothesized that the SBI score is lower among those who reported that the alcohol culture had impacted their overall sense of belonging at UW-Madison in comparison to those who reported that the alcohol culture had not affected it [21].

Finally, the academic performance was operationalized as self-reported accumulated and last-term GPA. It was expected that academic performance was better among those students who responded that they never received a poor grade because they had chosen to drink instead of study during the semester.

Redesign and Assessment for Questions With Low Performance and Developing the Final Questionnaire

For a section of questions showing low reliability, the answers to the open-ended questions and other series of in-depth interviews were used to generate a revised set of questions.

XSL•FO
RenderX

Then, online surveys were conducted with another sample of undergraduate students to evaluate reliability after changes.

Data Analysis

Descriptive statistics were calculated for the population and each item. Hypothesis tests were selected according to the variable distribution. Wilcoxon rank sum test with continuity correction and Kendall correlation coefficients were used to test the hypotheses related to construct validity.

The internal consistency was evaluated by calculating the Cronbach α coefficient by dimension. Additionally, we calculated the variation in the α coefficient after excluding each item from the analysis to assess the effect of dropping a particular item. A Cronbach α value of at least 0.7 is usually interpreted as adequate internal consistency [23]. Low values of α represent poor interrelatedness between items.

To assess test-retest reliability, the Cohen κ coefficient (dichotomous data), the Cohen weighted κ coefficient (ordinal data), and the intraclass correlation coefficient (for continuous data) and their 95% CI were calculated. The higher the coefficient, the stronger the test-retest reliability [13]. κ values between 0.41 and 0.6 were considered to be of moderate reliability, between 0.61 and 0.8 as substantial reliability and between 0.81 and 1 very high reliability [19]. κ is influenced by the trait prevalence and basal rates. κ may be low even though there are high levels of agreement and even though individual ratings are accurate, thus we have also calculated the proportion of observed and expected agreement only by chance. For the interpretation of the intraclass correlation coefficient, values lower than 0.5 were considered indicative of poor reliability, values between 0.5 and 0.75 indicate moderate reliability, values between 0.75 and 0.9 good reliability, and values higher than 0.9 excellent reliability [11].

All the analyses considered $\alpha < .05$ as statistically significant. Analyses were performed using R Statistical Software (version 4.1.3; R Foundation) and RStudio statistical software (version 2022.02.3 for Windows).

Ethical Considerations

This study was approved by the Institutional Review Board of the University of Wisconsin (Protocol Institutional Review Board ID 2017 - 0930). This study was conducted according to the guidelines established in the Declaration of Helsinki for studies involving human subjects. Written informed consent was obtained from all participants in the in-depth interviews, and online consent before the access to the survey in the Qualtrics platform. Students who completed the qualitative interview received US $20 on their campus card. Participants who completed both sets of surveys received US $10 on their student campus card. Data was de-identified for anaylsis.

Results

Cognitive Interviews

Table S1 in Multimedia Appendix 1 presents the characteristics of the students who participated in the interviews. The sample included 8 students, aged 19 to 22 years, representing diverse ethnicities, genders, and undergraduate years. The interview duration ranged from 20 minutes to 1 hour.

Overall, participants found most questions easy to answer and acceptable, with their interpretations “in their own words” aligning with the intended purpose of each question. However, for a few questions, 1 or more participants suggested that the interpretation could be improved by incorporating definitions, clarifications, or more specific terminology. Revisions based on these interviews are detailed in Table S2 in Multimedia Appendix 1.

The first version to assess the psychometric properties consists of 31 items (19 core questions+12 skip questions). Additionally, the survey includes 12 questions about sociodemographic characteristics.

Assessment of Psychometric Properties

A total of 181 students completed the first administration of the questionnaire between June and November 2022. Of these, 116 also completed the second administration. Six observations were excluded from the analysis due to missing answers in >50% of the questions (4 from the first administration and 2 from the second administration). All of them were from the group of students of color. Thus, 177 responses were available for the analysis of internal consistency, 115 for test-retest reliability assessment and 98 for construct validity.

Participants’ characteristics for each substudy are shown below in Table 1. Students of color represented 48.6% (86/177), 43.5% (50/115), and 57.1% (56/98) in substudies of assessment of internal consistency, test-retest assessment, and construct validity, respectively. Most of the students of color were Asian or Asian American, followed by those of Hispanic, Latinx, or Spanish origin. There were students representing all stages of academic studies. A larger number of students lived off campus, and the most frequent current financial situation was described as “tight but doing fine.”

[a]UW-Madison: University of Wisconsin-Madison.

[b]Q: question.

[c]Answer categories: never, rarely, sometimes, often, and most of the time

[d]Answer categories: not at all, slightly, somewhat, quite a bit, and a great deal.

[e]Answer categories: yes and no.

Test-Retest Reliability

Approximately 33% (38/115) and 30% (35/115) of the students reported that they do not drink alcohol or did not drink during the last 30 days in test and retest surveys, respectively. The mean number of drinking days within the last 2 weeks was 1.4 and 1.8 for test and retest, respectively. In summary, the section "alcohol use" showed moderate to substantial reliability (Table S3 in Multimedia Appendix 1).

On test and retest surveys, 9.6% (11/114) of the participants reported that the alcohol culture at UW-Madison had impacted their academics (Table S4 in Multimedia Appendix 1). Most items on the section "alcohol culture and academics" showed moderate to substantial test-retest reliability, but 1 of them showed low test-retest reliability.

On test and retest surveys, 51.8% (59/114) of the participants reported that during the semester they had avoided specific areas on or off campus due to concerns about alcohol use by others. The proportion in which participants were negatively impacted by other students' alcohol consumption was 35% (40/113) for the test and 28% (32/113) for the retest. Items from these 2 sections, "areas avoided" and "impact of by other students' alcohol consumption" also showed mostly moderate to substantial test-retest reliability (Table S2 in Multimedia Appendix 1).

Among the students of color, 47% (29/62) and 40% (25/62) reported having experienced a microaggression on campus or surrounding areas on test and retest surveys. On test and retest surveys, 71% (81/114) and 73% (83/114) of the students had witnessed at least once a microaggression on campus or surrounding areas during their time at UW-Madison. A summary of test-retest reliability assessment for experiencing, witnessing, and bystander intervention of microaggressions and alcohol intoxications is presented in Table S4 in Multimedia Appendix 1. Most of the items from these dimensions showed moderate to substantial test-retest reliability.

From test and retest surveys, 33% (37/112) and 25% (28/112) of the participants answered that their own or alcohol consumption by other students impacted their health during the time they attended UW-Madison. At test and retest, 43% (49/113) and 42% (47/113) of the students reported that the alcohol culture had impacted their overall sense of belonging at UW-Madison. Most of the items from the section "impact on health and sense of belonging" showed moderate to substantial test-retest reliability, except for 1 related to the impact on health (Table S4 in Multimedia Appendix 1).

Construct Validity

Students with AUDIT scores ≥7 reported a higher number of drinking days within the last 2 weeks than those with lower AUDIT scores. A similar association was found regarding the maximum number of drinks in a day and the AUDIT score with a cutoff point of 7 (Table 3). Correlations between the number of drinking days, the maximum number of drinks in a day and the AUDIT score as a continuous variable were moderate to high, r=0.630 (95% CI 0.533-0.719) and r=0.647 (95% CI 0.548-0.741), respectively (Table 3).

A few students reported that they received a poor grade because they had chosen to drink instead of study. Their GPA was lower than the other students' (Table 4).

Table . Construct validity. Drinking days within the last 2 weeks and a maximum number of drinks in a day among participants with AUDIT[a] scores less than and greater than or equal to 7. CoD[b] validation study, University of Wisconsin-Madison, 2022.

	AUDIT score		
	<7 (n=62)	≥7 (n=35)

Table . Construct validity. Self-reported grade point average (GPA[a]), microaggression subscale from the REMS[b] and SBI[c] according to selected items from the CoD[d] questionnaire validation study. UW-Madison[e], 2022.

Dimension: CoD questionnaire item	Variable (other instrument)	N	Mean (SD)	Median (IQR)	*P* value[f]
Dimension: alcohol consumption and academics					
CoD questionnaire, item 8.3 ("I received a poor grade because I chose to drink instead of study")	GPA, accumulated				.04
At least once during the current semester		7	3.19 (0.57)	3.3 (2.7 - 3.68)	
Never		71	3.6 (0.37)	3.7 (3.4 - 3.9)	
	GPA, last term				.02
At least once during the current semester		6	2.9 (0.77)	2.9 (2.28 - 3.55)	
Never		70	3.59 (0.58)	3.8 (3.5 - 4)	
Dimension: microaggressions					
CoD questionnaire, Q13. "In your time at UW-Madison, have you experienced a microaggression on campus or surrounding areas?"	Microaggressions subscale from REMS[g]				<.001
Yes		27	2.04 (1.83)	2 (0 - 3.5)	
No		40	0.68 (1.4)	0 (0 - 1)	
Dimension: impact on the sense of belonging					
CoD questionnaire, Q28. "Has the alcohol culture impacted your overall sense of belonging at UW-Madison?"	SBI[h]				<.001
Yes		41	16.07 (2.23)	16 (15-18)	
No		57	18.04 (2.15)	18 (17 - 19)	

[a]GPA: grade point average.

[b]REMS: Racial and Ethnic Microaggression Scale.

[c]SBI: Sense of Belonging Index.

[d]CoD: Color of Drinking.

[e]UW-Madison: University of Wisconsin-Madison.

[f]Wilcoxon rank sum test (*P* value).

[g]Score ranges from 0 to 5.

[h]Score ranges from 5 to 30.

Additionally, 27 of 67 students of color answered that in their time at UW-Madison they had experienced a microaggression on campus or surrounding areas. They scored higher on the REMS than the rest of the students.

Lastly, 41 of 98 students answered that the alcohol culture impacted their overall sense of belonging at UW-Madison. These students scored lower in the SBI in comparison with the rest of the students (Table 4).

Redesign and Assessment for Questions With Low Performance and Developing the Final Questionnaire

The "health impacts" section showed a low test-retest reliability. When the qualitative responses were evaluated, students brought

XSL•FO
RenderX

up different interpretations but also very profound answers and concepts, such as mental health struggles or experiencing sexual assault. Based on these results, the decision was made to rewrite and retest the validity of this question grounded on the evaluation of content validity, and other series of in-depth interviews were used to generate a revised set of questions. Eight items were developed for the personal consumption of alcohol on diverse aspects of health, and the same number of items were included for the consumption of others.

Online surveys were conducted including the 16 new items with another sample of undergraduate students selected following the same procedures. The sample included 118 students who completed the first questionnaire. Most participants were women (84, 71%), and 66 participants were self-identified as White. Sixty-seven participants also completed the second questionnaire.

The results for internal consistency and test-retest reliability were Cronbach α values of .735 and .855, for each set of questions, respectively, and most of the items presented κ coefficients from 0.476 to 0.877 (Tables S5 and S6 in Multimedia Appendix 1).

Discussion

The validation process outlined here included the assessment of reliability and validity of the Color of Drinking questionnaire, used in an exploratory study of the impact of UW-M's alcohol culture on students of color. The process of validating the original questionnaire resulted in a revised instrument, that showed good internal consistency, acceptable to good test retest reliability for most items and good construct validity.

In the alcohol and academics dimension, we found that questions related to personal academic consequences had higher internal consistency and a higher Cronbach α than the other questions in the same dimension. Questions about the secondhand negative academic consequences were found to be highly relevant but not highly correlated with each other. The question "my professors or TAs invited me out to places where alcohol is served" tested poorly when placed with the other secondhand academic consequences. For the finalized questionnaire we decided to separate the personal academic consequences, and secondhand negative consequences as 2 separate subdomains. We also removed the aforementioned question due to some unclearness about the scope and meaning of the item identified during the qualitative interview and little consistency with other items in the expected subdomain.

In the bystander intervention dimension, there were issues with test-retest reliability among 4 questions. Bystander discrimination questions from the questionnaire had low test-retest reliability. The questions were more prone to variation over time than the other bystander questions. The decision was made to remove these 4 questions from the finalized version of the questionnaire. Other validation processes in college settings show adequate validity and reliability when assessing other types of bystander interventions [24].

The health impacts section showed a low test-retest reliability, however based on responses there was important information to include in this section. Thus, the section was rewritten and tested, reaching good reliability.

A questionnaire designed for populational health studies should capture what it was meant to collect when designed in a reliable manner [25,26]. This validation process will not only allow us to measure what we want to measure but also will make our data comparable over time and with other college settings [27]
.

This study has limitations. Although there was a random selection of students invited to participate, we recognize that those more sensitive to racial issues may have been more likely to take part in this study. This potential selection bias could influence the generalizability of our findings to the broader university population.

In conclusion, the process of validating the original questionnaire for the Color of Drinking study resulted in a revised instrument, that showed good internal consistency, acceptable to good test-retest reliability for most items and good construct validity.

Abstract

Background: Adults who switch completely from smoking cigarettes to using electronic nicotine delivery systems (ENDS) substantially reduce their exposure to toxicants and carcinogens that are associated with smoking-related diseases.

Objective: This 6-week actual use study—a prospective uncontrolled real-world study designed to evaluate quasi-naturalistic product use—aimed to assess switching behavior among US adults who smoked cigarettes and were provided with JUUL2 ENDS products.

Methods: US adults who smoked cigarettes every day but were predominantly not ready to quit (N=1160; mean age 39.42, SD 11.03 years; 641/1160, 55.26% female participants; 667/1160, 57.5% non-Hispanic White; mean cigarettes per day 14.11, SD 8.96; only 1% [11/1160] planning to stop smoking within 30 days; and 481/1160, 41.47% dual users) were recruited to use JUUL2 ENDS products (18 mg/mL nicotine) in 1 of 5 flavors in real-world environments for 6 weeks. Participants who expressed sufficient interest in using JUUL2 products were enrolled at 24 different consumer research sites across the United States into one of the two following study arms: (1) traditional flavors (Virginia Tobacco and Polar Menthol, 10 sites); or (2) complex flavors (Autumn Tobacco, Summer Menthol, and Ruby Menthol, 14 sites). No instructions regarding JUUL2 product use or cigarette smoking were provided. After a 1-week trial period, participants were provided with their preferred flavor for 6 weeks of ad libitum use (10 pods per week). In total, 6 weekly web-based surveys were used to assess switching (smoking abstinence) and smoking reduction; dependence and respiratory symptoms were assessed at baseline and week 6.

Results: Across the 5 flavor groups at week 6, the rates of complete past-7-day switching away from cigarettes ranged from 38.2% (79/207) to 47.3% (95/201), and 24.3% (55/226) to 33.9% (74/218) of participants reported complete past-30-day switching. Participants who used the 3 menthol-flavored (vs 2 tobacco-flavored) JUUL2 products had significantly higher rates of past-30-day switching at week 6 (odds ratio 1.36, 95% CI 1.04-1.78). Compared to their baseline values when they were smoking, the past-30-day switchers at week 6 had significantly reduced their dependence (mean differences in dependence, cigarettes – JUUL2: 0.57-0.99; $P<.001$) and self-reported frequency of respiratory symptoms ($P<.05$). Among participants who continued to smoke at week 6, 50.9% (59/116) to 62.9% (73/116) reduced their daily cigarette consumption by at least 50% from baseline.

Conclusions: Adoption of JUUL2 ENDS products can likely help substantial proportions of US adults who smoke to switch completely away from cigarettes or meaningfully reduce their cigarette consumption, thereby reducing their dependence on tobacco products and improving their respiratory symptoms.

KEYWORDS

cigarette; smoking; electronic nicotine delivery system; switching; actual use study; real world

Introduction

Background

Evidence demonstrates that adults who switch completely from smoking cigarettes to using electronic nicotine delivery systems (ENDS) substantially reduce their exposure to toxicants and carcinogens that are associated with smoking-related diseases [1-4]. Accordingly, the primary public health benefit of ENDS is derived from facilitating switching behavior among adults who smoke.

For ENDS products that are currently marketed in the United States, observational studies and randomized trials have assessed switching behavior among adults who smoke [5-9]. However, for premarket ENDS products (ie, those not currently marketed in the United States), evaluating naturalistic product use behaviors and transitions over time in real-world settings requires providing the premarket product to adults who smoke cigarettes. Actual use studies—prospective uncontrolled real-world studies designed to evaluate quasi-naturalistic product use—are the primary method for assessing the use of premarket tobacco products under ecologically valid conditions. Actual use studies were initially developed for pharmaceuticals to determine whether prescription drugs could be switched to over-the-counter sale by assessing use and safety of the drug in real-world settings designed to mimic over-the-counter use [10,11].

In recent years actual use studies have evaluated use of tobacco products, including oral nicotine pouches [12,13] and heated tobacco (heat-not-burn) products [14,15], among adults who smoke to prospectively assess changes in cigarette smoking following quasi-naturalistic use of the new tobacco products in real-world settings. In contrast to randomized cessation trials, actual use studies do not require participants to have active plans to quit smoking to qualify, do not set explicit goals for product use or smoking, and do not provide instructions, encouragement, or behavioral support to quit. Thus, actual use studies are particularly well-suited to evaluate the ability of ENDS to facilitate switching behavior (smoking abstinence) following periods of unguided self-determined use.

The JUUL2 system is a next-generation pod-based ENDS product that is designed to facilitate high levels of complete switching away from cigarettes among adults who smoke cigarettes. Pharmacokinetic studies show that JUUL2 18 mg/mL (1.5% nicotine by weight) products can deliver similar levels of nicotine as ENDS products with higher nicotine concentrations due to increased aerosol production [16], and behavioral pharmacology data demonstrate that Polar Menthol–flavored 18 mg/mL JUUL2 pods are rated as significantly more satisfying than menthol-flavored pod-based ENDS with 5% nicotine concentrations [17]. The JUUL2 system is currently marketed in the United Kingdom; however, there is a lack of real-world data on the switching potential of these JUUL2 products among US adults who smoke.

Objectives

The primary aim of this actual use study was to evaluate complete switching away from cigarettes (ie, past-7-day and past-30-day smoking abstinence) among US adults who smoked cigarettes every day and were provided with JUUL2 products in their preferred flavor for 6 weeks. Secondary aims of the study were to assess: (1) changes in dependence and respiratory symptoms among participants who switched completely away from smoking at week 6; (2) changes in cigarette consumption among participants who continued smoking at week 6; (3) patterns of JUUL2 product use and subjective responses to JUUL2 products; and (4) factors associated with switching behavior, including JUUL2 study product flavor (menthol vs tobacco), cigarette flavor of usual brand (menthol vs nonmenthol), and baseline ENDS use (dual use along with cigarette smoking).

Methods

Design

The study was designed as an actual use study—a prospective real-world study intended to simulate quasi-naturalistic product use—in which US adults who smoked cigarettes were provided with JUUL2 study products in participant-selected flavors for 6 weeks of ad libitum use in their natural environment. All potential participants first completed an initial prescreening survey (in person or via telephone) and then the formal recruitment screening on the web. The study had 2 distinct arms, implemented at separate research sites with different geographic catchment areas that tested 1 of the 2 following flavor series: (1) traditional flavors (Virginia Tobacco and Polar Menthol), which correspond to ENDS flavors that have been authorized for marketing by US Food and Drug Administration (FDA; 10 sites); or (2) complex flavors (Autumn Tobacco, Summer Menthol, and Ruby Menthol), which represent adult-oriented flavor mixtures that have not yet received market authorization from FDA (14 sites). The 2 arms were conducted at distinct sites and did not share participant pools to evaluate traditional and complex flavors independently. The decision to separate the traditional and complex flavors was an a priori design based on differences in the composition of traditional and complex flavors (see Study Products section), with implied different regulatory positions (ie, FDA has authorized tobacco- and menthol-flavored ENDS, but has not yet authorized nontobacco or nonmenthol flavors or blends), and to avoid the complexity of each participant and site testing all 5 flavors. Study design and procedures for the 2 arms were identical, and the geographic and demographic position of the research sites were roughly parallel, but sites recruited participants from their local catchment area, thus there was no overlap in potential participants across study sites. Importantly, participants were not assigned to sites or arm by the study (randomly or otherwise) but were recruited from each site's distinct geographic catchment area. The study sponsor did not play any role in the recruitment of participants and individuals were primarily

XSL•FO
RenderX

recruited from existing databases maintained by the study sites or in person (not sponsor databases).

Eligible participants first completed a 1-week trial period to determine which flavor they would exclusively use for the 6-week actual use period. During the 6-week actual use period, participants completed weekly web-based survey assessments (Multimedia Appendix 1).

At prescreening, participants were informed that the research study involved using new electronic cigarette products for 7 weeks and that participation in the study did not require stopping smoking cigarettes—the study was not framed or described as a study of behavior change or smoking cessation. During the trial week and 6-week actual use period, no goals or instructions were provided regarding cigarette smoking; participants could smoke ad libitum throughout the study, or reduce or forego smoking, at their discretion. Similarly, no instructions (beyond the user guide included in the product package) were provided regarding use of the JUUL2 study products with respect to amount or persistence of use. The only directions were those that come with marketed products, describing how to use the product and how to charge the device.

Participants

The study sample included healthy non–treatment-seeking English-speaking US adults (aged 22 to 65 years) who smoked cigarettes every day and lived close to one of the 24 shopping-mall–based study sites distributed across 15 states (Multimedia Appendix 2). Eligibility criteria were as follows: (1) smoked ≥100 combustible tobacco cigarettes in their lifetime and smoked cigarettes for ≥12 months before screening; (2) smoked cigarettes every day and smoked an average of ≥5 cigarettes per day; (3) interested in trying and using JUUL ENDS products; (4) access to a computer or laptop, smartphone, or tablet with internet access; (5) provided consent for participation and acknowledged willingness and ability to comply with all study requirements. Interest in stopping smoking was not an eligibility criterion.

Exclusion criteria included the following: (1) use of any nicotine replacement therapy (eg, patch and gum) or prescription smoking cessation medications (eg, varenicline and bupropion) within 30 days before screening; (2) diagnosis of a clinically significant medical (eg, asthma, chronic obstructive pulmonary disease, heart disease, high blood pressure, and cancer) or psychiatric disease; (3) was pregnant, nursing, or intended to become pregnant at any time through the end of study; (4) participated in a research study about tobacco products or ENDS within the past 30 days; (5) was a current or former employee or related to a current or former employee of the tobacco or ENDS industry or any vendor associated with conduct of the study; and (6) operated or lived with family member who operated any home childcare or health care services. There were no eligibility criteria regarding prior use of ENDS; participants could be ENDS naive, former ENDS users, or current dual users. Recruitment aimed to enroll a diverse sample with respect to sociodemographic and tobacco product use characteristics, according to the following soft quotas: (1) ≤60% of male or female participants; (2) at least 35% of participants who identified as non-Hispanic White; (3) ≥50% participants aged <45 years; (4) ≥40% of participants who smoked mentholated cigarettes; and (5) ≥50% of participants who had ever used ENDS. Individuals were primarily recruited from existing databases maintained by the study sites and the study sponsor did not play any role in recruitment of participants.

Ethical Considerations

Participants provided written informed consent. All surveys were completed remotely on the web. Participants were compensated US $20 for completing the baseline assessment, US $15 for completing the product trial assessment, and US $25 for completing each weekly assessment. Additional compensation was provided for completing all study assessments and returning study products, with maximum total compensation of US $450. The Advarra Institutional Review Board approved the study protocol (Pro00068019).

Procedure

Following enrollment, participants completed the baseline survey on the web and visited their study site, where they were provided with a JUUL2 device, charging dock, and 2 pods of each of the flavors in their respective study arm (2 traditional flavors or 3 complex flavors) for a 1-week product trial period. Participants were instructed to use each flavor for at least one day, enough to form an opinion of the product; no other instructions were provided. After the trial period, participants completed a brief web-based survey in which they rated their interest in each of the trialed JUUL2 pod flavors. These responses were used to determine if participants qualified for the 6-week actual use period and which flavor they would use (see Interest in Using and Purchasing JUUL2 Products subsection of Measures).

At the start of week 1, participants received an additional JUUL2 device. Every 2 weeks (at the start of week 1, week 3, and week 5) participants were provided with 20 pods for use during the upcoming 2 weeks (10 pods per week, 60 pods total). Participants were invited by email to complete assessments at the end of each of the study weeks and received compensation upon completion of each weekly assessment. Participants had 3 days from the initial invitation to complete the weekly surveys and they received multiple reminder emails prompting them to complete the assessment (surveys not completed within this window were considered missing).

Participants were instructed in the informed consent form and by study staff to inform study staff of any adverse events (AEs) and intercurrent illnesses experienced during the study. In addition, a specific inquiry regarding AEs (ie, if participants had experienced any changes to their health [yes or no]) was made at the product trial (week 0), week 3, and week 6 surveys; at the week 1, 2, 4, and 5, surveys participants were prompted to report any changes to their health to the study staff. Reported health events were assessed and classified via clinical interviews by trained medical personnel.

Study Products

The JUUL2 system is closed-system pod-based ENDS that is inhalation-actuated and does not have any user-modifiable settings, controls, or buttons. Preclinical studies demonstrate

XSL•FO
RenderX

that the aerosol produced by the JUUL2 system contains substantially lower levels of harmful and potentially harmful constituents than cigarette smoke [18]. The 5 JUUL2 pod flavors evaluated in this study are all currently marketed in the United Kingdom. Virginia Tobacco and Polar Menthol have traditional tobacco and menthol flavors, respectively. The 3 complex flavors (Autumn Tobacco, Summer Menthol, and Ruby Menthol) consist of a tobacco or menthol base, respectively, with top notes of fruit: apple for Autumn Tobacco, tropical fruit for Summer Menthol, and berry for Ruby Menthol.

Measures

Participants Sociodemographic and Tobacco Use Characteristics

Sociodemographic and tobacco or nicotine product use characteristics were assessed in the recruitment screener and baseline assessment with items and measures adapted from national surveys, with some modified for relevance.

Interest in Using and Purchasing JUUL2 Products

At the end of the trial week, participants were asked 2 questions about each of the JUUL2 products they used as follows: (1) "How interested are you in using the JUUL2 study product for the next 6 weeks?" (5-point response scale, from 1 ["not at all interested"] to 5 ["extremely interested"]) and (2) "If the JUUL2 study products you tried this week were available for purchase, would you buy one or more of the products?" (4-point response scale, from 1 ["definitely would not buy"] to 4 ["definitely would buy"]). Only participants who responded 3 or higher to both items for at least one flavor continued to the 6-week actual use period. This was intended to mirror real-world self-selection for product use, as individuals who were not interested in using or purchasing a specific flavor of a consumer product would be unlikely to purchase and adopt it. Participants were provided with the single flavor they expressed the greatest interest in using for the 6-week period; those who expressed exactly equivalent interest in multiple flavors were assigned to the flavor group in their respective study arm that was most in need of enrollees, which helped balance the sample size of flavor groups.

Cigarette Smoking

At each weekly survey, participants were asked if they had smoked cigarettes (even one puff) in the past 7 days (yes or no). At the week 6, survey participants were asked if they smoked in the past 30 days: "no" responses were operationalized as switching. Participants who reported smoking in the past 7 days at any survey between weeks 3 and 6 (ie, within 30 days of week 6) were coded as past-30-day smokers, even if they did not complete the week 6 survey or reported past-30-day abstinence at week 6.

Participants who reported smoking in the past 7 days also reported frequency and intensity of cigarette smoking during that period—daily cigarette consumption was calculated as cigarettes smoked per day in the past 7 days, including nonsmoking days (ie, product of the past-7-day frequency and daily intensity).

Dependence on Cigarettes and JUUL2 Products

Dependence on cigarettes was assessed at baseline and dependence on JUUL2 products was assessed at week 6 among participants who had not smoked in the past 30 days with the Tobacco Dependence Index (range 1-5, with higher scores indicating greater levels of dependence), a measure psychometrically validated in the Population Assessment of Tobacco and Health study for cross-product comparisons [19,20].

Respiratory Symptoms

Frequency of respiratory symptoms was assessed at baseline, when all participants smoked cigarettes every day, and at week 6 among the past-30-day switchers using the Respiratory Symptoms Experience Scale (range 1-5, with higher scores indicating greater frequency of respiratory symptoms), which was developed and validated for adults who smoke cigarettes but may not have clinical respiratory disease [21].

Patterns of JUUL2 Product Use

At each weekly survey, participants who reported using JUUL2 products in the past 7 days reported the number of days they used JUUL2 products and completed 2 items that assessed intensity of use as follows: (1) number of use episodes per day and (2) number of puffs per day.

Subjective Responses to JUUL2 Products

Subjective responses to JUUL2 products were assessed at week 6 with the modified Product Evaluation Scale [22].

Statistical Analysis

The study was prospectively powered for its primary aim, to evaluate rates of the past-30-day switching using the Clopper-Pearson exact method [23] with an estimated expected switch rate of 20% (based on switch rates observed in a prior observational study of US adults who purchased JUUL products), achieving a CI of 5%. Power analyses were not conducted for the secondary analyses.

The rate of past-7-day switching was calculated at each weekly survey within each of the 5 flavor groups; the rate of past-30-day switching was also evaluated at the week 6 Survey. A logistic regression model tested the association of JUUL2 flavor group and past-30-day switching at week 6, with Virginia Tobacco as the reference group; separate models contrasted the 2 combined tobacco flavors (Virginia and Autumn Tobacco) to the 3 combined menthol flavors (polar, summer and Ruby Menthol), and the 3 individual menthol flavors, respectively, to Virginia Tobacco. A repeated-measure logistic regression model included the past-7-day switching averaged across all 6 weeks as the dependent variable and JUUL2 flavor group, menthol cigarette preference (mentholated vs nonmentholated), and time (week) since baseline (coded as continuous, range 1-6) as simultaneous regressors—all 2-way interaction terms and the 3-way JUUL2 flavor × cigarette flavor × time interaction term were also included.

A separate repeated-measure logistic regression model was used to assess the association of baseline ENDS use (past 30 days vs not past 30 days) and the past-7-day switching. In addition,

XSL•FO
RenderX

mixed effects models evaluated linear changes over time in metrics of daily JUUL2 product use across the 6-week period.

Paired *t* tests were used to assess within-person changes in levels of dependence from baseline to week 6 (from cigarettes to JUUL2 products) among participants who reported no past-30-day smoking at week 6; dual users were not included in this analysis as they continued to smoke cigarettes and their dependence on JUUL2 could not be isolated. Changes in respiratory symptoms from baseline to week 6 were similarly assessed among complete 30-day switchers to assess whether switching affected their respiratory symptoms. Among participants who reported past-7-day smoking at week 6, changes in daily cigarette consumption (cigarettes per day on smoking days) from baseline were also tested with paired *t* tests. The proportion of participants reporting reductions of ≥50% was also calculated.

The primary analyses of switching used all observed (nonmissing) data without imputing smoking status to missed observations. This approach is typical for observational studies [24], in contrast to smoking cessation treatment trials, where there is concern that participants might avoid reporting smoking to avoid admitting to "failure" in an agreed behavioral goal [25]. To assess the potential for missingness to introduce bias, analyses were performed to compare participant baseline characteristics between participants who completed all 6 weekly surveys and those who missed any follow-ups. As a sensitivity analysis, the primary switching analyses were repeated while imputing smoking to all missing observations (intent-to-treat).

In addition, among participants who smoked mentholated cigarettes, differences in sociodemographic and tobacco use characteristics were compared between those who selected tobacco-flavored and menthol-flavored JUUL2 products.

Data were analyzed using SAS version 9.4 (SAS Institute Inc) with alpha level set to 0.05; no adjustments were made for multiple testing.

Results

Participant Accrual and Disposition

The enrollment flow in the traditional and complex flavor arms is provided in Multimedia Appendices 3 and 4, respectively. In the traditional flavors arm, 1874 adults were invited to complete the prescreener; 72.68% (1362/1874) completed it and were sent the eligibility screener; and 54.99% (749/1362) subsequently completed the recruitment screener and met all eligibility criteria. Of the eligible participants, 667 (89.1%) provided informed consent and were sent the baseline assessment (Multimedia Appendix 3). Approximately 99% (661/667) of those who started the baseline assessment completed it and were invited to participate in the trial week, 78.8% (521/661) subsequently completed the trial week assessment and were eligible to continue into the 6-week actual use period; 87% (575/661) completed the trial week survey; and 8.2% (54/661) were ineligible to continue into the 6-week actual use period based on expressing insufficient interest in using the study products.

In the complex flavors arm 2625 adults were invited to complete the prescreener; 71.7% (1882/2625) completed it and were sent the eligibility screener and 56.7% (1067/1882) subsequently completed the recruitment screener and met all eligibility criteria. Of the eligible participants, 942 (88.3%) provided informed consent and were sent the baseline assessment (Multimedia Appendix 4). Approximately 98% (927/942) of those who started the baseline assessment completed it and were invited to participate in the trial week, 79.9% (741/927) subsequently completed the trial week assessment and were eligible to continue into the 6-week actual use period; 13.6% (126/927) did not complete the trial week survey; and 6.5% (60/927) were ineligible to continue into the 6-week actual use period because they did not express sufficient interest in using the study products.

At screening, 61 (1.9%) individuals were excluded due to lack of interest in trying JUUL products. At the end of the trial week, the mean ratings of interest in purchasing JUUL2 products ranged from 3.37 to 3.44 on the 4-point response scale; ratings of interest in individual JUUL2 flavors ranged from 3.65 (Virginia Tobacco) to 4.12 (Polar Menthol) on the 5-point response scale (Multimedia Appendix 5). In the traditional flavors arm, 42.2% (242/574) of the participants expressed equivalent interest in both flavors (Virginia Tobacco and Polar Menthol), and in the complex flavors arm, 29.3% (232/792) expressed equivalent interest in all 3 flavors—27.3% (216/792) rated 2 of the 3 flavors equally and 43.4% (344/792) expressed a unique preference for a single flavor. There was no significant difference in the proportion of participants in the traditional (54/661, 8.2%) and complex (60/927, 6.5%) flavors arms that did not continue in the study due to lack of interest in using JUUL2 products at the end of the trial week (χ^2_1=1.67, *P*=.20). In the traditional flavors arm, 20.3% (106/521) of the participants met the threshold for inclusion for only one flavor. In the complex flavors arm, 30.6% (227/741) qualified for 1 or 2 flavors (ie, did not meet threshold for at least one flavor) and 8.8% (65/741) qualified for only one flavor.

The analytic sample consisted of 1160 total participants, roughly evenly divided into the 5 flavor groups: 242 participants in the Virginia Tobacco group, 239 in the Polar Menthol group, 219 in the Autumn Tobacco group, 236 in the Summer Menthol group and 224 in the Ruby Menthol group (Multimedia Appendices 3 and 4).

Sample Characteristics

Characteristics of the sample are reported for all participants (Table 1) and separately within each of the 5 individual flavor groups (Multimedia Appendix 6). Baseline characteristics were generally similar between JUUL2 flavor groups, although larger proportions of participants who selected menthol-flavored JUUL2 products smoked mentholated cigarettes (Multimedia Appendix 6). The participants (mean age 39.42, SD 11.03 years) were majority female (641/1160, 55.26%) and primarily self-identified as non-Hispanic White (667/1160, 57.5%); 19.22% (223/1160) self-identified as non-Hispanic Black; and 16.47% (191/1160) self-identified as of Hispanic ethnicity (Table 1). Over half (632/1160, 54.48%) of them reported annual household income less than US $50,000 and 39.57% (459/1160)

XSL•FO
RenderX

did not complete education beyond high school. On average, the participants reported smoking for 16.20 (SD 9.87) years; currently smoked 14.11 (SD 8.96) cigarettes per day and reported high levels of dependence on cigarettes (Tobacco Dependence Index-Cigarettes, mean 3.65, SD 0.81); 73.3% (850/1159) smoked mentholated cigarettes; and only 0.95% (11/1160) planned to quit smoking in the next 30 days at baseline (832/1160, 71.72% planned to never quit smoking).

Nearly three-quarters (825/1160, 71.12%) of the participants had ever used ENDS and, of those, 58.3% (481/825) had used ENDS in the 30 days preceding baseline (ie, were dual users). Dual users, on average, used ENDS 15.25 (SD 9.82) days out of the past 30 days. Among current ENDS users, the use of menthol-flavored products (183/481, 38%) was more common than use of tobacco-flavored ENDS (50/481, 10.4%). JUUL was selected as the primary ENDS brand by 34.5% (166/481) of those currently using ENDS.

Analysis of Baseline Characteristics by Response to Weekly Surveys

In each flavor group, over 85% of participants who were enrolled and started the 6-week actual use period completed the week 6 survey (Virginia Tobacco, 207/242, 85.5%; Polar Menthol, 212/239, 88.7%; Autumn Tobacco, 190/219, 86.8%; Summer Menthol, 211/236, 89.4%; Ruby Menthol, 201/224, 89.7%) and over 70% completed all 6 weekly surveys (Virginia Tobacco, 178/242, 73.6%; Polar Menthol, 173/239, 72.4%; Autumn Tobacco, 158/219, 72.1%; Summer Menthol, 171/236, 72.5%; Ruby Menthol, 157/224, 70.1%). In the overall sample, there were a few statistically significant differences between the participants who completed all 6 weekly surveys and those who missed some surveys, and the magnitude of differences were small (Multimedia Appendix 7). Participants who completed all 6 surveys (vs 1-5 surveys) were significantly older, by 1.5 years (39.84 vs 38.34 years; *P*=.04), more likely to be female (481/837, 57.5% vs 160/323, 49.5%; *P*=.01), less likely to smoke menthol cigarettes (599/836, 71.7% vs 251/323, 77.7%; *P*=.04) and less likely to have ever used ENDS (575/837, 68.7% vs 250/323, 77.4%; *P*=.003). Among participants who had used ENDS, those who completed all 6 surveys initiated ENDS use about 2 years later (age 31.87 vs 30.01 years; *P*=.03). There were no significant differences by race or ethnicity, education, income, employment, plans to quit smoking, use of JUUL ENDS, or ENDS dependence among those using ENDS. Importantly, there were no differences in the heaviness of smoking or in cigarette dependence, which have been shown to be important predictors of switching. There were no significant differences in rates of survey completion among the JUUL2 flavor groups.

Switching Across 6-Week Actual Use Period

As displayed in Figure 1, in each of the 5 JUUL2 flavor groups, rates of past-7-day switching away from cigarettes increased across the 6-week actual use period: from 27.8% (62/223) at week 1 to 38.2% (79/207) at week 6 for Virginia Tobacco, 35.8% (73/204) at week 1 to 38.4% (73/190) at week 6 for Autumn Tobacco, 32.7% (73/223) at week 1 to 45.3% (96/212) at week 6 for Polar Menthol, 35.6% (77/216) at week 1 to 46.9% (99/211) at week 6 for Summer Menthol, and 37.3% (76/204) at week 1 to 47.3% (95/201) at week 6 for Ruby Menthol. In the combined sample that included all 5 flavors, there was a statistically significant linear increase in the rate of past-7-day switching over the 6-week actual use period (odds ratio [OR] 1.09, 95% CI 1.07-1.12; Multimedia Appendix 8).

Figure 1. Rates of past 7-day switching away from cigarettes across 6-week actual use period by JUUL2 flavor. Virginia Tobacco: week 1: n=223, week 2: n=234, week 3: n=223, week 4: n=220, week 5: n=215, week 6: n=207; Autumn Tobacco: week 1: n=204, week 2: n=206, week 3: n=200, week 4: n=203, week 5: n=191, week 6: n=190; Polar Menthol: week 1: n=223, week 2: n=222, week 3: n=213, week 4: n=218, week 5: n=210, week 6: n=212; Summer Menthol: week 1: n=216, week 2: n=217, week 3: n=210, week 4: n=214, week 5: n=210, week 6: n=211; Ruby Menthol: week 1: n=204, week 2: n=211, week 3: n=205, week 4: n=206, week 5: n=196, week 6: n=201.

XSL•FO
RenderX

At week 6, rates of past-30-day switching were 24.3% (55/226) for Virginia Tobacco, 28.6% (58/203) for Autumn Tobacco, 31.4% (70/223) for Polar Menthol, 33% (69/209) for Ruby Menthol, and 33.9% (74/218) for Summer Menthol (Table 2).

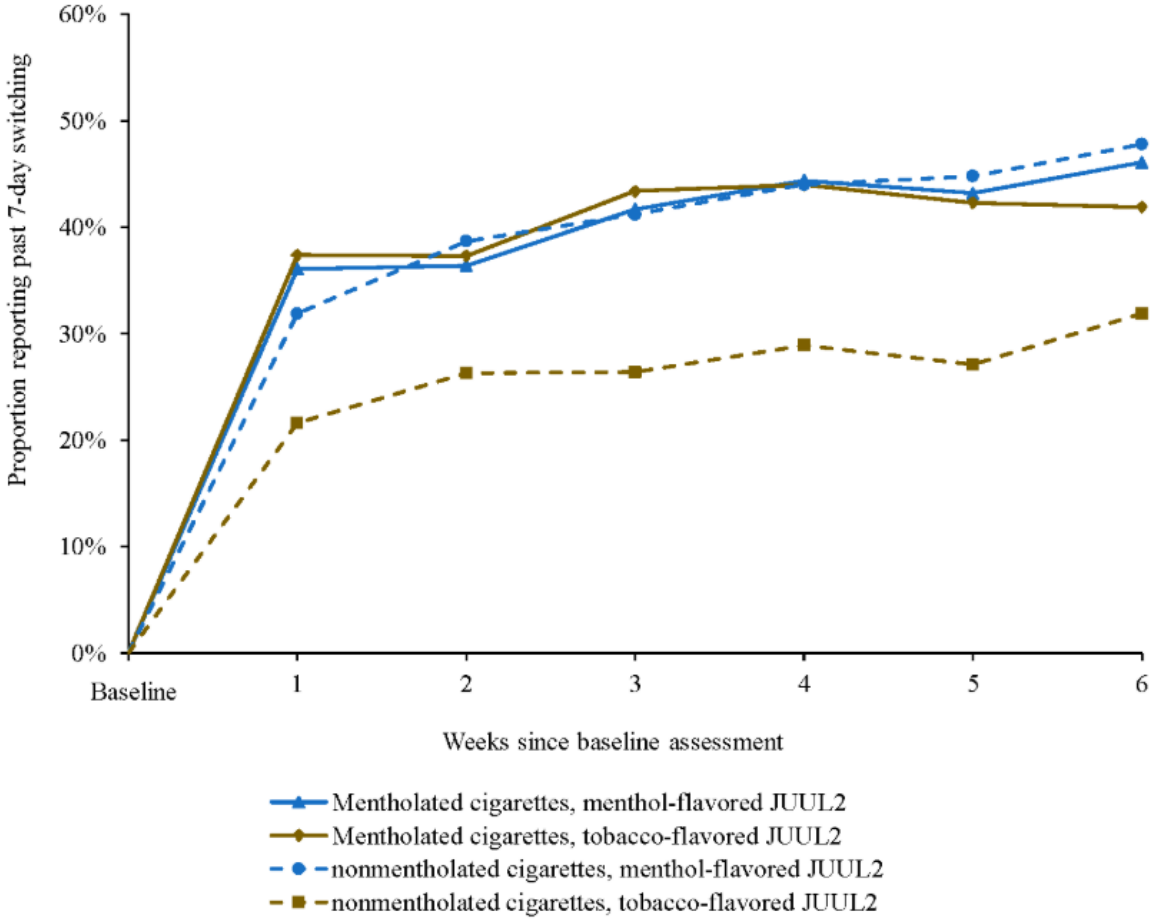
Sensitivity analyses in which smoking (ie, not being switched) was imputed to missing observations showed very similar results, although the absolute imputed switch rates were slightly lower (Multimedia Appendix 9). At week 6, the rates of past-7-day switching using the intent-to-treat approach ranged from 32.6% (79/242; Virginia Tobacco group) to 42.4% (95/224; Ruby Menthol group) and the rates of past-30-day switching ranged from 22.7% (55/242, Virginia Tobacco group) to 31.4% (74/236, Summer Menthol group).

Table 2. Rates of past-30-day switching at week 6 by JUUL2 product flavor.

JUUL2 product flavor	Proportion reporting past-30-day switching, % (SE; 95% CI)
Virginia Tobacco (N=226)	24.3 (2.9; 18.7-29.9)
Autumn Tobacco (N=203)	28.6 (3.2; 22.4-34.8)
Polar Menthol (N=223)	31.4 (3.1; 25.3-37.5)
Summer Menthol (N=218)	33.9[a] (3.2; 27.7-40.2)
Ruby Menthol (N=209)	33[a] (3.3; 26.6-39.4)

[a]Switch rate is significantly higher than Virginia Tobacco group (P<.05).

Association of JUUL2 Flavor Group and Menthol Cigarette Smoking With Switching



In the model assessing past-30-day switching at week 6, participants who used menthol-flavored (vs tobacco-flavored) JUUL2 products had statistically significant higher switch rates (OR 1.36, 95% CI 1.04-1.78; Multimedia Appendix 8)—there was no significant main effect of cigarette flavor (P=.06) and the interaction of JUUL2 flavor group and cigarette flavor was not significant (P=.10). Compared to the Virginia Tobacco group, rates of past-30-day switching were significantly higher in the Ruby Menthol group (OR 1.53, 95% CI 1.01-2.33) and Summer Menthol group (OR 1.60, 95% CI 1.06-2.42), respectively. These associations remained significant in the models that imputed smoking for missing data: Ruby Menthol versus Virginia Tobacco (OR 1.51, 95% CI 1.00-2.29) and Summer Menthol versus Virginia Tobacco (OR 1.55, 95% CI 1.03-2.33). The rate of past-30-day switching was numerically higher among the participants in the Polar Menthol group compared to the Virginia Tobacco group, but it did not show a statistically significant difference (OR 1.42, 95% CI 0.94-2.15).

The association of JUUL2 product flavor group and the rate of past-7-day switching was not significant as a main effect (OR 1.23, 95% CI 0.92-1.64; Multimedia Appendix 8). However, this association was significantly moderated by preferred cigarette flavor: among participants who smoked nonmentholated cigarettes, those who used menthol-flavored (vs tobacco-flavored) JUUL2 products had significantly higher switch rates (340/824, 41.3% vs 237/880, 26.9%; OR 1.71, 95% CI 1.04-2.83; Figure 2), whereas there was no significant difference in switch rates by JUUL2 product flavor among participants who smoked menthol cigarettes (1228/2975, 41.3% vs 668/1630, 41%; OR 0.88, 95% CI 0.65-1.18).

There was also a significant main effect of menthol cigarette smoking, with smokers of mentholated (vs nonmentholated) cigarettes demonstrating higher switch rates (OR 1.52, 95% CI 1.14-2.04; Multimedia Appendix 8), largely because of lower switch rates among participants who smoked nonmentholated cigarettes and used tobacco-flavored JUUL2 products (Figure 2). Among participants who smoked mentholated cigarettes, there were no statistically significant differences in sociodemographic or tobacco product use characteristics between those who selected tobacco-flavored and those who selected menthol-flavored JUUL2 products (Multimedia Appendix 10).

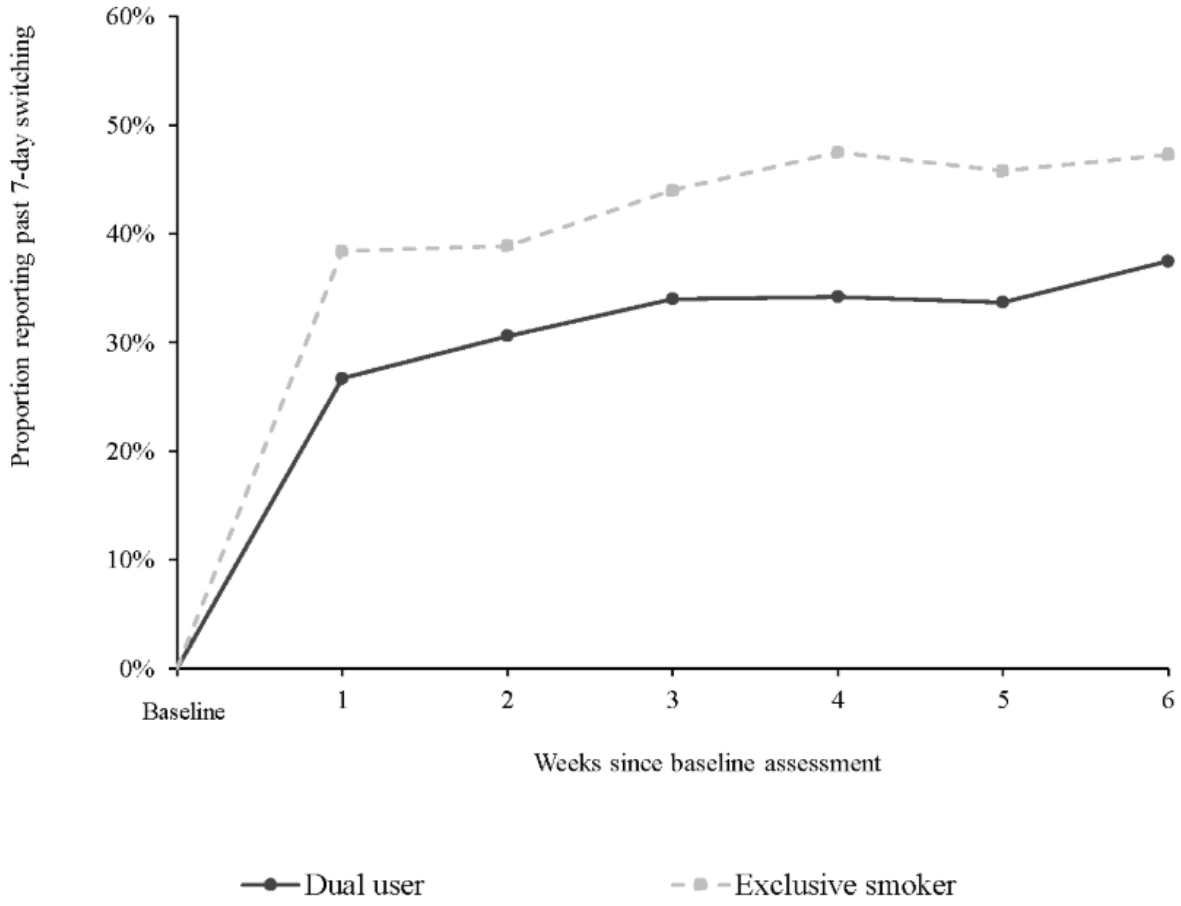
Figure 2. Past 7-day switching by JUUL2 product flavor and cigarette flavor across 6-week actual use period. Smoked menthol cigarettes, menthol-flavored JUUL2: week 1: n=499, week 2: n=508, week 3: n=492, week 4: n=504, week 5: n=482, week 6: n=490; smoked nonmentholated cigarettes, menthol-flavored JUUL2: week 1: n=144, week 2: n=142, week 3: n=136, week 4: n=134, week 5: n=134, week 6: n=134; smoked menthol cigarettes, tobacco-flavored JUUL2: week 1: n=273, week 2: n=287, week 3: n=274, week 4: n=273, week 5: n=265, week 6: N=258; smoked nonmentholated cigarettes, tobacco-flavored JUUL2: week 1: n=153, week 2: n=152, week 3: n=148, week 4: n=149, week 5: n=140, week 6: n=138.



Differences in Switching by ENDS Use at Baseline

There were significant differences in the rates of past-7-day switching according to ENDS use in the 30 days preceding baseline: participants who were smoking but did not use ENDS in the past 30 days had significantly higher switch rates than the dual users (1630/3740, 43.6% vs 843/2575, 32.7%) across the 6-week actual use period (Figure 3 and Multimedia Appendix 11).

XSL•FO
RenderX

Figure 3. Past 7-days switching among baseline dual users and exclusive smokers across 6-week actual use period. Dual users: week 1: n=430, week 2: n=448, week 3: n=435, week 4: n=433, week 5: n=413, week 6: n=416; exclusive smokers: week 1: n=640, week 2: n=642, week 3: n=616, week 4: n=628, week 5: n=609, week 6: n=605.

Changes in Dependence and Respiratory Symptoms Among Participants Who Completely Switched (Did Not Smoke) in the Past 30 Days at Week 6

Among participants who reported past-30-day switching at week 6, levels of dependence on JUUL2 products were significantly lower than their own levels of dependence on combustible cigarettes at baseline, for all 5 flavors (P<.001; Figure 4).

Participants who did not smoke in the past 30 days at week 6 also experienced significant decreases in frequency of self-reported respiratory symptoms relative to baseline when they were smoking cigarettes, across all 5 flavors (P≤.01; Figure 5).

RenderX

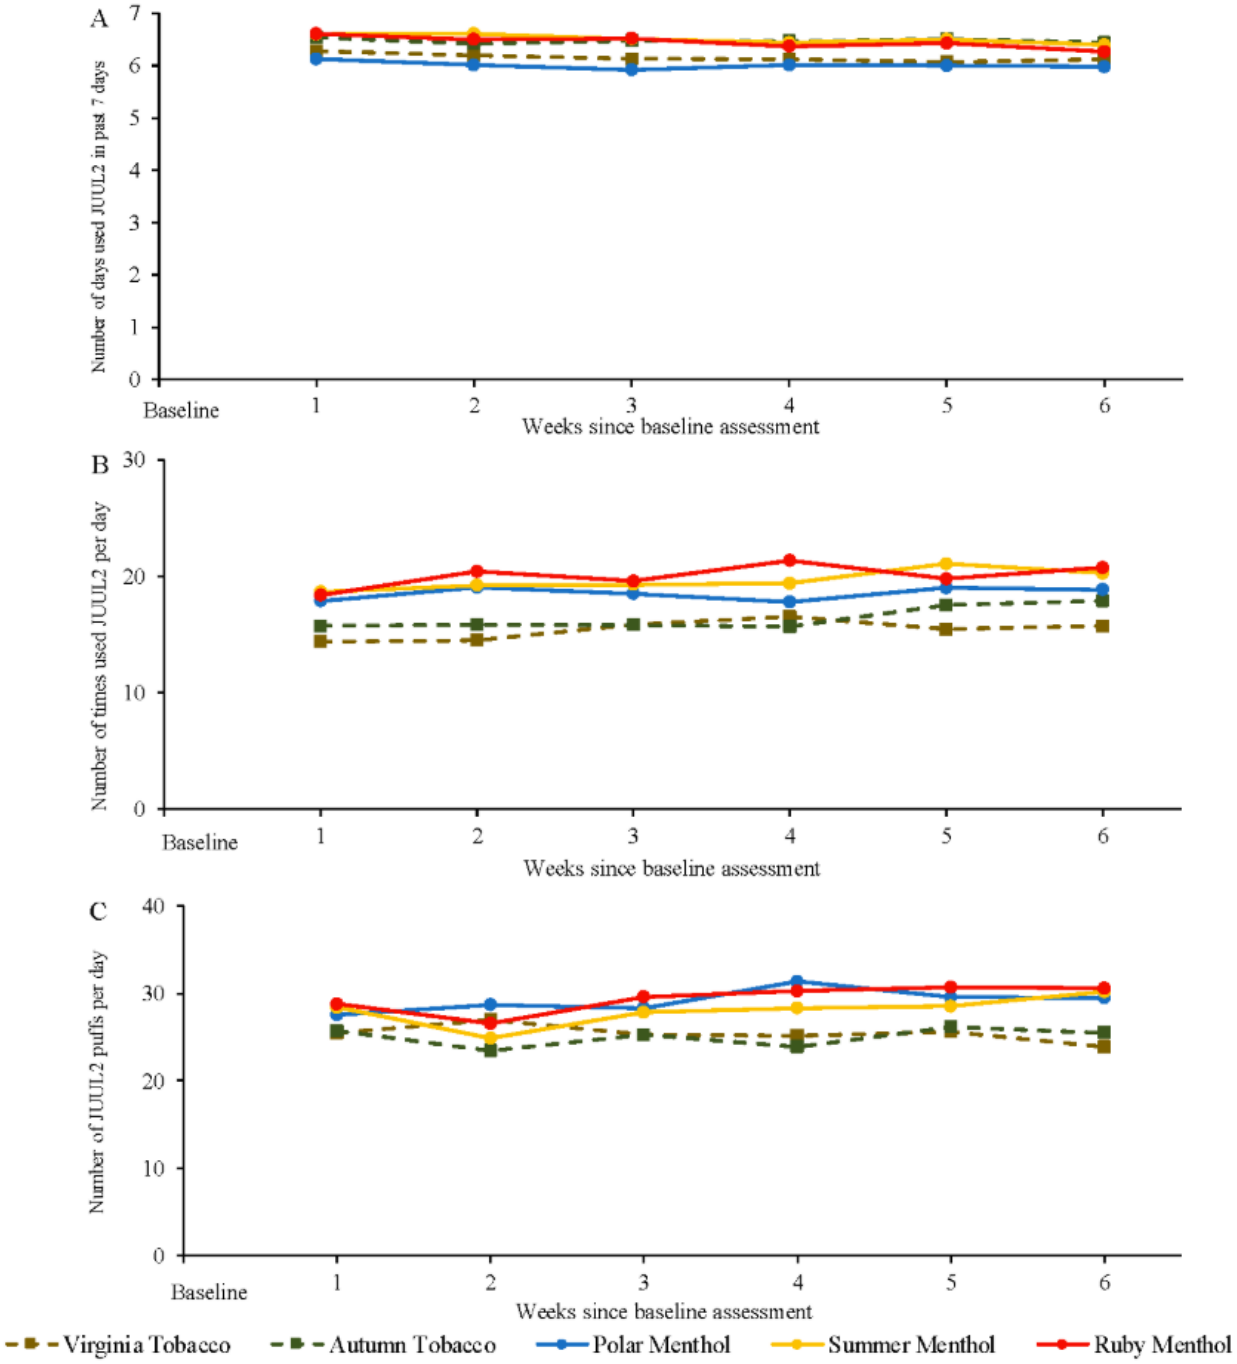
Smoking Reduction Among Participants Who Continued Smoking at Week 6

Among participants who continued to smoke at week 6, average daily cigarette consumption in all 5 JUUL2 flavor groups was significantly reduced relative to participants' own cigarette consumption at baseline (P<.001; Figure 6); across all flavor groups, the proportion of participants that reported reducing their daily cigarette consumption by at least 50% at week 6 relative to baseline ranged from 50.9% (59/116) to 62.9% (73/116; Multimedia Appendix 12).

Figure 6. Change in daily cigarette consumption from baseline to week 6 among participants who did not switch (mean, SE). *Statistically significant difference in number of cigarettes per day smoked at baseline and week 6 among participants who continued smoking (P<.001).



Patterns of JUUL2 Product Use and Subjective Effects

Across the 6-week actual use period, the prevalence of past-7-day JUUL2 product use was over 97% in each of 5 flavor groups (Multimedia Appendix 13). In each of the 5 flavor groups, the median frequency of JUUL2 product use at each weekly survey was 7 days of use in the past 7 days (ie, daily use; Figure 7A); participants generally reported using JUUL2 products between 15 and 20 times per day (Figure 7B) and 25 to 30 puffs per day (Figure 7C). Across the 6-week period, there were no statistically significant linear increases in JUUL2 use occasions per day in the Virginia Tobacco and Polar Menthol JUUL2 groups (P>.15; Multimedia Appendix 14); there were statistically significant linear increases over time in use occasions per day among participants who used Autumn Tobacco, Summer Menthol, and Ruby Menthol JUUL2 products but the magnitude of the increases was small (unstandardized β coefficients=.45−.54; Multimedia Appendix 14). Across the 6-week period, there were no statistically significant increases in JUUL2 puffs per day in the Virginia Tobacco and Autumn Tobacco JUUL2 groups (P>.09); there were statistically significant linear increases over time in puffs per day among participants who used Polar Menthol, Summer Menthol, and Ruby Menthol JUUL2 products but the magnitude of the increases was small (unstandardized β coefficients=.43−.60; Multimedia Appendix 14).

Subjective responses to the 5 JUUL2 products were similar across 5 flavors groups at the week 6 survey: ratings of satisfaction approximated "A lot," ratings of psychological reward approximated "Moderately," ratings of aversion approximated "Very little," and ratings of relief approximated "A lot" (Multimedia Appendix 15). When combined across all 5 flavors, ratings of subjective satisfaction (ie, modified Product Evaluation Scale Satisfaction subscale) at week 2 were significantly associated with higher likelihood of complete past-30-day switching at week 6 (OR 1.25, 95% CI 1.11-1.40).

XSL•FO
RenderX

Figure 7. Patterns of JUUL2 product use across 6-week actual use period. (A) Number of days used JUUL2 in past 7 days; (B) number of times used JUUL2 per day; and (C) number of JUUL2 puffs per day.

Adverse Events

The incidence of study-emergent AEs was low for each of the 5 JUUL2 products during the 6-week actual use period—in each group less than 2.5% of participants reported an AE (Virginia Tobacco, 1/262, 0.4%; for, Autumn Tobacco, 2/237, 0.8%, Polar Menthol, 2/262, 0.8%, Ruby Menthol 2/234, 0.9%, for Summer Menthol, 6/249, 2.4%; Multimedia Appendices 16 and 17). No serious AEs were reported in the study and all evaluable AEs were reported as mild or moderate in intensity and resolved during the study.

Discussion

Principal Findings

This actual use study enrolled a sample of >1000 US adults who smoked cigarettes daily, following them for 6 weeks as they used JUUL2 ENDS with their preferred flavor in their natural environment. The sample was sociodemographically diverse and predominantly included US adults who smoked mentholated cigarettes, were not ready to quit smoking (ie, were not planning to quit within 30 days), and had experience using ENDS. On average, participants were highly dependent on cigarettes when entering the study. The results demonstrate that the use of JUUL2 ENDS products was associated with high rates of

XSL•FO
RenderX

completely switching away from cigarettes among US adults who smoke cigarettes, including both those who smoke mentholated cigarettes and nonmentholated cigarettes and users and nonusers of ENDS. Moreover, participants who reported past-30-day switching at the end of the study experienced meaningful reductions in dependence on tobacco products and improvements in respiratory symptoms during this 6-week period.

Despite a profile that did not favor smoking cessation (eg, high levels of cigarette dependence, almost no participants intending to quit smoking in 30 days, and many never planning to quit), rates of 7-day point prevalence abstinence exceeded 40% after 6 weeks, and at week 6 over 24% of participants in each of the 5 flavor groups (Virginia Tobacco, 55/226, 24.3%; Autumn Tobacco, 58/203, 28.6%, Polar Menthol, 70/223, 31.4%, Ruby Menthol, 69/209, 33%, Summer Menthol, 74/218, 33.9%) reported they had not smoked in the previous 30 days—a criterion often used to evaluate smoking cessation in clinical trials [25]. The proportion reporting switching away from smoking increased over the 6-week period, a pattern that was observed to continue over longer periods in previous observational and randomized studies of JUUL product users [8,26]. Furthermore, the high rates of switching are consistent with participants' reports of high levels of subjective satisfaction in this study and in experimental studies evaluating JUUL2 products [17], which is an established predictor of switching behavior [26] that was confirmed in this study.

It was notable that high switching rates were observed even though participants reported relatively light use of JUUL2, reportedly averaging around 25 to 30 puffs per day. One factor for this observation may be that the participants appear to have spread their use over time, engaging in "grazing" [27]—they reported averaging 15 to 20 use occasions per day, implying just 1 or 2 puffs per occasion. The volume of aerosol produced by the JUUL2 device may also have made puffs more impactful, mitigating a need for more puffs. In any case, more research on patterns of use associated with switching, including using objective measures of puff topography, would be useful.

Participants who used menthol-flavored (vs tobacco-flavored) JUUL2 products had significantly higher rates of past-30-day switching at the end of the 6-week actual use period. In addition, the association of JUUL2 flavor group and past-7-day switching significantly varied by menthol cigarette smoking (ie, the JUUL2 flavor and menthol cigarette interaction term was statistically significant): participants who smoked nonmentholated cigarettes and used menthol-flavored (vs tobacco-flavored) JUUL2 products demonstrated significantly higher switch rates, but this was not true for those who smoked mentholated cigarettes. The finding that participants who smoked nonmentholated cigarettes and used menthol-flavored ENDS had higher switch rates than those using tobacco-flavored ENDS is consistent with observational studies of US adults who smoke and use ENDS, including JUUL products [28,29], and an actual use study that evaluated the use of heated tobacco products [15]. This suggests that the availability of menthol-flavored ENDS may particularly benefit adults who smoke nonmentholated cigarettes.

Participants who smoked cigarettes but did not use ENDS when they entered the study had significantly higher rates of past-7-day switching compared to those who were dual users (ie, used ENDS and smoked cigarettes concurrently) across the 6-week actual use period. Ongoing dual use may be a behavioral marker for difficulty in stopping smoking with ENDS, as the dual users were, on average, relatively frequent ENDS users at baseline but had not yet completely switched. Nonetheless, both baseline dual users and baseline non-ENDS users displayed high rates of past-7-day switching at the end of the study.

Among participants who reported switching for the past 30 days at week 6, levels of dependence on JUUL2 products were statistically significant and meaningfully lower than participants' own levels of dependence on cigarettes when they entered the study; the decrease exceeded the minimally important difference for the measure identified in a prior observational study [30]. This finding concords with a large body of evidence indicating that ENDS, including JUUL products, produce lower levels of dependence than cigarettes [1,30-32]. In addition, consumption of JUUL2 products minimally increased across the 6-week actual use period (increases of less than one use occasion and puff per week). In accordance with data from controlled laboratory studies [17], these results demonstrate that JUUL2 products have lower abuse liability than cigarettes.

Participants who completely switched to JUUL2 products for at least 30 days at the completion of the study also reported significantly lower frequency of respiratory symptoms relative to when they entered the study and were smoking cigarettes. This improvement in respiratory symptoms was statistically significant but modest in magnitude—below the minimally important difference of 0.57 proposed in a prior psychometric validation study (operationalized as the difference in frequency of respiratory symptoms between participants with vs without respiratory symptom-relevant diagnoses, including chronic obstructive pulmonary disease) [21]. However, these improvements in respiratory symptoms occurred after relatively short periods of smoking abstinence and 6 weeks of JUUL2 product use, thus it seems likely that respiratory symptoms will continue to improve over longer periods of switching. For example, a study of adults who switched to JUUL products for an average of 3 years found that they had meaningfully lower respiratory symptoms than a matched comparison group that had continued smoking [33]. In this study, the fact that participants reported low baseline respiratory symptom scores when entering the study (mean <2; approximating ratings of "rarely [1-5 days]"), suggested that changes were limited by floor effects.

Substantial proportions of participants who persisted in smoking (ie, were dual users) after 6 weeks of being provided with JUUL2 products significantly reduced their daily cigarette consumption by at least 50% compared to when they entered the study. These levels of reductions in cigarette consumption have been shown to meaningfully reduce exposure to toxicants in cigarette smoke that are associated with smoking-related diseases [34-36] and have been suggested to reduce risk of smoking-related disease [37]. Finally, the JUUL2 products were well tolerated, producing only infrequent and minor AEs.

XSL•FO
RenderX

Strengths and Limitations

Strengths of the study include the large sociodemographically diverse sample of US adults who smoked every day and reported high levels of cigarette dependence, including large numbers of participants who were not planning to ever quit smoking and smoked mentholated cigarettes. Allowing participants to select their preferred flavor for use during the 6-week actual use period replicated real-world consumer product use and allowed attribution of switching behavior to a single JUUL2 product. However, participants were not allowed to change their selected flavor during the 6-week actual use period, as they would be able to in the real world. In addition, this self-selection of flavors and lack of randomization should be considered when interpreting differences in switch rates between the flavor groups.

Rates of retention were high throughout the 6-week actual use period. In addition, comparisons of sociodemographic and tobacco product characteristics among participants who completed all 6 surveys (vs those who missed some surveys) showed that participants who missed some surveys were not meaningfully different from those who completed all the surveys, and were not heavier or more dependent smokers who would have been expected to have lower rates of switching, suggesting low likelihood of bias due to nonresponse and missing observations. Analyses imputing smoking to all missing observations were performed, and yielded results that paralleled those based on observed data, indicating a lack of material bias in survey response.

Only individuals who reported sufficient levels of interest in using JUUL2 products were eligible to enroll in the study, which may have led to higher switch rates, but also enhanced ecological validity by mirroring real-world use of consumer products, where people buy and adopt products they are interested in, and are not arbitrarily prescribed or assigned products in which they have little interest. Assignment to individual flavors was based on expressed interest, which again is consistent with real-world use. In any case, most participants in both study arms expressed sufficient interest in all the flavors offered to them. Despite this interest in multiple flavors, most of the participants did show substantial interest in one or more flavors offered to them. This is important, as it suggests that making a range of flavors available is likely to increase the proportion of adults who smoke adopt ENDS, thus increasing reach of ENDS and potential switching away from smoking.

Participants were provided with JUUL2 study products at no charge, which is not consistent with the real world, and could have resulted in heavier product use and greater retention or influenced switching. The actual use portion of the study was only 6 weeks in duration and there was no follow-up assessment after completion. Future studies could evaluate trajectories of switching among adults who smoke and adopt JUUL2 products over longer periods. A large study of real-world US adult JUUL purchasers showed that switch rates continued to increase over time, reaching 58% after 2 years of initial purchase [6].

A limitation was the analyses' reliance on self-report; cigarette smoking and JUUL2 product use were not biochemically verified, and respiratory symptoms were evaluated with a self-report measure. Although this is standard practice for actual use studies [12-14] and observational population-based studies more broadly [24], biomarker data could be useful in future studies. In addition, since the primary aim was descriptive (ie, assessing the proportion of smokers who switched), and did not involve any inferential tests, no adjustment was made for multiplicity. Causal inferences regarding switching are limited by the lack of a control group that did not receive JUUL2 products, hence it is not possible to determine how many participants would have switched or stopped smoking if they were not provided with JUUL2 products. However, almost all participants in the sample did not plan to quit smoking in the next 30 days at baseline, and many were not planning to ever quit, suggesting that quit rates would have been very low.

Conclusions

The data from this 6-week actual use study demonstrate that adoption of JUUL2 products is associated with substantial rates of completely switching away from cigarettes among US adults who smoke, and meaningful reductions in cigarette consumption among adults who do not completely switch after 6 weeks. Participants who completely switched from smoking cigarettes to use of JUUL2 products at the end of 6 weeks experienced significant reductions in dependence and improvements in respiratory symptoms. Switch rates were higher among participants who used menthol-flavored (vs tobacco-flavored) JUUL2 products, particularly among adults who smoke nonmentholated cigarettes. Although this study primarily focused on behavioral end points, when considered with data from clinical biomarker studies, these changes in tobacco product use behaviors (ie, complete switching and substantial smoking reduction) are likely to decrease exposure to harmful cigarette-related toxicants, and to ultimately reduce risk of tobacco-related diseases.

Acknowledgments

This study was funded by Juul Labs, Inc. The authors would like to thank Lauren C Smith for her assistance with the conduct and implementation of the study.

Authors' Contributions

NIG led the conceptualization of the manuscript, wrote the manuscript text, and prepared the tables and figures. Authors MAS and SP conducted the analyses and assisted in preparation of the tables and figures. Authors RAB, SS, and AS aided in

Abstract

Background: A growing body of evidence has identified that people's physical health could influence self-rated health and quality of life (QoL). However, only focusing on physical health is not adequate for the well-being of older adults. Studies focusing on the impact of psychological well-being on self-rated health and QoL are still rare.

Objective: This study aimed to identify the mediating effect of depression on the association between psychological well-being and self-rated health and QoL to comprehensively understand the relationship between them.

Methods: We used a cross-sectional study design and secondary data analysis from the Chinese Longitudinal Healthy Longevity Survey of 2017 to 2018. Path analysis was applied to examine the research questions.

Results: A large sample of 8839 older adults was included. Among them, more positive affect was found among those who were younger and had more years of schooling, higher household income, greater social security and social insurance, lower depression levels, and higher self-rated health levels. Depression had a partial mediation effect of psychological well-being on self-rated health and QoL, which explained 36% of the total variance (R^2=0.36). In addition, psychological well-being had a statistically significant direct effect on self-rated health and QoL (β=0.290; P<.001).

Conclusions: Our results indicate that psychological well-being had both direct and indirect effects on self-rated health and QoL. Depression was an important mediator that regulated the effect pathway in older adults.

KEYWORDS

aged; depression; health; quality of life; psychological well-being

Introduction

Populations are aging all over the world. The United Nations General Assembly announced in May 2020 that 2021 to 2030 would be the decade of healthy aging, emphasizing the need for worldwide policymakers to concentrate their efforts on enhancing the lives of older people now and in the future [1]. It is projected that the number of older adults worldwide will rise by approximately 20.6% by 2050, reaching an estimated 2 billion [2]. China has the largest population of older adults [3]. The percentage of Chinese citizens over 60 years of age is expected to reach 28% by 2040 [4]. The second baby boomers, those born between 1962 and 1975, will begin to retire in 2022, adding to China's aging problems [1].

Depression has become a prevalent mental health symptom among older adults [5,6]. Depression can be divided into clinical and nonclinical subtypes [7]. The clinical form, formally termed major depressive disorder, is a severe psychiatric syndrome marked by enduring dysphoria, anhedonia, and pervasive hopelessness [7]. In contrast, nonclinical depressive states exhibit milder symptoms and are usually precipitated by specific stressors or life events [7]. Community surveys indicate that the global prevalence of nonclinical depression in older adults ranges from 28.4% to 35.1%, whereas prevalence ranges from 27% to 37.3% in mainland China [5,6]. Epidemiological data further show that the frequency of clinical depression among older adults is 1.6% in the United States and 2.7% in China [8].

The course of depression in older adults tends to be more prolonged, and the therapeutic outcomes are generally less favorable compared to those of younger individuals [9]. Depression lowers quality of life (QoL) and raises the mortality risk of older adults [10]. In one study, compared to those without depression, older adults with depression reported lower QoL

XSL•FO
RenderX

[11]. A worse overall QoL was linked to a higher degree of depression regardless of the method used to measure QoL. The connections seemed to be steady over time [11].

Focusing on the psychological well-being of older people is essential to constructing a positive aging society and realizing the strategic goal of healthy aging. Healthy aging is defined as the process of developing and maintaining the functional ability that enables well-being in older age [12]. Self-rated questions are frequently used to evaluate health status and QoL, which are essential components of healthy aging [13,14].

Self-rated health (SRH) is the subjective assessment of an individual's current state of health. It is a valid and reliable measure among those without cognitive impairment [15]. Despite its seeming simplicity and subjectivity, SRH is an effective health indicator that predicts future health outcomes, including mortality, chronic disease incidence, and health care resource use [16]. SRH has also been shown to be stable across cultures, communities, and different age groups, and it has even been shown to be a more accurate predictor of all-cause death than tools created especially for this purpose [17]. A growing body of research reports that even after adjusting for demographic, social, and medical risk variables, SRH has been repeatedly demonstrated to be an independent predictor of mortality, exhibiting high reliability and validity as well as predictive value across a variety of health outcomes [17-19].

Self-rated QoL is one of the main elements that indicate healthy aging. QoL refers to the evaluation of the positive aspects of one's own life [20]. It is closely associated with social well-being and overall health; however, it is common for older adults to experience a decline in QoL as they age [20]. A recent study discussed a well-being paradox phenomenon that older adults with higher levels of SRH have worse health based on objective markers [21]. Another study pointed out that older adults may mitigate the disparity between potential and actual circumstances through the recalibration of expectations and internal benchmarks [22]. Therefore, they may experience improved QoL even if there are no appreciable health effects.

Prior studies have demonstrated that depression and anxiety mediate the relationship between social and biological factors and QoL [23]. Another longitudinal study indicated that increased depressive symptoms are associated with reduced SRH among Chinese individuals aged ≥45 years [24]. Most existing studies have primarily concentrated on social, biological, and psychopathological factors (depression and anxiety) as key determinants of SRH and QoL [23,24], thereby neglecting the underlying mechanisms that explain the connections between psychological variables (positive and negative affect) and SRH and QoL [25,26]. The mediating role of the main psychopathological factor (depression) in the relationship between psychological well-being and SRH and QoL remains unclear.

According to the hierarchy of needs theory by Maslow [27], humans will pursue higher-level needs only after their lower-level needs have been satisfied. We hypothesize that positive psychological well-being and the absence of emotional disorders are essential to the pursuit of self-actualization to obtain high SRH and QoL. The assumed relationships were that psychological well-being is positively associated with SRH and QoL, while depression is negatively associated with SRH and QoL. Based on this theory, we explored whether depression was a potential mediator of the association between psychological well-being and SRH and QoL in older people, and we applied further path analysis to clarify its potential mechanism. By examining this mediating effect, we can gain a comprehensive understanding of the complex interplay between these variables and potentially identify targets for intervention to improve the health and QoL of older adults. We obtained the data from a representative national survey and analyzed the statistics using path analysis. Our efforts may provide new insights into the mediating role of psychological well-being in promoting SRH and QoL in older people. We also hope to contribute to the body of knowledge on psychological well-being and its implications for the nursing care of older populations, ultimately aiming to promote positive aging.

Methods

Data and Study Design

The Chinese Longitudinal Healthy Longevity Survey (CLHLS) was launched in 1998 and continued through waves conducted in 2000, 2002, 2005, 2008-2009, 2011-2012, 2014, and 2017-2018 [28]. This cross-sectional study used data from the 2017-2018 survey wave of the CLHLS to undertake a secondary analysis. The CLHLS national survey was carried out in a randomly selected half of the counties and cities across 22 of the 31 provinces in China, which account for approximately 85% of the country's total population [28]. Nine provinces were excluded from the CLHLS, all located in western and northwestern China, where minority populations are comparatively large and age reporting tends to be less accurate [28]. The eligibility criteria for the CLHLS study were that the participants be aged 65 years or older [28]. The CLHLS tried to interview all centenarians who voluntarily agreed to participate in the study in the sampled counties and cities [28]. A targeted random sampling method was adopted to ensure the representativeness of the sample [28]. Specifically, it involved interviewing approximately equal numbers of men and women in their 90s, 80s, 70s, and 60s who lived in proximity to the centenarians [29]. We combined the data with complete statistics of demographics, a psychological well-being scale, the Center for Epidemiologic Studies Depression (CES-D) scale, SRH, and self-rated QoL question in the CLHLS survey. After excluding invalid questionnaires, the final sample size was 8839. The sample formula for path analysis was as follows: n=Z2P(1-P)d2, where *n* is the sample size, *Z* is a standard normal variate, *P* is the expected prevalence, and *d* represents precision or absolute error [30]. *P* was estimated based on the available literature, and its value ranged from 27% to 37.3% [5,6]. The admissible error (*d*) was set at 5% because the type I error rate of 0.05 was acceptable for the difference between the sample statistics and the population parameter to be no more than 5% of the population parameter with a standard 95% confidence level (*Z*=1.96) [30]. The values used in this calculation were *Z*=1.96, *P*=.27 to .37, and *d*=0.05. Accounting for a 20% loss to follow-up rate, the estimated sample size ranged from 362

XSL•FO
RenderX

to 429. Finally, the minimum sample size in this study was set at 429.

Variables

Independent Variable

Psychological well-being was measured using 7 items from the 1998 CLHLS, including positive affect and negative affect [31,32]. Positive affect was assessed using 4 positive items (optimistic: "Do you always look on the bright side of things?"; conscientious: "Do you like to keep your belongings neat and clean?"; sense of personal control: "Can you make your own decisions concerning your personal affairs?"; a positive attitude toward one's aging: "Are you as happy as when you were younger?"), and negative affect was assessed using 3 negative items (agitation: "Do you often feel fearful or anxious?"; loneliness: "Do you often feel lonely and isolated?"; perceived loss of self-worth: "Do you feel the older you get, the more useless you are?"), which were rated on a 5-point frequency scale from 0 ("never") to 4 ("always") in both cases [28]. After reverse coding the negative items, the sum of the scores for all 7 items ranged from 0 to 28, with a higher score indicating more positive psychological well-being [28]. The Cronbach α reached 0.704 to 0.752 in previous studies, which indicates an acceptable internal consistency [31-34].

Mediation Variable

The 10-item CES-D scale was developed by Andresen et al [35] in 1994 for use with older adults who were relatively well. The CES-D is a screening tool to identify individuals and population groups at elevated risk of nonclinical depression [36]. The internal consistency was satisfactory (Cronbach α=0.78-0.79), and moderate consistency over 3 years was also found to be significant (r=0.44; P<.01) [37]. The CLHLS used Chinese translations available at the Center for Epidemiologic Studies website [28]. Interviewees had 5 answers to choose from in the 10 CES-D items: "never," "rarely," "sometimes," "often," and "always." For questions 1, 2, 3, 4, 6, 8, and 9, we scored 3 for "always" and 0 for "never." For questions 5, 7, and 10, we scored 0 for "always (good)" and 3 for "never (very bad)" [28]. Therefore, CES-D scores ranged from 0 to 30, with 10 and 20 as cutoff points for the levels of depressive symptoms [38].

Dependent Variables

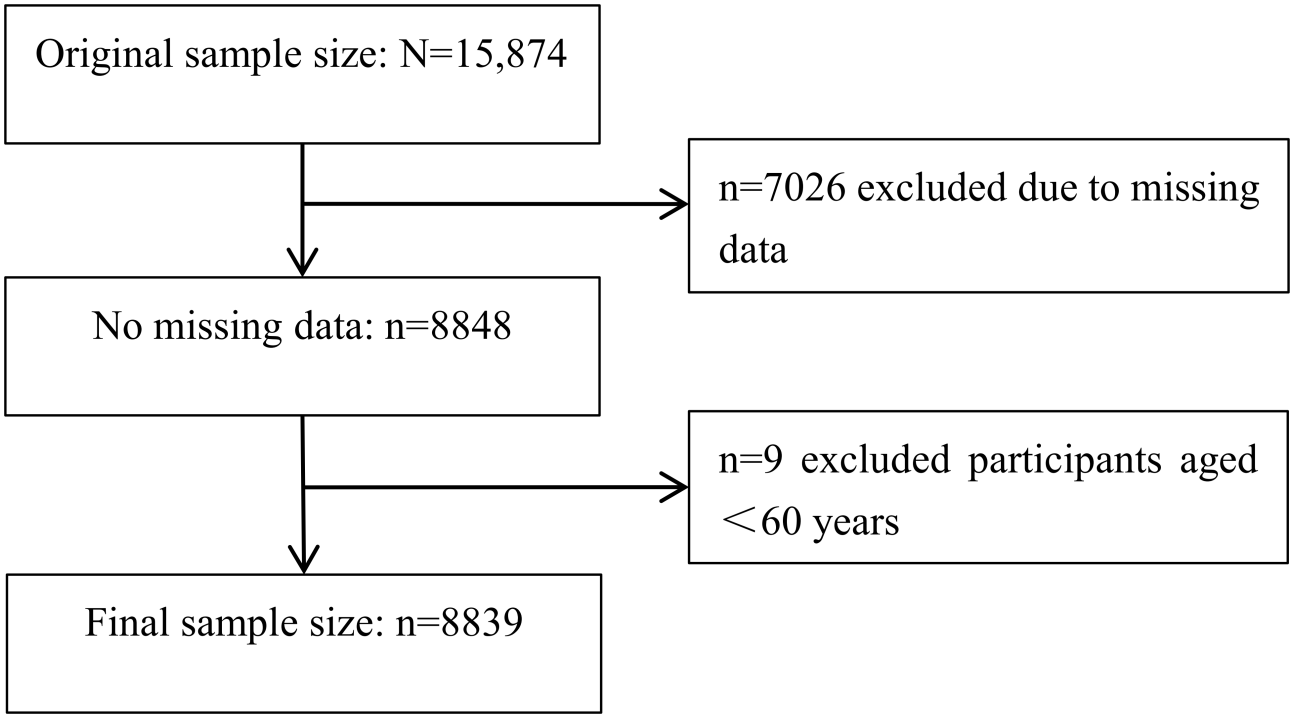
SRH, introduced in the 1980s, is a subjective indicator of health status for older adults [39]. It was measured using the following question: "How do you rate your life at present?" [39]. Self-rated QoL is a subjective assessment of QoL by individuals [40]. It was evaluated using the following question: "How would you rate your overall quality of life?" [40]. SRH and QoL were rated on a 4-point scale ranging from 0 ("very bad") to 4 ("very good") [39,40]. Higher scores represented better SRH and QoL status. The widely used single-question method has been found to be reliable and valid [13,41,42].

Data Analysis

SPSS Statistics (version 25.0; IBM Corp) and SPSS Amos (version 23.0; IBM Corp) were used to analyze the data. Continuous variables were represented using means and SDs or medians and IQRs, whereas categorical or ranked variables were represented using frequencies and percentages. The chi-square test was conducted to assess categorical data, and the Kruskal-Wallis test was conducted to evaluate continuously ranked data. The Spearman correlation was used to examine the relationship among sociodemographic variables, depression, SRH, and QoL. The hypothesized model was tested using the maximum likelihood method in the SPSS Amos statistical software. Several model fit indices were estimated to test the good fit of the model, including the chi-square test, root mean square error of approximation (RMSEA), standardized root mean square residual (SRMR), cumulative fit index (CFI), incremental fit index, goodness-of-fit index (GFI), normed fit index (NFI), and Tucker-Lewis index (TLI). A good fit model was considered when all path coefficients were significant at the level of .05, χ^2<5, SRMR<0.08, RMSEA<0.08, GFI>0.9, NFI>0.9, TLI>0.9, and CFI>0.9 [43]. All analyses were 2-tailed.

Ethical Considerations

The CLHLS study was approved by the Duke Health Institutional Review Board (Pro00062871) and the Research Ethics Committee of Peking University (IRB00001052-13074), and all participants provided written informed consent. The data were made publicly available for secondary analysis after being fully anonymized. No compensation was provided to participants.



Results

Participant Demographics

A total of 8839 older adults were included in this study (Figure 1), with 48.7% (4305/8839) being male and 51.3% (4534/8839) being female. The average age was 81.27 (SD 10.29) years, and they had a median of 3 (IQR 0-6) years of schooling. The median total income in the previous year was ¥30,000 (US $4212.57; IQR ¥8000 to >¥99998 [US $1123.35 to >US $14,041.62]). Approximately half (4384/8839, 49.6%) of the participants were currently married or living with a partner. More than 90% of the participants (8140/8839, 92.1%) had social security or social insurance. The average scores for depression, SRH, and QoL were 9.62, 2.51, and 2.91, respectively. A total of 52.1% (4607/8839) of the participants scored lower than 10 in the depression scale, 45.5% (4028/8839) scored between 10 and 20, and 2.3% (204/8839) scored higher than 20.

Figure 1. Flowchart of the sample selection.

Variables According to Different Psychological Well-Being Levels

A substantial difference was observed in age, sex, years of schooling, total household income in the previous year, social security and social insurance status, depression, QoL, and SRH (Table 1). Younger participants and those who had more years of schooling, higher household income, social security and social insurance, lower depression levels, and higher SRH and QoL levels indicated more positive affect. Female participants had higher positive affect levels than male participants.

Table . Variables according to different psychological well-being levels. Psychological well-being was divided into 3 levels based on tertile range.

Variable	Psychological well-being level			Statistic	
	More negative (score of <19; n=3832)	Moderate (score of 19-21; n=2124)	More positive (score of >21; n=2883)	Kruskal-Wallis *H* statistic	Chi-square (*df*)
Age (y), mean (SD)	81.72 (10.32)	80.77 (10.29)	81.02 (10.23)	13.72[a]	—[b]
Sex (female), n (%)	2063 (53.84)	1023 (48.16)	1448 (50.23)	—	19.6[c] (2)
Years of schooling, median (IQR)	2 (0 to 6)	3 (0 to 6)	4 (0 to 8)	76.55[c]	—

Correlation of Variables

Table 2 shows the correlation among psychological well-being, depression, SRH, and QoL. The Spearman correlation suggests that psychological well-being had a negative correlation with depression (β=–0.590) but psychological well-being had a positive correlation with QoL (β=0.326) and SRH (β=0.361). Moreover, depression was significantly negatively correlated with QoL (β=–0.354) and SRH (β=–0.382). In addition, QoL was significantly positively correlated with SRH (β=0.463).

Table . Spearman correlation of variables.

Variable	Psychological well-being (*r*)	Depression (*r*)	QoL[a] (*r*)	Self-rated health (*r*)
Psychological well-being (*r*)	1	—[b]	—	—
Depression (*r*)	−0.590[c]	1	—	—
QoL (*r*)	0.326[c]	−0.354[c]	1	—
Self-rated health (*r*)	0.361[c]	−0.382[c]	0.463[c]	1

[c]*P*<.001.

Mediator Model

Figure 2 illustrates the standardized effects of the coefficients in the mediator model. All path estimates were statistically significant (*P*<.001) and correlated with the hypothesized model. Depression had a partial mediation effect of psychological well-being on SRH and QoL, which explained 36% of the total variance (R^2=0.36). Psychological well-being had a statistically significant negative direct effect on depression (β=−0.603; *P*<.001), whereas depression had a further statistically significant negative direct effect on SRH and QoL (β=–0.378; *P*<.001). In addition, psychological well-being had a statistically significant positive direct effect on SRH and QoL (β=0.290; *P*<.001). Furthermore, the indirect effect of psychological well-being on general health was β = (−0.603) × (−0.378) = 0.228. In addition, SRH (β=0.716) contributed more to general health than QoL (β=0.663).

Fit indexes of the mediator model revealed a good fit of the data (χ^2_1=1.7; *P*=.19). The SRMR was 0.006, and the RMSEA was 0.009, which indicated good validity of the measurement construct. The scores of the GFI, NFI, TLI, CFI, and incremental fit index were over 0.9, further illustrating the good model fit.

Figure 2. Mediator model. DV: dependent variable (quality of life [QoL] and self-rated health [SRH]); e: the residual of the variable; IV: independent variable (psychological well-being); MV: mediation variable (depression).

Discussion

Principal Findings

Our study found that psychological well-being had a negative direct effect on depression, whereas depression had a further negative direct effect on SRH and QoL. In addition, psychological well-being had a positive direct effect on SRH and QoL. The results were consistent with those of previous research that highlighted the effect of psychological well-being and depression on SRH and QoL [33]. Moreover, the results also illustrated that younger older adults who had more years of schooling, higher household income, and greater social security and social insurance indicated more positive affect. These findings expand those of previous studies by exploring

XSL•FO
RenderX

the mediating role of depression among older adults in China, thus providing a reference for improving the psychological well-being of Chinese older adults.

Psychological well-being was regulated by older people's demographics, such as age, sex, educational background, and income. A very interesting finding was that people aged >81 years tended to have more positive affect or more negative affect. This could be explained by the "response shift" phenomenon, in which some older adults reconcile with the deterioration of health and functionality [22]. This reconciliation often involves the recalibration of expectations and internal benchmarks to mitigate the disparity between potential and actual circumstances through both biological and psychosocial transformations [22]. Our study found that women had more negative affect than men. The reason may be that women have more negative reactions when encountering negative stimuli in comparison to men [44]. The results also demonstrated that total income, years of schooling, and social security and insurance status were positively associated with psychological well-being. Previous studies have proved the modest correlations between socioeconomic status, such as income, educational level, and occupation, and personal psychological well-being, which is consistent with the results of our study [45].

This study indicated that positive affect decreased the incidence of depression and enhanced the SRH and QoL of older adults. Our results were aligned with those of a previous study [33] and provided a specific pathway and coefficient statistics among variables of psychological well-being, depression, SRH, and QoL. Psychological well-being is very important to an individual and may predict the occurrence of late-life depression in older adults. The older adults who had more positive affect were relatively more likely to look at the bright side of the world and focus on the goodness of things [46]. In positive psychology theory, the novel ideas and actions (eg, the urge to play and explore) brought by broadened mindsets have been proven to alleviate depression and improve general health [47].

The path analysis revealed that depression was a mediator of the effect of psychological well-being on SRH and QoL in older adults, which accounted for 36% of the variance. The size of its indirect effect of psychological well-being on SRH and QoL (β=0.228) was very close to the direct effect size (β=0.290), which implied that depression was an important mediator between psychological well-being and SRH and QoL. Depression is a mental health symptom and has adverse consequences for SRH and QoL in older adults. Approximately half (4232/8839, 47.9%) of the older adults in this study had CES-D scores of 10 and over, higher than the incidence in Indonesia and previous samples in China, such as the 2011 to 2012 wave [48]. Our findings are consistent with the hypothesis that depressive symptoms among Chinese older adults have risen in recent years [49]. Nevertheless, focusing on the psychological well-being of older adults is urgent to promote healthy aging.

Paying attention to psychological well-being and reducing depression may be an effective strategy for promoting the health and QoL of older people. Previous studies have indicated that people with depression show specific deficits in being able to anticipate future positive events [50]. The ability to think mindfully, develop a tolerant outlook, please oneself, or cope when confronting situations that lead to negative affect may be powerful measures to construct healthy psychological well-being. We should also focus on the support systems of older adults, which serve as a protective factor for psychological well-being to promote the health of older adults [51].

China has the fifth highest older adult population worldwide, which is frequently cited as an example for other middle-income nations [52]. Our results could also have implications for limited-income countries. Future research could involve additional countries to compare the influence of various cultures and health care systems on older adults' psychological well-being, health, and QoL.

Limitations

Although our data were derived from a large Chinese population-based older adult cohort, there were still some limitations to our study. First, the cross-sectional design could not explain the causal effects of the variables when compared with longitudinal studies. These results may not be temporally stable over time. Second, the participants may have provided biased responses due to memory recall issues when the data were collected. Third, our study only examined the relationships between 4 indicators: psychological well-being, depression, SRH, and QoL. If more indicators had been included, the conclusions may have been richer. Fourth, the analysis was based on self-reported questions on depression, well-being, and QoL. Moreover, the CES-D is a screening tool, not a clinical diagnostic tool.

Conclusions

Our study provides a new insight into the influence of the psychological aspect on older adults' health and QoL. We also discussed the variable of depression, a very common type of emotional distress, in the mediation pathway between psychological well-being and SRH and QoL. Depression was an important mediator of the effect of psychological well-being on SRH and QoL in older people. More attention should be paid to depression and the psychological well-being of older adults. Future tailored interventions should focus on relieving depression in older adults and promoting their psychological well-being.

Abstract

Background: Older adults engage in increased amounts of sedentary behavior (SB), which can result in a significant decline in muscle function and overall health. An understanding of the motivational driving factors that lead older adults to engage in SB can help to create effective intervention programs.

Objective: This study aimed to determine the association between prevention and promotion focus with SB in older adults, as well as compare these associations with two factors (ie, age and BMI) that are commonly known to have an association with SB among older adults.

Methods: A cross-sectional analysis was conducted among 93 community-dwelling older adults with a mean age of 74.98 (SD 6.68) years. Prevention and promotion focus were both assessed using the Regulatory Focus Questionnaire. Correlation analysis was performed to determine the associations between prevention focus, promotion focus, age, and BMI with SB. Anderson-Darling tests confirmed nonnormal data distributions for all factors (except age); therefore, Spearman rank correlation was used to determine correlations between factors. Comparative analysis of significant correlations was performed using Fisher Z transformation.

Results: Prevention focus had the greatest statistically significant correlation with SB (ρ=0.296; *P*=.004), followed by BMI (ρ=0.204; *P*=.049). Both age (ρ=0.116; *P*=.27) and promotion focus (ρ=0.002; *P*=.99) had statistically insignificant correlations with SB, indicating no associations. The correlation between prevention focus and SB did not significantly differ from the correlation between BMI and SB (*P*=.51).

Conclusions: Prevention focus was found to have a weak, but significant positive association with SB in older adults. Although age and BMI have been found to have an association with SB in previous literature, age was not associated with SB in this study, while BMI had a significant but relatively weaker association with SB than that with prevention focus. However, the association found between BMI and SB did not statistically differ from the association found between prevention focus and SB. These findings suggest that older adults could be driven to engage in increased amounts of SB due to having a dominant prevention focus, which revolves around thoughts of safety and avoiding negative consequences. The recognition of this association has the potential to aid in developing intervention programs that could promote shifting from prevention to promotion focus, thereby reducing SB in older adults.

Introduction

Sedentary behavior (SB) is most prevalent among older adults and negatively affects their physical health by increasing their risk for diseases, as well as overall mortality [1]. SB can be defined as any waking behavior that results in an energy expenditure of less than 1.5 metabolic equivalents while in a sitting or reclining position [2-4]. Various intervention programs that aim to reduce SB in older adults have been developed and focus primarily on changing psychological and behavioral factors, rather than environmental or physical factors [5]. These interventions include self-regulatory strategies, which include goal setting and behavioral feedback with participants [6-8]. Self-regulation is described as the process of aligning an individual's behavior and decision-making with their goals [9]. Regulatory Focus Theory builds on the idea of self-regulation by suggesting that individuals have two distinct motivational orientations that influence their decision-making and behavior: promotion and prevention focus [9-11]. Individuals with a prevention focus strive for feelings of safety and responsibility, and seek to minimize the negative outcomes or consequences in their lives (i.e., avoid losses) [10,11]. Conversely, individuals with a promotion focus strive for growth and advancement, seek opportunities for success, aim to maximize potential gains, and strive to obtain positive outcomes in life [10,11].

Regulatory focus theory has been found to relate to older adults, as evidenced by a positive relationship between negative self-perceptions on aging (ie, a pessimistic or unfavorable view toward aging) and trait prevention focus [12]. Negative self-perceptions of aging in older adults have also been found to have a negative relationship with self-reported physical activity (PA) and performance in daily activities [13-15]. This is likely due to a belief that PA and overall movement are not beneficial in the long term and could increase their risk of falling. Although regulatory focus theory has not yet been directly linked to SB in older adults, it has the potential to be related to SB, due to the previously found relationships with negative self-perceptions of aging. Establishing a link between regulatory focus theory and SB in older adults could potentially provide a better understanding of the motivational driving factors that lead older adults to engage more in SB.

Therefore, the aim of this study was to determine the association between prevention and promotion focus with SB in older adults and to compare these associations with two factors that are commonly known to be associated with SB among older adults (ie, age and BMI. We hypothesized that SB would have a significant positive association with age, BMI, and prevention focus, but a nonsignificant association with promotion focus.

Methods

Study Design

This cross-sectional investigation was part of a larger study that is federally funded by the National Institute on Minority Health and Health Disparities (R01MD018025) and has been pre-registered on ClinicalTrials.gov (NCT05778604). The protocol for the study has been previously published elsewhere [16]. The study was conducted in the Greater Orlando, metropolitan area, FL and recruitment was accomplished through word-of-mouth, flyer distribution, and partnership with local communities. A total of 141 community-dwelling older adults were recruited. Participants were included in this study if they were at least 60 years of age, could stand on their own, had low-income status based on the 2019 poverty thresholds relative to family size [17], had fully completed the Regulatory Focus Questionnaire (RFQ), and had at least 4 days of valid recorded ActiGraph data (each day≥10 hours of wear time). Participants who were unable to perform PA, receiving treatment from a rehabilitation facility, or hospitalized more than 3 times in the past 12 months were excluded. After screening for inclusion criteria, 93 participants were included and analyzed in this study.

Data Sources

Demographic Measurements

Demographic characteristics such as age and sex were collected using a self-reported survey. Height and weight were assessed without shoes using a digital physician scale with a built-in stadiometer (Health-O-Meter, Model 402KL, McCook). BMI was calculated using height and weight as kg/m^2.

Regulatory Focus Questionnaire

Participants were asked to complete the RFQ, an 11-item questionnaire that helps determine whether an individual's motivational orientation is primarily prevention- or promotion-focused [18,19]. The RFQ produces independent prevention and promotion focus scores. Six questions contribute to the calculation of the promotion focus score, while five contribute to the prevention focus score. Seven questions are reverse scored (three for promotion and four for prevention). The RFQ uses a 5-point Likert scale based on how frequently specific events occur or have occurred in an individual's life, ranging from 1 ("never or seldom"/ "never true"/ "certainly false") to 5 ("very often"/ "very often true"/ "certainly true"). An example of a promotion question on the RFQ is as follows: "Compared to most people, are you typically unable to get what you want out of life?" The type of motivational focus most dominantly exhibited by an individual is based on the higher of the two scores (ie, prevention or promotion). For the prevention domain, a higher score indicates a greater individual focus on prevention (eg, individuals focus on avoiding negative outcomes and ensuring safety when making decisions). Similarly for the promotion domain, a higher score reflects a greater findividual focus on promotion (eg, maximizing potential gains and seeking growth and advancement). The RFQ has internal reliability coefficients of α=0.73 for the promotion scale and α=0.80 for the prevention scale [18].

Sedentary Behavior

To objectively measure SB, an ActiGraph GT9X Link wireless activity monitor (ActiGraph LLC) was used. The GT9X Link is a small and lightweight device (3.5×3.5×1 cm; 14g) that contains a triaxial accelerometer, has a dynamic range of ±8 gravitational units (g), and can be worn on either the hip or wrist. This device was initialized to record at a sampling rate of 30Hz. Participants were instructed to wear the device on their nondominant wrist for 7 consecutive days and to remove it only

XSL•FO
RenderX

during showering or bathing. Accelerometer data were extracted from the GT9X Link using the ActiLife (version 6.13.5; ActiGraph LLC), R statistical software (version 4.3.1; R Foundation for Statistical Computing), and existing accelerometer data analysis code that use the *GGIR* R-package (version 3.1‐0) [20-23].

Total recorded SB (in minutes) was determined using the Euclidean Norm Minus One acceleration scalar metric in milli-gravitational units (mg) and classified as <30 mg [20]. Total SB was calculated for this study by summing the amount of SB (in minutes) for all valid days for each participant. For this investigation, participants were included if they had a minimum of 4 recorded days, with a minimum of 10 hours (600 minutes) each day, and a maximum of 7 recorded days. These requirements were consistent with previous PA research using the ActiGraph GT9X Link [24]. Data filtering was performed using the MATLAB multiparadigm program.

Statistical Analyses

Minitab (version 21.4.3; Minitab LLC) and R software (version 4.3.1; R Foundation for Statistical Computing) were used to perform statistical analyses for this study. Each factor was checked for normality before analysis using descriptive statistics and Anderson-Darling normality tests through Minitab. Spearman rank correlation coefficients (ρ) were used due to the nonnormal distribution of each variable. R software was used to calculate correlation coefficients, compare statistically significant correlation values using Fisher Z transformation, and perform power analysis using the *pwr* package (version 1.3‐0) [25]. The threshold for statistical significance was set at $P<.05$.

Ethical Considerations

This study was approved by the Institutional Review Board of the University of Central Florida (STUDY00003206), preregistered on ClinicalTrials.gov (NCT05778604), and carried out in accordance with the Declaration of Helsinki. The protocol has also been previously published elsewhere [16]. All participants gave written informed consent prior to participation. The data for this study were stored and managed using Research Electronic Data Capture (REDCap), a secure, web-based application that is designed to store data for research studies [26,27], and all participant data were deidentified. Participants were compensated US$50 in the form of a gift card upon completion of the study.

Results

After screening for inclusion criteria, a total of 93 participants were included in this analysis, with the majority being female participants (83/93, 89%). Further self-reported demographic information regarding participants (eg, education level and general health) is shown in Table 1. Sixty-seven percent (62/93) of participants had a dominant prevention focus (as indicated by a greater prevention score), while 33% (31/93) of participants had a dominant promotion focus. Descriptive statistics for each factor are presented in Table 2.

[a]RFQ: Regulatory Focus Questionnaire.

[b]SB: sedentary behavior.

[c] Due to having a normal distribution, the mean and standard deviation for the age factor (as opposed to the median and IQR) are presented elsewhere.

[d]*P* value represents the results from the Anderson-Darling normality tests ($P<.05$ indicates nonnormal distribution).

XSL•FO
RenderX

Correlational data is presented in Table 3 . The prevention focus score from the RFQ had the highest statistically significant correlation with total SB among the considered factors (ρ=0.296; *P*=.004). BMI had the second highest statistically significant correlation with total SB (ρ=0.204, *P*=.049). It was found through Fisher Z transformation that the correlation between prevention focus and SB was not significantly higher than that between BMI and SB (*P*=.51). Overall, the significant associations were found to be relatively weak. The association between RFQ promotion focus score and total SB was nonsignificant and near zero (ρ=0.002, *P*=.99). Age also had a weak, nonsignificant association with total SB (ρ=0.116, *P*=.27). Power analyses indicated that only the association between prevention focus and SB achieved adequate power of at least 80% (82.86%), exceeding the required sample size needed for achieving the Spearman coefficient of 0.296 (N=84). All other associations required a sample size that exceeded the total study sample size of 93 participants to achieve adequate power and therefore had relatively lower and inadequate power (<50%).

Table . Associations between age, BMI, RFQ[a] prevention score, and RFQ promotion score with SB[b].

Variables	Spearman rank correlation (ρ)	*P* value
Age	0.116	.27
BMI	0.204	.049
RFQ[a] prevention focus score	0.296	.004
RFQ promotion focus score	0.002	.99

[a]RFQ: Regulatory Focus Questionnaire.

[b]SB: sedentary behavior.

Discussion

Principal Findings

The purpose of this study was to determine the association between prevention and promotion focus with SB in older adults, as well as to compare those associations with two factors that are commonly known to have an association with SB among older adults(ie, age and BMI). Analysis showed that SB has a significant positive association with BMI and prevention focus. This finding supports our initial hypothesis. Consistent with the hypothesis, promotion focus was not significantly associated with SB. Contrary to expectations, we did not observe an association between age and SB. BMI was associated with SB, but this association with SB was relatively weaker than that of prevention focus. Overall, the associations were weaker than expected. Comparative analysis of the significant correlation values using Fisher Z transformation showed that the correlation between prevention focus and SB was not significantly higher than the correlation between BMI and SB.

A key finding of this study is the observation of a weak, but positive association between a prevention-focused regulatory style and SB, indicating that individuals with a primarily prevention-focused mindset may engage in increased amounts of SB. This result may be attributed to the cautious, safe, and loss-avoidant mindset associated with the prevention focus orientation. This result aligns with previous work, which found that safety concerns of older adults are a barrier to reducing their sedentary time, whether in their own homes or in their neighborhoods [28,29]. Individuals that exhibit such personality traits may be more likely to avoid engaging in PA and overall movement due to the possibility of injury. An injury may result in losses, specifically the possible expenses associated with recovery, as well as the loss of time needed for physical recovery and possible loss of independence. Individuals with such mindsets may view PA or increased movement as dangerous or unsafe, thus leading to avoidance. Environmental factors such as a neighborhood safety can also contribute to this mindset, further preventing PA and movement outside of one's home if an individual perceives that their safety in their neighborhood could be at risk.

The promotion focus scores and total SB were weakly associated, which may have been attributed to the possibility that decreased SB, as well as the benefits associated with it, are not considered as growth or advancement to older adults. Furthermore, older adults' decision to engage in SB may be more influenced by a prevention focus because the desires associated with it (eg, desires for safety, avoidance of negative consequences, and avoidance of losses) are perceived as more of a "need" rather than a desire. In contrast, the desires associated with a promotion motivation orientation (eg, desire to achieve growth, advancement, and maximize potential gains), which could be considered as less of a "need."

It was expected that BMI would have a significant positive association with SB, due to the directly proportional association between BMI and weight. Increased time in SB can potentially lead to weight gain and has been positively related to the risk of obesity and diabetes [30-33]. Furthermore, studies have shown that SB is positively associated with BMI [34,35]. Interestingly, despite the difference being statistically insignificant, the prevention focus scores from the RFQ had a relatively greater correlation coefficient value than BMI when compared to total SB. For years, BMI has been used as an index of obesity to classify individuals based on their body weight relative to height. BMI continues to be used in medical practice and research due to being an affordable and readily obtained metric [36]. However, BMI has faced numerous backlashes, primarily due to its inability to differentiate between body lean mass and body fat mass [36-39]. For example, an individual with a greater amount of body lean mass could have the same BMI as an individual with a greater amount of body fat mass. This variability present in BMI could explain the relatively lower correlation value when relating to SB. Furthermore, the

XSL•FO
RenderX

motivation orientation of an individual, specifically an older adult can influence their decision-making and behavior, which could drive them to engage in SB, therefore directly resulting in changes to their BMI.

Various studies have shown a positive correlation between age and SB in older adults [40,41]. However, a nonsignificant association between the two variables was observed in this study. Previous work has found that a multitude of factors contribute to the SB levels of older adults beyond age, such as accessibility to transportation, living environment, and weather [42]. The sites from which participants in this study were recruited from, varied in terms of social life. Some sites held weekly social activities (eg, exercise classes and bingo nights), while others did not hold any social events. These differences could adversely affect the decision of older adults to engage in SB and could explain the weak and nonsignificant association between age and total SB in this study.

Strengths, Limitations, and Future Directions

Overall, despite the weak associations, the findings of this study show that the characteristics associated with a prevention focus may be a factor that leads older adults to engage in SB. The results from this study support the idea that older adults might be less inclined to engage in SB if they are given suggestions on how to maintain safety during PA or reassured that it is acceptable to make mistakes. This idea can be used to create new or improve existing intervention programs aimed toward improving the PA levels of older adults, which can ultimately result in a reduction in their fall risk. Spearman rank correlation was chosen for the analysis of this study due to its ability to adequately manage both normally and nonnormally distributed data. Although an appropriate test was used to perform correlation analysis, certain limitations exist within this study. First, a power analysis showed that only the association between the prevention focus score from the RFQ and total SB produced adequate power (82.86%). Although this value indicates reasonable sensitivity for detecting the observed association, all other associations produced a power significantly below this value (<50%).

Second, this study did not identify the causal relationship between the considered factors and only focused on pairwise correlations, as opposed to considering confounding effects. For example, there was a significantly greater number of females included in the sample than male participants (83/93). It has been previously found that female participants tend to be more prevention-focused than male participants [43], which explains the larger number of prevention-focused individuals (62/93). The exploration of confounding effects could provide a deeper understanding of the associations presented in this study. Future work should involve increasing the sample size to include more promotion-focused individuals and raising the power of the correlation tests to adequately determine the associations between the factors, as well as using techniques such as regression to incorporate confounders and conduct formal causal analysis.

Conclusions

Although many environmental factors drive older adults to engage in SB, psychological factors also play a role in influencing this behavior. Prevention focus, as determined by the RFQ was found to have a weak but significant positive association with SB in older adults. The association between BMI and SB was relatively weaker in comparison, but no significant differences were found between the two associations. These findings suggest that older adults may be driven to engage in increased amounts of SB due to having a dominant prevention focus, which revolves around thoughts of safety and the avoidance of negative consequences. Identifying an older adult's motivational orientation can provide useful insight into understanding their decisions to engage in SB and further identify what strategic approach would be most effective when setting goals and implementing safeguards to decrease SB.

Abstract

Background: China has the largest elderly population globally; the growth rate of the aged tendency of the population was higher than that of Western countries. Given the distinctions in historical, ethnic, and economic status as well as socio-cultural background, Chinese adults had different sleep patterns compared with adults in other countries. Considering the heavy disease burden caused by activities of daily living (ADL) disability, we conducted a cross-sectional analysis using data from the China Health and Retirement Longitudinal Study (CHARLS) to test the hypothesis that individuals with short and longer sleep duration are more likely to have ADL disability.

Objective: ADL disability is a common condition affecting the quality of life among older people. This study aimed to explore the associations between sleep duration and ADL disability among middle-aged and older adults in China.

Methods: This cross-sectional study used data from 17,607 participants from the 2018 CHARLS (from 2018 to 2020), an ongoing representative survey of adults aged 45 years or older and their spouses. Self-reported sleep duration per night was obtained from face-to-face interviews. The ADL was measured using a 6-item summary assessed with an ADL scale that included eating, dressing, getting into or out of bed, bathing, using the toilet, and continence. Multiple generalized linear regression models—adjusted for age, sex, education, marital status, tobacco and alcohol use, depression, place of residence, sensory impairment, self-reported health status, life satisfaction, daytime napping, chronic disease condition, and sample weights—were used.

Results: Data were analyzed from 17,607 participants, of whom 8375 (47.6%) were men. The mean (SD) age was 62.7 (10.0) years. Individuals with 4 hours or less (odds ratio [OR] 1.91, 95% CI 1.60 - 2.27; *P*<.001), 5 hours (OR 1.33, 95% CI 1.09 - 1.62; *P*=.006), 9 hours (OR 1.48, 95% CI 1.13 - 1.93; *P*<.001), and 10 hours or more (OR 1.88, 95% CI 1.47 - 2.14; *P*<.001) of sleep per night had a higher risk of ADL disability than those in the reference group (7 hours per night) after adjusting for several covariates. Restricted cubic splines analysis suggested a U-shaped association between sleep duration and ADL disability. When sleep duration fell below 7 hours, an increased sleep duration was associated with a significantly low risk of ADL disability, which was negatively correlated with sleep duration until it fell below 7 hours (OR 0.83, 95% CI 0.79 - 0.87; *P*<.001). When sleep duration exceeded 7 hours, the risk of ADL disability would increase facing prolonged sleep duration (OR 1.19, 95% CI 1.12 - 1.27; *P*<.001). ADL disability should be monitored in individuals with insufficient (≤4 or 5 hours per night) or excessive (9 or ≥10 hours per night) sleep duration.

Conclusions:: In this study, a U-shaped association between sleep duration and ADL disability was found. Future longitudinal studies are needed to establish temporality and examine the mechanisms of the associations between sleep duration and ADL disability.

Introduction

The World Health Organization (WHO) survey of 2022 reported that 46.1% of adults aged 60 years and older are living with a disability globally [1]. Furthermore, according to the WHO projections, there will be 66 million older adults in China who live with a functional handicap by 2050 [1]. Activities of daily living (ADL) disability are one of the most common health problems in older adults, affecting about 1 in 6 older adults worldwide [2]. The prevalence of ADL disability increased with aging and had become a significant factor that increases the risk of mortality in older adults [3,4]. ADL disability seriously affected the quality of life and placed a high burden on care providers and the care system. Current research has focused on the prevention of, rehabilitation from, or management of ADL disability, with growing interest in the role of sleep patterns, such as sleep duration [5-7].

Sleep duration has become a significant public health issue [8], associated with the increasing risk of cardiovascular diseases, stroke, and mortality [9-11]. The WHO launched the ”World Mental Health Report—Transforming Health for All” on June 17, 2022 [12]. This report emphasizes that sleep loss is an extremely important risk factor for mental health issues. At present, the relationship between sleep duration and ADL disability has received much attention [13]. A longitudinal observational study suggested that short sleep duration during inpatient rehabilitation might be against greater functional ability at discharge among individuals with acute stroke [14]. The data from the National Health and Nutrition Examination Survey in the United States found that only short sleep duration was significantly associated with ADL disability [15]. The New Integrated Suburban Seniority Investigation Project study also reported that sleeping <6 hours/day was associated with a higher risk of incident disability among older Japanese people [16]. Although the above study did not find a relationship between long sleep and physical activity, the data from the English Longitudinal Study of Ageing cohort showed that both reduced and increased sleep duration were associated with limited agility and mobility disability [17]. A cross-sectional study in Taiwan also reported long sleep duration had a positive association with grip strength performance among older adults [18]. There is still no unified conclusion in the research on the relationship between sleep duration and ADL disability. So far, research on the relationship between sleep duration and ADL disability is well worth conducting.

China has the largest population of older adults globally; the growth rate of the aged tendency of the population was higher than that of Western countries [19,20]. Given the distinctions in historical, ethnic, and economic status as well as socio-cultural backgrounds, Chinese adults had different sleep patterns compared to those from other countries [21,22]. Considering the heavy disease burden caused by ADL disability, we conducted a cross-sectional analysis using data from the China Health and Retirement Longitudinal Study (CHARLS) to test the hypothesis that individuals with short and longer sleep duration are more likely to have ADL disability.

Methods

Ethical Considerations

The CHARLS protocol was approved by the Peking University Biomedical Ethics Review Board (IRB00001052-11015) [23,24]. This cross-sectional study adhered to the reporting guidelines stipulated by the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guideline [25]. According to the Common Rule (45 CFR part 46), this study was exempt from institutional review board approval and the requirement for informed patient consent because we did not use clinical data or involve human participants.

Study Participants

This cross-sectional study used data from the 2018 survey of the CHARLS conducted from 2018 to 2020, a survey of residents aged 45 years or older in 28 provinces across China [26,27]. The national baseline survey of the CHARLS included 17,708 respondents in 150 counties or districts and 450 villages or urban communities throughout the country. Detailed methods of the CHARLS have been described previously [23]. We applied the latest CHARLS wave in 2018 to 19,816 individuals to investigate the relationship between sleep duration and ADL disability. In the current study, we formulated the inclusion criteria for the study subjects: age ≥45 years, respondents with complete information on sleep duration, the ADL scale, and other covariates. We excluded the following outliers: missing date of sample weights, birth date, sleep duration, and ADL scale.

Sleep Duration

Similar to the English Longitudinal Study of Aging [28] in England, the CHARLS evaluated subjects’ sleep duration by utilizing the questions: “During the past month, how many hours of actual sleep did you get at night (average hours for one night)? (This might be shorter than the number of hours you spend in bed).” The response was an average sleep duration of typical usual weekdays or workdays within a month. Consistent with the previous CHARLS sleep study [29-32], we separated respondents into 7 sleep duration groups (≤4, 5, 6, 7, 8, 9, and ≥10 hours out of each evening) in the research. The CHARLS used this question to assess participants’ daytime napping: “In the past month, how long have you taken on average for a nap after lunch?” On the basis of 4 nap time groups considering the results [33,34], the participants were classified as nonnappers (0 min), short nappers (<30 minutes), moderate nappers (30 - 90 minutes), and extended nappers (>90 minutes).

XSL•FO
RenderX

ADL Disability

The CHARLS employed a 6-item summary derived from an ADL scale to quantify ADL utilizing a comprehensive series of inquiries that asked: "Are you experiencing any difficulties with performing any everyday activity due to physical, mental, emotional, or memory impairments, excluding any that you anticipate will persist for less than three months?" The daily tasks encompassed dressing, bathing or showering, eating, getting into or out of bed, using the toilet, and controlling urination and defecation. The response scale contained 4 options: (1) No, I don't have any difficulty; (2) I have difficulty but can still do it; (3) Yes, I have difficulty and need help; and (4) I cannot do it. The ADL scale was extensively used in previous studies among Chinese older adults and has shown good reliability and validity [35,36]. Individuals classified as independent possessed the capability to perform all 6 activities without any difficulty, whereas those who indicated a need for assistance in any of the aforementioned tasks were considered to have an ADL disability [37,38].

Covariates

The CHARLS collected information on sociodemographic characteristics and health-related factors using a structured questionnaire. Covariates that might confound the associations included age, sex, education (elementary school and below, secondary school, and college and above), marital status (married and others), residence (rural or urban), smoking and drinking status (never vs current), visual impairment, hearing impairment, self-reported general health status (ie, very good, good, fair, poor, and very poor), self-reported life satisfaction (ie, completely satisfied, very satisfied, somewhat satisfied, not very satisfied, or not at all satisfied), daytime napping, depression, chronic disease condition (ie, none, mild, and severe), and sample weights. Respondents were deemed to have visual or hearing impairment if they reported fair or poor vision (for either long-distance or near vision) or hearing difficulties. The respondents' chronic disease status was documented based on the count of self-reported noncommunicable diseases, encompassing hypertension, diabetes, dyslipidemia, heart conditions, stroke, renal diseases, asthma, pulmonary disorders, arthritis, liver ailments, and gastric issues. As for sampling weights, the CHARLS constructed cross-sectional sample weights directly from the sampling probabilities for households and individuals, taking into account death and divorce. In the 2018 survey, the CHARLS provides two sets of cross-sectional household weights, one with corrections for nonresponse and one without. Our study adopted the sets of cross-sectional individual weights with corrections.

Statistical Analysis

In the current study, comparisons of respondents' general characteristics based on ADL disability status were conducted using analysis of variance (ANOVA) for numerical variables and ordinal χ^2 tests for categorical variables. Numerical variables were presented as the mean (SD). Categorical variables were reported as numbers and percentages. Given the dichotomous nature of the ADL disability measure utilized in this study, we adopted multivariable generalized linear models with binomial family and log links to examine the associations between sleep duration and ADL disability; meanwhile, the odds ratios (ORs) and 95% CIs were reported. Restricted cubic splines with four knots at the 5th, 35th, 65th, and 95th centiles were used to examine the association between sleep duration per night and ADL disability. The generalized linear analytic models incorporated a range of covariates, including age, sex, education, marital status, tobacco and alcohol consumption, depression, place of residence, sensory impairment, self-reported health status, life satisfaction, daytime napping, chronic disease status, and sample weights. Multiple imputation with 5 replications and a chained equation approach was adopted to deal with missing data. We also conducted analyses stratified by sex to investigate sex-specific associations. A two-sided $P<.05$ was considered to be statistically significant. All data analyses were performed with Stata version 14.0 (StataCorp).

Results

Sample Characteristics

A schematic flow diagram of the study sample is shown in Figure 1. After filtering, our final study sample included 17,607 people with and without ADL disability.

XSL•FO
RenderX

Figure 1. Flowchart of the study sample from the 2018 China Health and Retirement Longitudinal Study (CHARLS).

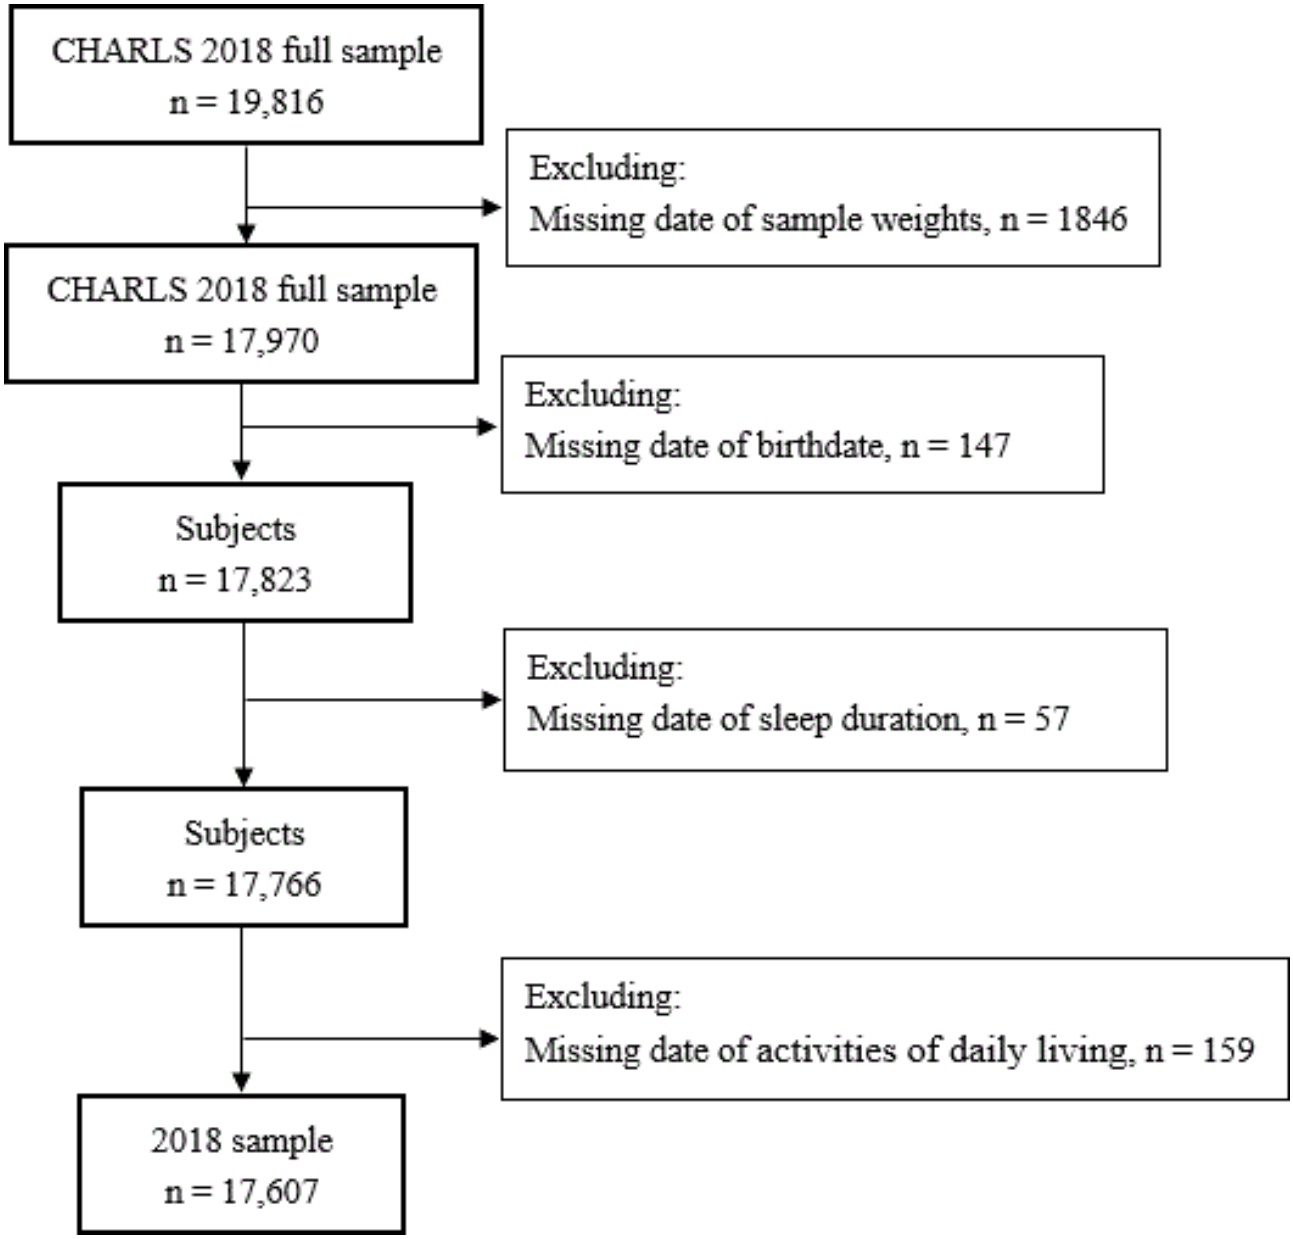

Table 1 shows the characteristics of the study population in the 2018 wave of the CHARLS. Among the 17,607 participants, 8375 (47.6%) were men and 9232 (52.4%) were women, with a mean (SD) age of 62.7 (10.0) years. A total of 3350 participants (19.0%) reported ADL disability. Compared with people with normal ADL function, individuals with ADL disability were more likely to have extremely shorter (≤4 hours) sleep duration and longer (≥10 hours) sleep duration (all P<.001). Participants with ADL disability also tended to have long napping during the day (≥90 minutes). In addition, there were significant differences between ADL disability groups concerning sex, education, tobacco and alcohol use, married status, residence, depressive status, chronic disease conditions, sensory impairments, life satisfaction, and self-reported general health status (all P<.001).

Hearing impairment, n (%)	11,706 (66.6)	2695 (80.7)	9011 (63.3)	<.001
Life satisfaction (satisfied), n (%)	14,365 (81.6)	2267 (67.7)	12,098 (84.9)	<.001
Self-reported general health status (good), n (%)	3846 (21.8)	218 (6.5)	3628 (25.5)	<.001

[a]Missing data for the following characteristics: tobacco use (184, 1.0%), residence (43, 0.2%), visual impairment (77, 0.4%), hearing impairment (35, 0.2%), life satisfaction (1354, 7.7%), and self-reported general health status (1241, 7.0%).

[b]ADL: activities of daily living.

Association Between Sleep Duration and ADL Disability

The association between sleep duration and ADL disability is shown in Table 2. In the model adjusting for age and sex (Model 1), individuals who slept ≤4 hours, 5 hours, 6 hours, 9 hours, and ≥10 hours had a higher risk of ADL disability than the reference group (7 hours per night). After adjusting for age, sex, and other potential confounders (Model 2), the association between 6 hours per night and ADL disability disappeared, while the associations between short (≤4 and 5 hours) and long (9 and ≥10 hours) sleep duration and ADL disability remained the same, with ORs of 1.91 (95% CI 1.60 - 2.27; *P*<.001), 1.33 (95% CI 1.09 - 1.62; *P*=.006), 1.48 (95% CI 1.13 - 1.93; *P*<.001), and 1.88 (95% CI 1.47 - 2.41; *P*<.001), respectively.

Table . Associations between sleep duration and activities of daily living (ADL) disability among participants from the 2018 China Health and Retirement Longitudinal Study.

	OR[a] (95% CI)	*P* value
Sleep duration per night, hours		
Model 1[b]		
≤4	2.85 (2.48 - 3.26)	<.001
5	1.51 (1.30 - 1.76)	<.001
6	1.17 (1.01 - 1.36)	.031
7	[Reference]	-[c]
8	1.08 (0.92 - 1.25)	.342
9	1.41 (1.14 - 1.75)	.002
≥10	2.03 (1.68 - 2.46)	<.001
Model 2[d]		
≤4	1.91 (1.60 - 2.27)	<.001

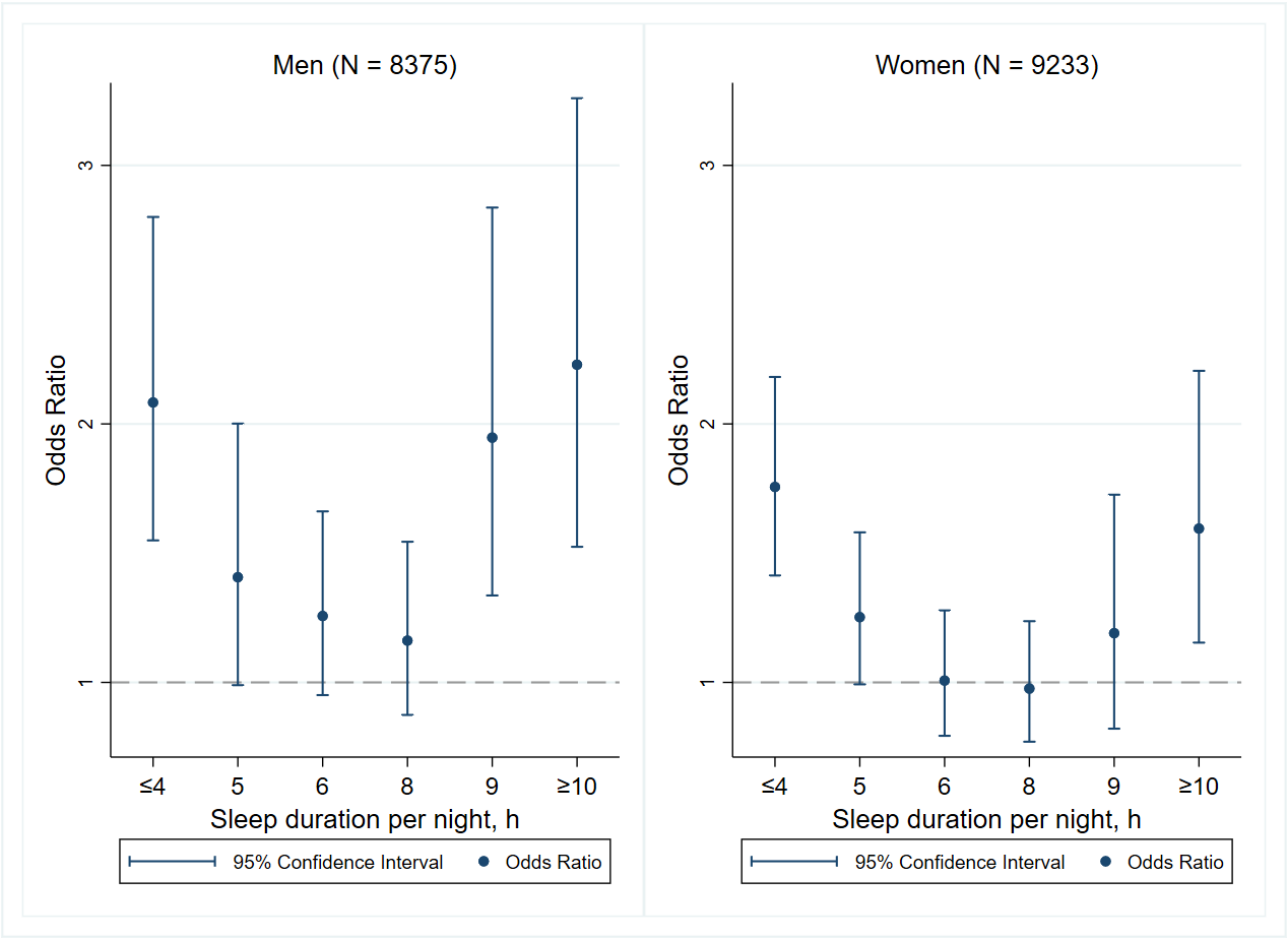
9	1.48 (1.13 - 1.93)	<.001
≥10	1.88 (1.47 - 2.41)	<.001

[a]OR: odds ratio.

[b]Model 1 was adjusted for age and sex.

[c]Not applicable.



[d]Model 2 was adjusted for age, sex, education, marital status, tobacco use, alcohol use, afternoon napping, residence, depression, chronic disease conditions, visual impairment, hearing impairment, life satisfaction, self-reported health status, and sample weights.

Sensitivity Analyses

Figure 2 provides the results of stratified analysis by sex. Our findings found that for both men and women, short (≤4 hours) and long (9 and ≥10 hours) sleep duration were associated with higher ADL disability compared to the reference group. However, after adjusting for covariates, men with less than 4 hours (OR 2.08, 95% CI 1.55 - 2.80), 9 hours (OR 1.95, 95% CI13.4 - 2.84), and above 10 hours per night (OR 2.23, 95% CI 1.52 - 3.26) had a higher risk than women did.

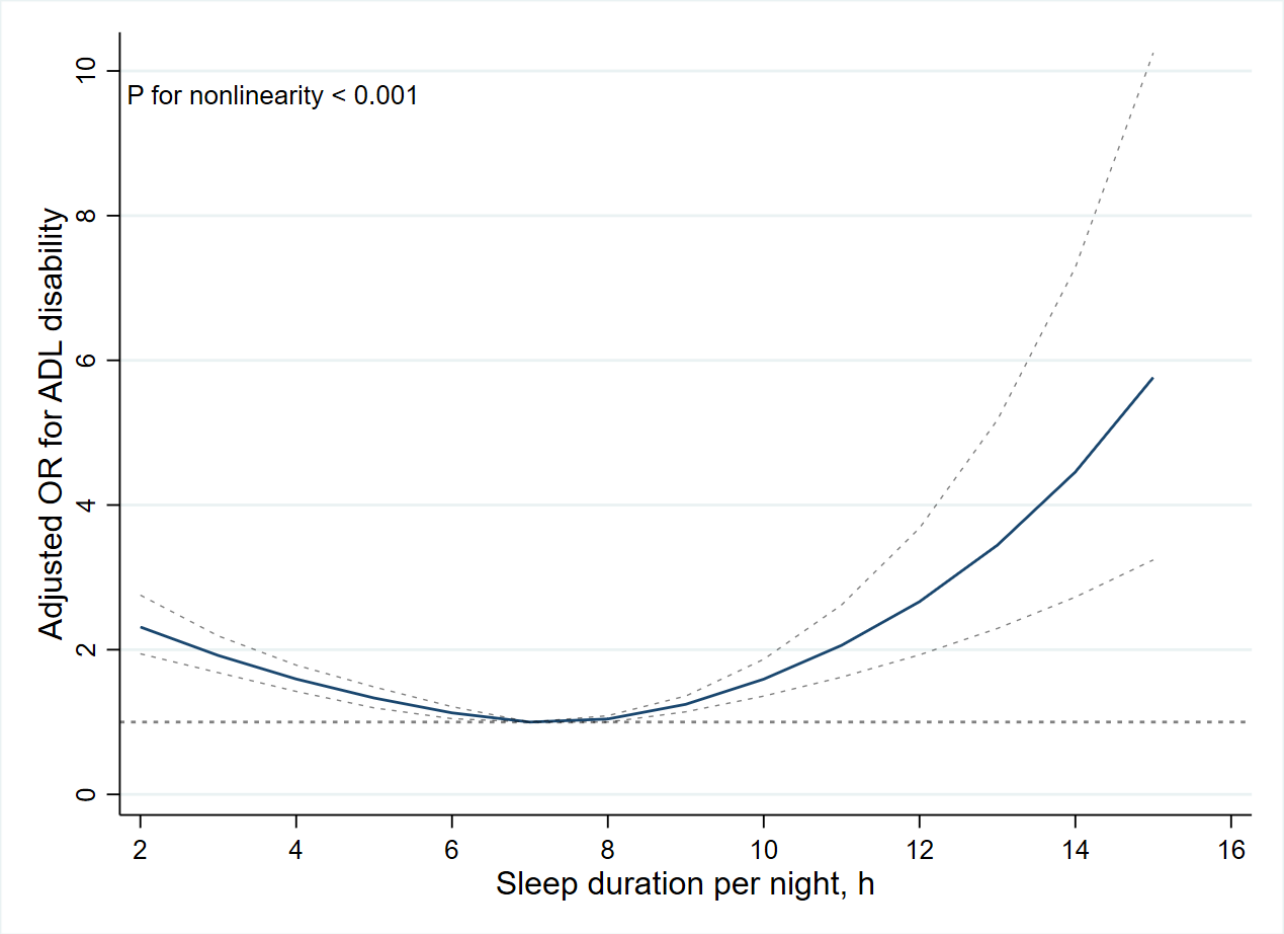
Figure 2. Sex-specific effect of sleep duration on the activity of daily living disability.



Nonlinear Relationship Between Sleep Duration and ADL Disability

In Figure 3, restricted cubic splines were used to flexibly model and visualize the relations between predicted sleep duration and ADL disability. Multivariable-adjusted restricted cubic splines analyses suggested U-shaped associations between sleep duration and ADL disability. The risk of ADL disability was negatively correlated with sleep duration until it bottomed out at 7 hours (OR 0.83, 95% CI 0.79 - 0.87; *P*<.001). However, when the sleep duration was higher than 7 hours, the risk of ADL disability increased significantly (OR 1.19, 95% CI 1.12 - 1.27; *P*<.001).

Discussion

Principal Findings and Comparison With Previous Works

In this nationally representative study, using the CHARLS database, a statistically significant U-shaped association was found between sleep duration and ADL disability. Individuals with short and long sleep duration were associated with a higher risk of ADL disability. To the best of our knowledge, the current study stands as one of the most extensive examinations of the correlation between sleep duration and ADL disability in the Chinese population.

Compared to other countries, the prevalence rates of ADL disability among older adults were higher in China [39], with one study observing a rate as high as 41% [40]. In contrast, in America, the percentage of older adults aged 65 - 74 years living with functional disability was 25.4% in 2015 [41]. The measurement of ADL disability serves as a crucial tool for monitoring the efficacy of therapeutic interventions across a range of diseases [42]. Given the well-established link between ADL disability and functional ability, it is important to conduct a study on the relationship between sleep duration and ADL disability.

Previous studies have estimated the correlation between sleep duration and ADL disability. The National Health & Aging Trends Study in the United States has demonstrated that insomnia symptoms were correlated with increased likelihood of functional limitations in later life [43]. The Centers for Disease Control and Prevention reported that adults who slept less than 7 hours per night were more prone to difficulties with daily activities than those who slept 7 - 9 hours per night [44]. Data from the New Integrated Suburban Seniority Investigation Project in Japan also suggested a heightened risk of incident disability in older adults associated with sleeping less than 6 hours per night [16]. However, this study found no significant link with long sleep duration, potentially due to its limited sample size (n=256) and subject detection bias. Conversely, data from 486,619 stroke survivors from the National Health Interview Survey revealed that long sleepers (≥9 hours) were more likely to experience problems with instrumental activities of daily living compared to average sleepers [13]. Our results are in accordance with the studies highlighting the increased risk of ADL disability associated with both short and long sleep. Meanwhile, our findings also align with a previous CHARLS study [45], which indicates that sleep durations of short (4 hours or less) and long (9 hours or more) predicted incident ADL disability.

Our results of multivariable-adjusted restricted cubic splines analyses also observed a U-shaped association between sleep duration and ADL disability. Our results lent support to the conclusion that adults aged 18 - 60 years were recommended to sleep at least 7 hours each night to foster optimal health and well-being, as suggested in previous studies [8,46]. Furthermore, “Healthy China 2030” echoes this advice, advocating for a sleep

XSL•FO
RenderX

duration of 7 - 8 hours per day for Chinese adults. Insufficient or excessive sleep duration per night was associated with an increased risk for coronary heart disease, cognitive decline, and functional limitations [30,45,47]. The evidence from China Kadoorie Biobank indicated that 23% of Chinese adults reported getting below 6 hours of sleep duration and 16% reported exceeding 10 hours [48]. The observed nonlinear association underscores the ongoing necessity for public education regarding sleep health and opportunities for healthcare providers to engage patients in discussions about the significance of sleep and to promote sleep health initiatives. Future research to prevent functional limitations may consider intervention strategies focused on sleep hygiene and inform the development of health policies.

The mechanisms by which sleep duration influences ADL disability remain unclear. Several plausible explanations have been proposed to explain the correlation between sleep duration and ADL disability. One possible explanation is tied to the pathology of age-related macular degeneration pathology. An exploratory study involving 277 patients with age-related macular degeneration found significant alterations in the expression levels of immediate early response 3 (IER-3), tissue inhibitor of metalloproteinase-3 (TIMP-3), beta 3-glucosyltransferase (B3GALTL), hepatic lipase (LIPC), and HtrA serine peptidase 1 (HTRA1) among individuals with sleep deprivation or patients with age-related macular degeneration who experienced an increase in sleep duration [49]. Meanwhile, physical activity markedly contributed to exacerbating the severity of age-related macular degeneration. Furthermore, IER-3 and TIMP-3 also had a role in regulating mechanisms in circadian rhythms [49]. The second explanation links the relationship between sleep duration and ADL disability to psychological distress [50]. Similarly, sleep duration also affected the relationship between ADL disability and psychological distress as a mediating pathway, which might also affect ADL disability by causing psychological distress [6]. However, the underlying mechanism governing the association between sleep duration and ADL disability remained uncertain.

In addition, our stratified analysis revealed an elevated risk of ADL disability among men with short and long sleep durations. Sex differences in sleep duration cannot be ignored, as men generally tend to sleep less than women throughout their lifespan [51]. Our findings align with those from the Swedish panel study of living conditions among the oldest old, which showed stronger associations between ADL and instrumental activities of daily living as well as other health indicators among men compared to women between 1992 and 2002 [52]. A longitudinal observation study of 3609 adults aged 65 - 89 years from the Korean National Health and Nutrition Examination Survey also found that men had 2 - 3 times higher odds of developing ADL disability than women [53]. One plausible explanation for this sex difference could be the more severe impact of conditions such as stroke, cancer, and pulmonary disease on older men compared to women, potentially due to men's greater propensity for alcohol and tobacco consumption, thereby increasing the greater risk of ADL disability.

Strengths and Limitations

Our study boasts significant strengths, notably its utilization of a nationally representative sample of Chinese adults aged 45 years and older, rather than relying on clinical samples or occupational cohorts. Furthermore, to our knowledge, it stands as one of the pioneering population-based studies to incorporate both sleep duration and ADL disability. However, several limitations of the current study merit consideration. First, due to its cross-sectional design, we are unable to establish causal relationships between sleep duration and ADL disability based on the observed associations, necessitating a cautious interpretation of the findings. Second, sleep duration was solely assessed through self-reporting, which may introduce potential biases. Third, the CHARLS questionnaire lacks comprehensive sleep-related information, such as objective assessments of the sleep quality, sleep disturbance, and difficulties initiating sleep, which could potentially act as a confounding factor, influencing our estimates. Finally, the binary classification of ADL disability, rather than a continuous scale, might underestimate the associations between sleep duration and ADL disability. Additionally, despite controlling for a range of covariates in the analysis, we cannot discount the influence of unknown factors in this study.

Conclusions

A nationally representative sample in China revealed a statistically significant U-shaped relationship between sleep duration and ADL disability. The U-shaped pattern underscores the importance of monitoring ADL disability in middle-aged and older individuals who exhibit either insufficient or excessive sleep duration. It is imperative for future longitudinal studies to elucidate the causal or bidirectional links between sleep duration and ADL disability, while also delving into the potential mechanisms underlying this intricate interplay.

Acknowledgments

This work was supported by Fundamental Research Funds for the Central Universities (No. 2022-JYB-PY-013). We thank the China Health and Retirement Longitudinal Study team for providing data and simple training in using the database.

Authors' Contributions

HR and XG provided the conception of the research design. HF conducted the data analysis and wrote the first version of the manuscript. WY, XG, and HR provided comments related to the presentation of the findings and critically reviewed the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Physical activity and appropriate nutrition are essential for older adults. Improving physical health and quality of life can lead to healthy aging.

Objective: This study aims to investigate the long-term effects of multihealth promotion programs on the physical and mental health of older adults in communities.

Methods: A quasi-experimental method was used to recruit 112 older adults voluntarily from a pharmacy in central Taiwan between April 2021 and February 2023. Participants were divided into an experimental group receiving a multihealth promotion program and a control group with no specific intervention. The study measured frailty, nutritional status, well-being, and quality of life using standardized tools such as the Clinical Frailty Scale (CFS), Mini-Nutritional Assessment-Short Form (MNA-SF), Well-being Scale for Elders, and the EQ-5D-3L. Data were analyzed using descriptive statistics, independent *t* tests, Pearson correlation, and generalized estimating equations.

Results: A total of 112 participants were recruited. There were 64 (57.1%) in the experimental group and 48 (42.9%) in the control group. The experimental group exhibited significantly better quality of life (EQ-5D index) at weeks 12 (β=–.59; *P*=.01) and 24 (β=–.44; *P*=.04) compared to the control group. The experimental group muscle mass significantly increased at weeks 24 (β=4.29; *P*<.01) and 36 (β=3.03; *P*=.01). Upper limb strength improved significantly at weeks 12 (β=3.4; *P*=.04) and 36 (β=5; *P*=.01), while core strength showed significant gains at weeks 12 (β=4.43; *P*=.01) and 36 (β=6.99; *P*<.01). Lower limb strength increased significantly only at week 12 (β=4.15; *P*=.01). Overall physical performance improved significantly at weeks 12 (β=5.47; *P*<.01), 24 (β=5.17; *P*<.01), and 36 (β=8.79; *P*<.01).

Conclusions: The study's findings highlight the practical benefits of interventions, including physical and social activities and nutritional support, in enhancing the quality of life and general physical health of older adults. This study's findings have significant implications for clinical practice. These findings can aid in the establishment of effective interventions for older adults.

older adult; body composition; physical activity; health promotion; exercise; nutrition; diet; well-being; quality-of-life; QoL; gerontology; geriatrics

Introduction

As the challenges of global aging intensify, it is projected that by 2050, individuals aged 60 years and older will account for 22% of the global population [1]. This demographic shift brings a surge in health concerns among older adults, necessitating increased attention. Aging is commonly associated with significant changes in body composition, including substantial loss of muscle strength and mass, which elevates the risk of sarcopenia and functional decline [2]. In addition, older adults are particularly vulnerable to moderate-to-severe malnutrition, further exacerbating health deterioration and reducing quality of life (QoL) [3]. Consequently, health promotion strategies should prioritize improving the nutritional status of older adults and encouraging regular physical activity to support overall health and QoL [4]. Research consistently demonstrates that older adults who engage in regular physical activity experience significantly better physical and mental health outcomes than sedentary individuals, underscoring the undeniable benefits of exercise interventions [5]. As such, exercise interventions are widely regarded as a practical approach to enhancing QoL in older adults [6].

Exercise interventions for older adults encompass a variety of methods, including yoga, breathing exercises, meditation, Baduanjin, Western gymnastics, 24-form Tai Chi, aerobic exercises, outdoor activities, balance, strength, and resistance training [4,5,7]. These interventions typically last 12 weeks, with sessions ranging from 30 to 90 minutes, 2 to 5 times per week, with 3 sessions per week being the most common frequency. However, systematic reviews and meta-analyses reveal that current health promotion studies predominantly focus on single exercise modalities, yielding inconsistent effects on physical function and lacking in-depth exploration of multicomponent exercise interventions, particularly in practical applications and comprehensive outcome assessments [4,5,7]. Specifically, Frost et al [7] conducted a meta-analysis of 7 randomized controlled trials (RCTs), of which only one combined exercise with nutritional interventions. This study found that strength training supplemented with protein significantly improved muscle mass. However, the effects on psychological health and well-being were not adequately explored, highlighting the need for further research on the holistic benefits of multicomponent interventions. Similarly, Iwano et al [8] emphasized in their systematic review that the variation in intervention types (eg, art therapy and social activities) and measurement tools (eg, well-being scales and depression indices) in studies on older adults' well-being limits the comparability and generalizability of intervention effects, underscoring the necessity for further research. Wei et al [5] advocated for future studies incorporating diverse forms of physical activity to investigate their effects on physical and mental health systematically. They also encouraged older adults to engage in various activities to enhance QoL effectively.

In addition, Sirikul et al [4] conducted a meta-analysis of multicomponent exercise interventions (combining strength, balance, flexibility, and endurance training) and nutritional interventions among frail older adults aged 65 years and above in community settings. Their findings suggest that combining nutritional interventions, such as protein supplementation, with exercise interventions, particularly strength training, effectively improves older adults' muscle mass and physical function. These findings underscore the potential value of multicomponent strategies and emphasize the importance of integrating exercise and nutritional interventions in future health promotion programs to enhance older adults' overall health and functional outcomes.

Although exercise interventions are widely recognized for their potential to improve QoL in older adults, their effects on physical function and psychological health remain inconsistent. For example, Sirikul et al [4] conducted a meta-analysis of 21 exercise intervention studies, reporting predominantly positive effects on muscle strength and balance. However, their findings also highlighted the lack of comprehensive evaluations of multicomponent interventions (eg, combining exercise and nutrition). Frost et al [7] reported that only one of 7 RCTs included combined exercise and nutritional interventions, showing that strength training with protein supplementation significantly increased muscle mass. Nevertheless, the effects of this combined intervention on mental and psychological health were not thoroughly explored. Marcos-Pardo PJ et al [9] found that moderate-to-high intensity resistance circuit training significantly improved muscle strength in older adults but had no significant impact on QoL. Conversely, Chittrakul et al [10] reported that multisystem exercise training significantly enhanced QoL in older adults. Existing studies suggest that exercise interventions should be tailored to the physical condition of older adults. Combining social participation, autonomy enhancement, nutritional interventions, physical training, and cognitive activities in multicomponent health promotion programs improves nutritional status and overall physical function. It effectively enhances QoL and well-being while reducing fall risks [4,5,7].

Well-being, a subjective experience characterized by happiness or satisfaction, is a core goal universally pursued by humans. It is closely associated with reduced risks of depression, diminished feelings of hopelessness, improved mental health, enhanced QoL, and strengthened family relationships. For older adults, well-being often stems from life achievements and successful experiences [11]. Enhancing well-being helps older adults maintain health and encourages them to adopt a more positive outlook on life. However, previous research has predominantly focused on treating and managing physical diseases in older adults, with relatively little attention given to well-being [12]. Furthermore, significant disparities remain in the findings of studies investigating the effects of interventions on older adults' well-being [8]. Studies have shown that social activities significantly improve psychological health by engaging older adults in meaningful, hopeful, and enjoyable interactions

XSL•FO
RenderX

[13,14]. Maintaining QoL in older adults is essential for individual health and reflects their adaptability and resilience during aging. High QoL effectively reduces mental health issues, promotes active community participation, strengthens social connections, and alleviates feelings of loneliness [6].

In addition, smart devices provide precise data and enhance older adults' engagement and adherence to exercise [15,16]. However, further research is needed to compare the effects of specific multicomponent intervention models. This study investigates the comprehensive effects of a multihealth promotion program combining smart exercise devices, social activities, and nutritional prescriptions on the physical function, QoL, and well-being of older adults in community settings. The long-term benefits will also be tracked to provide evidence-based recommendations for promoting healthy aging.

Methods

Design and Sample

This study adopted a quasi-experimental design, with participants voluntarily recruited from a pharmacy located in central Taiwan between April 2021 and February 2023. The participants themselves determined allocation to the experimental and control groups. The trial design was registered with ClinicalTrials.gov (identifier: NCT05412251) and followed the CONSORT (Consolidated Standards of Reporting Trials) guidelines (Multimedia Appendix 1). The inclusion criteria for this study were participants (1) aged 65 years or older and (2) fluent in Mandarin (speaking or reading). The study excluded participants who had a history of cognitive impairment, cancer, myocardial infarction, or congestive heart failure. This study used G power software to estimate the sample size. The effect size was calculated based on the pre- and posttest scores of the quality of life of older adults in the intervention group and the control group in a previous study [17]. The effect size was 0.19, the detection power was 0.8, the significance level (α) was .05, and the number of measurements was four times. The results showed that 40 participants were required in each group to ensure that a statistically significant difference in quality of life between the two groups could be detected during the follow-up period. Considering the attrition rate in interventional studies can be as high as 40% [18], at least 56 participants were recruited in each group at baseline. Data were collected at baseline (T0) and 12 weeks, 24 weeks, and 36 weeks postintervention (T1, T2, and T3). The data was collected face-to-face and self-reported by participants.

Multihealth Promotion Program Intervention

The design of the multihealth promotion program was based on previous studies. We combined 3 intervention strategies: social activities, physical training, and nutritional support, and used artificial intelligence exercise equipment as an assessment tool to measure physical performance during the exercise process [5,13,19]. For 12 weeks, participants in the experimental group engaged in social and physical activities while receiving nutritional support. (1) Social activities: this was combined with activities held at community base C, such as makeup, reading picture books, art classes, board games, and more, for at least 120 minutes, once a week. (2) Physical training: the utilization of artificial intelligence exercise equipment, suitable for middle-aged and older people's exercise training and approved by the Food and Drug Administration of the Ministry of Health and Welfare. This was carried out at least 60 minutes, 3 times a week, including 8-10 minutes of warm-up exercise before exercise, after exercise, aerobic exercise, muscle strengthening training, and balance training, each requiring 15-20 minutes. Before each exercise, researchers used the exercise assessment and screening for you (EASY) tool to assess participants' exercise risks, and the AI-enabled exercise equipment will evaluate participants and provide appropriate exercise prescriptions. Throughout the exercise, the researchers observed the physical condition of the participants constantly. If there were signs of discomfort, participants were asked to stop immediately. (3) Nutritional support: nutritionists screened participants' nutritional status based on the mini nutrition assessment tool and based on personal wishes, provided free protein nutrition products in this plan. During the entire study period, the control group did not receive the intervention program for social activities, physical activity, or nutritional support. They only took measurements and questionnaires at monitoring time points (baseline, 12, 24, and 36 weeks). The on-site nutritionist was available for any questions from the control group.

Measurements

The study measured demographic and baseline characteristics, frailty, nutrition status, well-being, and quality of life.

Demographic Data Form

A researcher-made demographic form was prepared based on a literature review. It included age, gender, BMI, education level, lived conditions, and chronic disease.

Clinical Frailty Scale

The Clinical Frailty Scale (CFS) is used to assess frailty in older adults and was developed by Rockwood et al in 2005. This scale was updated to version 2.0 in 2020. The frailty scale ranges from 1 to 9, where level 1 indicates very fit and level 9 indicates terminally ill, corresponding to a survival time of fewer than 6 months [20].

Mini-Nutritional Assessment-Short Form

The Mini-Nutritional Assessment-Short Form (MNA-SF) consists of 6 questions that assess key areas of nutritional assessment: decline in food intake, weight loss, mobility, psychological stress or acute disease, neuropsychological problems, and BMI. The total score classifies individuals into 3 categories, normal nutritional status (12-14 points), at-risk of malnutrition (8-11 points), and malnourished (0-7 points). The MNA-SF has been validated in various studies and settings, demonstrating high sensitivity and specificity [21].

The EASY Tool

The EASY is an exercise screening and assessment tool designed to help older adults choose safe and effective exercise modalities and physical activity programs. There are 6 questions, each of which can be answered with "yes" or "no." If the answer to one of the questions is "yes," the participant must find a health care

XSL•FO
RenderX

provider to discuss an appropriate exercise plan before exercising [22].

Well-Being Scale for Elders

The Well-being Scale for Elders is a 9-item self-report questionnaire, including emotional, psychological, and social well-being. The higher scores indicate better well-being. It has good reliability and construct validity and can be effectively used to measure the happiness of older adults. The Cronbach α is 0.91, and the factor analysis results explain 59.67% of the variation [12]. In this study, Cronbach α is 0.82.

EQ-5D-3L Instrument

The EQ-5D 3L is a standardized instrument developed by the EuroQol Group to measure general health status. It is widely used in both clinical and economic evaluations to assess health-related quality of life. The EQ-5D index comprises 5 dimensions: mobility, self-care, daily activities, pain or discomfort, and anxiety or depression. Each dimension has 3 levels of severity (no problems, moderate problems, and extreme problems). Higher scores on this index indicate a poorer health-related quality of life. EQ-VAS (European Quality of Life Visual Analogue Scale) is a visual analog scale ranging from 0 to 100, with higher scores indicating a better-perceived quality of life. Respondents evaluate their overall health on a scale from 0, indicating the worst possible health, to 100, indicating the best possible health [23]. The EQ-5D-3L has demonstrated good reliability, validity, and sensitivity for measuring health-related quality of life [24]. In this study, Cronbach α is 0.8.

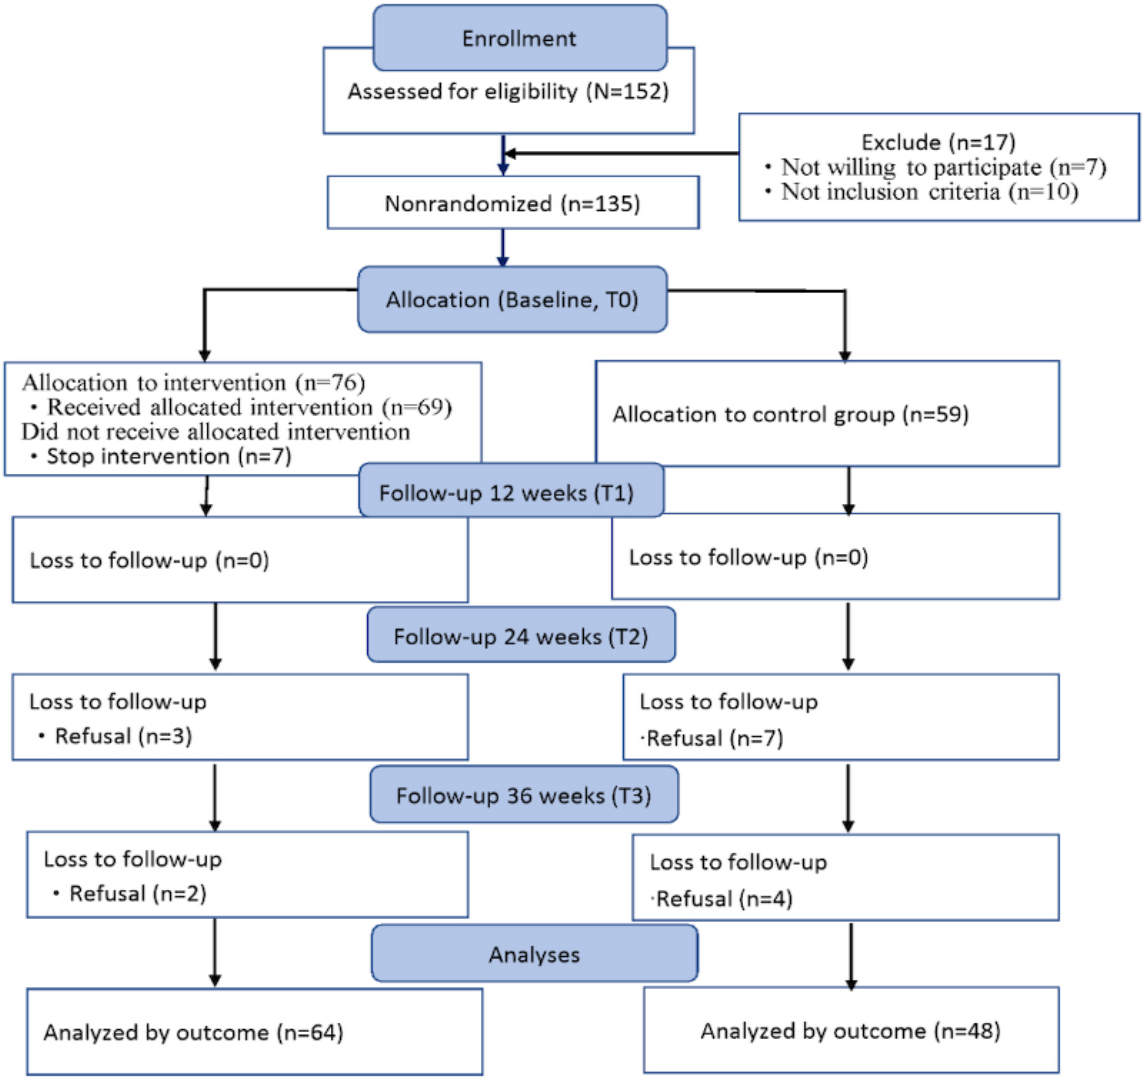
Statistical Analysis

All data were analyzed using the SPSS software program (version 24; IBM Corp). This research uses descriptive statistics to analyze frequencies, means, and SD. Differences in outcome variables at baseline between the two groups are analyzed using the chi-square test and an independent *t* test. The Generalized Estimating Equations (GEE) analyze changes over time, group differences, and group-by-time interactions, including body composition, frailty, well-being, and quality of life.

Ethical Considerations

This study was conducted with the utmost ethical considerations and approved by the National University Institutional Review Board (YM110168EF). All participants were respected, and their autonomy was upheld, as they provided written informed consent before enrollment. Participants were fully informed by a research assistant about the study's purpose, procedure, benefits, and potential risks, ensuring transparency and respect for their rights and welfare. The participant data has been deidentified for privacy concerns.

Results



In this study, after excluding ineligible participants and those who dropped out, a total of 112 older adults (64 in the experimental group and 48 in the control group) completed the study, with 15.8% and 18.6% attrition rates, respectively (Figure 1). Most participants were female (67%), with an average BMI of 24.5 (3.6) kg/m². Overall, 23.2% (26/112) of the participants lived alone; the average frailty score was 2.2 (SD 0.9). Baseline characteristics showed good homogeneity between the 2 groups. As of February 2023, we have recruited 152 participants (Table 1).

Table 2 reveals average baseline BMI in the control group as 24.13 (SD 3.89) kg/m², which slightly decreased to 24.06 (SD 3.63) kg/m² at week 36. Frailty scores rose from 2.31 to 2.45, while the average well-being scores improved from 38.21 (SD 5.42) to 38.59 (SD 5.45). Quality-of-life scores showed improvement, decreasing from an average of 5.50 (SD 1.07) to 5.35 (SD 0.90). In the experimental group, average baseline BMI was 24.79 (SD 3.34) kg/m², which reduced to 24.43 (SD 3.42) kg/m² by week 36. Frailty scores increased slightly from 2.11 to 2.16, and average well-being scores rose from 37.86 (SD 5.99) to 38.91 (SD 4.97). Quality-of-life scores improved significantly, decreasing from an average of 5.98 (SD 1.46) to 5.42 (SD 0.79).

Table 3 shows that the GEE analysis revealed significant BMI reductions across all participants in the first 12 weeks. At week 36, the experimental group had a significantly lower BMI compared to the control group. Notably, BMI reductions were more pronounced in the experimental group at weeks 12 (β=–.22; *P*=.02) and 24 (β=–.20; *P*=.06), with a smaller decrease at week 36 (β=.15; *P*=.23). The interaction effect between groups at week 36 was significant (β=–.51; *P*<.001), highlighting a greater BMI reduction in the experimental group. Frailty assessment showed no significant interaction between time and group, suggesting stable frailty levels during the intervention. Similarly, no significant differences in well-being were observed. However, the experimental group exhibited significantly better quality of life (EQ-5D index) at weeks 12 (β=–.59; *P*=.01) and 24 (β=–.44; *P*=.04) compared to the control group. No significant differences were observed in EQ-VAS scores between groups.

Table 4 shows that GEE analysis revealed no significant changes in body fat percentage at weeks 12 (β=–.03; *P*=.69) and 36 (β=–.31; *P*=.27). However, muscle mass significantly increased at weeks 24 (β=4.29; *P*<.001) and 36 (β=3.03; *P*=.01), demonstrating the intervention's effectiveness in enhancing muscle mass. Upper limb strength improved significantly at weeks 12 (β=3.40; *P*=.04) and 36 (β=5; *P*=.01), while core strength showed significant gains at weeks 12 (β=4.43; *P*=.01) and 36 (β=6.99; *P*<.001). Lower limb strength increased significantly only at week 12 (β=4.15; *P*=.01). Overall physical performance improved significantly at weeks 12 (β=5.47; *P*<.001), 24 (β=5.17; *P*<.001), and 36 (β=8.79; *P*<.001).

Discussion

Principal Findings

This study's findings indicate that an intervention program encompassing exercise, social activities, and nutritional prescriptions significantly improved muscle mass, muscle strength, and QoL in the experimental group. Exercise programs have been demonstrated to enhance physical function, body composition, QoL, and muscle strength in older adults [6,9,10,16]. However, their effects on mental health and subjective QoL are less consistent and warrant further investigation. In this study, the experimental group's QoL (measured by the EQ-5D index) was significantly higher than the control group at weeks 12 and 24. However, no significant difference was observed in EQ-VAS scores. By week 36, the experimental group showed a trend of improvement in QoL, suggesting that the intervention may have long-term benefits for mental health. These findings align with Marcos-Pardo et al [6,9], who reported that resistance training interventions

XSL•FO
RenderX

improved lean body mass, muscle strength, and QoL. In a randomized controlled trial (RCT) by P J Marcos-Pardo et al [6], the experimental group participated in an 8-week outdoor resistance training program involving bi-weekly sessions with weight machines. Results revealed significant increases in lean body mass, reductions in fat mass, and improvements in muscle strength (arm and leg), functional activity, and QoL. At the same time, the control group experienced declines in muscle strength, activity capacity, dynamic balance, and QoL. Another RCT by Marcos-Pardo et al [9] demonstrated that older adults in the experimental group engaging in moderate-to-high intensity resistance circuit training for 12 weeks experienced significant reductions in body weight, fat mass, and BMI, along with significant improvements in lean body mass, functional independence, and upper and lower limb strength. However, no significant changes in body fat or visceral fat were observed in the experimental group during the study period. Chittrakul et al [10] conducted an RCT involving prefrail older adults with a 12-week exercise intervention and a two-year follow-up. The experimental group exhibited significant improvements in muscle strength at week 12, with enhancements in knee extension, balance, and reaction time persisting through week 24. The experimental group's health-related QoL was significantly higher than the control group at week 12. However, by week 24, despite the control group engaging in thrice-weekly stretching exercises, there was no significant difference in QoL between the groups, contrasting with this study's sustained improvements in the experimental group beyond week 24. This study also observed a BMI reduction at week 36, differing from previous findings [9], underscoring the need to explore further BMI changes and their relationships with muscle mass and strength.

Unlike the QoL findings, this study did not detect significant differences in well-being between the experimental and control groups, contrasting with the findings of Lai et al [25] and Jung et al [26]. The quasi-experimental study by Lai et al [25] demonstrated that a 6-day outdoor activity program, including kayaking, rafting, hiking, and camping, significantly improved well-being, self-image, and mental health among older adults, differing from this study's results. Similarly, Jung et al [26] reported that a 6-week integrated cognitive function improvement program significantly enhanced cognitive function and well-being in the experimental group, with no significant changes observed in the control group. The lack of significant well-being improvements in this study might be attributable to participant characteristics, cultural contexts, or the predominantly indoor nature of the intervention activities. Notably, previous research [27] has highlighted the mediating and moderating roles of outdoor and group exercise in enhancing well-being, emphasizing the psychological benefits of these activities. This underscores the importance of environmental and social factors in promoting well-being. The findings related to well-being suggest that additional intervention components beyond physical and nutritional strategies may be necessary. Factors such as depression risk, social relationships, and leisure activities have been shown to influence well-being [11]. Furthermore, Yang et al [27] emphasized that outdoor environments and group interactions significantly enhance well-being by fostering social connections and providing meaningful engagement. Future studies should consider integrating these elements to maximize the psychological benefits of multicomponent interventions.

Exercise and nutritional interventions have positively affected older adults' physical function and weight management. Liao et al [19] showed that combining exercise with nutritional support improved grip strength and walking speed despite limited changes in lean body mass. Similarly, in this study, while there were no significant changes in body fat or visceral fat in the experimental group, muscle mass significantly increased at week 24, with effects sustained through week 36. Upper limb strength improved significantly up to week 36, whereas lower limb strength showed significant improvements only at week 12. These findings highlight the need for more targeted designs in future interventions to address lower limb training.

This study underscores the potential of multidisciplinary active aging programs to improve physical function, QoL, and muscle strength among community-dwelling older adults. Such programs have been shown to reduce frailty risk, enhance flexibility, and promote social participation [28]. However, single-component nutritional interventions may have limited effects on individuals without malnutrition or unintentional weight loss [4], consistent with this study's findings. Clinicians should prioritize integrating physical, nutritional, and social interventions into comprehensive strategies tailored to older adults' needs. Muscle mass and muscle strength are positively correlated, and increasing muscle mass is key to improving muscle strength in older adults. Muscle mass and body fat percentage are important predictors of muscle strength. With aging, physical fitness declines, and body composition changes (eg, decreased muscle mass and increased obesity) are common [29]. Enhancing muscle strength is critical for clinical health care providers, contributing to improved stability, coordination, flexibility, and balance, ultimately reducing injury risk [30]. As global life expectancy rises and the proportion of older adults increases, promoting healthy aging is not merely a slogan but an urgent priority. However, physical inactivity and nutritional issues are prevalent among older adults [31], and these challenges are closely tied to their health and QoL [3]. While this study did not delve deeply into the influencing factors of QoL, well-being, and nutritional status, the results suggest these areas are important directions for future research.

Limitations

This study has several limitations that must be noted. First, the quasi-experimental design may introduce selection bias, as participants were not randomized. Second, the predominantly indoor nature of the activities may have limited the potential psychological benefits. Third, this study did not explore the influence of individual variability in adherence and baseline activity levels on the outcomes. Fourth, it was unable to determine the potential for individuals in either the experimental or control group to participate in additional outdoor or physical activities outside of the intervention program, which could have influenced the results. Further studies should address these limitations by employing randomized controlled trial designs, which include outdoor and group-based activities, examining

XSL•FO
RenderX

the effects of participant adherence and baseline characteristics, and tracking any additional activities performed outside of the intervention.

Conclusion

In conclusion, this study confirms the beneficial effects of multicomponent intervention programs on older individuals' physical function and quality of life. However, the limited benefits on well-being underline the importance of more comprehensive solutions that consider psychological and social aspects. Future studies should concentrate on the long-term assessment of nutritional status, quality of life, and well-being and the creation of individualized intervention programs that incorporate outdoor activities to promote active and healthy aging.

Acknowledgments

The authors thank YuSen Biotechnology Co., Ltd. and Keisei Pharmacy, which led to the successful completion of this research project. This study was funded by YuSen Biotechnology Co., Ltd. and Keisei Pharmacy.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors contributed to the conceptualization, writing—review and editing, and approval of the submitted manuscript and will be accountable for its contents. HHT and GL supervised the study. HHT and LYL curated the data. HHT, GL, YRY, SJL, and ZYC performed the investigation and methodology. LYL conducted the formal analysis. HHT, GL, and LYL handled project administration. GL and SJL managed resources. LYL and HHT performed visualization. LYL and HHT wrote the original draft. GL acquired the funding.

Conflicts of Interest

The authors declare that this study was financially supported by YuSen Biotechnology Co., Ltd. and Keisei Pharmacy. Among the authors 2 coauthors are employees of YuSen Biotechnology Co., Ltd. While efforts were made to maintain research integrity and objectivity, this relationship may be considered a potential conflict of interest.

Abstract

Background: Age-related hearing loss (ARHL) is associated with severe negative outcomes, including social isolation, depression, and cognitive decline. Despite this, routine ARHL screening is often neglected in primary care due to low awareness, resource limitations, and inefficiencies. A practical risk assessment tool could effectively address this gap.

Objective: This study aims to develop and validate a user-friendly nomogram for identifying older adults at high risk of ARHL in community settings, thereby facilitating targeted screening and timely interventions.

Methods: This multicenter retrospective cohort study included 34,983 older adults from 3 primary health care centers in Beijing (January 2020 to October 2023). Data from center A (n=18,707) were used for model development, with external validation performed on cohorts from center B (n=11,008) and center C (n=5268). Least absolute shrinkage and selection operator and logistic regression identified the final predictors. Model performance was evaluated using discrimination, calibration, and decision curve analysis, leading to the development of an online nomogram.

Results: In the training cohort (center A), 1177 participants (6.3%) had hearing loss. Six key predictors were identified: age, education, exercise frequency, physical function, dietary habits, and hypertension. The multivariate logistic regression model demonstrated good discrimination in internal validation (area under the curve [AUC] 0.806, 95% CI 0.782-0.831; sensitivity 0.774; specificity 0.820). External validation confirmed its generalizability (AUC 0.720, 95% CI 0.670-0.771 and AUC 0.747, 95% CI 0.712-0.782). Decision curve analysis highlighted a substantial clinical net benefit. A user-friendly online prediction web page was also developed.

Conclusions: We successfully developed and validated a dynamic, online nomogram for predicting ARHL in older adults. Comprising 6 readily available predictors, this model shows potential as a practical, online tool for proactive risk identification in primary care. However, further validation in larger and more diverse populations is essential to confirm its generalizability and real-world clinical utility.

Introduction

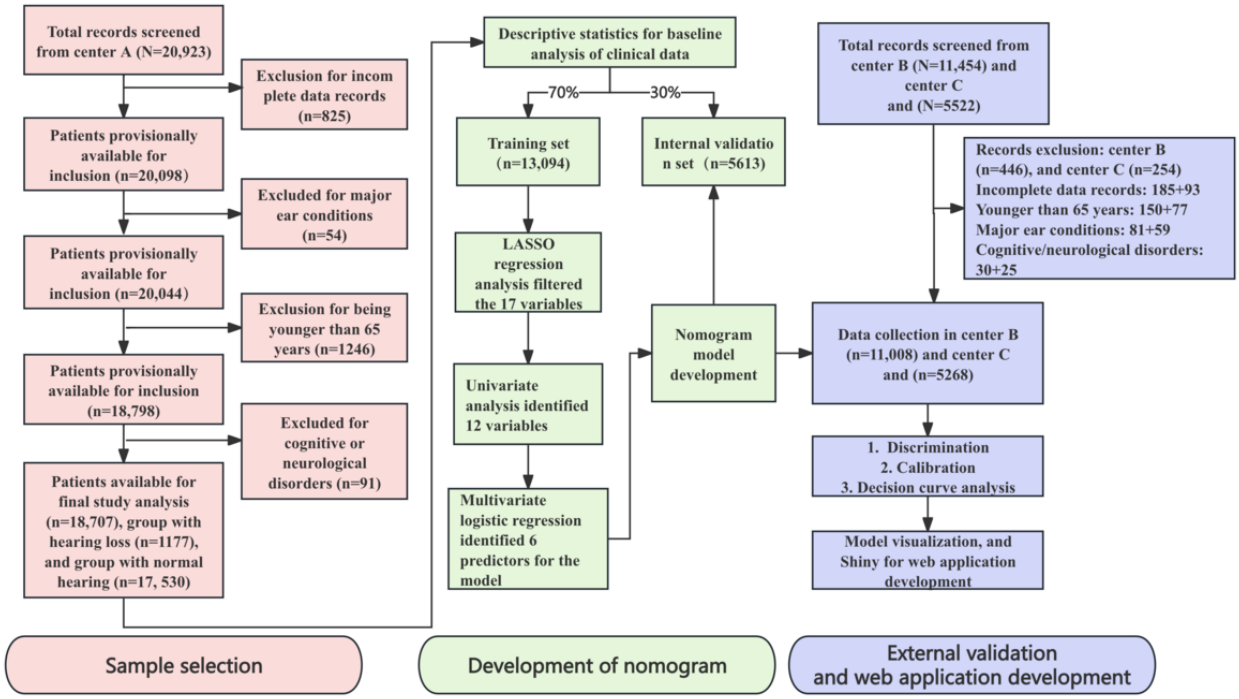
Age-related hearing loss (ARHL) is the third most prevalent health condition among older adults, after hypertension and arthritis, and has become a significant public health issue [1]. The World Health Organization estimates that more than 1.5 billion people worldwide experience hearing loss, a number projected to reach 2.5 billion by 2050 [2]. In China, hearing loss affects 30% of adults older than 60 years and rises to 50% for those older than 70 years, totaling at least 70 million cases [3]. ARHL can hinder communication and social interaction, leading to greater risks of social isolation, depression, cognitive decline [4-6], frailty, and falls [7,8].

Despite these negative health consequences, routine hearing screening remains significantly underused, with rates below 25% in older populations [9,10]. Key barriers include limited patient awareness and financial constraints; for example, a diagnostic audiogram in China can cost ¥100 (US $14.1) to ¥300 (US $42.3), a substantial out-of-pocket expense for many older adults; these challenges are further compounded by limited time, training, and equipment among primary care clinicians [11-14]. Furthermore, high false-positive rates from some hearing screening methods can increase costs, prompting policymakers to adopt a cautious approach [3,15].

Leveraging primary health care centers for the management of hearing loss is the most suitable and cost-effective approach [16,17]. A preliminary prediction tool designed for these centers could accurately identify individuals with high risk for targeted audiometric screening, thereby optimizing referrals and specialist resources. While previous models have been developed using known risk factors for hearing impairment, such as age, environmental noise [18], comorbidities [19], exercise, and nutrition [20], their clinical applicability is often limited by small sample sizes, a lack of external validation, and reliance on complex variables.

Therefore, this study aimed to develop a streamlined nomogram-based prediction model for ARHL among community-dwelling older adults, using a large sample derived from health check-ups conducted in primary health care institutions in Beijing, China. Additionally, the model was externally validated in 2 independent datasets. An online tool was used to deploy the model as an interactive application, enabling primary health care providers to perform risk prediction without requiring any software installation or programming expertise. This study adhered to the Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis guidelines [21].

Methods



Study Population

This multicenter retrospective cohort study used electronic health examination records from 3 community primary health care centers (center A, center B, and center C) in Beijing, China. Data were collected from older adults who participated in the annual health checkup under the National Public Health Service Project between January 1, 2020, and October 30, 2023. The dataset included comprehensive information on demographics, medical history, physical examination results, and chronic disease records. For this study, the dataset from center A, which had the largest sample size, was used for model development and internal validation, while data from center B and center C were used for external validation. A detailed study design and sample selection are shown in Figure 1.

From center A, a total of 20,923 patient records were initially screened. First, 3.94% (825/20,923) records with incomplete data were excluded. After subsequently excluding 0.26% (54/20,923) individuals with major ear conditions, 5.96% (1246/20,923) individuals aged younger than 65 years, and 0.43% (91/20,923) individuals with cognitive or neurological disorders, a final cohort of 89.41% (18,707/20,923) participants was included in the analysis. The external validation cohorts were derived from center B and center C. Initially, 11,454 records from center B and 5522 records from center C were screened. After applying the exclusion criteria, a total of 3.89% (446/11,454) participants were excluded from center B and 4.60% (254/5522) from center C. This process resulted in final validation cohorts of 96.11% (11,008/11,454) participants from center B and 95.40% (5268/5522) from center C.

Figure 1. Flowchart for hearing loss prediction model development and validation.

Assessment of Hearing Loss

The outcome variable for this study was hearing loss, which was assessed using the whispered voice test as specified by the standardized protocol in the National Basic Public Health Service Standards (Third Edition) [22], issued by China's National Health Commission. This screening was performed by trained primary health care professionals to ensure consistency across all centers.

Specifically, the whispered voice test, a widely recognized and validated screening tool, was used due to its simplicity, cost-effectiveness, and reliability in detecting hearing loss in clinical and community settings [23,24]. The protocol dictates the following procedure: the examiner stands approximately 0.5 m from the participant's tested ear, positioned slightly behind them to prevent lip-reading. The participant's nontested ear is occluded (blocked) by the examiner to isolate the tested ear. After a full exhalation, the examiner whispers a simple, standardized phrase (eg, What is your name?). Failure to correctly repeat the phrase was classified as the presence of hearing loss. For the purpose of our model, this binary outcome (presence vs absence of hearing loss) was used as the dependent variable [22].

Sample Size Estimation

The determination of an adequate sample size for a multivariate predictive model requires a sufficient representation of individuals and outcome events relative to predictor parameters [25]. The combined sample size from 3 primary health care institutions provided robust support for using 33 predictive variables in both modeling and validation. Specifically, according to the widely applied 10 events per variable principle, at least 330 events (33 variables×10 events) are required [26]. Given an event rate of 0.063, this translates to approximately 5239 cases. The modeling dataset comprised 18,707 cases and 1177 events, which is more than 3 times the minimum requirement of 330 events. This large number of events per variable provides sufficient statistical power and minimizes the risk of model overfitting.

Model Development and Validation

Variable selection was conducted using the least absolute shrinkage and selection operator (LASSO) regression, which applies a Least Absolute Deviations penalty to shrink some regression coefficients to 0, simplifying the model while preserving variables with strong predictive power. Tenfold cross-validation determined the optimal penalty parameter λ (λ_min), and variables with nonzero coefficients in the final model were chosen as candidate predictors [27,28]. Next, univariate analysis was performed on the LASSO-selected variables. Variables with P values <0.05 were considered for inclusion in the multivariate logistic regression model. A forward stepwise regression approach was applied to identify the final predictors to be included in the model. To handle missing data, a complete case analysis was used. This approach, which excludes records with any missing data on key variables, was considered appropriate because the proportion of such records was low across all cohorts (3.94% in center A, 1.62% in center B, and 1.68% in center C), consistently remaining below 5%.

Statistical analysis was performed using R software (version 4.2.2; R Foundation for Statistical Computing). To facilitate clinical application of the prediction model, we developed an interactive online application using the *Shiny* framework (RStudio, PBC). The final logistic regression model and coefficients were embedded into the server logic using the *rms* package to ensure consistency with the nomogram. A user-friendly interface was created with *Shiny*, *shiny Widgets*,

XSL•FO
RenderX

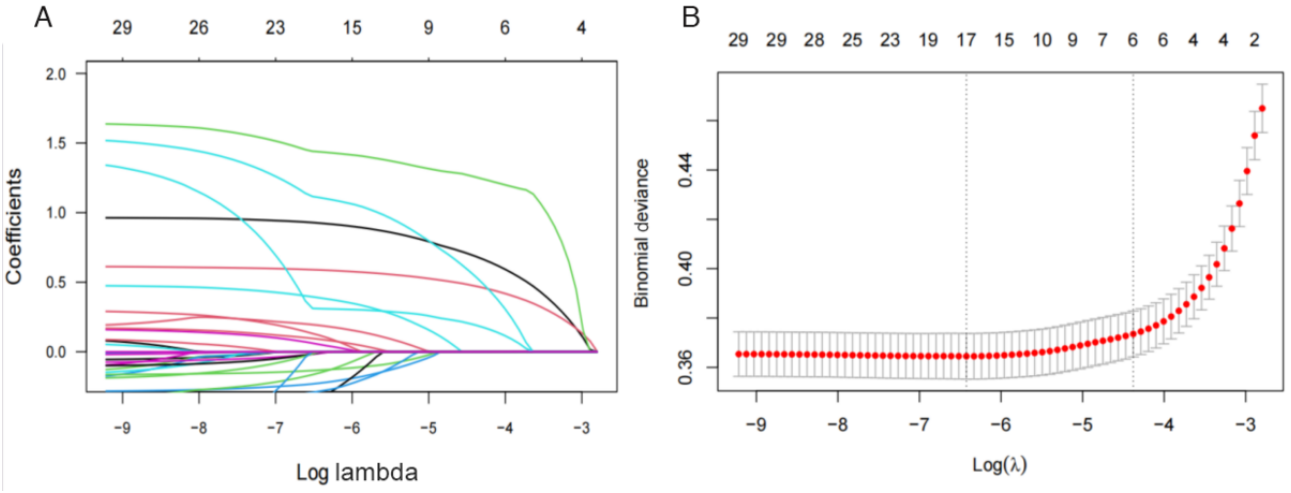
and *shiny themes* packages, allowing real-time input and calculation of predicted risk. Dynamic visualizations of individualized risk were implemented using *plotly*, providing immediate graphical feedback. The application was deployed on a cloud-based *Shiny* server to allow online access without requiring local installation.

Model validation included 3 aspects: discrimination, calibration, and clinical utility [29]. Discrimination was assessed using the area under the receiver operating characteristic curve (AUC), sensitivity, specificity, and Matthews correlation coefficient to evaluate the model's ability to distinguish between individuals with hearing loss and those without hearing loss. The calibration of the model was assessed using calibration plots generated through 1000 bootstrap resamples, in addition to the Brier score and mean absolute error, to evaluate the consistency between the predicted and actual observed hearing loss outcomes. Risk stratification strategy was based on the optimal cutoff value (the hearing loss risk probability when the Youden index is maximum, Youden=sensitivity+specificity−1) [30]. Finally, the clinical utility of the final model was evaluated using decision curve analysis.

Ethical Considerations

The study was approved by the ethics committee of Capital Medical University, Beijing, China (Z2024SY071). Informed consent was obtained from participants during routine health examinations, and no additional consent was required for this secondary analysis. All data were anonymized and securely stored with access restricted to the research team. No financial or other compensation was provided, as the data were derived from routine public health services.

Results



Population Characteristics

A total of 18,707 participants were included in the analysis in center A. Of these, 44.20% (8268/18,707) were male and 55.80% (10,439/18,707) were female, with a mean age of 72.89 (SD 7.15, range 65-99) years. A total of 6.29% (1177/18,707) participants were identified as having hearing loss, while 93.71% (17,530 /18,707) had normal hearing. The participants were then randomly divided into training (13,094/18,707, 70%) and internal validation sets (5613/18,707, 30%) in a 7:3 ratio. Additionally, 96.11% (11,008/11,454) and 95.40% (5268/5522) of participants were included from center B and center C, respectively, for external validation.

Model Development and Performance

The most significant features selected by LASSO from the training set were used to identify potential predictors for the model. The screening process is detailed in Figure 2. Initially, 33 variables were identified, guided by systematic reviews, meta-analyses, and expert clinical opinions. These factors encompass demographic characteristics, lifestyle factors, physiological measurements, and chronic diseases. The model's bias showed minimal variation within the interval (λ_{1se}, λ_{min}). When λ_{min} was set to 0.002 in the LASSO model, 17 variables exhibited nonzero coefficients, as shown in Table 1.

Figure 2. Feature selection using the least absolute shrinkage and selection operator (LASSO) regression. (A) The LASSO coefficient profile plot. Each colored line represents the coefficient path for 1 of the 33 candidate predictor variables as the regularization penalty (log lambda) increases. As the penalty grows, the coefficients of less important variables are shrunk toward 0. (B) Identification of the optimal penalization coefficient (λ) was achieved by 10-fold cross-validation and the minimum criterion. The left vertical line represents the mean square error, and the right vertical line represents the cross-validated mean square error within 1 SE of the minimum.

First, univariate analysis was conducted on the 17 variables identified through LASSO regression to evaluate their independent associations with hearing loss. The detailed results of this analysis, including odds ratios and *P* values for all variables, are presented in Table 1. The results indicated that age, education level, marital status, BMI, physical function, exercise frequency, dietary habits, smoking, alcohol consumption frequency, hypertension, left systolic blood pressure, and right systolic blood pressure were significantly associated with hearing loss.

Subsequently, a forward stepwise regression approach selected 6 predictors—age, education, exercise frequency, physical function, dietary habits, and hypertension—which were then included in the multivariate logistic regression model (Table 2). A user-friendly nomogram was developed, as illustrated in Figure 3. The optimal cutoff value was 0.805 based on the maximum Youden index. Accordingly, the population was classified into low (predicted probability <80.5%) and high (predicted probability≥80.5%) hearing loss risk groups. A comparison of the model's predicted risk classifications against the observed outcomes is presented in Table 3. For example, in the training set, of the 814 individuals, the model correctly identified 639 (78.5%) with hearing loss (true positives) and of the 12,280 individuals, 10,099 (82.2%) with normal hearing (true negatives), corresponding to the sensitivity and specificity values reported.

In the training set, the model achieved an AUC of 0.828 (95% CI 0.813-0.842), sensitivity was 0.785 (639 out of 814 participants who actually developed hearing loss were correctly predicted as high-risk), specificity was 0.822 (10,099 of the 12,280 participants who did not develop hearing loss were correctly predicted as low-risk), and balanced accuracy was 0.804. In the internal validation set, AUC was 0.806 (95% CI 0.782-0.831), sensitivity was 0.774, specificity was 0.820, balanced accuracy was 0.797, and Matthews correlation coefficient was 0.350.

Table 3. Comparison of model-predicted risk stratification and observed hearing loss across training and validation cohorts.

Predicted risk group	Observed hearing loss, n	Observed no hearing loss, n	Row total, n
Training set			
Model-predicted high risk[a]	639	2181	2820
Model-predicted low risk[b]	175	10,099	10,274
Column total	814	12,280	13,094
Internal validation set			
Model-predicted high risk[a]	281	946	1227
Model-predicted low risk[b]	82	4304	4386
Column total	363	5350	5613
External validation set A			
Model-predicted high risk[a]	87	1285	1372
Model-predicted low risk[b]	39	9597	9636
Column total	126	10,882	11,008
External validation set B			
Model-predicted high risk[a]	148	791	939
Model-predicted low risk[b]	89	4240	4329
Column total	237	5031	5268

[a]The model-predicted low-risk group was defined as predicted probability <80.5%.

[b]The model-predicted high-risk group was defined as predicted probability ≥80.5%. Percentages are omitted because row percentages and column percentages represent different concepts. Absolute counts and all marginal totals are provided to allow direct calculation of any desired proportion.

External Validation

In external validation set A, the AUC was 0.720 (95% CI 0.670-0.771), with a sensitivity of 0.690, a specificity of 0.882, a balanced accuracy of 0.786, and a Matthews correlation coefficient of 0.204. In external validation set B, the model achieved an AUC of 0.747 (95% CI 0.712-0.782), with a sensitivity of 0.624, a specificity of 0.843, a balanced accuracy of 0.734, and a Matthews correlation coefficient of 0.270. These results highlight the model's good predictive performance for identifying hearing loss in older adults. The receiver operating characteristic curves are shown in Figure 4.

The nomogram's calibration plots are shown in Figure 5. Quantitative metrics supported the visual assessment of calibration. In the external validation set A, the Brier score was 0.125 and the mean absolute error was 0.002. In the external validation set B, these values were 0.221 and 0.003, respectively. Lower Brier scores and mean absolute error values suggest that the model provides probability estimates close to the true risk, helping clinicians avoid unnecessary interventions for patients with low risk and missed diagnoses in patients participants with high risk.

Figure 6 presents the decision curves for the nomogram. The high-risk threshold probability represents the predicted probability of hearing loss, above which clinicians would consider routine audiometric screening and early interventions, such as lifestyle modifications. In the decision curve analysis plots for both cohorts, the model (red line) consistently demonstrated greater net benefit than the default strategies (treat all or none) across a conservative overlapping threshold range of approximately 5% to 75%. Using the model to guide ARHL prediction and implement routine screening and early interventions provided an additional net benefit of up to 20% compared with alternative strategies that assume all patients are either severely or nonseverely affected.

Visualization of Predictive Models: Development of a User-Friendly Web Page

To facilitate the clinical application of our nomogram, we developed an interactive and user-friendly web application using the R Shiny framework. The application features a simple, single-panel user interface where clinicians can input a patient's 6 predictor variables—age, education, exercise frequency, physical function, dietary habits, and hypertension—using a combination of numeric input fields and dropdown menus (Figure 7).

Upon clicking a *Predict* button, the tool instantly computes and displays the patient's predicted probability of hearing loss. The output is presented as a clear percentage, along with a corresponding risk stratification (*High risk* or *Low risk* based on the 80.5% cutoff) to aid in immediate clinical decision-making. The web application is publicly accessible and requires no software installation or programming knowledge, ensuring its broad utility for primary care providers [31].

Discussion

Principal Findings

The principal finding of this large, multicenter study is the development and external validation of a practical, 6-predictor nomogram for predicting hearing loss in community-dwelling older adults. Our model, which uses readily available data from routine health checkups (age, education, exercise frequency, physical function, dietary habits, and hypertension), demonstrated good discriminative ability (AUC>0.720 in all cohorts) and calibration.

A key clinical implication of this finding is the model's potential to shift primary care from reactive secondary screening to proactive primary prevention. The online tool, developed as a proof of concept, illustrates how this model could be integrated into clinical workflows. For example, if embedded within electronic medical record systems, it could provide real-time risk scores, creating a risk-stratified screening pathway. This would allow general practitioners to prioritize formal audiometry and targeted interventions for individuals at the highest risk, potentially improving the efficiency of health care resource allocation.

Comparison With Prior Work

Our risk prediction model incorporates demographic, lifestyle, and chronic disease factors, aligning broadly with previous studies. It is well established that age is strongly associated with hearing loss. Hearing decline along with aging is primarily attributed to progressive degeneration of cochlear sensory hair cells, stria vascularis, and spiral ganglion neurons, leading to impaired sound transmission [18,32]. Consistent with previous studies, we found a higher risk of hearing loss in individuals with lower education levels [33,34]. This may be attributed to its correlation with lower socioeconomic status [35], which can limit health care access and use, ultimately leading to poorer health status. Additionally, lower education levels are often associated with unhealthy lifestyle attributes (eg, smoking, alcohol consumption, and exercise habits) that were included in our model [36]. Interestingly, while recent studies have suggested a potential link between diabetes and hearing loss [37,38], our study did not identify a statistically significant association between the two. Instead, hypertension was included as a predictor in the model. It may contribute to hearing decline by reducing blood supply to the stria vascularis, a cochlear structure dependent on terminal arteries without collateral circulation [39,40].

Recent studies have focused on a prediction model for hearing loss. Ge et al [41] developed a logistic regression model for ARHL using 18 key factors based on 401 older adults. Their model achieved an AUC value of 0.777, and the sensitivity and specificity were 70.9% and 75.3%, respectively; however, due to limited sample size and absence of internal and external validation, further scrutiny is required regarding its predictive performance. Similarly, Wang et al [42] developed a predictive model comprising 22 features. While the model achieved an AUC of 0.864 and 0.844 during training and internal validation, the large number of variables and complex operation may hinder its clinical applicability and generalizability. Predictive models should strike a balance between performance and practicality, aiming to achieve the highest possible predictive accuracy with the fewest possible variables [43].

Strengths and Limitations

The primary strengths of this study include its large, multicenter sample, which enhances the robustness and generalizability of our findings, and a rigorous variable selection process. The resulting 6-predictor model is simple, and its variables are accessible from routine physical examinations without requiring specialized tests. Furthermore, the development of an online tool highlights its potential feasibility for real-world implementation. Finally, the selection of an interpretable *white-box* model (logistic regression) was a deliberate choice. While more complex *black-box* algorithms may offer marginal gains in accuracy, their lack of transparency is a significant barrier to clinical adoption. Our model achieves an optimal balance between its robust, externally validated performance and the essential need for interpretability, making it well suited for guiding real-world clinical decisions.

However, this study is not devoid of limitations. First, our study was conducted exclusively in primary health care centers within Beijing. While we attempted to mitigate this by validating across 3 distinct centers, the shared urban setting may influence the results by limiting the model's generalizability. Second, our model intentionally omits key risk factors such as genetic predisposition, long-term noise exposure, and ototoxic medication use. This was a necessary trade-off to create a practical tool based solely on variables routinely collected in health checkups. However, we acknowledge that the absence of these predictors may limit the model's accuracy in populations where such factors are highly prevalent. Third, hearing loss was assessed using the whispered voice test rather than pure-tone audiometry. To mitigate this, all professionals followed a standardized protocol. However, this method may influence the results by underestimating mild hearing loss and being subject to interexaminer variability. Fourth, several predictors (eg, physical function, exercise frequency, and dietary habits) were based on self-report, which may be prone to information bias and reduce predictive precision. Finally, as a retrospective cohort study, our analysis can suggest temporal relationships between exposures and outcomes but cannot establish definitive causal inferences due to potential confounding and selection biases.

Future Directions and Conclusions

Building on this work, several avenues for future research are recommended. The immediate priority is to validate the current nomogram in broader and more diverse geographic and demographic cohorts, using pure-tone audiometry as the gold standard outcome for a more precise assessment. Future prospective studies could also enhance the model's accuracy by incorporating key variables not available in our dataset, such as genetic predisposition, long-term noise exposure, and objective measures of physical activity. Finally, as the current online tool is a proof of concept, dedicated implementation research is required. This should address the practical challenges of integrating the tool into diverse electronic medical record

XSL•FO
RenderX

systems and evaluate its real-world impact on clinical decision-making, patient outcomes, and cost-effectiveness.

In conclusion, this study provides a validated, practical tool that shows promise for identifying older adults at high risk of hearing loss. If confirmed in future studies, this nomogram could become a valuable asset in the primary prevention of ARHL.

Acknowledgments

The authors would like to thank the study participants, as well as the nurses and general practitioners from the primary health care institutions, for their invaluable support. The authors gratefully acknowledge the financial support from the Beijing Municipal Social Science Foundation (23SRB007). The authors used the generative AI tool (Google Gemini), to assist with language editing and improve the text's readability. The authors take full responsibility for the final publication.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to patient privacy regulation but are available from the corresponding author on reasonable request.

Investigating the Association Between Mean Arterial Pressure on 28-Day Mortality Risk in Patients With Sepsis: Retrospective Cohort Study Based on the MIMIC-IV Database

Abstract

Background: Sepsis is a globally recognized health issue that continues to contribute significantly to mortality and morbidity in intensive care units (ICUs). The association between mean arterial pressure (MAP) and prognosis among patients with patients is yet to be demonstrated.

Objective: The aim of this study was to explore the association between MAP and 28-day mortality in ICU patients with sepsis using data from a large, multicenter database.

Methods: This is a retrospective cohort study. We extracted data of 35,010 patients with sepsis from the MIMIC-IV (Medical Information Mart for Intensive Care) database between 2008 and 2019, according to the Sepsis 3.0 diagnostic criteria. The MAP was calculated as the average of the highest and lowest readings within the first 24 hours of ICU admission, and patients were divided into 4 groups based on the mean MAP, using the quadruple classification approach. Other worst-case indications from the first 24 hours of ICU admission, such as vital signs, severity of illness scores, laboratory indicators, and therapies, were also gathered as baseline data. The independent effects of MAP on 28-day mortality were explored using binary logistic regression and a two-piecewise linear model, with MAP as the exposure and 28-day mortality as the outcome variables, respectively. To address the nonlinearity relationship, curve fitting and a threshold effect analysis were performed.

Results: A total of 34,981 patients with sepsis were included in the final analysis, the mean age was 66.67 (SD 16.01) years, and the 28-day mortality rate was 16.27% (5691/34,981). The generalized additive model and smoothed curve fitting found a U-shaped relationship between MAP and 28-day mortality in these patients. The recursive algorithm determined the low and high inflection points as 70 mm and 82 mm Hg, respectively. Our data demonstrated that MAP was negatively associated with 28-day mortality in the range of 34.05 mm Hg-69.34 mm Hg (odds ratio [OR] 0.93, 95% CI 0.92-0.94; P<.001); however, once the MAP exceeded 82 mm Hg, a positive association existed between MAP and 28-day mortality of patients with sepsis (OR 1.01; 95% CI 1.01-1.02, P=.002).

Conclusions: There is a U-shaped association between MAP and the probability of 28-day mortality in patients with sepsis. Both the lower and higher MAP were related with a higher risk of mortality in patients with sepsis. These patients have a decreased risk of mortality when their MAP remains between 70 and 82 mm Hg.

KEYWORDS

mean arterial pressure; 28-day mortality; sepsis; MIMIC-Ⅳ; retrospective study; Medical Information Mart for Intensive Care IV

Introduction

Sepsis is a life-threatening organ dysfunction caused by a dysregulated host response to infection [1-3]. While mortality from sepsis has decreased over time after age standardization, it remains high [2-6]. According to the Global Burden of Disease Study, 48.9 million cases of sepsis were reported worldwide in 2017, accounting for 11 million deaths [7]. Additionally, sepsis is the most expensive disease to treat in the United States, costing $23.7 billion annually and accounting for 6.2 percent of all hospital admissions [8]. In low-income nations with a

XSL•FO
RenderX

high sepsis burden, this cost could be significantly greater [9,10]. Sepsis has thus emerged as a serious public health concern with substantial global implications and economic cost.

Despite significant attempts to provide novel organ support strategies and identify the underlying etiology of sepsis, the mortality rate remains high [5,9]. Research indicates that early treatment of sepsis can improve prognosis [1,11]. Therefore, early detection of possible risk factors is crucial for patients with a poor prognosis [12]. Mean arterial pressure (MAP) is one of the most commonly used parameters for the evaluation of sepsis severity [13]. MAP is the driving pressure of tissue perfusion and plays a key role in maintaining the perfusion of tissue and organs. While autoregulation of regional perfusion may protect vital organs such as the brain or kidney from systemic hypotension, tissue perfusion becomes linearly dependent on arterial pressure below a certain MAP (approximately 60 mm Hg) [13]. However, the optimal range of MAP during sepsis resuscitation remains undetermined. The 2016 and 2021 SSC Surviving Sepsis Campaign guidelines recommend that MAP be maintained at ≥65 mm Hg in septic shock [14,15] for improving tissue perfusion and prognosis [14,15]. However, a study by Vincent et al [16] found that MAP did not have a linear relationship with ICU mortality, and several other studies have shown that increased MAP does not necessarily improve clinical outcomes in patients with sepsis or septic shock [13,17-22]. On the contrary, excessively high blood pressure may increase the incidence of adverse events [17].

Given that the appropriate blood pressure range is yet to be determined in patients with sepsis, and considering limitations in sample sizes, differences in study design, variability in covariate adjustments, and the heterogeneity of patient populations included in previous studies, it is necessary to study and identify the appropriate blood pressure range for patients with sepsis based on large databases. Therefore, our study aims to investigate the relationship between MAP and the 28-day risk of mortality in patients with sepsis using Medical Information Mart for Intensive Care (MIMIC-IV), a large sample of US sepsis databases, to identify the inflection point value associated with a lower 28-day risk of death in sepsis. This large sample size will provide more stable and reliable results, allowing us to gain a better understanding of the relationship between MAP and the 28-day risk of mortality in sepsis.

Methods

Study Design and Setting

This retrospective cohort study analyzed data from the MIMIC-IV database, including patients admitted to Beth Israel Deaconess Medical Center between 2008 and 2019.Our study complied with the RECORD (Research Reports Using Observational Routine Collection of Health Data) statement [23].

Participants

The study population comprised adult patients with sepsis identified through *ICD-9* (*99,591 - 99,592*) and *ICD-10* (*R652*, *R6520*, *R6521*) diagnostic codes. Inclusion criteria were patients aged ≥18 years and with a confirmed sepsis diagnosis. Patients lacking MAP data were excluded. Of the initial 377,207 records, 34,981 patients met the eligibility criteria and were included in the final analysis.

Data Collection and Variables

Data extraction was performed by certified researchers following standardized MIMIC-IV database procedures. The primary exposure variable, MAP, was calculated as the average of highest and lowest readings within 24 hours of ICU admission. While MAP values naturally fluctuate during the course of sepsis, we chose this approach to provide clinically actionable targets, acknowledging that a more complex time-varying analysis might capture additional nuances in the relationship between MAP and outcomes. MAP was analyzed both as a continuous variable and categorized into quartiles (Q1: 34.05 - 69.34 mm Hg; Q2: 69.34 - 74.94 mm Hg; Q3: 74.94 - 81.87 mm Hg; and Q4: 81.87 - 159.47 mm Hg). The primary outcome was 28-day all-cause mortality, recorded as a binary variable (1=death, 0=survival).

Covariates were selected based on clinical relevance and previous literature [3,24-26]: demographic characteristics (gender, age, and race), vital signs (heart rate, respiratory rate, and temperature), laboratory measurements (eg, lactate), disease severity indices such as Charlson Comorbidity Index, sequential organ failure assessment (SOFA) score, and acute physiology and chronic health evaluation (APACHE III score), therapeutic interventions (ie, mechanical ventilation, renal replacement therapy, corticosteroids, vasoactive drugs, immunoglobulin, and antibiotics).

Statistical Analysis

The analytical approach comprised three sequential steps. First, we constructed univariate and multivariate binary logistic regression models with progressive covariate adjustment: model 1 (unadjusted), model 2 (adjusted for demographics), and model 3 (fully adjusted for all covariates). Continuous variables were presented as mean (SD) or median (range), and categorical variables as frequencies (percentages). Second, we employed generalized additive models (GAM) with smooth curve fitting to evaluate potential nonlinear relationships between MAP and mortality. For identified nonlinear associations, we determined inflection points using recursive algorithms and constructed piecewise linear regression models. Third, we conducted sensitivity analyses using alternative outcome measures (30-day mortality), different MAP calculation methods (median values), and varying covariate selection approaches. All analyses were performed using R software (version 4.3.2; R Foundation for Statistical Computing) and Empower Stats software (X&Y Solutions, Inc. Boston, MA) [27], with statistical significance set at $P<.05$ (two-sided).

Missing Data Handling

Patients with missing values for any of the following key variables were excluded from the analysis: MAP measurements, age, SOFA score, lactate levels, and mortality outcomes. To assess potential selection bias, we compared the characteristics of included and excluded patients.

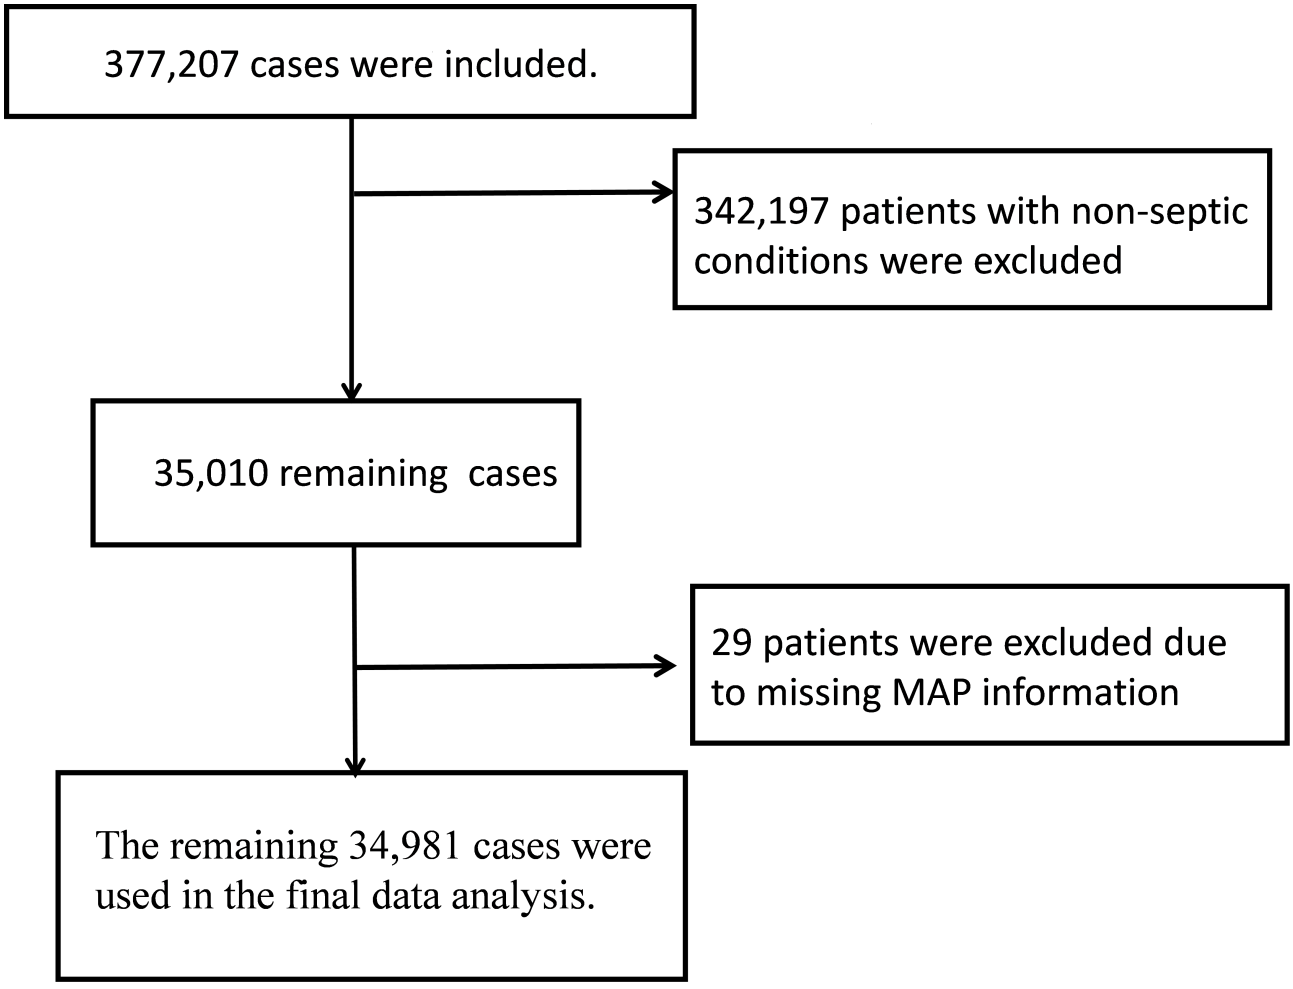
RenderX

Ethical Considerations



The study protocol received approval from the institutional review boards of Beth Israel Deaconess Medical Center (2001-P-001699/14) and Massachusetts Institute of Technology (0403000206). The data used in this study were obtained from the MIMIC-IV database, which is a freely accessible, deidentified public database [28]. Given the deidentified nature of the database, the requirement for informed consent was waived. Participants were not financially compensated, as the study used data from publicly accessible databases rather than data provided directly by participants.

Results

Study Population Screening

This study initially comprised 377,207 patients, of which 342,197 patients without sepsis and 29 patients lacking MAP data were excluded, with 34,981 cases remaining for final data analysis. The patient selection process is shown in the flowchart (Figure 1). Missing data were minimal (<5%, range 0 - 4.1%) across all variables. Given the low proportion of missing data, a complete case analysis was employed. The validity of this approach was confirmed by comparison of baseline characteristics between included and excluded patients, revealing no significant differences in key features.

Figure 1. The flowchart of study. MAP: mean arterial pressure.

Baseline Characteristics

Among the 34,981 included patients, 20,171 (57.66%) were men. The patients age was 66.67 (SD 16.01) years and the overall incidence of death within 28 days was 16.27% (5691/34,981). The patients' baseline characteristics are summarized in Table 1. Patients were divided into 4 groups based on MAP at admission. The distribution of intravenous immunoglobulin use did not differ significantly among the MAP subgroups (P=.09). Compared with the other three groups (Q2-Q4), patients in the Q1 group were older, had higher age, Charlson Comorbidity Index, SOFA scores, APACHE III scores, and lactate levels. They also had a higher frequency of renal replacement therapy, and use of norepinephrine, dopamine, dobutamine, cortisone, and antibiotics such as carbapenem, cephalosporin, and vancomycin. These characteristics, which are associated with poor prognosis, explain why patients in the Q1 group had the highest 28-day mortality rate. In contrast, as MAP increased from Q1 to Q4, age of the patient, severity of the disease, and the proportion of patients using relevant medications progressively decreased between groups. It may be a potential mechanism for the observed differences in 28-day mortality risk across MAP levels.

Relationship Between Mean Arterial Pressure and 28-Day Mortality

Univariate and Multivariate Analysis

We conducted univariate and multivariate analyses to investigate the relationship between MAP and 28-day mortality in patients with sepsis. Table 2 displays the results of the association between MAP and mortality in sepsis using various covariate adjustment strategies. In the nonadjusted model 1, each 1 mm Hg increase in MAP reduced the risk of 28-day mortality by 3% (odds ratio [OR] 0.97, 95% CI 0.971-0.974; *P*<.001). After adjusting for demographic factors such as gender, age, and White race, model 2 showed that the trend of OR was not altered (OR 0.97, 95% CI 0.97-0.98; *P*<.001). However, after adjusting for all covariables presented in Table 1, model 3 demonstrated that each 1 mm Hg increase in MAP resulted in a 1% decrease in the risk of 28 day-mortality (OR 0.99, 95% CI 0.99-1.00; *P*<.001). In model 3, the association between MAP and the probability of death in 28 days reduced to 1%, which was lower than the 3% decline seen in Models 1 and 2. This distinction was further explored and analyzed; we screened for covariates and discovered that SOFA score, age, and the Charlson comorbidity index had the greatest influence on the outcomes. The methodological rationale for this analysis was to include or exclude the effect of covariates on the regression coefficients of the main independent variables when constructing regression models. For example, in the unadjusted model, we included the main independent variable, MAP and found that the regression coefficient with the outcome was −0.0304. However, in the fully adjusted model, we added a number of covariates such as age, Charlson Comorbidity Index, SOFA score, and heart rate, the regression coefficient of MAP decreased to −0.0072 when these covariates were included (Multimedia Appendix 1). This implies that these factors “explain” or “mediate” the relationship between MAP and outcome to some extent. Specifically, age, Charlson index, and SOFA scores, which might reflect the patients’ baseline status and illness severity, contributed to the influence of MAP on outcome. This methodological aspect, namely the change in regression coefficients of the independent variables observed between the basic and full models, allows us to gain a deeper understanding of the complex link between independent factors and outcomes. It can help us uncover potential interactions or mediating effects that give a foundation

XSL•FO
RenderX

for understanding study findings. In addition, we performed a sensitivity analysis to verify the robustness of our findings by converting the MAP from a continuous variable into categorical variables (quartiles) and performing a trend test. The Q1 MAP was used as a reference; therefore, the same association was observed (P<.001) (Table 2).

Nonlinear Association Between MAP and 28-Day Mortality

We used smoothed curve fitting and GAM to evaluate the nonlinear relationship between MAP and 28-day mortality. After adjusting for all covariables listed in Table 1, our results demonstrated a U-shaped association between MAP and 28-day mortality with both low and high MAP associated with an increased risk of 28-day mortality (Figure 2). Furthermore, we employed a two-piecewise linear regression model and a recursive algorithm to determine the inflection points of MAP. The inflection points refer to points on the curve, where the curve transitions from falling to rising or rising to falling. Identifying these inflection points can help us better understand the complex relationship between MAP and 28-day mortality, as a single linear model may not fully capture this nonlinear relationship. We calculated the low and high inflection points at 70 and 82 mm Hg, respectively. When MAP was between 34.05 mm Hg and 70 mm Hg, the risk of 28-day mortality decreased by 7% for every 1 mm Hg increase (OR 0.93, 95% CI 0.92-0.94; P<.001). When the MAP was 70-82 mm Hg, there was no significant correlation (OR 1.01, 95% CI 0.99-1.02; P=.28). However, when MAP increased from 82 mm Hg to 159.47 mm Hg, the probability of 28-day mortality increased by 1% for every 1 mm Hg rise (OR 1.01, 95% CI 1.01-1.02, P=.002) (Table 3).

Subgroup Analysis

The interaction analysis revealed significant effect modification by hypertension status (*P* for interaction=.03) and heart failure status (*P* for interaction=.03) on the association between MAP and 28-day mortality (Table 4). In hypertensive patients, each 1 mm Hg increase in MAP was associated with a slightly stronger protective effect against mortality (OR 0.993, 95% CI 0.992 - 0.994) compared to nonhypertensive patients (OR 0.984, 95% CI 0.982 - 0.986). Conversely, in patients with heart failure, the protective effect was marginally attenuated (OR 0.989, 95% CI 0.988 - 0.990) compared to those without heart

XSL•FO
RenderX

failure (OR 0.995, 95% CI 0.992 - 0.997). The use of vasopressors did not significantly modify the association between MAP and mortality (*P* for interaction=.14), with similar protective effects observed in both vasopressor users (OR 0.988, 95% CI 0.984 - 0.992) and nonusers (OR 0.991, 95% CI 0.990 - 0.992). These findings suggest that the optimal blood pressure management strategy may need to be tailored according to patients' comorbidity profile, particularly in those with hypertension or heart failure.

[c]Model Heart failure adjusted for: gender; age at admission; ethnicity; Charlson Comorbidity Index; dexamethasone; IVIG, intravenous immunoglobulins; methylprednisolone; MV, mechanical ventilation; cortisone; SOFA, Sequential Organ Failure Assessment; glucocorticoids; cephalosporin; penicillin; respiratory rate; vancomycin; body temperature and the interaction terms for following variables: age at admission, dexamethasone, IVIG, SOFA, glucocorticoids, cephalosporin, vancomycin, body temperature.

Sensitivity Analysis

Our sensitivity trials yielded results that confirmed the robustness of our findings (Multimedia Appendix 2). The regression coefficient for MAP was –0.0068 (95% CI –0.0123 to –0.0013) when the endpoint was 30-day mortality. When the median was used, the regression coefficient for MAP was –0.0065 (95% CI –0.0118 to –0.0012). Following the exclusion of individuals receiving medication for hypertension, the MAP regression coefficient was –0.0070 (95% CI –0.0128 to –0.0012). Other covariate selection methods produced results that were comparable. These results support our main finding, which confirms that the chance of patient mortality is inversely correlated with the MAP in all conditions.

Discussion

Main Findings

We investigated the relationship between MAP and the 28-day risk of mortality in patients with sepsis using data from a large, multicenter retrospective cohort study in the United States. We found a nonlinear association between MAP and 28-day mortality using a GAM and a two-piecewise linear regression. The findings revealed a U-shaped connection, indicating that both high and low MAP was associated with an increased risk of 28-day mortality in patients with sepsis. We discovered that each 1 mm Hg increase in MAP below 70 mm Hg resulted in a 7% decrease in the 28-day risk of mortality. When MAP exceeded 82 mm Hg, the 28-day mortality risk increased by 1% for each 1 mm Hg rise. This implies that maintaining MAP between 70-82 mm Hg may help improve the outcome in individuals with sepsis. While previous studies, including the work by Zhong et al [29] have explored the relationship between MAP and sepsis outcomes using MIMIC-III data, our study extends these findings in several important ways. First, we used the updated MIMIC-IV database with a larger sample size (34,981 vs. 14,031), providing more statistical power. Second, we employed more sophisticated statistical methods, including GAM models and two-piecewise linear regression, which allowed us to identify specific inflection points. Most importantly, our study identified a precise optimal MAP range (70-82 mm Hg) for clinical practice, whereas previous studies were unable to determine such specific thresholds. These differences explain why our findings provide more detailed and clinically applicable guidance for MAP management in patients with sepsis. There is no substantial relationship between MAP and 28-day mortality in this range, and organ damage from hypoperfusion or hyper-perfusion can be avoided. This finding provides clinicians with a reference range that can help guide blood pressure management in patients with sepsis. Further, more clinical studies are needed to validate these findings. However, this study provides a valuable reference for optimizing blood pressure management in patients with sepsis.

XSL•FO
RenderX

Most previous studies have explored the effect of low MAP on the outcome in patients with sepsis; our study further discovered a U-shaped relationship with specific inflection points. Our findings regarding the lower MAP threshold (70 mm Hg) are consistent with several previous studies. In a single-center retrospective cohort study of 1395 patients with severe sepsis or septic shock, []the 28-day mortality rate with an average MAP<65 mm Hg was 39.7%, which was significantly higher than other groups [30]. Similarly, in another retrospective cohort study based on the MIMIC III database by Cao et al. [31], which included 14,607 patients with sepsis, it was found that a lower MAP was significantly associated with higher 30-day mortality rates, with the lowest inflection point at 68.6 mm Hg.

However, our study differs from previous research in several important aspects. First, we used more sophisticated statistical methods including GAM models and two-piecewise linear regression, enabling us to identify both lower and upper thresholds. Although previous studies comparing the effects of higher and lower MAP on sepsis outcomes have yielded negative results, our findings uniquely identified 82 mm Hg as a critical upper threshold, above which there is an increased risk of death [17,18]. This increased risk could be due to secondary damage caused by excessive workload on organs and ischemia-reperfusion injury [31,32].

We speculate that the disparities between our findings and previous studies can be attributed to several factors: (1) the populations studied were not identical; (2) we provided more comprehensive covariate adjustment, whereas previous studies did not adjust for potential confounders; and (3) our analytical approach using the GAM model allowed us to detect nonlinear associations that might have been overlooked in previous studies. Further research is needed to determine whether these findings can be applied across populations.

Strengths and Limitations

This study has several key advantages. First, we used data from the updated MIMIC-IV cohort, which provides a larger sample size and, consequently greater statistical power. Second, we adjusted for a broader set of covariate indicators and focused on treatment strategies that were more closely related to patient outcomes. To better determine the true relationship between MAP and mortality, we used a GAM and two-piecewise linear models, which are advanced algorithms. Furthermore, we calculated the U-curve and identified two inflection points that provided a safe MAP range associated with lower mortality risk. Third, as this study used a large number of sensitivity analyses, the results are more robust. More informative, supporting evidence for MAP monitoring and clinical decision-making based on this metric is provided through this study.

Several limitations of this study should be noted. First, our findings are based solely on the MIMIC-IV database, which predominantly includes patients from a single geographic region and may not be representative of other populations. Given potential racial and ethnic differences in cardiovascular responses and outcomes, external validation of our findings in different 17 populations, particularly among Asian populations including Chinese patients, would be valuable. Such validation studies could help establish whether the optimal MAP range identified in our study is universally applicable or needs to be adjusted for different populations. Second, while we adjusted for measurable confounders, we could not account for unmeasurable confounding. Additionally, due to substantial missing data in lactate measurements, we were unable to conduct subgroup analyses based on lactate levels. This limitation prevents a deeper understanding of how the optimal MAP targets might differ among patients with varying degrees of tissue hypoperfusion, as indicated by lactate levels. Third, as this was an observational study, and therefore, inherently constrained, we could only observe relationships rather than evaluate causality.

Conclusion

There is a U-shaped association between MAP and the mortality risk in patients with sepsis. Both increases or decreases in MAP are linked to increased mortality risk. Our findings suggest that patients with sepsis have a lower risk of death when their MAP is maintained between 70-82 mm Hg.

Acknowledgments

The manuscript's English language quality was enhanced using AI-assisted proofreading tools, while maintaining the original content and meaning. This study was supported by the grants from National Natural Science Foundation of China [82160365]. This manuscript utilized AI tools exclusively for language enhancement and proofreading purposes. The intellectual content, research design, analyses, and conclusions were entirely conceived and executed by the authors.

Additionally, we confirm that one of our co-authors, LC, has completed the required human subjects training and obtained access to the MIMIC-IV database by signing the Data Use Agreement.

Abstract

Background: The emergence of problematic digital use is increasingly alarming, affecting between 7% and 20% of the world's adolescent population. However, there is no validated questionnaire in French to measure this. Only a few questionnaires, either self-reported by adolescents or hetero-reported by parents, have been translated and validated in English.

Objective: This study aims to translate into French the Digital Addiction Scale for Children (DASC), which is self-reported by adolescents, and the Problematic Media Use Measure (PMUM), which is hetero-reported by parents of adolescents.

Methods: We used the "forward and backward" method to establish the translation and achieve cross-cultural adaptation with 8 parents and 8 adolescents aged between 12 and 17 years. There were three stages: (1) initial translation and synthesis or reconciliation of the translations phase; (2) back translation and expert committee phase; and (3) pretesting phase, during which 8 parents completed the PMUM questionnaire and 8 adolescents completed the DASC questionnaire.

Results: Despite slight variations in translation for both questionnaires, the translators quickly reached a consensus during the translation phase. The expert committee did not propose any other conceptual changes. In the final phase, the parents made no comments to improve the questions or the wording. Although some adolescents mentioned repetition between certain questions, they did not suggest any improvements to the DASC questionnaire in French.

Conclusions: Although the translated versions of the DASC and PMUM questionnaires provide a foundation for detecting problematic digital use, they require further validation studies to confirm their reliability and applicability in the French adolescent population.

KEYWORDS

internet addiction; screen time; questionnaire and surveys; translations; adolescents; mobile phone

Introduction

While smartphones make it easy to be entertained anywhere, computers, tablets, and video game consoles can also be a source of entertainment with negative impacts on health [1-3]. Meng et al [4] determined that 26% of the world's population have problematic use of smartphones and 16% have problematic use of social networks. Internet gaming disorder, recognized in the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*) [5], affects 6% of the population, rising to 22% of French adolescents [4].

Today, there is no consensus for defining digital addiction, but some researchers agree to say that, as a behavioral addiction, it is characterized by intensive use of all types of digital content with difficulty in self-regulation [4]. This implies difficulty in being aware, planning, controlling, and evaluating its limits regarding this use, both in time and in content [4,6]. We will refer to this as problematic digital use (PDU). Among the consequences of the PDU, we find that major exposure to television or video games has deleterious effects on students' attitudes toward school and is even linked to poorer academic performance [7,8]. In addition, this type of use is known to be linked to a lower sleep quantity and sleep quality [9,10], a more sedentary lifestyle [11], lower self-esteem, and more anxiety-depressive symptoms [10,12].

XSL•FO
RenderX

To estimate the prevalence of PDU, questionnaires are most often used in research, and some of them have already been validated in several countries and with several age profiles. To measure problematic smartphone use, we have identified 3 scales already validated in French. The first is the Internet Addiction Test (IAT)–smartphone [13] and is strongly inspired by the IAT developed by Young [14]. The second scale, Smartphone Addiction Scale short version [15], comprises 10 items and is based on the 6 symptoms present in the *DSM-5* to assess internet gaming disorder [5], such as loss of control or disruption of family. A final scale, Problematic Mobile Phone Use Questionnaire by Lopez-Fernandez et al [16], measures the same problem with 15 items divided into 3 dimensions: dangerous use, forbidden use, and dependent use of the smartphone. Three other questionnaires were translated and validated in French to assess problematic internet use. The IAT [17] has been validated on medical students, the Compulsive Internet Use Scale [18] is intended for adults, and the Generalized Problematic Internet Use Scale-2 [19] targets a general student population. Finally, the only questionnaire that measures problematic video game use in French is the Internet Gaming Disorder-20 [20], which has been validated with 20 items divided into 6 categories: salience, mood, tolerance, craving, conflict, and relapse.

To date, there exists no validated scale in French for quantifying digital addiction, and no measure has specifically addressed the adolescent population. However, adolescents are robust consumers of diverse digital content, perceiving it as a means to satisfy their autonomy needs and identity development, and to establish or maintain interpersonal connections [21,22]. While short-term benefits are highly valued by young people, the costs of intensive use are significant, leading to more risky behaviors, lower self-esteem, depressive symptoms, and suicidal ideation [23,24]. PDU can significantly alter the development of adolescents by causing neuronal dysfunctions in subcortical, frontal, and parietal areas involved in attention and behavioral control [21].

To measure PDU in adolescents, the English scale by Hawi et al [25], the Digital Addiction Scale for Children (DASC), is a promising tool. The scale is based on the 9 criteria recognized for diagnosing internet gaming disorder in the *DSM-5*. An existing alternative or complementary solution involves asking parents to assess their adolescents' PDU. Domoff et al [26] proposed a questionnaire in 2 versions: the final versions of the Problematic Media Use Measure (PMUM; 27 items) and the PMUM Short Form (9 items). The PMUM has been validated in English and considers the 9 criteria of the *DSM-5* for internet gaming disorder. Although translated into English and Arabic, it has never been translated into French.

Whereas most questionnaires measure specific device use (eg, smartphone) [13,15,16], this study aims to better measure PDU in the French adolescent population by linguistically translating 2 questionnaires: the DASC, administered to adolescents, and the PMUM, administered to parents of adolescents. The translation process was carried out using the "forward and backward" method.

Methods

Ethical Considerations

This study was approved by the Grenoble Alpes University Hospital Center and has received ethics approval from the South-East I Ethics Committee for the Protection of Individuals (approval 2022-A01943-40). The collected data were anonymized throughout the analysis process, in compliance with the MR003 methodology approved by the National Commission on Informatics and Liberty. For minor participants, consent to participate was obtained from the teenagers and their parents. Adult participants gave their own consent. Furthermore, no compensation was provided to the participants.

Cross-Cultural Adaptation Procedure With the "Forward and Backward" Method

Overview

We assessed the conceptual equivalence of the 2 questionnaires following the recommendations of Epstein et al [27] and used the most commonly adopted technique for cross-cultural research: the "forward and backward" method. Conceptual equivalence—evaluating whether items in the original language have a similar meaning in French—was emphasized by systematically analyzing item, semantic, idiomatic, operational, and experiential equivalence [28].

The forward and backward method is divided into 3 main phases of analysis, which we describe below.

Initial Translation and Synthesis or Reconciliation of the Translations Phase

We recruited 4 independent translators who are native French speakers and bilingual in English to translate the original French version. Two of the translators were familiar with the concept of PDU in their professional activities, while the other 2 did not work with this concept. From the 4 translations, the translators reconciled their differences to produce a single unified version.

Back Translation and Expert Committee Phase

The French version was back translated into English by a native English speaker to verify the accuracy of the translation and highlight any confusing wording. Then, 2 expert researchers familiar with the concept of PDU evaluated the equivalence of the questionnaire by comparing the back translated version with the original version. They proposed modifications to the items in French if necessary.

Pretesting Phase

We carried out a preliminary pilot study with adolescent participants and parents to assess the clarity, intelligibility, and acceptability of the French translations. The sampling was conducted using a convenience method through calls for participation in schools and libraries. A call for participation was shared during conference activities that we led about digital addiction. Participant criteria were specified to select specific settings such as age and region. Adolescents and parents responded to the call if they agreed to participate. Between December 2022 and June 2023, a total of 8 parents completed the PMUM questionnaire, and 8 adolescents aged between 12

XSL•FO
RenderX

and 17 years completed the DASC questionnaire. Accompanied by a student observer who cross-checked information to minimize interpretation biases, the principal researcher spoke with the participants, who gave their opinions on the questionnaires and assessed whether the questions were relevant to their age group. To categorize participants' feedback, we conducted a qualitative thematic analysis by manually coding their comments into four categories: (1) linguistic incomprehension, (2) linguistic ambiguity, (3) suggestions for modification, and (4) redundancies.

The protocol consisted of an individual interview with each participant, who completed the questionnaires. Each interview lasted a maximum of 30 minutes.

Instruments

The DASC questionnaire designed by Hawi et al [25] is composed of 25 statements distributed across 9 dimensions taken from the *DSM-5* video game addictive disorder criteria [5]: preoccupation in daily life, tolerance, withdrawal symptoms, mood changes, social and psychological consequences, relapses, physiological problems, deception regarding its use, and family disconnection. In the absence of the original online guideline that introduces the questionnaire to the participants, we took inspiration from the PMUM scale [26] by specifying that we want to capture adolescents' experiences with their screens (ie, television, video games, tablets, smartphones, portable game consoles, laptops, or computers). The adolescent must reflect on his or her experiences over the past year. The response scale ranges from 1=never to 5=always, and the total score can vary from 25 to 125.

The PMUM questionnaire is composed of 27 statements and was designed by Domoff et al [26], who based the instrument on the diagnostic criteria for online gaming addiction disorder in the *DSM-5* [5]. The guideline consists of asking parents how their child uses screens (ie, television, video games, tablets, smartphones, portable game consoles, laptops, or computers). For each statement, they select the option that is true for their child during the last year. For each question, the response scale is from 1=never to 5=always; the total average score on this scale can vary from 1 to 5.

Data Analysis

Data were analyzed using a qualitative approach with the forward and backward method, involving iterative interpretation of the interview responses. Descriptive statistics were conducted on the sample characteristics, such as age and gender. The qualitative analysis focused on identifying 4 key themes from the interviews.

Results

Characteristics of the Translators and the Participants

The age, gender, and specific cultural characteristics of the translators, the parent and adolescent participants are detailed in Table 1

XSL•FO
RenderX

Table . Age, gender, and cultural characteristics of the translators and the participants.

Step and participants	Age (years), mean (SD; range)	Gender	Cultural characteristics
Forward translation			
4 translators	25.5 (4.51; 20-31)	2 women and 2 men	• 2 native English speakers and 2 native French speakers • 2 were familiar with the concept of problematic smartphone use (eHealth and psychology) • 2 were not familiar with the concept (economics and education) • 2 were from the south and 2 from the north of France
Backward translation			
1 translator	28	1 woman	• Native English speaker • No clinical or medical expertise
Linguistic verification			
2 experts	27.5 (4.95; 24-31)	1 woman and 1 man	• 2 native French speakers
Final verification			
8 parents	43.1 (2.59; 40-48)	4 women and 4 men	• Good health and not experiencing any severe medical conditions • 2 from rural areas and 6 from urban areas in France
8 adolescents	13.8 (1.83; 12-17)	6 girls and 2 boys	• Good health or enduring any medical condition • 3 from rural areas and 5 from urban areas in France • 6 from middle school and 2 from high school

Forward Translation

Four translators translated the titles, dimensions, guidelines, response categories, and statements of the 2 questionnaires. The 4 proposals were grouped to arrive at a consensual version. Although the titles, response categories, and guidelines did not pose a translation problem, there was less consensus on some dimension names. This mainly concerns the "withdrawal" dimension present in the 2 questionnaires, which has ultimately been translated as "sevrage." The second, more problematic dimension to translate was that of the DASC scale: "displacement." In the context of behavioral addiction, displacement corresponds to the implementation of intense or compulsive displacement behaviors when an individual is in a stressful situation [29]. We opted for the "déplacement" term that is adapted and used in French [30]. Similarly, for the DASC scale, although "device" is generally translated in French as "appareil," we opted for "écrans" to better suit the context. For item 15, "enjoyable" offered multiple translation options, we translated it as "amusant" to adapt it to our context. For item 20, "I check my device…" had 4 different translations among the 4 translators as "to check" has a wide range of relevant translations. Therefore, we decided to translate it as "vérifier" even though it is not the most common word among all translation options, but as it is the most close translation from the original sentence without impacting the overall item meaning and conveying an intentional and repeating action. For item 25, "grades" was translated by "notes scolaires" as the raw translation "notes" would add too much ambiguity on the overall item.

For the PMUM questionnaire items, 23 of them were very similar between the 4 translations. Four items varied slightly for 1 or 2 translators. For instance, for item 10, the term "enjoys" offered multiple translation options; to achieve both semantic and idiomatic equivalence, we chose "apprécier," resulting in: "Il n'y a rien que mon enfant n'apprécie autant que les écrans." In 2 items, the term "amount of time" lacks a direct French equivalent. To preserve the operational and semantic meaning, we chose "la quantité de temps" for item 13 and "des périodes de plus en plus longues" for item 14. In item 22, the ambiguous term "sneaks" was resolved as "en cachette."

As for the DASC questionnaire items, 22 reached consensus, and 3 items varied slightly for 1 or 2 translators. Although "device" is typically rendered as "appareil," we selected "écrans" for better contextual equivalence. For item 15, to

XSL•FO
RenderX

capture the intended semantic nuance of "enjoyable," we chose "amusant." In item 20, given the wide semantic range of "to check," we opted for "vérifier" to best preserve the original meaning and indicate a repeated action. Finally, for item 25, "grades" was translated as "notes scolaires" to avoid ambiguity and ensure semantic clarity.

Backward Translation and Linguistic Verification

After the questionnaires were translated from the consensus version into English by the native English translator, we observed that all 21 out of 27 items of the PMUM questionnaire and all 25 items of the DASC questionnaire were accurately retranslated into English. For the PMUM questionnaire, some formulations or terms varied but did not modify the meaning of the items. One item's semantic meaning was strongly altered during the back translation: "My child attempts to use screen media for increasing amounts of time." was retranslated as "My child keeps using screens for longer periods." At the semantic level, this back translation does not reflect the intention of using the screen more and more—as covered by the initial item. Consequently, we modified the French item translation to better capture the original meaning of the item.

After these modifications, 2 researchers reread the latest French translation during a final professional translation step. No suggestions or conceptual modifications were proposed for the 2 questionnaires.

Final Verification

The final versions of the PMUM and DASC questionnaires were delivered to adolescents and parents in the pilot study. The 8 parents had no comments for improvement for any of the items or the statements, including linguistic incomprehension, linguistic ambiguity, suggestions for modification, or redundancies.

Although some adolescents noted repetitive phrasing (redundancies) across items addressing withdrawal symptoms—for example, items 12 and 21 use "frustrated" while items 3 and 8 use "upset," reflecting potential linguistic ambiguity—the expert team determined that these repetitions were essential for capturing subtle distinctions in behavior and experience, ensuring a comprehensive assessment of the construct, even if the phrasing occasionally feels redundant to adolescents, because "frustrated" and "upset" have close semantic meaning in French. No linguistic incomprehension was reported at this stage, and this feedback did not lead to suggestions for modification of the 25 items of the DASC questionnaire. The final translated versions are listed in Multimedia Appendix 1.

Discussion

Principal Findings

We effectively conducted a cross-cultural adaptation of 2 original questionnaires into French to measure PDU among adolescents. These questionnaires are intended to be filled out by adolescents themselves (DASC) or by their parents (PMUM). Although the DASC and PMUM questionnaires were originally validated in children aged 9 - 12 and 4 - 11 years, we applied these instruments to adolescents aged 12 - 17 years. One of the advantages of considering these 2 questionnaires is that, given that PDU in adolescents may manifest as extreme resistance to limits imposed by parents, leading to significant intrafamilial conflicts, questioning parents in addition to adolescents provides valuable information to better understand the extent of PDU. To make these questionnaires accessible in French, we translated them from English using the forward and backward method by following the 3 stages of translation of the method recommended by Epstein et al [27] and that has already been used for prior related French translations [31]. The conceptual equivalence of the French questionnaires was close to that of the English questionnaires. Regarding our results, neither parents nor adolescents encountered major difficulties in understanding the items, and experts recognized that the final translations were equivalent to the original questionnaires. Limitations include the small sample size, although the minimum number of participants for linguistic validation is not clearly defined [28], and the lack of validation. Further studies are required to validate these translations in larger populations and confirm their psychometric properties, particularly since adolescents reported that some items of the DASC questionnaire were redundant. Although other cross-cultural adaptations studies incorporated additional steps, such as confirmatory and exploratory factor analyses, to examine the instrument's internal structure and reliability in a simulated clinical setting [32-34], our study did not include these analyses. Yet, as the DASC questionnaire aims to assess PDU—a construct that is not directly observable and is composed of multiple dimensions such as tolerance, withdrawal symptoms, and overuse or physical and psychological consequences—future research should further investigate its structure validity. Additionally, researchers will need to assess the convergent validity of the questionnaires by showing that the scores obtained from the 2 translated questionnaires are positively correlated with other similar or closely related measures. These questionnaires can also be supplemented by objective and passive measurements derived directly from digital tools [35]. The last step will consist of evaluating the reliability of the questionnaires about their consistency and stability with longitudinal test-retest analyses.

These questionnaires, validated in French, will be useful in research to make intercultural comparisons in PDU demographics. Additionally, they can be used for professional purposes as part of medical or psychological care to detect PDU among adolescents.

Conclusions

This study enabled the effective cross-cultural adaptation of 2 questionnaires on the PDU of adolescents into French.

This study revealed that parents and adolescents easily understood the items, and experts confirmed the final translations' equivalence with the originals. Once validation of the questionnaires in French is completed, these 2 questionnaires can be used in French-speaking regions to screen or measure PDU among adolescent populations. Limitations of this research include the small sample size and the lack of psychometric validation, which are necessary to establish the reliability and validity of the translated questionnaires.

XSL•FO
RenderX

This study provides a questionnaire enabling adolescents to assess their own digital addiction (DASC), and another on parents' perceptions of their children's use (PMUM), which will enable the research community to better detect or assess the prevalence of the PDU in the French adolescent population.

Acknowledgments

This study would not have been possible without the support of Université Grenoble Alpes, Grenoble Alpes University Hospital Center, and Linksium (Society of Technology Transfer and Startup, Grenoble Alpes). This work was partially funded by MIAI (Multidisciplinary Institute in Artificial intelligence) Cluster (ANR-23-IACL-0006) and the French National Research Agency (Agence Nationale de la Recherche) within the framework of the "Investissements d'avenir" program (ANR-10-AIRT-05, 2012; ANR-15-IDEX-02, 2016). The funders played no role in this study's design, data collection, analysis, and interpretation of data, or writing of this paper. We used OpenAI's generative artificial intelligence tool, ChatGPT [36], to perform semantic reformulations to improve the overall quality of the English and to better understand the reviewers' expectations during the peer review process. The original ChatGPT transcripts are provided as Multimedia Appendix 2.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to confidentiality considerations but are available from the corresponding author on reasonable request.

Authors' Contributions

IEB collected data, reviewed and assessed the results, wrote the original draft, wrote and reviewed the revised version of this paper, and acquired funding. MR collected, analyzed, and interpreted data; wrote the original draft; wrote and reviewed the revised version of this paper; and acquired funding. AB conceptualized and designed this study, reviewed and assessed the results, and wrote and reviewed the revised version of this paper. NV conceptualized and designed this study, supervised the project, reviewed and assessed the results, wrote and reviewed the revised version of this paper, and acquired funding. Abstract

Background: In the United States, transgender, nonbinary, and gender diverse (TGD) young adults experience a higher risk of depression compared to their cisgender peers. Understanding factors associated with increased risk of depression within the TGD young adult population is important to guide clinical care as well as inform the development of interventions to reduce mental health disparities.

Objective: This exploratory study investigated the prevalence and correlates of positive screening for depressive symptoms among TGD young adults to inform the design, development, and implementation of national interventions aimed at improving mental health in this at-risk population.

Methods: In August 2022, a cross-sectional, nationwide online survey was conducted among TGD young adults aged 18 - 25 (N=104) in the United States. Measures included sociodemographic variables, family characteristics, mental health care utilization, and the two-item Patient Health Questionnaire-2 (PHQ-2) screener for depression. Poisson regression models with robust variance estimation were fitted to estimate adjusted prevalence ratios (aPR) and 95% CI for correlates of PHQ-2 depression (score ≥3).

Results: The study sample had a mean age of 22 (SD 2) years; 48/104 (46%) individuals identified as Black, Indigenous, or other People of Color, and 69/104 (66%) were nonbinary. Overall, 44 (42%) individuals screened positive for depression using PHQ-2. In a multivariable model adjusted for age, race and ethnicity, US census region, and health insurance status, factors associated with increased depression prevalence using PHQ-2 included low versus high family support (aPR 1.54, 95% CI 1.05 - 2.27) and identifying with a nonChristian religion versus being unaffiliated (aPR 1.66, 95% CI 1.04 - 2.63). Factors associated with reduced depression prevalence included living in a rural versus suburban area (aPR 0.48, 95% CI 0.26 - 0.92) and receiving mental health therapy versus not (aPR 0.71, 95% CI 0.53 - 0.97).

Conclusions: The high prevalence of depressive symptoms among TGD young adults in this study sample highlights the need for comprehensive mental health evaluation and support in this population. Depression risk is increased among certain subgroups, such as those with low family support. These findings are valuable in informing the development of interventions that aim to improve mental health outcomes among TGD young people.

KEYWORDS

transgender; depression; preventive screening; young adult; LGBTQ+; nonbinary; gender minority; gender diverse; mental health; prevalence; cross-sectional; survey; questionnaire; nationwide; USA; United States; North America

Introduction

In the United States, major depression is a leading cause of morbidity and mortality, affecting an estimated 21 million adults aged ≥18 years (8.3% of all US adults) [1,2]. It is most prevalent among young adults aged 18 - 25 (18.6%) [3]. The peak incidence of depression occurs between ages 12 - 25 years, and 1 in 5 adolescents (20.1%) aged 12 - 17 in the US has had at least one major depressive episode, highlighting the importance of early detection and intervention efforts [3,4]. The US Preventive Services Task Force recommends routine preventive screening for depression among the general adult population aged ≥18 years in primary care settings, using tools such as the Patient Health Questionnaire (PHQ) to identify individuals who should be further evaluated for depression and facilitate appropriate referrals to mental health services [5-7].

Transgender, nonbinary, and gender diverse (TGD) young adults in the United States have a two- to four-fold higher risk of major depression [8] and are more likely to screen positive for clinically elevated depressive symptoms relative to their cisgender counterparts [9]. For example, in a national random sample of 65,231 college students drawn from 71 US college campuses, the prevalence of past 2-week depression using PHQ-9 was 57.8% for TGD young adults compared to 28.4% for cisgender young adults [9]. Other studies report similarly high prevalence rates of past 2-week elevated depressive symptoms, which vary depending on the screening instrument used and specific age range sampled: 56.7% (PHQ-9 depression in a clinical TGD sample aged 13 - 20 y) [10], 57.9% (two-item Patient Health Questionnaire, PHQ-2 depression in a representative school-based sample of TGD 9th and 11th graders in Minnesota) [11], and 75% (PHQ-2 depression in nonprobability online sample of 5753 TGD young people aged 13 - 24 y) [12]. Additional research is needed to understand factors associated with screening positive for depression among TGD young people, particularly using brief instruments appropriate for universal screening in clinical settings. Identifying TGD young people at increased risk for depression may facilitate more effective clinical care and inform the development of interventions to address mental health disparities.

Sociodemographic differences in depression prevalence based on gender identity and race or ethnicity have been inconsistent across studies among TGD young people [13], although nonbinary individuals reported consistently high rates of depression [9]. Other sociodemographic factors, such as geographic region and urbanity, are also important to consider, particularly in the context of legislation restricting elements of care for TGD populations. Several studies document the adverse negative health impacts of antitransgender legislation, even among TGD people who do not live in states with active or pending legislation [14]. While family support is protective for TGD mental health [15,16], other family-related factors, such as religiosity, necessitate further exploration [11], particularly since TGD young people have reported mixed quantitative findings on religiosity and mental health [17], and attitudes toward TGD people may differ by religious affiliation [18,19]. Additionally, both current utilization of mental health services and a history of seeking resources or information about mental health services may be relevant for future intervention implementation for TGD young adults. Consistent with a transformative paradigm in mental health that emphasizes early prevention and intervention of emerging mental health disparities in individuals aged 12 - 25 years [20], patterns of adolescent help-seeking may persist into young adulthood. Some TGD young people may have sought mental health information, while others may not have, highlighting the need to better understand whether help-seeking behaviors differ between those with and without depression. This knowledge can inform targeted intervention strategies to reach those who may need help.

This exploratory study sought to investigate the prevalence and correlates of depression using PHQ-2 in a nationwide US sample of TGD young adults to understand factors associated with increased risk of depression among TGD young people and to inform the development of interventions aimed at reducing mental health disparities in this population.

Methods

Setting

In August 2022, a cross-sectional survey was conducted with a nationwide US sample of young adults recruited and enrolled through Prolific, a survey platform that hosts a diverse panel of adults aged ≥18 years. The survey was conducted as part of TransHealthGUIDE, a National Institutes of Health (NIH)-funded project (U01MH136558) aimed at designing and implementing strategies to address mental health disparities among TGD young adults. Early in-depth key informant interviews with TGD young adults, caregivers, and health care providers identified the need to better understand the context of depression among TGD young adults. Specifically, the interviews highlighted the need for further information on the characteristics of TGD young adults with and without depression, the role of family, mental health service utilization, peer support, and recalled help-seeking behaviors in adolescence. This exploratory self-reported survey was developed as an extension of the key informant interviews and was designed to expand upon and quantify each of these factors for intervention development.

Participants

Eligibility criteria included: age 18 - 25 years, TGD identity (self-identifying as TGD or having a gender identity different from sex assigned at birth), and US residency. The sample was

XSL•FO
RenderX

stratified to enroll approximately 50 Black, Indigenous, and People of Color (BIPOC) people and 50 White young people. A total of 104 individuals were surveyed; additional details on survey methodology can be found elsewhere [21].

Assessments

PHQ-2 Depression Status

The psychometrically validated PHQ-2 assessed the frequency of depressed mood and anhedonia over the past two weeks [22]. The two items were (1) "little interest or pleasure in doing things" and (2) "feeling down, depressed, or hopeless." The response options were 0=not at all, 1=several days, 2=more than half the days, 3=nearly every day. The two items were highly correlated (r=0.81; P<.001) and summed. Scores ranged from 0 - 6, and a score ≥3 was considered a positive screen for depression, based on a previously validated threshold for screening for major depression (sensitivity: 83%, specificity: 92%) [22].

Sociodemographic Variables, Family Context, Mental Health Services, Peer Support, and Mental Health Help-Seeking in Adolescence

Sociodemographic variables included age in years (continuous and categorized: 18 - 20, 21 - 23, 23 - 25), race or ethnicity (ie, BIPOC monoracial, BIPOC multiracial, White), gender identity (ie, transgender men, transgender women, nonbinary), US Census region (ie, Northeast, Midwest, South, West), geographic context (ie, urban, suburban, rural), health insurance status (ie, private, public, both, none), and self-identified religion (eg, Agnostic, Atheist, Baptist, Buddhist, Catholic, Christian, Evangelical Protestant, Hindu, Jehovah's Witness, Jewish, Latter-day Saint or Mormon, Mainline Protestant, Muslim, Orthodox Christian, Pagan, Sikh, Spiritual but not religious, Unitarian/Universalist, Unaffiliated, Other, not applicable; coded as Christian, not Christian, unaffiliated, more than one religion, or not applicable).

Family-related variables included family support, assessed using the question: "How much trouble did your parents or caregivers have accepting your gender identity?" Responses were coded as high family support (none/a little), low family support (a moderate amount/a lot), or not applicable (not applicable/they don't know I'm trans); and family religion was self-reported by the young adult (using the same categories as for self-identified religion and coded as Christian, not Christian, unaffiliated, more than one religion, or not applicable).

Participants were queried on mental health services and peer support, including receiving care from a mental health therapist (yes, no) and whether they had ever participated in a peer support group (yes, no). Recalled frequency of mental health help-seeking in adolescence was assessed using 0-to-4-point Likert scales: (1) "When you were a teenager, how often were you looking for information about finding mental health support or a therapist?" (0=never to 4=very often; categorized as never/occasionally versus sometimes/often/very often), (2) "How useful would it have been to have reliable information on finding mental health support or a therapist?" (0=not at all to 4=extremely; categorized as not at all/slightly vs moderately/very/extremely), and (3) "How interested were you in getting therapy related to your gender? (0=not at all to 4=extremely; categorized as not at all/slightly, moderately/very/extremely, or not applicable).

Study Size

This exploratory survey was designed to be complementary to key informant interviews conducted with TGD young adults, caregivers, and health care providers as part of the NIH-funded TransHealthGUIDE project. After an initial round of key informant interviews, the research team identified the need for feedback from a larger group of diverse TGD young adults, than those were accessible for the interviews, and designed this survey to capture additional feedback.

Data Analysis

Descriptive statistics (ie, frequencies, percentages, means, standard deviations) summarized variables for the overall sample and by PHQ-2 depression status. Bivariate tests (2-tailed t tests for continuous variables; χ^2 tests for binary or categorical variables) were used to compare participants with and without depression detected using PHQ-2. Poisson regression models with robust variance were fit to estimate prevalence ratios (PR) and 95% CI for correlates of depression [23]. Bivariate models were fit for each variable, followed by a single multivariable model with all variables to estimate adjusted prevalence ratios (aPR). Variables for modeling were selected *a priori* through a review of existing TGD research, conceptual salience, and findings from key informant interviews. Analyses were conducted using R software (version 4.4.3; R Foundation for Statistical Computing) [24] with statistical significance at P<.05 [24].

Ethical Considerations

After review, the study protocol was deemed exempt by the Boston Children's Hospital Institutional Review Board (IRB-P00043127). This study was performed in accordance with the ethical standards outlined in the 1964 Declaration of Helsinki and its subsequent amendments. Participants completed an informed consent process. This was an anonymized survey, and participants indicated consent by opting into the survey. Participants were compensated $3 for completing the survey in accordance with the standards of the Prolific survey platform.

Results

Study Sample

Sample characteristics are displayed in Table 1 for the total sample and stratified by PHQ-2 depression scores. Overall, 44 of 104 (42%) of the sample had clinically elevated depressive symptoms.

[a]PHQ-2: Two-item Patient Health Questionnaire (score ≥3 is the validated cut-off and indicates clinically elevated depressive symptoms).

[b]Depression was assessed using the PHQ-2.

[c]Fisher's exact tests were used to obtain *P* values for cell sizes ≤5.

[d]*t* test (*df*).

[e]χ^2test (*df*).

[f]BIPOC: Black, Indigenous, and Other People of Color.

[g]Own Religion: Christian (57.1% Catholic, 14.3% Baptist, 14.3% Orthodox, 14.3% Christian); Not Christian (38.5% Pagan, 30.8% Jewish, 23.1% Buddhist, 7.7% Misotheist); Unaffiliated (41.9% Agnostic, 29.1% Atheist, 19.8% Spiritual, 9.3% Unaffiliated). Percentages may not sum to 100% due to rounding.

[h]Family Religion (self-reported by TGD young adults): Christian (49.2% Catholic, 20.6% Orthodox, 11.1% Mainline Protestant, 4.8% Evangelist, 3.2% Latter-day Saints, 3.2% Christian, 3.2% Baptist, 1.6% Muslim, 1.6% Jehovah's Witness, 1.6% Unitarian); Not Christian (66.7% Buddhist, 33.3% Jewish), Unaffiliated (39.3% Atheist, 28.6% Agnostic, 17.9% Spiritual, 14.3% Unaffiliated). Percentages may not sum to 100% due to rounding.

Participants' mean age was 21.8 (SD 1.9) years; a total of 25/104 (24%) were BIPOC multiracial individuals, while 23/104 (22%) were BIPOC monoracial individuals, and 69/104 (66%) participants identified as nonbinary. The majority (n=64, 61%) of participants resided in a suburban area, and 11/104 (11%) did not have health insurance. Regarding their religious affiliation, 68 (65%) participants described themselves as unaffiliated, while 55 (53%) described their family's religion as Christian. Half (49/104, 47%) of the participants were not out to their family, 31 (30%) reported low family support, while 24 (23%) participants reported high family support.

Among the participants, 56 (46%) had received mental health therapy and 28 of 104 (27%) had participated in a peer support group. When asked to recall their mental health needs during adolescence: 59 (57%) participants reported seeking information about mental health support or therapy, 88 (85%) indicated that reliable information on mental health support or therapy would have been useful, and 53 (51%) participants expressed having had an interest in therapy related to their gender.

Correlates of PHQ-2 Depression Score

In bivariate models (Table 2), increased PHQ-2 depression prevalence was associated with (1) being BIPOC multiracial versus White (PR1.39; 95% CI 1.05 - 1.84), (2) having low family support versus high (PR 1.53; 95% CI 1.09 - 2.15), (3) seeking information about mental health therapy in adolescence (PR 1.31; 95% CI 1.02 - 1.67), and (4) being interested in mental health therapy related to gender during adolescence (PR 1.41; 95% CI 1.09 - 2.05). Conversely, residing in a rural versus suburban area was associated with decreased PHQ-2 depression prevalence (PR 0.54; 95% CI 0.32 - 0.92). No other variables reached statistical significance in bivariate models.

[a]PHQ-2 score ≥3 indicating clinically elevated depressive symptoms (validated cut-off).

[b]Models include N=103 participants; 1 participant was excluded due to missing data on health insurance.

[c]PR: prevalence ratio.

[d]aPR: adjusted prevalence ratio.

[e]BIPOC: Black, Indigenous, and Other People of Color.

In a multivariable model (Table 2), after adjusting for all other variables, identifying one's own religion as not Christian versus unaffiliated (aPR 1.66; 95% CI 1.04 - 2.63) and low family support (aPR 1.54; 95% CI 1.05 - 2.27) were associated with increased prevalence of positive depression screening. Residing in a rural versus suburban area (aPR 0.48; 95% CI 0.26 - 0.92) and ever receiving mental health therapy (aPR 0.71; 95% CI 0.53 - 0.97) were associated with decreased PHQ-2 depression prevalence in this model. Age, race or ethnicity, gender identity, US Census region, health insurance, family religion, peer support, history of interest in mental health therapy for gender during adolescence, frequency of information-seeking about mental health resources in adolescence, and desire for reliable mental health information during adolescence, were not significantly correlated with depression based on PHQ-2 scores.

Discussion

Principal Results

In this nationwide online study, depression identified using PHQ-2 scores was highly prevalent, with more than 4 in 10 TDG young adults showing clinically elevated symptoms. Low levels of family support and nonChristian religious affiliation were associated with an increased likelihood of positive PHQ-2 depression screening. This exploratory study highlights the high rates of depressive symptoms among TGD young adults as well as the need for tailored interventions to improve mental health among those at the highest risk.

Comparison With Prior Work

This study found that TGD young people with low family support had a higher prevalence of PHQ-2 depression compared to those with highly supportive families. This finding corroborates prior research on the protective role of family support on TGD young peoples' mental health and has informed intervention development for the broader TransHealthGUIDE

XSL•FO
RenderX

study [15,16]. For example, a key intervention component that has been developed for the overall study includes app-based education for TGD young adults and their caregivers on ways to improve family communication, connection, and support.

No differences in PHQ-2 depression prevalence were found for family religion, despite religious affiliation influencing attitudes toward TGD issues in the United States [18,19]. The TGD young people identifying their own religion as nonChristian (eg, Jewish, Muslim, Buddhist) had a higher prevalence of PHQ-2 depression than those identifying as unaffiliated; however, no significant differences were found between Christian and unaffiliated TGD young adults. The association between religious affiliation and depression has been inconsistent in prior research on young people [25], including a recent systematic review of religion, spirituality, and mental health among TGD youth [17]. Future mental health research may benefit from measuring not only religious affiliation but also the degree of religiosity, which was not assessed in this study.

This study found that a history of mental health help-seeking, specifically in young adults receiving mental health therapy was significantly associated with reduced PHQ-2 depression prevalence. This highlights the need for interventions that connect TGD young adults to necessary mental health services. The American Academy of Pediatrics recommends that adolescents aged 12 years and older be screened annually for depression using a formal self-report screening tool to identify and treat those with depression early in the course of illness, potentially reducing long-term depression-related morbidities [26]. This finding underscores the importance of improving mental health care access for TGD young adults to address depression, including telehealth and other online or digitally delivered services and interventions [27].

Regarding sociodemographic differences, we found no evidence of gender identity differences in PHQ-2 depression prevalence, inconsistent with prior research demonstrating the highest depression burden among nonbinary young adults [9]. However, previous studies have reported mixed findings regarding gender identity differences in depression [13], suggesting the need for ongoing research. While BIPOC multiracial TGD young people exhibited elevated PHQ-2 depression in bivariate analyses, consistent with national US population data, this finding did not remain significant in the adjusted model [3]. Geographic context emerged as a significant factor in this study, in alignment with psychiatric epidemiologic research showing lower depression rates in rural settings in high-income countries [28]. The TGD young adults residing in rural areas had lower PHQ-2 depression prevalence compared to those living in suburban areas. Prior studies have found greater mental distress symptoms among rural versus nonrural TGD adults but did not distinguish between the urban and suburban subgroups [29]. More recent research identified the lowest levels of depressive symptoms in rural versus urban-dwelling TGD adults [30]. Additional research is needed to better understand PHQ-2 depression prevalence and set of symptoms among TGD young adults in rural, urban, and suburban settings.

Limitations

These findings should be interpreted alongside this study's limitations. First, analyses were exploratory, and the small sample size limits statistical power to detect significant associations; the findings will require replication. Further, given the cross-sectional design, the study findings are associational only, and longitudinal research is recommended. Second, related to study measures, the global measure of family support may have overlooked important details about family dynamics, such as communication, acceptance, and explicit expressions of care and support [31]. Relatedly, mental health care utilization variables were self-reported rather than objectively measured. Future research that includes self-reported data alongside electronic health record data would strengthen the evidence base. Third, this study did not assess nonpsychiatric aspects of participants' medical histories, and unmeasured confounding due to gender-affirming medical treatments cannot be ruled out [10,12]. Lastly, there are few validated measures for assessing mental health help-seeking behaviors [32]. Further research to understand online help-seeking behaviors for TGD young people using validated measures is warranted to inform future interventions [33].

Conclusions

The high prevalence of PHQ-2 depression in this online sample of TGD young adults underscores the importance of universal screening for depression in this population. It also highlights the need for appropriate systems to ensure prompt diagnosis, treatment, and follow-up for TGD young adults with PHQ-2 depression. Further, tailored interventions may be necessary for subgroups at increased risk for depression, such as TGD young adults with low family support, to decrease mental health disparities. The continued expansion of online interventions may facilitate the engagement of TGD young adults who would benefit from mental health prevention and treatment efforts [27]. This study's findings have important implications for clinical care and the design, development, and implementation of interventions aimed at improving mental health outcomes and reducing health disparities among TGD young adults.

Acknowledgments

The authors wish to thank Jessica Kremen, MD, Meg Quint, BS, and the Community Advisory Board for their feedback on the survey questionnaire.

Abstract

Background: Good communication between health authorities and citizens is crucial for adherence to preventive measures during a pandemic. Crisis communication often appeals to worries about negative consequences for oneself or others. While worry can motivate protective behavior, it can also be overwhelming and lead to irrational choices or become a mental health problem. Also, the levels and consequences of worry can differ between different groups of citizens. Little is known about the evolution of worries during the pandemic and adherence to measures in distinct groups.

Objective: This study aimed to evaluate worries in the Swiss population as well as associations between worry levels and citizens' adherence to government restrictions during different phases of the COVID-19 pandemic.

Methods: We carried out an observational study with 4 cross-sectional online surveys of adults in the Canton of Vaud, Switzerland. Questionnaires were distributed through social media and websites during 4 periods: survey 1: April 17 to May 14, 2020; survey 2: May 15 to June 22, 2020; survey 3: October 30 to December 12, 2020; and survey 4: June 18 to December 30, 2021. On visual analog scales from 0 to 100, participants reported worry, self-adherence to pandemic restrictions, and their perceived adherence to others. We used multivariable linear regression, adjusting for age, gender, health literacy, and education to assess associations between self-reported worry, adherence, and study periods.

Results: We collected 7106 responses. After excluding 2377 questionnaires (incomplete, age <18 years, residence outside Vaud), 4729 (66.55%) were analyzed (mean age 47, SD 15.6 years, 63.96% women). Mean worry across the 4 periods was 42/100, significantly higher in women (44.25/100, vs 37.98/100; P<.001) and young people (43.77/100 in those aged 18-39 years, vs 41.69/100; P=.005; in those aged 40-64 years and 39.16/100; P=.002; in those aged >64 years). Worries were higher during survey 1 and survey 3 (52.41/100 and 56.32/100 vs 38.93/100, P<.001; and 35.71/100, P<.001) than during survey 2 and survey 4, respectively. This corresponds to pandemic peaks during which federal restrictions were better followed with self-reported adherence of 84.80/100 and 89.59/100 in survey 1 and survey 3 versus 78.69/100 (P<.001) and 78.64/100 (P<.001) in survey 2

XSL•FO
RenderX

and survey 4. A 2.9-point increase in worry score, adjusted for the pandemic period, gender, age, education, and health literacy, was associated with a 10-point increase in personal adherence score (95% CI 2.5-3.2; *P*<.001).

Conclusions: Worries were higher in women, young people, and during the peak of the COVID-19 pandemic. Higher worry levels were associated with increased self-reported adherence to federal restrictions. Authorities should consider population worry levels and population subgroups in the planning and design of pandemic communication.

Introduction

Effective communication between health authorities and the population is crucial to achieving public health goals during a pandemic. Providing clear, consistent, and reliable information that motivated behavior changes without triggering resistance was a major challenge during the COVID-19 pandemic. Sanitary restrictions were often rapidly issued and modified to contain the spread of the disease [1-3]. Citizens were expected to make drastic behavioral changes.

Public health authorities stressed the seriousness and risks of the pandemic to justify restrictions and encourage citizens' adherence to them. In support of such an approach, the Health Belief Model argues that preventive health behaviors are influenced by perceived susceptibility to illness, the severity of the disease, benefits of and barriers to health-promoting actions, cues to action, as well as self-efficacy [4]. Also, during the COVID-19 pandemic, protective behaviors were associated with these factors, especially when the "perceived benefit" of a measure was clear [5].

Appealing to emotions such as fear can hence be a persuasive way of motivating respect for protective measures [6,7]. Indeed, fear leads to behavioral change if people feel capable of dealing with the threat, while they become defensive when feeling helpless and incapable of acting [8-10]. Overdriven or ill-conceived fear-based communication may even provoke counterproductive behavior.

Levels of anxiety, worry, and stress were high during the pandemic. According to a systematic review and meta-analysis, anxiety prevalence was around 30% worldwide after the first COVID-19 wave [11]. Others have confirmed these findings [12,13]. Among professionally active persons, 42% of participants reported being worried about the COVID-19 pandemic in August and September 2020 [14]. Young adults in the city of Zurich, Switzerland, reported elevated stress levels in April 2020, in the aftermath of the first wave [15], as was found more generally in Swiss adults too [16]. In terms of risk factors, anxiety was higher in women, younger people, and vulnerable persons [17-19].

In our previously published cross-sectional population survey, performed during the first wave of the pandemic, we found high self-reported adherence to official restrictions, which increased with age and level of worry [20]. As in the aforementioned studies, worry was high, particularly among people in isolation and with lower health literacy. Nearly half of the respondents felt that government responses were adequate or, associated with higher levels of worry, even insufficient. Neither the aforementioned nor our cross-sectional study could determine the evolution of these associations throughout the pandemic.

Thus, we conducted surveys during different phases of the pandemic to describe the evolution of worries in the Swiss population as well as associations between worries and adherence to governmental restrictions. Our overall aim was to contribute new insights to this understudied area to help improve crisis communication during future pandemics.

Methods

Study Design and Setting

We conducted repeated cross-sectional online surveys in Vaud, a French-speaking canton of 823,000 inhabitants (2021) in Switzerland. We launched 4 surveys between April 2020 and December 2021: survey 1 between April 17 and May 14, 2020 (4 weeks); survey 2 between May 15 and June 22, 2020 (5.5 weeks); survey 3 between October 30 and December 1, 2020 (4.5 weeks); and survey 4 between June 18 and December 30, 2021 (28 weeks, Table 1). Some of the survey items were adapted or replaced to capture changes in federal measures. We followed the CHERRIES (Checklist for Reporting Results of Internet e-Surveys) guidelines [21]. Self-reported worry was an outcome of the study of worry levels and an exposure variable for the study of associations between worry and self-reported adherence during these 4 COVID-19 pandemic periods.

Table 1. Surveyed periods and sentinel pandemic-related events.

Survey	Period	Number of weeks	Sentinel events
Survey 1: End of the first pandemic wave	April 17, 2020, to May 14, 2020	4	• March 16, 2020: Semiconfinement, only essential shops open, gatherings of a maximum of 5 people • April 27, 2020: Partial reopening of shops • May 11, 2020: Reopening of schools
Survey 2: After the first pandemic wave	May 15, 2020, to June 22, 2020	5.5	• June 19, 2020: End of an extraordinary situation
Survey 3: During the second pandemic wave	October 30, 2020, to December 1, 2020	4.5	• Mandatory wearing of masks in indoor public spaces; gatherings limited to 15 people
Survey 4: Following pandemic waves	June 18, 2021, to December 30, 2021	28	• Vaccination available to all, use of COVID-19 vaccination certificate

Table 1 presents the COVID-19 waves and their duration in the French-speaking part of Switzerland. The first and second forms were distributed at the end of the first wave, corresponding to the gradual emergence from confinement. The third form was distributed over a longer period, which included the second wave and the resumption of restrictive measures. The fourth form was distributed once vaccination was available for the entire population.

Participant Recruitment

Using a weblink, we distributed the surveys on the social media platforms of multiple community organizations to collect a convenience sample of the population. These organizations were a regional consumer organization, regional disease leagues for cancer and diabetes, the association of senior citizens as well as the cantonal websites for the COVID-19 testing and vaccination decisions. These cantonal sites were used by large portions of the population. The organizations advertised the study through links on their websites and some social media accounts. The links were accompanied by a short explanation of the study and its purpose. No incentives to participate were given. The online interface for the survey was created in REDCap (Research Electronic Data Capture, Vanderbilt University).

Surveys

The development and testing of the survey are described in our previous publication with results from survey 1 [20]. Each survey was submitted to 5 nonmedical persons to test the understandability of questions. There was no review step for this short questionnaire. The first, second, and fourth surveys had 20 items, and the third survey had 25 items. A total of 12 items remained unchanged throughout all surveys. We included demographic data, such as age, sex, number of persons per household, canton of residence, level of education, literacy, and whether the respondent had been tested for the COVID-19 pandemic. For the literacy question, we used a validated item from Chew et al [22]. Employment status was included in surveys 2-4. Respondents rated (1) worry about the pandemic situation, (2) self-reported adherence to government restrictions, and (3) perceived adherence of others to government restrictions, on visual analog scales from 0 to 100 (0=not at all; 100=in all situations). Items were not randomized. Participants could go back to earlier questions at any time. Adaptive questioning was used for several items. The first 2 surveys took up 6 screens, and the 2 latter, 7. REDCap automatically generated a completeness variable if participants went all the way to the end of the survey. Anyone who opened the survey generated a response. We did not determine unique site visitors, establish view or participation rates, or IP address checks, as surveys were entirely anonymous and the risk of repeating them was low. The time used to fill them in was not registered. No cookies were used, and there were no other techniques to analyze the log file of our database. Statistical corrections were not used. The 4 surveys can be found in Multimedia Appendices 1-4.

Statistical Analyses

The item “Level of education” was dichotomized into “university or college education” or other. Health literacy was dichotomized according to ease of answering a medical form on one’s own: low literacy (“never,” “rarely,” or “sometimes” at ease) and “high literacy” (“often” or “always”). This was based on a validated item [22] and our previous article [20].

We limited our analysis to complete questionnaires for 2 reasons. First, the survey was distributed using an online link on government websites and a large number of persons clicked the link but only completed 1 or 2 questions. Second, no single question had many missing responses and we preferred to maintain consistency across surveys. We calculated means with SD and frequencies with IQR as appropriate. Independence between surveys was tested with the *t* test for continuous variables (eg, age), and with the chi-square test for gender, education, and health literacy. We performed linear regressions to analyze associations between the 4 periods and level of worry (model A), self-reported adherence (model B), and perceived adherence of others to restrictions (model C). First, we performed univariate linear regression, followed by multivariable linear regression controlling for age (grouped as 18-39 years, 40-64 years, and 65 years or older), sex (dichotomized male-female), level of education (dichotomized university education or other), and health literacy (dichotomized high or low health literacy). We subsequently used the margins command in Stata (StataCorp) to report absolute differences in the predicted levels of worry or adherence with each model. The level of significance was set to $P<.05$. Statistical analyses were performed in Microsoft Excel and Stata (version 16.1).

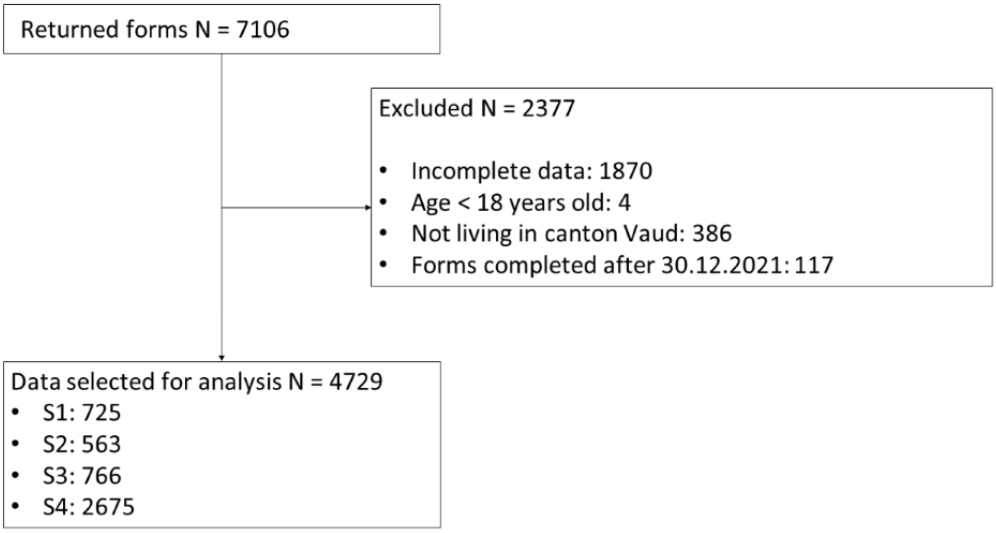
Ethical Considerations



According to the Cantonal Commission on Ethics in Research Involving Human Beings of the Canton of Vaud, Switzerland the study was exempted from ethical review because it did not qualify as human subjects research and all data collection was anonymous (2024-010901).

Participant Characteristics

Citizens completed 7106 surveys between April 17, 2020, and December 20, 2021. After the exclusion of minors, persons living outside the Canton, and incomplete questionnaires, 4729 (66%) surveys remained. The number of questionnaires per period ranged between 563 and 2675 (Figure 1).

Figure 1. Study participants.

The participants were more often women (3025/4729, 63.96%) and between 40 and 64 years old (2442/4729, 51.64%). Furthermore, 2526/4729 (53.42%) of participants had attended university or college, and 4510/4729 (95.37%) reported high health literacy. The participants were younger in survey 3 (mean age 43.2, SD 14.6 years; $P<.001$) than in the other surveys (survey 1: mean age 47.9, SD 14.6 years; survey 2: mean age 47.3, SD 15.6 years; and survey 4: mean age 48.7, SD 15.3 years; Table 2).

Main Results

Self-Reported Worry

Overall, the mean level of self-reported worry was 42.0% (SD 28.9). Upon univariate regression, self-reported worry levels differed significantly across surveys, with significantly higher levels in survey 1 (52%, 95% CI 50-54) and survey 3 (56%, 95% CI 54-58; Figure 2). Upon multivariable regression, the female gender was associated with a 4-point increase in level of worry (95% CI 2-5 points). Worry levels were 2 (95% CI 1-4) and 4 (95% CI 1-6) points lower among respondents aged 40 to 64 and over 64, respectively, when compared with the 18- to 39-year group. Higher health literacy was associated with a 3-point lower worry level (95% CI –6 to –1). Education was not associated with significant changes in self-reported level of worry (Table S5 in Multimedia Appendix 5).

Figure 2. Boxplots on a 0-100 scale of (A) worry, (B) self-reported adherence, and (C) perceived adherence of others to restrictions during four COVID-19 pandemic periods (April 17, 2020, to December 30, 2021), Switzerland. S: survey; survey 1: April 17 to May 14, 2020; survey 2: May 15 to June 22, 2020; survey 3: October 30 to December 1, 2020; survey 4: June 18, 2021, to December 30, 2021.

Self-Reported Adherence to Restrictions

Overall, respondents evaluated their own adherence to government restrictions at 81.4% (SD 21.1). Self-reported adherence was significantly (P<.001) higher in survey 1 (mean 84.8%, SD 14.2) and survey 3 (mean 89.6%, SD 15.5; Figure 2). A 2.9-point increase in the worry score was associated with a 10-point increase in self-reported adherence (95% CI 2.5-3.2; P<.001) after adjusting for the pandemic period, gender, age, education, and health literacy. These effects were more pronounced in women and older participants (Table S5 in Multimedia Appendix 5). Moreover, both older age categories (40-64 years and more than 64 years) were associated with a 7-point higher self-reported adherence than in the 18-39 years group (95% CI 6-8 for 40- to 64-year-olds and 6-9 for >64-year-olds). Higher health literacy was associated with a 4-point increase in self-reported adherence (95% CI 2-6) while the educational level was not (Table S5 in Multimedia Appendix 5).

Perceived Adherence of Others to Restrictions

Overall, respondents evaluated the adherence of others to government restrictions at 50.4% (SD 24.5%). Evaluated adherence did not differ between survey 1 and survey 3 nor between survey 2 and survey 4 but was significantly higher (P<.001) in survey 1 (mean 60.1%, SD 20.0%) and survey 3 (59.6%, SD 24.6%) than in survey 2 (45.1%, SD 22.5%) and survey 4 (46.2%, SD 24.5%; Figure 2). Adjusting for participant characteristics, age groups 40-64 years and >64 years were associated with, respectively, a 5- or 7-point higher perceived adherence of others (95% CI 3-6 and 5-9, respectively). A 10-point increase in worry level was associated with a 1-point decrease in perceived adherence of others to restrictions (95% CI –0.9 to –0.4). Higher education level was associated with a 1.5-point higher perceived adherence of others (95% CI, 0-3), whereas gender and health literacy were not (Table S5 in Multimedia Appendix 5).

Changes to the Daily Lives of Respondents

During the first period (survey 1), most respondents had experienced changes in their daily life (Table S6 in Multimedia Appendix 6). Later (surveys 2-4), 35% to 49% had either lost their job or had to close their business and 21% to 34% had lost part of their income. Respondents also reported feeling isolated, lonelier, and less productive during surveys 2 to 4. In decreasing order of importance, concerns during survey 3 were for “vulnerable people,” “living conditions,” the “economy,” “self and family,” “working conditions,” and the “possibility of another wave.” During survey 4, these concerns were similar but generally rated lower. Interestingly, “deterioration of working conditions” moved up from fifth to third rank, which had been “self and family” in survey 3 (Multimedia Appendix Table S7 in Multimedia Appendix 7 and Table S8 in Multimedia Appendix 8).

Discussion

Principal Findings

We conducted online surveys during different phases of the COVID-19 pandemic to describe the evolution of worry levels and to assess how these were associated with adherence to government restrictions. In Switzerland, the self-reported worry was highest during the first and second pandemic waves, corresponding to survey 1 and survey 3, at times of many COVID-19–related hospitalizations and deaths, and when a vaccine was not yet available. Women and younger people

XSL•FO
RenderX

reported higher levels of worry than men and older people. Education did not influence worry levels, while lower health literacy was associated with higher worry. Higher worry levels were associated with higher self-reported and perceived adherence of others to federal restrictions.

We found elevated worry levels during the more dramatic phases of the pandemic. In a systematic review covering 204 countries in 2020, higher anxiety was associated with higher COVID-19 incidence [23], a finding that was confirmed by Salanti et al [13]. In March 2020, Fitzpatrick et al [24] found that in a national sample in the United States, worry was higher in the regions with high COVID-19 incidence. In Ontario, Canada, COVID-19–related worry in young persons also increased during the early phases of the pandemic and then again in the autumn of 2020, when the incidence was higher [25]. So, anxiety and worry varied during the pandemic and increased repeatedly with the rising incidence of COVID-19. This is in line with findings on decreased mental health on a larger scale during the pandemic [11,26].

In periods of increased worry, we found higher self-reported adherence to government restrictions. Similarly, a study in Saudi Arabia described an association between higher anxiety levels and preventive practices among health care workers [27]. Another study identified fear as a predictor of behavioral change [28]. The association between worry and adherence in our study could indicate that worry was not overwhelming and that citizens felt in control of risks by respecting restrictions. We cannot exclude that this might have been different with higher anxiety levels.

Considering population subgroups, young adults were often the most anxious despite being less at risk of hospitalization or death [17,18,23,29]. Young people were worried about social isolation and develop depressive symptoms during school closings [30]. In Switzerland, students were concerned about whether they would be able to finish the 2020 university year [31], and lockdowns as well as their socioeconomic consequences were stressful for students [15]. Apart from concerns about the future, young people were not only worried about their own health but also about that of relatives. For example, in a study in Zurich, Switzerland, students were more concerned about the health of their parents and grandparents than their own [32]. Also, our finding of higher worry levels in women echoes several publications [17-19,33]. General factors potentially contributing to worry were the increasing risk of unemployment or loss of income, as well as loneliness and feeling less productive. One-third of respondents had lost part of their income by surveys 2 and 3 (31%, and 34%, respectively), with a slightly better situation in survey 4 (21%). The reported feelings of isolation, loneliness, and being less productive could further contribute to worry in some respondents. For example, studying for exams through online classes only, without any campus life, can be a source of worry compared with when stress from studying and exams is compensated by in-person interactions with teachers and colleagues. Four years after the pandemic, Sayed et al. [34] insist on the importance of addressing mental health of children and young adults during global crises and of recognizing long-term impacts. They further emphasize the need for research and public health prioritization of these important topics.

Overall, our findings are in line with publications that highlight the importance of addressing the many individual and collective aspects that influenced mental health during the COVID-19 pandemic, such as isolation, loneliness, and fear [35]. Many individuals demonstrated remarkable resilience, allowing society to avoid a general increase in loneliness [36]. However, population estimates may mask individual heterogeneity; loneliness is indeed a major public health concern and must be considered as a negative determinant of health [35]. Even though the pandemic is over, we must not forget its long-term effects on mental health and public health authorities should consider the differing impact of governmental decisions on the general population versus on individuals with pre-existing mental health conditions [37]. Our results of the worries of citizens and adherence to pandemic measures can be useful in preparing for future pandemics, for example, in considering criteria for and potential impact of restrictions on different subgroups of the population.

Strengths and Limitations

The strengths of our study were repeated surveys with similar questions and our relatively large sample size, allowing us to examine subgroups of the population.

Concerning limitations, data were collected through the online distribution of surveys in a simple, cost-effective, and feasible way during the rapidly evolving pandemic. Participation was more attractive to women and younger people with higher literacy and education. Also, participation was variable during data collection periods. The participant sample was more representative in the last and longest period (survey 4). This selection and variation need to be considered in the interpretation of our data which are prone to desirability, information, and selection bias. Different distribution channels and methods are probably needed for disadvantaged populations, as we showed in a recent study using our survey in a population of refugees and migrants [38]. Finally, another inherent limitation of our anonymous data collection is that we could not follow a cohort of persons throughout the pandemic.

Conclusion

Worry reached moderate levels and varied with COVID-19 incidence during the pandemic. Higher worry levels were associated with increased self-reported and perceived adherence of others to government restrictions. Younger people and women reported higher worry levels. Authorities should take population worry levels into account in planning and designing pandemic communication. Adapting communication to population subgroups should be considered for future health crises.

Abstract

Background: Excessive use of smartphones is recognized as a major problem in our modern society and can have dramatic consequences on the health of adolescents and young adults. Measuring problematic smartphone use in research and clinical practice is generally operationalized with self-reported questionnaires. In order to comprehensively assess the issue of problematic smartphone usage within the French population, it is imperative to employ validated French-language questionnaires. However, at this point, existing questionnaires are primarily available in English. Furthermore, to the best of our knowledge, these English questionnaires have yet to undergo validation processes for French-speaking cohorts.

Objective: The aim of this study was to perform a cross-cultural translation of the Smartphone Addiction Scale, Nomophobia Questionnaire, Problematic Use of Mobile Phones scale, and Smartphone Addiction Proneness Scale to French.

Methods: The translation process was performed using the forward/backward method. The first translation phase involved asking 4 independent French translators to translate the original English version of the questionnaires into French. In the second phase, the French version was backtranslated to English by a native English speaker. In the third phase, 2 concept experts were asked to comment and suggest modifications to the statements if necessary. Finally, the last version of the translated questionnaires was presented to 18 participants to assess the clarity, intelligibility, and acceptability of the translations.

Results: During the forward translation step, the translation differences were minor. During the backward translation, the English native speaker correctly backtranslated 18 of the 33 items of the Smartphone Addiction Scale, 17 of the 20 items of the Problematic Use of Mobile Phones scale, and 13 of the 15 items of the Smartphone Addiction Proneness Scale. Backtranslation for the Nomophobia Questionnaire was less satisfactory, with only 10 out of 20 items that were correctly backtranslated. The linguistic verification step revealed a minimal modification for the 4 questionnaires. The participants also suggested few improvements that we have considered for the final version. We produced the final version directly after this step.

Conclusions: We successfully adapted and effectively translated 4 questionnaires that assess problematic smartphone use to French. This step is a prerequisite for the validation of the French questionnaires. These adapted measures can serve as valuable research instruments for investigating and addressing issues related to problematic smartphone use in French-speaking countries and for making international comparisons.

Introduction

Today, the excessive use of smartphones and screens, in general, is recognized as a major problem in our society. Recent world events that have led to individuals being confined to their homes for several months have intensified the amount of scientific and political concerns surrounding this issue. Excessive smartphone use can have dramatic consequences for the health and cognitive development of adolescents and young adults [1]. Indeed, difficulty in regulating smartphone use can lead to serious pathological disorders such as addiction to video games [2].

Although health care professionals, researchers, and politicians recognize that excessive smartphone use is problematic, its legitimacy as a pathological disorder is not yet recognized by the American Psychiatric Association [2]. For this reason, the notion of problematic smartphone use is favored by a large number of researchers. Problematic smartphone use does, however, refer to symptoms of dependence such as loss of control, overuse, increased tolerance (ie, spending more time on the smartphone to be satiated), or withdrawal symptoms once individuals are no longer in possession of their smartphones [3].

In order to identify individuals at risk of problematic use, the measurement of smartphone use practices is generally operationalized in research by using self-reported questionnaires. Three very recently published systematic reviews [3-5] identified 4 measurement scales most commonly used to measure problematic smartphone use, 3 of which are used with young adult students, that is, the Smartphone Addiction Scale [6], the Nomophobia Questionnaire [7], and the Problematic Use of Mobile Phones scale [8], and 1 for adolescents, that is, the Smartphone Addiction Proneness Scale [9]. What these 4 scales have in common is that they assess problematic smartphone use across several dimensions, often inspired by the fourth and fifth versions of the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV and DSM-V) [2,10].

The Smartphone Addiction Scale was designed by Kwon et al [6] based on the diagnostic criteria for internet gaming addiction in DSM-IV [10]. It measures problematic smartphone use along 6 dimensions: disruption of daily life due to smartphone use, positive anticipation of use, withdrawal symptoms, overuse, tolerance, and importance of the virtual world for social relationships. This scale has the advantage of being validated in several languages, including English [6], Arabic [11], Brazilian [12], Malaysian [13], and Persian [14]. It also has good cross-cultural consistency, with Cronbach α ranging from 0.93 to 0.97. Although the Smartphone Addiction Scale has been translated and validated in French in a shorter 10-statement version [15], the original 33-items scale has not been translated and validated in French.

The Nomophobia Questionnaire was designed by Yildirim and Correia [7] and measures individuals' fear of being separated from their smartphones. It measures 4 dimensions of smartphone separation fear: not being able to communicate, losing connection with the outside world, not being able to access information, and giving up comfort. According to the research work of Jahrami et al [16], this questionnaire has been translated into 7 languages (eg, Chinese [17], Italian [18]) and consistently has very good internal consistency ($0.88 \leq \alpha \leq 0.96$).

The Problematic Use of Mobile Phones scale, designed by Merlo et al [8], draws heavily on the criteria for online gaming addiction in DSM versions IV [10] and V [2]. This scale considers 10 dimensions of problematic smartphone use in young adults: tolerance, withdrawal symptoms, smartphone use longer than expected, time spent on the smartphone, irrepressible desire to use the smartphone, abandonment or reduction of other activities, smartphone use despite physical and psychological consequences, smartphone use in risky situations, smartphone use despite social consequences, and inability to fulfill obligations due to use. Although being less validated, this scale has been translated into English [8], German [19], and Arabic [20], and its consistency appears very satisfactory ($0.90 \leq \alpha \leq 0.94$).

To date, 2 other scales measuring problematic smartphone use by young adults have been validated in French. The first scale, that is, the Implicit Association Test (smartphone) [21] is strongly inspired by the internet addiction test developed by Young [22] and not according to a set of diagnostic criteria for problematic smartphone use. However, the factor structures and internal consistency of the scale ($\alpha=0.93$) were good. The other scale, that is, the Problematic Mobile Phone Use Questionnaire by Lopez-Fernandez et al [23] is divided into 3 categories and has good internal consistency: dangerous use ($\alpha=0.81$), prohibited use ($\alpha=0.74$), and dependent use ($\alpha=0.90$). The strength of this scale lies in its cross-cultural validity (eg, French, German, Hungarian, English, Finnish, Italian, Polish, Spanish), but surprisingly, it is one of the few scales that is not based on any version of DSM. However, recent research has shown that taking inspiration from gaming disorder criteria to measure problematic smartphone use is a way to better understand this phenomenon [24].

The Smartphone Addiction Proneness Scale by Kim et al [9] is inspired by the assessment criteria of Young's [22] Internet Addiction Test scale. To our knowledge, it is one of the few scales designed to measure problematic smartphone use in adolescents. The Smartphone Addiction Proneness Scale assesses 4 main dimensions: craving symptoms, tolerance, predominance of virtual life, and disruption of coping in daily life. To date, it has been translated into Korean (ie, translated from English) [9], Malaysian [25], German [26], and Chinese [27]. The interrater internal consistency of this Korean scale is consistently acceptable ($\alpha=0.88$).

Given the importance of completing proposals for measuring problematic smartphone use based primarily on the findings of DSM and to better understand this societal issue, the aim of this study is to linguistically translate the Smartphone Addiction Scale, the Nomophobia Questionnaire, the Problematic Use of Mobile Phones scale, and the Smartphone Addiction Proneness Scale to French so that they are conceptually equivalent to their original versions. The cross-cultural adaptation process will be performed using the forward/backward method, a commonly used method [28-32] and recommended by the World Health Organization [33]. The translation will be considered valid when the tests performed by the participants are considered conclusive.

XSL•FO
RenderX

This step is a prerequisite for the quantitative validation of the questionnaires.

Methods

Background

To assess the conceptual equivalence of the questionnaires, that is, whether the items in the original language have a similar meaning to the French version, we opted for the forward/backward translation method. This is the most commonly used technique for cross-cultural research, and we followed the recommendations of Epstein et al [34]. We have decided to validate these instruments for use exclusively in France.

Ethics Approval

This study was approved by the Grenoble Alpes University Hospital Center and has received ethics approval from the South-East I Ethics Committee for the Protection of Individuals (approval 2022-A01943-40).

Questionnaires

The 4 questionnaires targeted for the cross-cultural procedure were as follows. The Smartphone Addiction Scale [6] contains 33 items, and the response scale ranges from 1 (strongly disagree) to 6 (strongly agree). Each participant's total score can range from 33 to 188 points, and a higher score indicates more problematic smartphone use. The Nomophobia Questionnaire [7] contains 20 items, and the response scale ranges from 1 (strongly disagree) to 7 (strongly agree); each participant's total score can therefore vary from 20 to 140 points, and a higher score indicates more problematic smartphone use. The Problematic Use of Mobile Phones scale contains 20 items [8]. The response scale ranges from 1 (not at all in agreement) to 5 (totally in agreement), and each participant's total score can vary from 20 to 100 points, and a higher score indicates more problematic smartphone use. Finally, the Smartphone Addiction Proneness Scale by Kim et al [9] contains 15 items. The response scale ranges from 1 (not at all in agreement) to 4 (totally in agreement), and each participant's total score can vary from 15 to 60 points, and a higher score indicates more problematic smartphone use.

Forward Translation

The first translation phase involved recruiting independent translators who were both 2 native French speakers bilingual in English and 2 native English speakers bilingual in French and asking them to translate the original English version into French. It was recommended that at least one of the translators knows the concept of the questionnaires to be measured and that at least one of them does not know the objective of the questionnaire. In this study, 4 qualified translators were involved: 2 translators were familiar with the concept of problematic smartphone use, while the other 2 were not. Two of the experts had backgrounds in health and psychology research: one was a novice and the other had prior experience in translation. At the end of the 4 translations, a single version was obtained after a reconciliation meeting of the 4 translators. Each questionnaire was checked for errors in spelling, grammar, punctuation, and translation of terminology and style against the original English version.

Backward Translation

In the second phase, the French versions were retranslated into English by a native English speaker who had no clinical or medical expertise. The instructions that were given to the native English speaker were to translate each questionnaire literally. By comparing the translated English versions with the original questionnaires, the French translations were modified to be consistent with the originals. This step ensured the accuracy of the translations and highlighted any phrasing that could cause confusion.

Linguistic Verification

In the third phase, 2 professionals familiar with the concept of problematic smartphone use were asked to comment and suggest modifications to the statements if necessary. We followed a universalist approach for equivalence, assessing conceptual, item, semantic, operational, measurement, and functional equivalence [35].

Final Verification

The final verification phase involved performing a preliminary pilot test with participants involved in the problem being measured to assess the clarity, intelligibility, and acceptability of the translations. Between December 2022 and June 2023, 18 French native speaker participants—10 students older than 18 years (ie, 6 girls and 4 boys) and 8 adolescents aged 12-17 years (ie, 6 girls and 2 boys)—completed the questionnaires for the final version during face-to-face interviews. Each interview lasted a maximum of 30 minutes. For minor participants, consent to take part in the study was obtained from the parents, while adult participants gave their own consent. Participants could be in good health or experiencing any medical condition and they could come from rural or urban areas in France. During the interviews, a researcher asked the participants questions such as "Did you understand the instructions, the items, and the response scales?"; "How did you interpret this item?"; or "What would you suggest as a reformulation?" The principal investigator checked the proofs of the final version and corrected any errors.

Data Analysis

To analyze the qualitative data from the translation process, we employed a thematic approach focused on assessing the conceptual equivalence of the translated items. Responses from the participants during the individual interviews were transcribed and systematically analyzed to identify elements that could pose comprehension issues. Particular attention was given to semantic discrepancies between the original and translated versions as well as suggestions for reformulation provided by the participants. The data were then coded according to the types of mistranslations identified (eg, item comprehension, appropriateness of terms used) and grouped into recurring themes. This approach enabled us to evaluate the clarity and acceptability of the translations as well as to adjust the problematic items.

Results

Characteristics of the Translators and the Participants

The age, gender, and specific cultural characteristics of the translators and the student and adolescent participants are detailed in Table 1.

Table 1. Age, gender, and cultural characteristics of the translators and the participants.

Translation type	Translators/participants (n)	Mean age (years)	Gender	Cultural characteristics
Forward translation	4 translators	25.5 (range 20-31)	2 females, 2 males	• 2 native English, 2 native French • 2 were familiar with the concept of problematic smartphone use (eHealth and psychology) • 2 were not familiar with the concept (economics and education) • 2 were from the south of France and 2 were from the north
Backward translation	1 translator	28	1 female	• Native English • No clinical or medical expertise
Linguistic verification	2 experts	27.5 (range 24-31)	1 female, 1 male	• 2 native French
Final verification				
	8 adolescents	14.5 (range 12-17)	6 females, 2 males	• Good health or experiencing any medical condition • 5 from rural areas and 3 from urban areas in France
	10 students	19.8 (range 18-24)	6 females, 4 males	• Good health or experiencing any medical condition • 6 students in health sciences, 3 students in psychology, 1 student in philosophy

Forward Translation

The 4 translators translated the titles, dimensions, instructions, response modalities, and statements of each questionnaire. These 4 translations were synthesized into a consensual version A. Concerning questionnaire dimensions, a few terms were more difficult to translate from English to French. For example, the dimension “withdrawal” of the Smartphone Addiction Scale, the Problematic Use of Mobile Phones scale, and the Smartphone Addiction Proneness Scale was translated as “sevrage.” For the Nomophobia Questionnaire, 1 dimension was more challenging to translate into French: “giving up convenience.” The term “convenience” can have several meanings in French, but its translation as “confort” (comfort) appears to be the most appropriate, especially when defining this dimension as the loss of the comfort provided by smartphone use. The concept of “craving” for the Nomophobia Questionnaire is particularly complex to define in French as it does not have a direct equivalent. In clinical terms, craving corresponds to a strong impulsive desire to use one’s object of addiction, which in our context is the respondent’s smartphone use. Therefore, in French, we have defined this dimension as “désir” (desire). For the other dimensions, the terms used in French were mostly similar.

For the items in the Smartphone Addiction Scale, rather than using the infinitive form of verbs as proposed in the original version, we translated them by systematically beginning the verb with the first-person singular conjugation. For example, for the original item “missing planned work due to smartphone use,” we translated it as “J’oublie du travail planifié à cause de l’utilisation du smartphone.” This will help participants better understand the statements. Three statements were more difficult to translate into French: “feeling pleasant or excited while using a smartphone” and “feeling impatient and fretful when I am not holding my smartphone.” The term “pleasant” was suggested in French as “calme” (calm), and since the term “impatient” does not have a direct equivalent in French, we propose the homograph “impatient.” The verb “to annoy” present in 2 items of the Nomophobia Questionnaire required more debate regarding its translation. This term can imply constraint, boredom, or irritation depending on the context; therefore, we chose to translate it as “contrariété” (contrariety) to preserve the statement and its dimension without distorting it. The statement “using a smartphone is more enjoyable than spending time with family or friends” from the Smartphone Addiction Proneness Scale also sparked discussions among translators because not everyone agreed on how to translate “enjoyable.” This term can signify a pleasant or amusing moment depending on the context. Here, we opted for the most common translation, “agréable” (pleasant). For the other items, the differences in translation were minor and did not alter the literal meaning of the statements.

Backward Translation

Following this first translation, a native English translator backtranslated the questionnaires from the consensus version A into an English version B. This version B was compared to the original questionnaire in English. For the Smartphone

XSL•FO
RenderX

Addiction Scale, 18 items were perfectly backtranslated, while 14 were slightly modified, but this did not alter their meaning and understanding. One item was retranslated, changing its meaning: “missing planned work due to smartphone use” was backtranslated as “I use my smartphone longer than planned.” We reworked this item in French to maintain its original meaning as “Je manque du travail planifié à cause de l’utilisation du smartphone.” For the Problematic Use of Mobile Phones scale, 17 statements were perfectly backtranslated, and the others underwent slight modifications without impacting their meaning and understanding. Backtranslation was even better for the Smartphone Addiction Proneness Scale, with 13 out of 15 items perfectly backtranslated and 2 having slight modifications without consequence. The backtranslation for the Nomophobia Questionnaire was satisfactory, with 10 out of 20 items varying slightly in wordings but without altering their meaning. The others were perfectly backtranslated. Thus, we obtained a translated version C for the 4 questionnaires.

Linguistic Verification

The 2 researchers responsible for linguistic verification submitted 4 suggestions for conceptual modifications for the Smartphone Addiction Scale, 3 for the Nomophobia Questionnaire, and 1 for the Problematic Use of Mobile Phones scale, some of which were incorporated into the final C version. No additional modifications were suggested for the Smartphone Addiction Proneness Scale.

Final Verification

In this final step, feedback from adolescents and students was minimal; therefore, we produced a final version D based on their input. Overall, they understood all the instructions, items, and response modalities well. Participants encountered no comprehension problems except for 3 items. For the Nomophobia Questionnaire, 2 students reported a comprehension difficulty with item 18. In English, it refers to checking “online connections and networks,” and we translated it as “online notifications and networks.” However, “online networks” made less sense than “social networks” for these students. We therefore modified the item. In addition, item 6 of the Problematic Use of Mobile Phones scale was difficult for one student to understand, as the translators had translated it by mixing the present and past tenses. We therefore modified the item from “J’ai pensé par le passé qu’il n’était pas normal de passer autant de temps sur le smartphone comme je le fais” to “Il m’est arrivé de penser qu’il n’était pas normal de passer autant de temps que moi à utiliser un smartphone.” In this way, students gained a better understanding of the item. Finally, item 22 of the Smartphone Addiction Scale had to be clarified, as 2 participants did not understand what “losing a friend” meant. In fact, the meaning of loss is important in French, as it could mean literally losing a friend through death or signify a friendship breakup. We have therefore clarified at the end of the item that this refers to friendship breakup in this context. The final translated versions are listed in Tables 2-5.

Discussion

Principal Findings

The Problematic Use of Mobile Phones scale, the Smartphone Addiction Scale, the Smartphone Addiction Proneness Scale, and the Nomophobia Questionnaire for young adult students and adolescents have been developed and validated in English to measure problematic smartphone use, but they are not available in French. In this study, we provide their translations and linguistic validation in French.

Translating questionnaires into other languages can be complex, as terms in one language can be interpreted in different ways in another, leading to errors in meaning. For this reason, we

XSL•FO
RenderX

have followed the rigorous and standardized steps of linguistic validation defined by the forward/backward method [34].

The results of the translations showed that after 4 stages of translation, the content of the French questionnaires was identical to that of the English ones. The translators, adolescents, and young adults from different educational/professional and geographical backgrounds did not reveal any differences in understanding, suggesting that the cultural adaptation of the questionnaires was respected. These translations suggest that cross-cultural adaptation can be used for comparative purposes in other languages such as English, Portuguese, Arabic, or German.

However, 3 limitations need to be addressed in this study. First, the number of adolescents and young adult participants was less than 20. Although it would be more robust to interview more participants, the minimum number of participants for linguistic validation is not clearly defined [35]. Moreover, the adolescents and young adults provided only few comments on the clarity and understanding of the questionnaires. Second, although 4 volunteer translators were consulted, a more diversified panel of experts would have enabled us to avoid any cultural bias in the translation of the questionnaires. We were able to bring together 4 translators of different genders (ie, 2 men and 2 women) and from different disciplines (ie, eHealth, psychology, education, and economics) who did not have professional knowledge of the concept of problematic smartphone use. Despite these considerations, France is a country with a rich cultural diversity, which may include some regional and linguistic differences. We could have included native experts from different regions with marked linguistic peculiarities (eg, Brittany, Corsica). It is important to note that the 4 translators selected came from different regions of France, which ensures that we have reduced at least some of the cultural biases in translation. The last limitation was that this study focuses solely on linguistic validation without demonstrating quantitative validation. According to Terwee and colleagues [36], the translation process is the first necessary step for validation, but it is essential to verify content validity, internal consistency, criterion validity, construct validity, and reproducibility. This is particularly important here because problematic smartphone use, as measured by the questionnaires, is often assessed across multiple dimensions such as tolerance, withdrawal symptoms, overuse, or physical and psychological consequences [3]. These validation steps, especially regarding psychometric properties, are essential and must be completed before any use of these questionnaires in French. They can then be reliably used to better understand problematic smartphone use among French speakers and for conducting cross-cultural comparisons. These questionnaires will be relevant for gaining a better understanding of how problematic smartphone use is characterized among French adults and adolescents and can be utilized for screening and potentially monitoring patients with conditions associated with problematic smartphone use [5,37].

Conclusion

We succeeded in adapting and effectively translating 4 questionnaires assessing problematic smartphone use in a French-speaking context. This step remains a prerequisite to validating the questionnaires, which can serve as valuable research instruments for investigating and addressing issues related to problematic smartphone use in French-speaking countries and for making international comparisons. Given that problematic smartphone use is an emerging concern with significant health impacts [1], it is imperative that researchers and health care professionals use reliable measurement instruments.

Acknowledgments

This study would not have been possible without the support of Université Grenoble Alpes, Grenoble Alpes University Hospital Center, and LINKSIUM (Society of Technology Transfer and Startup, Grenoble Alpes). This work was partially funded by MIAI Cluster (ANR-23-IACL-0006) and the French National Research Agency (Agence Nationale de la Recherche) within the framework of the “Investissements d’avenir” program (ANR-10-AIRT-05, 2012; ANR-15-IDEX-02, 2016). The funders played no role in the study design, data collection, analysis and interpretation of data, or writing of this manuscript.

Authors' Contributions

IEB collected data, reviewed and assessed the results, wrote the original draft, wrote and reviewed the revised version of the manuscript, and acquired funding. MR collected analyzed and interpreted data, wrote the original draft, wrote and reviewed the revised version of the manuscript, and acquired funding. AB conceptualized and designed the study, reviewed and assessed the results, wrote and reviewed the revised version of the manuscript. NV conceptualized and designed the study, supervised the project, reviewed and assessed the results, wrote and reviewed the revised version of the manuscript and acquired funding. All authors reviewed and agreed to the published version of the manuscript.

Abstract

Background: Personality disorders (PDs) are typically associated with higher mental health service use; however, individual patterns of engagement among patients with complex needs are poorly understood.

Objective: The study aimed to identify subgroups of individuals based on patterns of service receipt in secondary mental health services and examine how routinely collected information is associated with these subgroups.

Methods: A sample of 3941 patients diagnosed with a personality disorder and receiving care from secondary services in South London was identified using health care records covering an 11-year period from 2007 to 2018. Basic demographic information, service use, and treatment data were included in the analysis. Service use measures included the number of contacts with clinical teams and instances of did-not-attend.

Results: Using a large sample of 3941 patients with a diagnosis of PD, latent profile analysis identified 2 subgroups characterized by low and high service receipt, denoted as profile 1 (n=2879, 73.05%) and profile 2 (n=1062, 26.95%), respectively. A 2-profile solution (P<.01) was preferred over a 3-profile solution, which was nonsignificant. In unconditional ($t_{3941,3939}$=19.53; P<.001; B=7.27; 95% CI 6.54-8) and conditional ($t_{3941,3937}$=−3.31; P<.001; B=−74.94; 95% CI −119.34 to −30.56) models, cluster membership was significantly related to receipt of nursing contacts, over and above other team contacts.

Conclusions: These results suggest that routinely collected data may be used to classify likely engagement subtypes among patients with complex needs. The algorithm identified factors associated with service use and has the potential to inform clinical decision-making to improve treatment for individuals with complex needs.

Introduction

Personality disorders (PDs) are typically associated with poorer health outcomes [1] and high mental health service use [2], yet PD treatments remain poorly understood and are often not specific to the individual [3]. Understanding patterns of service use across the diagnostic spectra of PD comprises an important and novel area of research in the applied domain. There are also considerations of optimizing UK National Health Service (NHS) service capacity and improving relationships between services and service users, which are often challenging given the relational sequelae component within a PD diagnosis [4].

The longstanding needs of patients with PDs require effective management and treatment approaches. Being able to understand likely patterns of service use could help allocate resources in secondary care, given limited resources. Predictive modeling for more personalized treatments is vanishingly rare in conventional health care models of service delivery [5], yet there are growing calls in the methodology and policy literature for improvements in both treatments and relationships [6] for patients with complex needs.

Effective prediction of treatment outcomes is an area of continued interest in general mental health care [7]. To our knowledge, this body of work has yet to be applied to PD treatments; however, there are promising opportunities offered by large-scale applied health data research, greater availability of relevant datasets [8], and increasing sophistication of relevant computer software and analytical approaches. This paper expounds formative work in this sphere by conducting formal validation in understanding diagnostic patterns of service receipt, as a key step toward formal prediction and more tailored treatments.

Given the engagement difficulties that come with a PD diagnosis [9], there is clinical interest in better understanding patterns of service use across the swathe of *International Classification of Diseases, Tenth Revision* (*ICD-10*) PD diagnoses [10,11]. Enabling services to predict likely patterns of service contact can help personalize the treatment pathway, given likely service demand, and optimize resource allocation. In turn, if treatment pathways can be tailored to the needs of service users at presentation, this may reduce the propensity for harmful treatments [12], directly improve therapeutic relationships, indirectly reduce long-term service use [13], and aid capacity management and resource allocation [14].

Individuals with a diagnosis of PD are reported as misunderstood, at least in mental health care [15]. In addressing this impasse, this study provides mental health services with the necessary functionality to move away from uniform PD treatments and toward more personalized approaches [16]. Decision support studies in health care are gaining momentum [17], and although the adoption of such systems has been slower in mental health care, the past decade has seen a rise in pilot implementations [18,19]. There is also a need for more advanced methodologies beyond “first-generation” regression-based approaches, which face increasing challenges and scrutiny in the age of data scientific [20], such as mediation and structural equation models, both in PD management [21] and in clinical psychology [22,23].

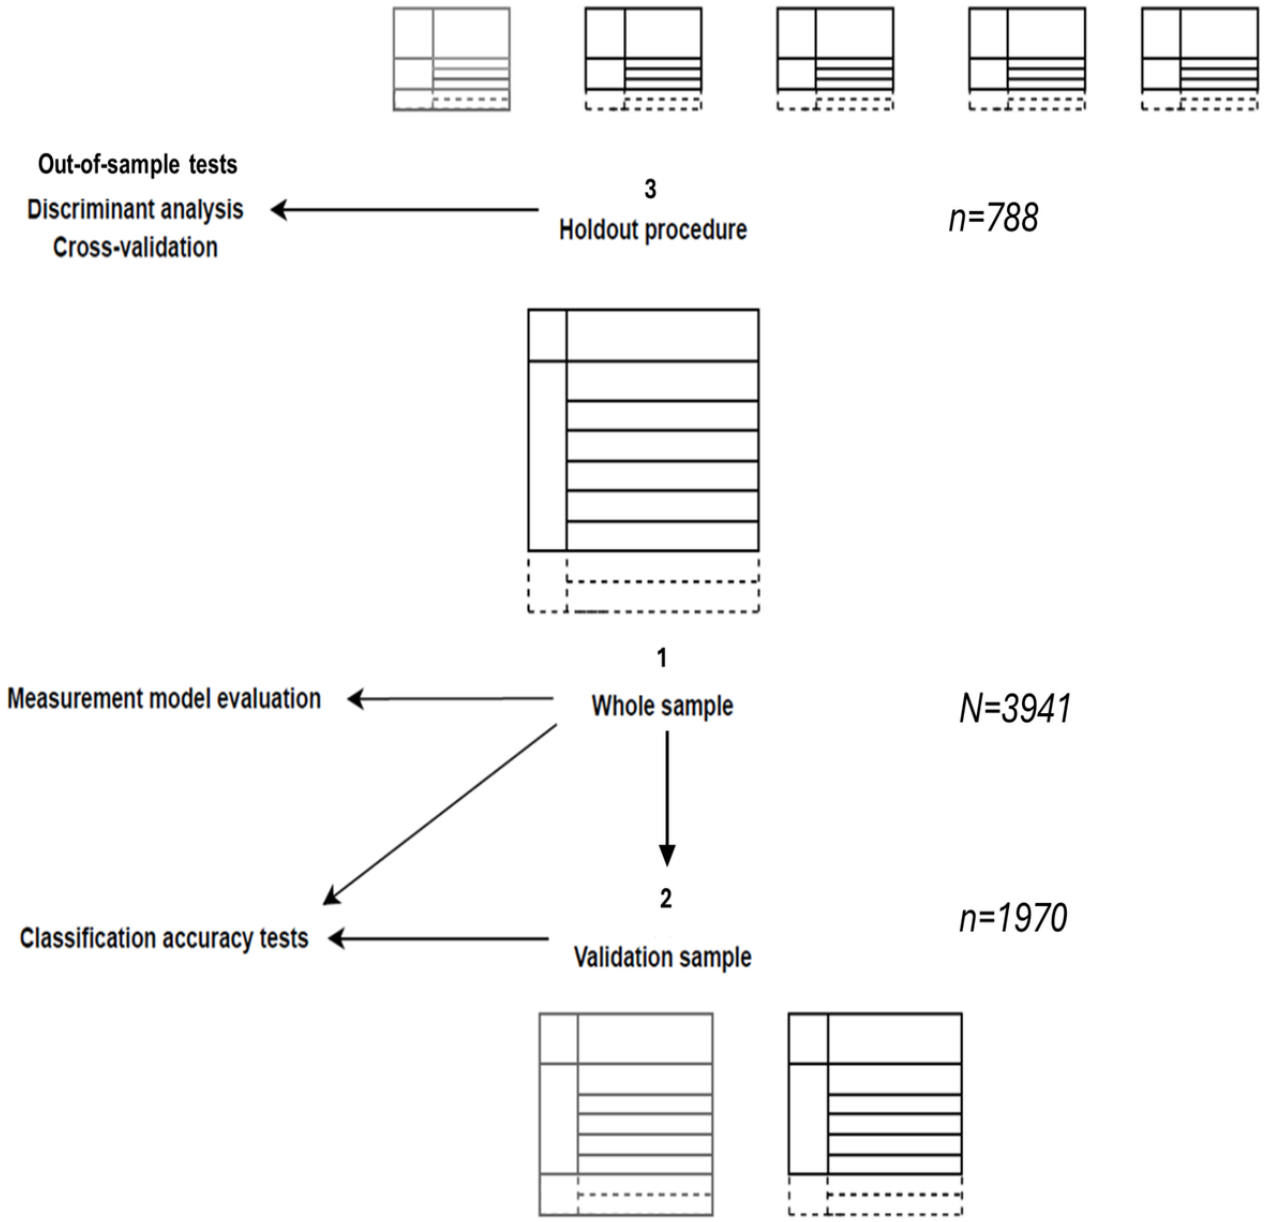
There has been growing interest in person-centered approaches [24] driven by calls for methodological and analytical advancements [25], efforts to improve access [26,27], initiatives to democratize treatments [28], and a rising focus on the personalization of mental health care [16]. These, in turn, have resulted in developments in theory [29] and modeling [30,31]. For example, latent class analysis (LCA) comprises an increasingly researched, novel approach, especially relevant in unpicking potential sources of observed heterogeneity [32,33]. This paper integrates these research perspectives using latent profile analysis (LPA). LPA is an extension of LCA, statistically described as finite Gaussian mixture models [34].

Person-centered approaches, such as clustering methods, LCA, and LPA, provide a useful first step in dimension reduction [35], argued as a key focus in reducing heterogeneity encountered in PD treatments, research, and theory [36]. In the context of psychiatric comorbidity, the number of potential co-occurring factors that make up disorders can challenge traditional variable-centered approaches, which may struggle to model all potential interactions [29]. In contrast, clustering approaches comprise an important first step in the aim to personalize treatments and treatment pathways, such as with physical medicine in cancer treatments [37]. In addition to these clinical and methodological motivations, the search for subgroups in complex mental health treatment is further motivated by relevant policy calls in the treatment literature [38].

The aim of this study was to characterize the patterns of service receipt in a large sample of patients with a diagnosis of PD in an urban, secondary care setting. The research question considered how to best characterize service receipt, as part of the specialist PD treatment pathway, using routinely available treatment, diagnostic, and demographic data.

Methods

Overview



LPA was conducted to identify statistically distinct patterns of service contact within a sample of individuals with a diagnosis of PD receiving treatment in secondary care in South London. In addition to identifying the optimal class solution in this setting, formal validation aimed to inform generalization estimation, reporting both average-level and individual-level classification errors. This paper further extends LPA research through consideration and evaluation of the structural model and extends such evaluation through protocolized resampling.

Validation-focused analyses assessed the structural model [39], with parameters tested for relevance when considering cluster membership. Out-of-sample approaches to prediction are well researched in wider structural equation modeling perspectives, for example, partial least squares structural equation modeling [40]. Importantly, while findings of mixture models may prove interesting, classes may not necessarily reside in the wider population [41], further motivating explicit consideration of generalization in study design.

XSL•FO
RenderX

LPA guidelines suggest using 3 sampling frames as good practice to validate findings [42,43]. To begin, the initial whole sample was "sample frame 1," comprising the final analytical set. Validation samples randomly split the whole sample into two equal groups of 3941, resulting in "sample frame 2" [42,44] and 2 validation samples (1970/3941, 49.98%). Finally, cross-validation requires a holdout procedure [45], which partitions the dataset into test and training samples, to assess "out-of-sample" performance. This procedure split the whole sample into 5 parts, with 80% or $k-4$ parts designated as the training sample (3153/3941, 80%) and the remaining 20% or $k-1$ part designated as the test sample (788/3941, 20%). As shown in Figure 1, there were 3 sampling frames as a result.

Figure 1. Analysis plan and sampling procedure.

In this study, posterior probabilities of cluster membership were identified using sample frames 1 and 2. The comparison between sampling frames (Tables S1 and S3 in Multimedia Appendix 1) describes the formal relevance of the model regarding validation. Posterior probabilities of cluster membership were calculated from the e-step of the expectation maximization algorithm [46] and describe how the person i belongs to the class k [47,48], also described as their modal class assignment, according to the selected model [42].

Setting

Patient data for the study were extracted from the Clinical Record Interactive Search platform at the South London and Maudsley NHS Foundation Trust. South London and Maudsley (SLaM) provides comprehensive, near-monopoly specialist mental health services to a geographic catchment area of 4 boroughs of southeast London (Croydon, Lambeth, Lewisham, and Southwark) with a population of approximately 1.3 million residents.

XSL•FO
RenderX

Ethical Considerations

The Clinical Records Interactive Search (CRIS) system was set up in 2007-2008 through codevelopment of a data security and governance model with service users [49]. The CRIS system and related linked data have received successive research ethics approvals since 2008 as an anonymized data resource for secondary analyses (current approval: Oxford Research Ethics Committee C, approval number 23/SC/0257). The institutionally approved governance model has been described in detail elsewhere [50], but in summary, it includes automated deidentification of the record, standard researcher approval, a locally publicized opt-out facility, and an oversight committee with patient leadership and membership reviewing all data use.

Sample

The inclusion criteria comprised having an *ICD-10* PD diagnosis [41] at any time, being aged between 20 and 101 years at initial presentation, and being in contact with SLaM due to referral, although 10.38% (409/3941) of the sample had no recorded team contacts in the analysis set. Given the population of interest and generalization intention, those aged <20 years (318/3941, 8.07%) and >101 years (8/3941, 2.02%) were excluded to reduce possible inclusion bias and to encourage greater sample representativeness.

The inclusion criteria were applied over an exposure period of 11 years, with care episodes sampled between 2007 and 2018. This study sought to identify a matched, complete set of service use data at service users' first and final points of contact with services (time 1 and time 2, respectively). Time points were denoted by episode start and end dates, such that time 1 represented the start and end of the first episodes of care and time 2 represented the same at the final episodes of care. Dataset assembly resulted in a complete, matched set of data points, ascribed by time 1 and time 2 and organized by episode of care. An episode of care was calculated as the elapsed time between patients being referred to and in contact with services and subsequent discharge from secondary services. In the final matched pairs set, the average length of an episode of care was 131.86 (SD 309.69) days. Moreover, "discharge" is defined by SLaM Trust policy as "discharging a patient from an in-patient setting to a community team or from the Trust completely to primary care or another provider" [51]. Importantly, this follows when a patient is deemed to no longer benefit from either reduced risk or improved well-being [51] and suggests a shift in presentation and overall needs.

Working with the CRIS team, a custom data extract resulted in 82,265 episodes of care from 8510 service users. The inclusion of contacts from clinical teams data resulted in a reduced set of 6068 individuals, which was further processed to include complete "matched pairs" data for 3941 service users, at their first and final episodes of care (T1 and T2, respectively; Figure S1 in Multimedia Appendix 3). A complete dataset was preferred as there were no missing data, which strengthened the design using a large sample. T1 and T2 contained episode start and end dates, respectively, as discussed in the Statistical Analysis section. The authors acknowledge that the nature of this experimental design necessitated service users engaging with services on more than one occasion. Therefore, individuals with only a single episode of care (2127/3941, 53.97%) were omitted from the analysis. Notwithstanding, PD is typically a chronic condition [52,53], and in general, service users are likely to have ongoing needs and therefore present to services on more than one occasion.

Measurements

Quantitative Variables

Mixture modeling research typically uses cross-sectional data [54]. In the search for the best model, LPA compared model solutions using both repeated measures (T1 and T2) and T1 data only. Analytically, the episodic shaping of the data did not account for the timing or point of diagnosis, resulting in some patients being diagnosed after the initial T1 episode of care. Once again, however, given the longstanding nature of PD [52] and difficulties in accessing effective treatments [55], the precise timing of when a patient receives a diagnosis can be considered less important than it may initially appear.

Preliminary modeling [56] identified negligible "loading" or lambda values when including more granular detail regarding ethnicity (Table S1 in Multimedia Appendix 4). For example, including ethnicity categories such as Asian (λ=0.25) and mixed ethnicity (λ=−0.23) in the demographic construct failed to meet statistical significance, and the strongest performing model was the one that only included the presence or absence of White ethnicity.

Demographic data were modeled to include ethnicity (White or non-White), neighborhood-level deprivation, age, and gender (proportion of female and other). Deprivation was measured using the Multiple Indices of Deprivation [57]. This measure comprises nationally recorded data and measures multiple deprivation at the Lower Super Output Area level (a standard administrative geography encompassing approximately 1500 residents), including a nominal variable of 10 categories, with 1 describing most deprived and 10 describing least deprived [57].

Service receipt was modeled to include the total number of face-to-face contacts, as well as the number of unattended appointments, for each episode of care. Clinical input data were counted as the number of contacts from each treating team during each episode of care, that is, the cumulative total number of contacts within the specified time frame of a care episode. The number of contacts from care teams included medical, psychology, nursing, therapy, social work, and other. The CRIS system uses the General Architecture for Text Engineering [58], a natural language processing engine that captures recorded diagnostic statements. This output was used to ascertain PD diagnoses (Table S2 in Multimedia Appendix 4) in addition to prestructured primary diagnosis fields, which provide all options from the *ICD-10* [59].

ICD-10 lists a range of PD diagnoses, denoted by category membership, in contrast to *ICD-11*, which characterizes PD by severity. Accumulating evidence indicates limited support for the foregoing polythetic approaches [11,60]. To aid meaningful comparisons, diagnoses were collated and assigned to relevant clusters used routinely in psychiatric care (Table S2 in Multimedia Appendix 4). Diagnostic and Statistical Manual

XSL•FO
RenderX

cluster A diagnoses are characterized by "odd and eccentric" presentations, including paranoid, schizoid, and schizotypal PD diagnoses. These were distinguished from cluster B diagnoses, described as "overly dramatic, overly emotional, or unpredictable" presentations, as well as cluster C diagnoses, namely, "fearful or anxious" presentations.

As with ethnicity data, preliminary statistical modeling [56] highlighted the negligible impact on model performance of including more specific diagnostic information (Table S1 in Multimedia Appendix 2), beyond the presence or absence of cluster A diagnoses alone. Specifically, this was exemplified by low lambda loading values (λ<0.40) when including cluster B (λ=0.25), cluster C (λ=−0.20), and cluster other (λ=−0.07) onto the overall construct of diagnosis (refer to Tables S1 and S2 in Multimedia Appendix 4 for data cleaning descriptions of ethnicity and diagnostic data, respectively). Following these inferences, the proportion of *DSM* A diagnoses were taken as the proportion of *internalizing* diagnoses [61].

Statistical Methods

As formulated in the study by Nylund et al [62] and discussed in the study by Masyn [42], the null hypothesis in mixture modeling is the one-class model. Comparative likelihood ratio approaches, using the likelihood ratio test (LRT), describe and compare the likelihood of the two models under comparison, given the data [63]. In the first stage, different model solutions (namely, 2-, 3-, or 4-cluster solutions) were tested against this null sample. In the second stage, the number of groups, or "G," was varied using *mclust* [35], and relevant likelihood ratio statistics were then entered into *tidyLPA* [64]. Second-stage testing specified the null (ie, the 2-class solution) versus the alternative (ie, the 3-class solution) hypothesis. The LRT statistic then compares the likelihood of either model, given the data [63].

Model evaluation then proceeds from the measurement model, in terms of number of classes, to the structural model, in terms of the relation of parameters to classes. Across the range of "stepwise" configurations, 1- and 3-step procedures are typical of the literature [39,62], with different approaches varying in their inclusivity and efficiency [65,66]. In practice, comparing the relationship between parameters and clusters can assist in model evaluation. These relationships describe the structural model of the mixture model, and structural model evaluation compares these relationships.

Discriminant analyses are popular in machine learning perspectives on mixture models [67,68]. Discriminant validity assesses the classification accuracy of a mixture model by comparing the performance of a testing subsample on a training subsample (Figure 1). In this study, discriminant analysis was developed using the eigenvalue decomposition discriminant analysis [35,41]. The eigenvalue decomposition discriminant analysis constrains the discriminant analysis model to have a single component for each class, with the same covariance structure among classes. More recent discriminant analysis models are available [69]; however, these models impose stricter requirements, such as a different number of mixture components and covariance structures for each class, which were deemed unsuitable for this analysis.

Discriminant analysis was conducted over 10 folds. For each "fold," a separate dataset was assembled, comparing actual values versus those predicted by the model. As is typical in prediction studies, prediction error tests the predictive performance of the model on a holdout sample, with results summarized using common prediction metrics [45]. Typically, these include the root mean squared error, mean absolute error (MAE), and mean absolute percentage error (MAPE) [45,70]. In predictive applications, the MAE was selected as the metric of choice, given its greater resistance to distributional skewness [70]. To assist interpretation, both the MAE and MAPE are reported, with the MAPE calculated using the *Metrics* package [71]. The MAPE is calculated using the absolute error in each fold divided by the observed values that are evident for that fold. Averaging these fixed percentages yields the MAPE, which indicates how much error arises from the prediction model compared with the true value [72].

LPA was chosen for its flexibility in data requirements and its suitability for modeling a heterogeneous population that cannot be effectively represented by a single-component distribution [34]. Indicator variables included demographic variables, number of face-to-face contacts, number of did-not-attends, and number of contacts with clinical teams, per episode of care. Data preparation was assisted using the *tidyverse* package [73]. Analyses were conducted using the packages *mclust* [35] and *tidyLPA* [64] using R statistical software (R Core Team) [74,75].

Statistical Analysis

Fitting the Measurement Model

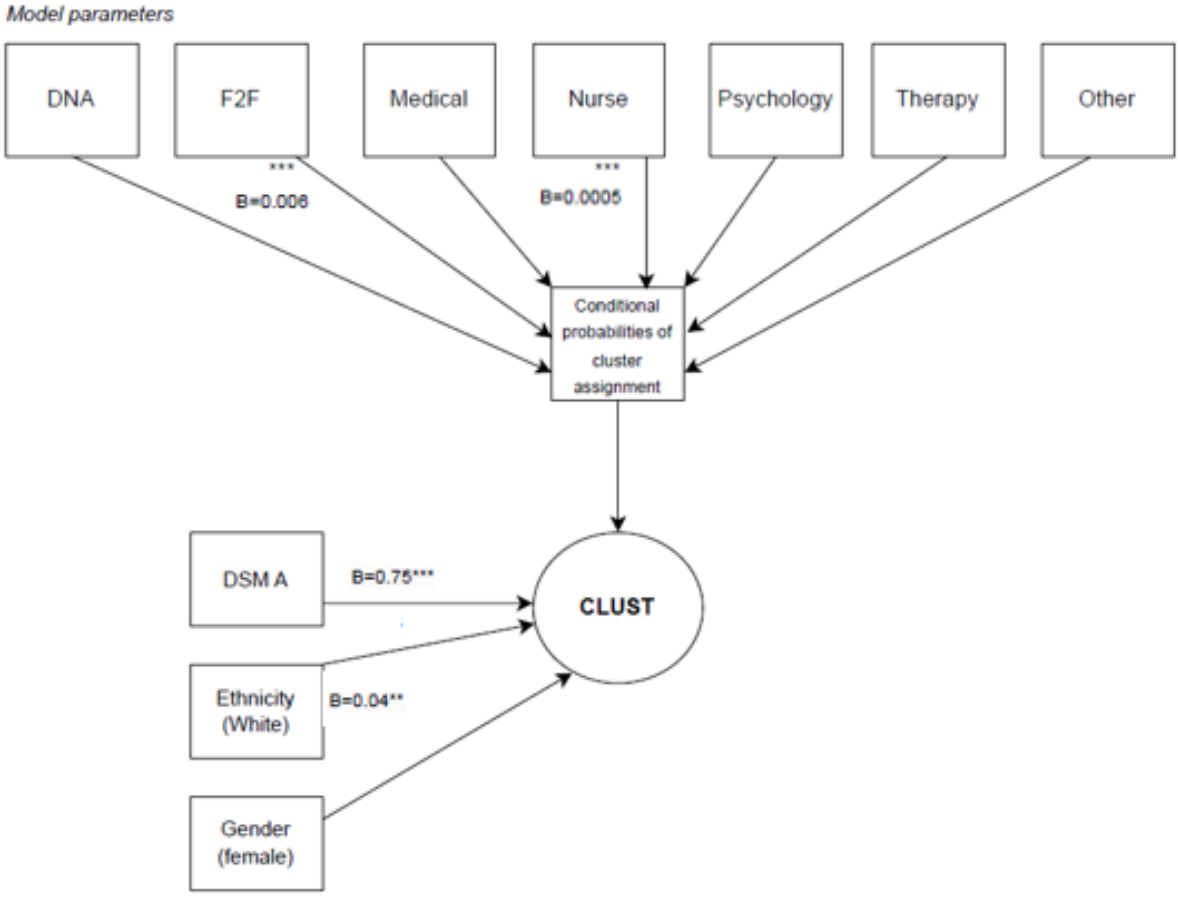
The purpose of this analysis was to identify the patterns of service receipt in a large sample of patients with a diagnosis of PD in a secondary care setting, with the goal of enhancing contemporary models of care [76]. LPA scholarship was further extended through formal validation, as a precursor to prediction, which used protocolized resampling to ascertain the discriminatory relevance and possible scale potential of the proposed model solution.

To establish the best-fitting model, a range of metrics were considered. These included the Vuong-Lo-Mendall-Rubin LRT [77] and the bootstrapped LRT [39,78]. Alongside likelihood ratio tests, fit statistics included the Akaike information criterion, the Bayesian information criterion (BIC), and values of entropy. Both the LRTs, the Vuong-Lo-Mendall-Rubin LRT and bootstrapped LRT compare the K model (the current model with a number of k profiles) to $K-1$ model (a model with one less profile). Significant P values from these tests assert that the K model fits the data better than a comparable model with one less profile [43]. Conversely, a nonsignificant P value ($P\leq.05$) indicates that the model with one less profile provides a better fit for the data, with more parsimonious models preferred. Smaller Akaike information criterion and BIC values indicate better model fit, while higher values of entropy suggest higher accuracy in classification of the model.

As no prior hypotheses for the number of profile groups were suggested, model selection compared solutions derived from either a repeated measures design, consisting of T1 and T2 data, or a contemporaneous design, consisting of T1 data only.

XSL•FO
RenderX

Episodes of care were defined across two levels: (1) at the patient level, including demographic and diagnostic information, and (2) at the episode level, including "start" and "end" date of episodes, whereby service receipt measures were collected as properties, or descriptors, of that episode.



Episode descriptors were used as indicators for the LPA, including sociodemographic measures (age, ethnicity, and gender); diagnostic factors (percentage of internalizing diagnoses); general measures of contact (the number of face-to-face contacts and the number of did-not-attends); and the number of contacts from specific clinical teams (medical, nurse, psychology, therapy, and other).

Fitting the Structural Model

Assessment of the structural model considered the explanatory relevance of parameter values on cluster membership. Exogenous, pretreatment variables (ie, demographics) were limited to 1-step evaluation procedures. For service contact parameters, inferential tests were developed for both 1- and 3-step procedures [39]. Three-step procedures assert the importance of conditional probability of class membership in post hoc testing. Corrected by assignment probability [42], the 3-step procedure helps control for the individual validity of profiles. In contrast, the 1- and 2-step approaches can often omit the nonzero classification accuracy of derived clusters [39]. However, in the case of models with high classification accuracy, 1-step procedures may be justified [65,79]. As such, this paper reports both 1- and 3-step procedures, comparing unconditional versus conditional structural mixture models.

For the adapted 3-step procedure, the first step identified and enumerated cluster solutions, which were compared using model fit statistics. In the second step, conditional probabilities were extracted from the e-step of the EM algorithm using *mclust* [35] and vectorized "row wise" at the level of each individual. For the third step, individual conditional probabilities were included as covariates (ie, general linear models mapped the interaction between parameters with conditional probabilities). General linear models compared cluster assignment as a function of each parameter. Results of these analyses are summarized in Figure 2 and presented in Table 1.

Figure 2. Conditional structural model evaluation showing the significance of paths and pretreatment covariates in determining cluster membership.

[a]$P<.001$.

Latent Profile Cross-Validation Strategy

Cross-validation uses the data to test "the predictive power" of the model [80]. For the procedure, cross-validation splits the dataset into k subsamples of equal size, repeating k times, each time using a different test set (Figure 1). The best-fitting parameters of the model are then fit using k−1 subsamples, with the model's error then computed on the unused subsample or test set [81].

In line with the discriminant analysis procedure, cross-validation was conducted using sample frames 1 and 2 (in sample and out of sample, respectively), as shown in Figure 1. The Brier score [82,83] indicates the predictive usefulness of the model for individuals who, theoretically, may be unseen. Applied research in mental health has shown increased experimentation with the Brier score as a forecasting tool, such as for predicting suicidal ideation in individuals at near-term suicide risk [84] or identifying patients likely to drop out of psychotherapy [85]. In related psychotherapy research, the Brier score ranges from 0 (best prediction) to 1 (worst prediction), and it measures the accuracy of probabilistic predictions [85].

A detailed sampling strategy enabled both explanatory and predictive appraisal of the derived model solution, as shown in Figure 1. As well as the whole sample (frame 1), validation samples (frame 2) divided the dataset randomly, 2 × 50%. LPA was conducted on both frames 1 and 2 (total sample and validation samples, respectively), as shown in Figure 1, informing sample comparisons and confirming the profile structure [43]. Subsequently, LPA was rerun on the whole sample to aid interpretation of the findings.

Sample frame 3 for discriminant analyses split the total sample into 5 parts, with 80% (3153/3941) or $k-4$ parts designated as the training sample and the remaining 20% (788/3941) or $k-1$ part designated as the test sample. The holdout procedure was repeated over 10 folds, in line with best practices [45]. Discriminant analyses tests were then applied over sampling frames 1 and 3 (Figure 1), with cross-validation describing classification accuracy for both total and holdout sampling frames using the classification error and Brier scores. As discussed earlier, the Brier score is a proper score function that measures the accuracy of probabilistic predictions [85]. More technically, the Brier score comprises the mean square difference between the true classes and predicted probabilities [82,83].

Latent Profile Resampling Testing Strategy

Discussions on prediction-focused structural equation modeling consider discriminant validity in terms of in-sample versus out-of-sample perspectives [45]. Bootstrapping has gained prominence in sample validation; however, this remains a decidedly in-sample approach. In this study, larger sample sizes permitted a combination of k-fold assessments of discriminant validity, combined with cross-validation modeling, which ascertain both in-sample and out-of-sample classification accuracy.

LPA was then conducted on the "T1 and T2" dataset, while a holdout procedure (Figure 1) tested the predictive relevance of the profile solution across 10 partitions, or "folds," of this procedure. Predictive performance was summarized by prediction metrics, namely, the MAE and MAPE [86,87]. The MAPE was calculated using the absolute error in each fold divided by the observed values that are evident for that fold. Averaging these fixed percentages yields the MAPE, which indicates how much error arises from the prediction model compared with the true value [72].

Results

This study broadly follows the reporting guidelines from the Consolidated Standards of Reporting Trials (CONSORT) [88], although it specifically adheres to the Strengthening the Reporting of Observational Studies in Epidemiology [89] and Reporting of Studies Conducted Using Observational Routinely-Collected Data [90] guidelines, which were more suited for improving the reporting of observational epidemiological research.

Participants

The flow of participants throughout the study is shown in Figure S1 in Multimedia Appendix 3. In brief, the initial analytical set comprised 82,265 episodes and 8510 patients. Data were prepared to include team contacts and ensure completeness,

resulting in 170,365 episodes and 6421 patients. Further processing resulted in the final analytical set of 7882 episodes from 3941 patients to optimize the analysis, with this complete dataset having no missing values.

Descriptive Statistics

Tables 2 and 3 display the distribution of patient characteristics from the LPA and across sampling frames. Descriptive statistics for holdout samples were limited to the initial fold (of 10). Comparing latent profiles to the whole sample means and distribution provides an understanding of the characteristics of each group of patients across identified latent profiles (LPs)—LP1 and LP2—in the 2-profile solution. Service receipt, measured as the number of contacts from clinical teams, was markedly higher for LP2 than for LP1. The LPA best characterized service receipt as being either high or low, captured through LP2 and LP1, respectively. While LP1 counted no psychology contacts, LP2 on average had almost 6 per episode of care. This pattern was consistent for medical teams and, in particular, nursing teams.

In general, LP2 received treatment at a rate 10 times higher than LP1. The derived profiles were not differentiated by sociodemographic characteristics; both latent profiles had similar proportions of female and White individuals as well as comparable levels of neighborhood deprivation. In total, 11.3% (120/1062) of LP2 had internalizing diagnoses, with no such diagnoses present in LP1.

Evaluation of the Measurement Model

Analyses identified 2 profiles emerging from the contemporaneous (T1) dataset and 4 profiles from the repeated measures dataset (T1 and T2; Table 4). Profiles were enumerated according to the BIC using mclust [35] for T1 versus T1/T2 dataset, selecting 2 and 4 profiles, respectively. The comparison of classification and likelihood indices shown in Table 4 suggested that the 2-profile solution from T1 data was preferred, showing superior model fit. Stage-1 LRT tests compared 2 and 3 class solutions against the null hypothesis, that is, the 1-class model. Both solutions demonstrated superior likelihood than the null hypothesis; however, the 2-profile solution was preferred. Stage-2 LRT tests compared 3-profile (the alternative) versus 2-profile (the null) solutions and failed to demonstrate any advantage of a 3-profile solution over a 2-profile solution.

Table 4. Model fitting statistics[a].

Fit values	1-cluster	2-cluster	3-cluster	4-cluster
Log-likelihood criteria				
Log likelihood	−119,761	−72,497.47	−81,918.54	−118,721.9

In model selection, comparative LRTs described how a 3-cluster solution significantly outperformed the 1-class model but not the 2-class model (Table 4); therefore, a 2-cluster solution was preferred.

XSL•FO
RenderX

Posterior probabilities were calculated as the proportion of correctly assigned patients to the respective clusters. These probabilities are "posterior," in the sense that they are calculated *after* individuals have been assigned a cluster membership [91]. Table S2 in Multimedia Appendix 1 displays classification indicators and posterior probabilities, and the classification error of the model was also negligible, being near 0. The Brier scores further demonstrate near-perfect classification accuracy of the model in forecasting individuals' likely engagement subtype, given the values of routinely collected indicators. High posterior probabilities are also considered clear indicators of classification accuracy, with values ideally exceeding 0.80, in line with established guidelines [66].

Evaluation of the Structural Model

Findings from evaluation of the measurement model, taken with the near-perfect degree of classification accuracy (Table S3 in Multimedia Appendix 1), suggest the usefulness of combined parameters in predicting cluster membership.

Relating parameter values to clusters is expressed in the language of direct and controlled direct effects [92]. The direct effect describes the (unconditional) relationship between parameters and clusters, while the controlled direct effect describes this relationship based on the individual probabilities of cluster assignment. In the unconditional model, all parameters determined class assignment, apart from gender (Table 5). Figure 2 displays conditional model evaluation, where face-to-face contacts ($t_{3940,3939}$=5.73; P<.001; B=0.006; 95% CI 0.005-0.006) and the number of nursing contacts ($t_{3940,3939}$=5.52; P<.001; B=0.0005; 95% CI −0.003 to 0.0006) significantly determined class assignment.

Likelihood-based approaches tend to dominate the mixture modeling landscape; however, there can be inferential challenges when adhering to the orthodoxy [63,93]. A more Bayesian approach may consider the likely parameter value, given the cluster membership. Structural model evaluation using this approach followed the same 3-step procedure as advised by Nylund-Gibson et al [39] and described in the section Fitting the Structural Model. Results from these analyses are presented in Table 1 and further detailed in Figure 3.

In the unconditional model and of all care contacts, psychology demonstrated the strongest relationship to clusters ($t_{3940,3937}$=23.83; P<.001; B=0.02; 95% CI 0.02-0.02); however, this was not upheld in the conditional model ($t_{3940,3937}$=1.72; P=.09). Overall, key prognostic targets of service receipt given the knowledge of cluster membership were nurse contacts. In both unconditional (t_{3940}=19.53; P<.001; B=7.27; 95% CI 6.54-8) and conditional (t_{3939}=5.52; P<.001; B=−74.94; 95% CI −119.34 to −30.56) models, cluster membership was significantly related to the receipt of nursing contacts.

Further testing modeled an interaction term between nursing contacts and cluster membership in determining nonattendance, as shown in Figure 3. The interaction term was significant both for face-to-face contacts ($t_{3940,3937}$=5.81; P<.001; B=0.74; 95% CI 0.49-0.99) and did-not-attends ($t_{3940,3937}$=3.62; P<.001; B=0.12; 95% CI 0.06-0.20), with confirmatory testing indicating that the rate of did-not-attends did not significantly differ from a Poisson distribution (N=3941, χ^2_8=10.3; P=.20).

Table 5. Direct and controlled effects of parameters and additional covariates on cluster membership.

	t test (*df*)	Direct effect, 95% CI	*t* test (*df*=3939)	Controlled effect, 95% CI

Figure 3. Plot showing the interaction term between nursing contacts and cluster in determining the rate of did-not-attends (DNAs).

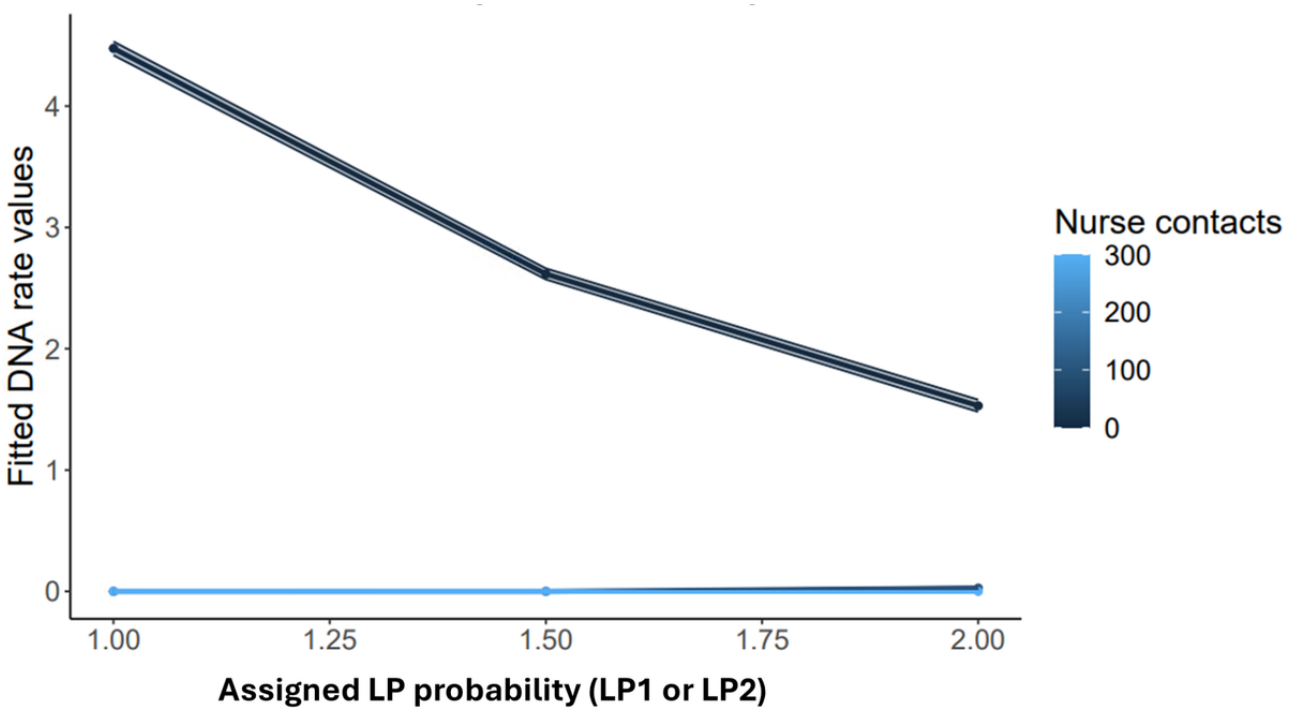

Figure 3 shows this relationship visually and indicates how did-not-attend rates vary between clusters as a function of nursing contacts. The assignment of profiles is shown probabilistically between either latent profile 1 and latent profile 2, which allows for assignment likelihood or uncertainty in clinical practice. For LP2, the number of nursing contacts made less of a difference in fitted rates of did-not-attends, compared to LP1. As it represented the majority of the sample, LP1 was more sensitive to the effect of nursing contacts regarding fitted rates of attended appointments.

Resampling Performance

Discriminant analysis modeling indicated high classification accuracy of the selected model (Table S3 in Multimedia Appendix 1). Both the MAE and MAPE were taken as summative indicators regarding the overall prediction error of the model. Over 10 folds of the holdout procedure, or train × test runs, the "grand" MAE was 0.004 (Table S3 in Multimedia Appendix 1), meaning that the model predicted correct class assignment with near-perfect accuracy. Conversely, out-of-sample tests on the replicative utility of engagement measures were less favorable. For face-to-face contacts, the MAE was 11.27, whereas for the number of did-not-attends, the MAE was 1.97. The MAPE may aid interpretation of these results, specifying that the number of face-to-face contacts erroneously predicts cluster membership in 11% (86/788) of cases (of 10 "folds"; Table S2 in Multimedia Appendix 1).

In the explanation-focused in-sample approach, the Brier score was 0.005. From an out-of-sample perspective, the average Brier score was 0.19 (Table S1 in Multimedia Appendix 1). The average classification error over 10 folds was 0.005, indicating substantially high classification accuracy. In addition, the average (out-of-sample) Brier score was 0.19 (SE 0.005), suggesting a nearly 80% rate of forecasted classification accuracy from an out-of-sample perspective.

Discussion

Summary of Findings

This study aimed to characterize the patterns of service receipt in a large sample of patients with a diagnosis of PD in an urban, secondary care setting. The main findings of this study were identification of 2 LPs that best characterize service receipt in specialist PD treatments. LP2, at 26% (1062/3941) of the sample, received almost 5-fold as many nursing contacts as LP1 (9.43 vs 3.98) and 6-fold as many medical contacts (5.90 vs 1). In addition, general service use was almost 10 times greater in LP2 than LP1. Sociodemographic characteristics were not associated with LPs, but diagnostic factors were associated. Specifically, LP1 had no internalizing diagnoses. These findings suggest important distinctions of service receipt as a function of routinely collected data and suggest the discriminatory relevance of such descriptors in determining likely profile membership.

LPA identified statistically reliable categories of service use using routine observational data for those with a diagnosis of PD. Profiles distinguish service receipt for those with a diagnosis of PD and were replicated across a range of sampling frames. Discriminant analyses and cross-validation modeling suggest substantial discriminatory performance in secondary settings using these types of data. This study described 2 LPs, primarily distinguished by diagnostic information. Of the approximately 3000 patients in LP1 (n=2879, 73.05%), none had internalizing PD diagnoses. In inferential testing, patients in LP1 were twice as likely to have less service contact.

Interpretation

The literature discussing PD and service use describes greater service use in the general presence of PD [94,95]; however, this has yet to be robustly applied between different PD diagnoses.

XSL•FO
RenderX

One study delineates the interplay between personality (disorder) and health [96], and there is rigorous work, such as comparisons of service use based on ethnicity in PD treatments [97]. Despite economies of scale offered by population-based interventions, these programs should be customized for subgroups on the basis of personality [96]. This study details foundational work in this area using a large sample in secondary care and attempts to export this comparative focus to diagnostic factors within PD treatments.

In a large study using administrative data in Quebec, emergency department visits were compared between "externalizing" or *Diagnostic and Statistical Manual* cluster B PD and schizophrenia, those diagnosed with both conditions, and the general population [98]. General practitioner visits were highest in the cluster B group, while the use of psychiatric (vs nonpsychiatric specialist or generalist) services differed in the presence of a PD diagnosis, with 1 mean annual visit versus 4, for schizophrenia.

Similar findings were captured in this study, which demonstrates lower service use for noninternalizing diagnostic groups. Greater service use was shown for the smaller latent profile, LP2. In practice, greater patterns of service use from the minority group arguably have predictive relevance in profile determination and tailoring treatment pathways accordingly. "Hotspotting," as it is known in general practice [99], is a data-driven practice that aims to identify patterns of "extreme" use [100]. Complex needs and PD populations are similarly characterized by high use [101]. This responsive concept is well known in general practice but has yet to be specifically applied to mental health care. In the case of PD and complex needs, general practice is often a key contact [102]. As demonstrated in this study, understanding individual (stratified) patterns of service use offers an example for expanding hotspotting practices, commonly used by general practitioners, to address historical challenges in generalist service provision for complex needs. By applying advanced techniques such as LPA, this approach can help create more tailored treatment pathways.

Therefore, this study argues that more data-enabled, proactive service provision, engendered by hotspotting practices, may assist modernization of mental health provision and encourage more individually intelligible and tailored treatment pathways. The assertion is that the determination of cluster membership, given the routinely measured parameters, may help inform similar practices in secondary care with complex needs. Related work in improving access to psychological therapies highlights 8 LPs [43], which contrasts with the solution presented in this study.

Interestingly, the rates of nonattendance were stable across profiles, averaging around 1 in 10, which is broadly in line with the literature in general practice [103]. Service use was poorly distinguished as a function of the treating team. Structural evaluation revealed nursing contacts and did-not-attends of key interest; modeling the interaction term showed that the fitted rate of did-not-attends differs between clusters as a function of nursing contacts. The implication is that more intensive treatment pathways with more nursing contacts result in greater fitted nonattendance for LP1. However, for LP2, greater nursing contacts had much less of an effect on did-not-attends.

The use of a large sample, the multiplicity of analyses, and the development of a protocolized resampling scheme for validation comprise key strengths of this study. Discriminant validity and classification accuracy tests showed near-perfect classification for individuals with a diagnosis of PD into LPs (Table S2 in Multimedia Appendix 1). Generalizability was explicitly considered pursuant to resampling and validation, which may have implications regarding wider (national) policy implementation. From an out-of-sample perspective, for example, the model accurately predicted cluster assignment in nearly 80% of cases, across 10 "folds" of the holdout procedure, or train × test runs, compared with a Brier score of 0.005 for in-sample model performance (Table S1 in Multimedia Appendix 1). At least, for explanatory purposes, the model was able to classify all cases correctly.

Limitations

A limitation of this study is that both exposure and outcome were measured over the same periods. This contemporaneous design was indicated in model selection; however, more frequent measurement may have resulted in more precise model solutions. Comparative modeling between both T1 and T1/T2 data suggested that a 2-cluster solution using T1 measurement showed superior model performance. In addition, the analytical design only included those who had more than 1 episode of care, which may exclude more sporadic or crisis presentations. Covariates were also drawn over time, rather than at presentation, rendering this study more suitable for validation than for strict prediction.

In addition, clinical outcomes were not assessed in this study, although there is scope to include these in future research. Finally, the direction of causality remains unclear—specifically, whether service receipt determines latent profile, or vice versa—along with the relationship between service receipt, profile, and clinical outcomes.

Conclusions

Truly "predictive" models of care are currently uncommon in mental health [5]. However, this study plays an important role in moving toward more predictive models of care in the medium term, following the formal validation of LPs and deployment of a rigorous resampling procedure in testing classification uncertainty at both average and individual levels. Through the identification and description of LPs, services are envisioned to be equipped to include such information in more personalized treatment approaches. More reflexively, such approaches can be seen as facilitating preventative models of care rather than reactive ones [104,105], representing a radical and, if not timely, necessary shift in care delivery.

Acknowledgments

The first author would like to thank Dr William Marsh for their assistance in the development of the required code to sample episodes of care as well as their supervisory assistance for work related to this study. In addition, JF would like to thank MF for their indispensable assistance and supervision throughout this study and for highlighting the funding opportunity. Finally, R Saunders helped inspire the conceptualization of this research, offering invaluable methodological and theoretical assistance at key periods, for which the authors are profoundly grateful. The authors would also like to thank the dedicated editors and peer reviewers from *JMIR Interactive Journal of Medical Research* for their insightful comments and attention to detail, which helped this study fulfill its potential. This report is an independent research funded by the National Institute for Health and Care Research Applied Research Collaboration North Thames. This paper represents an independent research partly funded by the National Institute for Health Research (NIHR) Biomedical Research Centre at South London and Maudsley National Health Service (NHS) Foundation Trust and King's College London. The views expressed are those of the authors and not necessarily those of the NHS, NIHR, or Department of Health and Social Care. This project was made possible through additional NIHR funding through the NIHR Short Placement for Applied Research Collaboration award.

R Stewart is partly funded by (1) the NIHR Biomedical Research Centre at South London and Maudsley NHS Foundation Trust and King's College London; (2) the NIHR Applied Research Collaboration South London at King's College Hospital NHS Foundation Trust; (3) the Datamind Health Data Research United Kingdom Mental Health Data Hub (Medical Research Council grant MR/W014386); and (4) the United Kingdom Prevention Research Partnership (Violence, Health and Society; MR-VO49879/1), an initiative funded by United Kingdom Research and Innovation Councils, the Department of Health and Social Care (England) and the United Kingdom–devolved administrations, and leading health research charities.

Data Availability

The datasets generated or analyzed during this study are not publicly available.

Authors' Contributions

The project was developed by JS with assistance from R Stewart and supervisory support from MF. Data were curated by R Stewart. JS analyzed the data and drafted the paper as first author. Formal analyses were conducted by JS. R Saunders assisted in conceptualization at key points of designing the methods and analysis. Resources were provided by R Stewart. All authors reviewed the manuscript, which was drafted by the first author, JS.

Conflicts of Interest

R Stewart received research support from GSK and Takeda in the last 3 years prior to manuscript submission. All other authors declare no conflicts of interest.

Abstract

Background: Concussion has been a major public health concern due to the substantial cognitive sequelae it results. Although the dysfunctions of the frontal lobe and corpus callosum owing to concussions have been documented, the existing concussion screening tools merely examine cognitive functions in isolation of motor functions and failed to detect the chronic cognitive-motor impairments following concussions. Yet, there has been no concussion screening test aimed specifically to assess the coupled cognitive-motor functions.

Objective: This study aimed to provide preliminary evidence for using computerized eye-hand coordination tasks to detect chronic cognitive-motor deficits associated with concussion history.

Methods: The computerized eye-hand coordination tasks were used to assess the coupled cognitive-motor functions of the participants with and with no history of concussion. In experiment 1, a total of 12 participants (6 young adults with a history of concussion and 6 healthy controls) completed longitudinal assessments of coordination profiles across a year. Experiment 2 examined a total of 20 participants (10 participants with a history of concussion and 10 healthy controls) using an iterated single-session protocol. *Just noticeable difference* (JND) and *proportion of time-on-task* (PTT) were used to assess cognitive-motor performance. Mixed-design ANOVAs were used to examine group differences, and the effect sizes were assessed using Cohen *d* test.

Results: In experiment 1, participants with a history of concussion exhibited more inconsistent ability to visually discriminate the in-phase coordination pattern (coefficient of variation of JND: participants with a history of concussion = mean 0.27, SD 0.04, and healthy controls = mean 0.17, SD 0.07; t_{10}=2.93; *P*=.02). Similarly, their performance on unimanual and bimanual in-phase and anti-phase coordination patterns was significantly poorer (at in-phase: $PTT_{Concussed}$=mean 0.63, SD 0.10, and $PTT_{Healthy}$=mean 0.73, SD 0.08 [$F_{1,10}$=8.49; *P*=.02]; at anti-phase: $PTT_{Concussed}$=mean 0.46, SD 0.14, and $PTT_{Healthy}$=mean 0.60, SD 0.10 [$F_{1,10}$=10.67; *P*=.008]). In experiment, 2 where only the unimanual coordination tasks were implemented for screening, participants with a history of concussion showed impaired performance in both in-phase and anti-phase tasks (at in-phase: $PTT_{Concussed}$=mean 0.62, SD 0.13, and $PTT_{Healthy}$=mean 0.74, SD 0.07 [$F_{1,54}$=4.20; *P*=.045]; at anti-phase: $PTT_{Concussed}$=mean 0.37, SD 0.15, and $PTT_{Healthy}$=mean 0.56, SD 0.14 [$F_{1,54}$=10.26; *P*=.002]), and they also failed to show the differentiated performance between anti-phase and 90° coordination patterns ($PTT_{Anti\text{-}phase}$=mean 0.37, SD 0.15, and $PTT_{90°\ coordination}$=mean 0.37, SD 0.13).

Conclusions: Due to their ability to detect both impaired and undifferentiated performance in producing intrinsic and novel coordination patterns, the unimanual coordination tasks appear to be a sensitive screening tool for chronic cognitive-motor deficits associated with history of concussion.

Introduction

Most concussions fall in the category of mild traumatic brain injury (mTBI) [1,2]. More than 81% of the 69 million traumatic brain injuries that occur annually worldwide are considered mTBI [3]. Despite the label of "mild," individuals with concussion often experience cognitive, physical, psychological, and social dysfunctions that severely impact the quality of their lives, causing huge social and economic burdens [4-6]. Although individuals who experienced concussions could recover spontaneously within a few weeks to months, persisting symptoms and permanent deficits could remain as severe sequelae [7]. Thus, the National Institute of Neurological Disorders and Stroke and the National Institutes of Health declared concussion as a major public health concern, and efforts to improve early diagnosis and reduce postconcussion disability should be one of the national research priorities [8,9].

The frontal lobe is known as a brain area where the primary motor cortex (M1) is located and responsible for both cognitive and motor functions (eg, attention, memory, action planning, and decision-making). It has been reported that the functions of the frontal lobe are significantly impaired following a severe or moderate traumatic brain injury [10,11] or with enduring multiple mTBI [12,13]. Although brain atrophy could result from multiple concussions [14], clinical neuroimaging is not routinely performed for a reported case of concussion due to the high cost and the likelihood of undetected brain structural damage [15,16]. Therefore, numerous neurobehavioral assessment tools have been developed to examine the frontal lobe dysfunctions associated with concussion. For instance, the Sport Concussion Assessment Tool is a standardized screening tool that has been widely adopted for immediate assessment of a sport-related concussion, which consists of a series of tasks to assess cognitive (eg, attention and memory) and motor (eg, movement speed or accuracy and balance) functions of athletes. Although effective, the existing screening tools of concussion have two limitations. First, they are insensitive to capture the subacute and chronic cognitive-motor impairments following concussions. A scoping review [17] showed that a large proportion of individuals with a single concussion continued to demonstrate the measurable cognitive impairment, whereas the standard neurobehavioral assessments indicated no cognitive impairments. Accordingly, Sport Concussion Assessment Tool 5th edition has been recommended to be inappropriate for assessing people in the subacute and chronic phases of injury [18]. Second, they examine the cognitive functions in isolation with the motor functions, which consequently increases testing time and decreases efficiency due to the need of integrating different testing scores for overall rating. Given the high integration of cognitive and motor functions in the frontal lobe [19], assessing the coupled cognitive-motor functions should be more straightforward and efficient than the uncoupled approaches, which unfortunately have been missing in the current neurobehavioral screen tools for concussion.

Coordination is required for many functional motor tasks such as walking and running. The brain areas involved in performing and learning coordination tasks are the frontal lobe and cerebellum [20,21]. Research suggests an important link between coordination capability and cognitive-motor functions. Young adults diagnosed with developmental coordination disorder often demonstrate deficits in performing tasks that demand attention, working memory, or cognitive flexibility [22]. Due to its high relevance to cognitive-motor functions, coordination tasks including finger-to-nose test [23], the visuomotor tracking task [24], the divided-attention gait task [25], and bimanual coordination task [26] are often included in neurobehavioral screen tools for concussion. Meanwhile, many studies [27,28] have reported that the brain's largest white matter structure, corpus callosum (CC), is vulnerable to concussion. Since CC is known for its function in interhemispheric processing, the structural damage of CC from concussions is associated with the impaired coordination performance demonstrated by the participants with a history of concussion, which makes coordination task alone as a decent screening tool for concussion. However, in using coordination tasks to assess cognitive-motor dysfunctions associated with concussion, the coordination task is often treated as a motor task with a variety of performance outcome measures (eg, speed, accuracy, motion asymmetry, motion continuity, or pattern stability). In view of the perception-action theory of coordination [29,30], the ability to coordinate limb movements is coupled with the ability to perceive the coordination pattern. Therefore, a comprehensive coordination assessment should involve both performing and perceiving the coordination pattern. Yet, there has been no concussion screening test aimed to assess the coupled cognitive-motor functions associated with coordination.

In this study, we explored whether the computerized eye-hand coordination tasks, implemented to assess the coupled cognitive-motor functions, could be used to detect the chronic and subacute cognitive-motor deficits associated with history of concussion. Three different coordination tasks were implemented through human-computer interaction to assess people's ability to both perform and perceive different coordination patterns. Coordination performance was assessed by the established measures in psychophysical studies [31-33]. Adult participants with a history of concussion were recruited and gender-matched with healthy controls in 2 experiments, and their coordination performance was compared to determine whether a specific coordination task has the power to detect the group difference. Three coordination tasks (visual discrimination, unimanual, and bimanual) were implemented in experiment 1 to detect the group difference longitudinally and determine the sensibility of task and task measures for screening. We hypothesized that the impaired cognitive-motor functions could be detected by the respective task measures.

Experiment 2 was then followed to determine whether a simplified coordination screening test was sufficient to differentiate people with a history of concussion from those with no history of concussion in a single testing session. Based on the findings from experiment 1, we adjusted the testing protocol to assess participants' performance of 3 coordination patterns (in-phase, 90°, and anti-phase) in just 1 testing session. Each pattern was examined by a bout of five 20-second-long trials. Such an adjustment was made to examine whether the unimanual coordination task could serve as a quick and efficient screening tool for concussion. It was hypothesized that the

XSL•FO
RenderX

performance of 3 coordination patterns would differ between participants with a history of concussion and healthy participants.

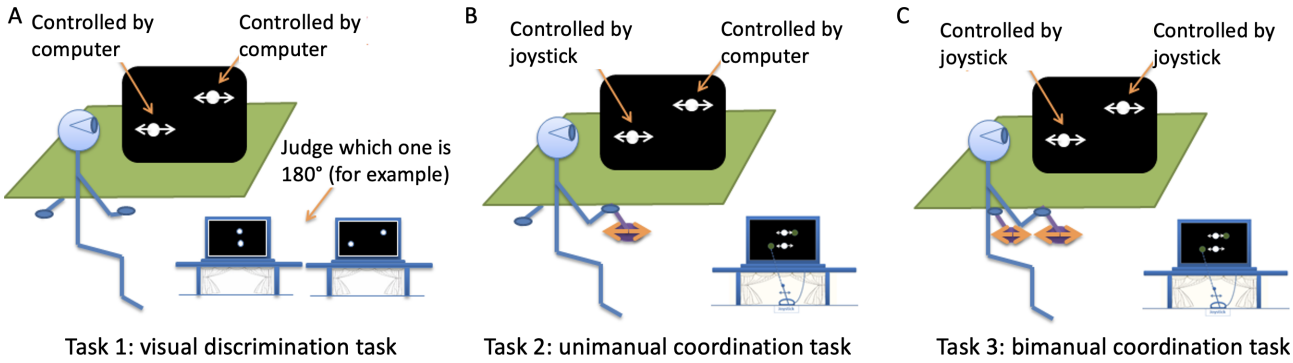
Methods

Experiment 1

Participants

Six young adults with a history of concussion (mean age 22.00, SD 4.34 years; mean time from last concussion 38.67, SD 31.94 months: 2 males and 4 females) and 6 gender-matched healthy controls with no history of concussion (mean age 20.83, SD 2.64 years) were recruited on campus at the University of Wyoming. All concussions were medically diagnosed with accessible records. All participants had no history of substance abuse (drugs, alcohol, or controlled medication), peripheral neuropathy (including loss or decreased sensation or motor function in the upper extremity), or any neurological disorders that could impair coordination abilities (such as ataxia, giant axonal neuropathy, or multiple sclerosis).

Ethical Considerations



This study was approved by the institutional review board at the University of Wyoming (protocol number 20170220SH01461). All participants provided written informed consent prior to participation and were informed of their right to withdraw from the study at any time without penalty. All data collected were deidentified prior to analysis to ensure participant privacy and confidentiality. No personally identifiable information was stored. No monetary compensation was provided to participants for their participation in this study.

Apparatus

A joystick-computer interaction system was used for implementation of the visual discrimination, unimanual, and bimanual coordination tasks. Participants sat on a stool that could be adjusted for height to see a laptop screen at their eye-height level. A 15" PC laptop with a screen resolution of 1024×768 and a refresh rate of 60 Hz was set on top of a custom-built shelf facing the participant. Two Logitech Force 3D joysticks were connected via USB to the PC laptop, one opposite the left shoulder of the participant and the other opposite the right shoulder. Participants manipulated both joysticks in performing the bimanual task, while only the right joystick was used in performing the unimanual tasks. None of the joysticks was used for the visual discrimination task. The joysticks were hidden underneath by a tablecloth covering the shelf. All participants were able to reach and grasp the joysticks comfortably without seeing them.

The computer displayed 2 white dots against a black background on screen, one above the other. In the visual discrimination task, both dots were controlled by the computer, and participants were asked to watch the computer displays and make the judgments by pressing the assigned keys. In the unimanual task, participants controlled only the bottom dot via the right joystick, while the top dot was controlled by the computer. Finally, in the bimanual coordination task, the top dot was controlled by the left joystick and the bottom by the right joystick all the time (see Figures 1A-1C for experimental setting and tasks). The movement amplitude of the dots was 300 pixels, and they were each 60 pixels in diameter. The viewing distance was 70 cm, yielding an oscillating movement spanned at approximately 7.5° visual angle, equivalent to the movement amplitude of 18 cm in the horizontal plane on the joysticks. Stimulus presentation, data recording, and all data analyses were handled by a custom MATLAB toolbox written by ADW incorporating the Psychtoolbox [34].

Figure 1. An illustration of experimental setting for (A) visual discrimination task; (B) unimanual coordination tasks, and (C) bimanual coordination tasks. Visual feedback about the correctness of the produced pattern was provided by changing the color of dots to green in unimanual and bimanual tasks.

Procedure

All participants were assessed by the following 3 eye-hand coordination tasks in a year period with 6 assessments separated by 2 months. The experimental procedures were designed to assess participants' visual perception and motor coordination abilities.

Visual Discrimination Task

Participants performed a 2-alternative forced choice judgment task with a computer. Each trial started with a 4-second visual demonstration of a target rhythmic pattern (2 dots kept oscillating to one another) on the screen, followed by a pair of 4-second visual displays of rhythmic patterns for judgment: one being the target pattern and the other the distracting pattern. Both target and judgment patterns were played at 0.75 Hz.

XSL•FO
RenderX

Participants must tell which 1 of the 2 presented judgment patterns was the target pattern by pressing a key: "A" for the first presented pattern, and "L" for the second presented pattern. Two intrinsic coordination patterns (in-phase and anti-phase) were used as target patterns. The in-phase pattern showed 2 dots moving in the same direction at the same speed, while the anti-phase pattern showed 2 dots moving in the opposite direction at the same speed, both in the top-bottom configuration. The number of trials was determined using 2 independent but interleaved transformed staircase procedures (see details about the staircase procedure in section "Data Analysis"). Thus, the total number of trials and duration of the task varied for each participant.

Unimanual Coordination Task

Participants performed 36 trials of unimanual joystick task with the joystick-computer interaction system, including 3 trials at the in-phase pattern, 3 trials at the anti-phase pattern, and 30 trials at a novel coordination pattern (90° relative phase, ie, half of the time the 2 dots move in the same direction and half of the time they move in the opposite direction). For each pattern, participants started with a 5-second visual demonstration of a target coordination pattern at 0.75 Hz, followed by trials (10 seconds each) in which they controlled 1 joystick to move 1 dot on the screen together with another dot controlled by the computer to replicate the target coordination pattern. Visual feedback about the correctness of the produced 90° coordination pattern was provided by changing the color of dots to green.

Bimanual Coordination Task

Similar procedures were followed as in the unimanual coordination task. However, instead of controlling 1 joystick, participants controlled 2 joysticks to move the 2 dots on the screen in order to replicate the target coordination pattern. Two intrinsic coordination patterns (ie, in-phase and anti-phase) and the novel coordination pattern were assessed with visual feedback provided only for the latter.

In this study, we were specifically interested in participants' ability to learn a novel coordination pattern with visual feedback. As numerous studies have shown that in-phase and anti-phase are intrinsic coordination patterns that healthy people can produce readily [35,36], while 90° coordination is challenging and requires a significant amount of training to produce [37], we provided more trials and visual feedback about the correctness for participants to perform 90° coordination in both unimanual and bimanual tasks.

Data Analysis

The staircase method was used to calculate the *just noticeable difference* (JND) in the visual discrimination task. The staircase is a psychophysical procedure for estimating perceptual thresholds, which makes the judgments harder or easier as a function of the correctness of the last trials. In this study, the magnitude of distracting patterns (the difference between the 2 displayed coordination patterns) was determined by a 1-up or 2-down rule defined in the staircase method. Considering the time constraint for a screening task and based on a previous study on the perception of coordination patterns [38], we applied a step size "up" of 1° and a stop rule of 3 reversals (errors) to the in-phase, and a step size "up" of 5° and a stop rule of 2 reversals (errors) to the anti-phase. Step size "down" was fixed based on Table 5.1 of Kingdom and Prins [39]. Thus, it was 0.55° for in-phase and 2.74° for anti-phase. The initial difference was set to 5° and 40° for in-phase and anti-phase, respectively. Each time the trial stepped down until the first error occurred, then it repeated until meeting the stop rule. In addition, the *coefficient of variation* (CV) was calculated for JNDs collected from the 6 assessments, respectively, for in-phase and anti-phase patterns to examine how consistent the participant was able to discriminate intrinsic coordination patterns.

In unimanual and bimanual coordination tasks, the *proportion of time-on-task* (PTT) was automatically calculated by the system and used to quantify the coordination performance. Specifically, the proportion of each continuous relative phase time series (trial) that fell within the range of the target phase ±20° tolerance was computed. PTT has been proven as a valid measure of performance at the required relative phase that can capture both accuracy and stability of coordination performance in numerous studies [32,33,40].

To examine the group difference in each of the eye-hand coordination tasks across the 6 testing sessions, the mixed-design ANOVA was performed on JNDs in the visual discrimination task and mean PTTs in both unimanual and bimanual coordination tasks, respectively, treating group (group with a history of concussion vs healthy controls) as a between-subject variable and testing sessions (1 through 6) as a within-subject variable. Prior to conducting ANOVAs, the normality of outcome variables was assessed using the Shapiro-Wilk test and all variables met the normality assumption. For post hoc pairwise comparisons following the detection of significant ANOVA effect, we applied Tukey HSD (Honestly Significant Difference) corrections to adjust for multiple comparisons. Since the study purpose was to examine the use of eye-hand coordination tasks to detect the postconcussion cognitive-motor deficits, we were more interested in the main effect of group, and the main effect of testing sessions would indicate only the learning effect associated with participants being familiar with the assessment tasks. In addition, the 2-tailed independent samples *t* test was performed on CV of JND at in-phase and anti-phase patterns, respectively.

Finally, due to the small sample size that might have limited the power of the study to detect the effects of interest, Cohen *d* effect size was calculated for each investigated factor. According to Cohen [41], d=0.20, d=0.50, and d=0.80 were considered as "small," "medium," and "large" effect sizes, respectively. A large effect size would indicate a strong effect to be detected in the future by a larger sample size.

Experiment 2

Participants

Another 10 young adults with a history of concussion (mean age 20.90, SD 1.45 years; mean time from last concussion 23.88, SD 17.04 months: 6 males and 4 females) and 10 gender-matched healthy controls (mean age 22.30, SD 1.70 years) were recruited on campus at the University of Wyoming.

XSL•FO
RenderX

The inclusion and exclusion criteria were identical to those used in the first experiment.

Ethical Considerations

This study was approved by the institutional review board at the University of Wyoming (protocol number 20180425SH01973). The same informed consent process, privacy protections, and compensation policies applied as in experiment 1.

Apparatus and Procedure

Only the unimanual coordination task was used, and participants were tested with 3 coordination patterns (in-phase, anti-phase, and 90° coordination) using the same apparatus as in experiment 1. Participants performed 1 bout of 5 trials for each pattern. Each bout was started with a 10-second visual demonstration of a target coordination pattern at 0.75 Hz, followed by five 20-second trials of replicating the target pattern by moving 1 joystick to move 1 dot on the screen together with another dot controlled by the computer. No visual feedback was provided during each trial.

Data Analysis

PTT was calculated to quantify the eye-hand coordination performance at each coordination pattern. A mixed-design ANOVA was performed on mean PTT data, treating group (participants with a history of concussion vs healthy controls) as a between-subject variable, and target coordination pattern (in-phase vs 90° vs anti-phase) as a within-subject variable. Prior to conducting ANOVAs, the normality of outcome variables was assessed using the Shapiro-Wilk test, which showed that all variables met the normality assumption. Cohen *d* effect size was again calculated to demonstrate the power of the study due to the small sample size.

Results

Experiment 1

Visual Discrimination of Coordination

No group difference was detected for JND at either in-phase or anti-phase (in-phase: $F_{1,10}$=1.11, P=.32; anti-phase, $F_{1,10}$=0.48, P=.50), indicating that the threshold for identifying the in-phase and anti-phase coordination pattern was similar between the participants with a history of concussion ($JND_{in\text{-}phase}$=mean 1.53°, SD 0.46°; $JND_{anti\text{-}phase}$=mean 14.29°, SD 4.87°) and the healthy participants ($JND_{in\text{-}phase}$=mean 1.39°, SD 0.29°; $JND_{anti\text{-}phase}$=mean 13.19°, SD 4.26°). The effect of testing sessions was detected only for JND of anti-phase pattern ($F_{5,50}$=3.01; P=.02), suggesting that both groups increased their ability to discriminate anti-phase coordination patterns in later testing sessions (see Table 1 for test means).

Table . Test means for all task measures across 6 tests (mean, SD) in experiment 1.

	Test 1	Test 2	Test 3	Test 4	Test 5	Test 6
JND[a] (degree)						
JND of in-phase	1.66° (0.47°)	1.54° (0.34°)	1.32° (0.36°)	1.30° (0.30°)	1.45° (0.38°)	1.49° (0.42°)
JND of anti-phase	16.80° (4.59°)[b]	14.96° (5.06°)	12.64° (3.57°)	13.80° (5.53°)	11.53° (3.99°)	12.71° (3.09°)
Mean proportion of time-on-task						
Unimanual in-phase	0.61 (0.08)[c]	0.65 (0.13)	0.68 (0.09)	0.71 (0.07)	0.71 (0.09)	0.74 (0.08)
Unimanual anti-phase	0.46 (0.14)	0.50 (0.13)	0.53 (0.19)	0.59 (0.11)	0.56 (0.14)	0.57 (0.11)
Unimanual 90°	0.33 (0.09)[d]	0.43 (0.13)	0.47 (0.13)	0.49 (0.13)	0.52 (0.13)	0.55 (0.14)

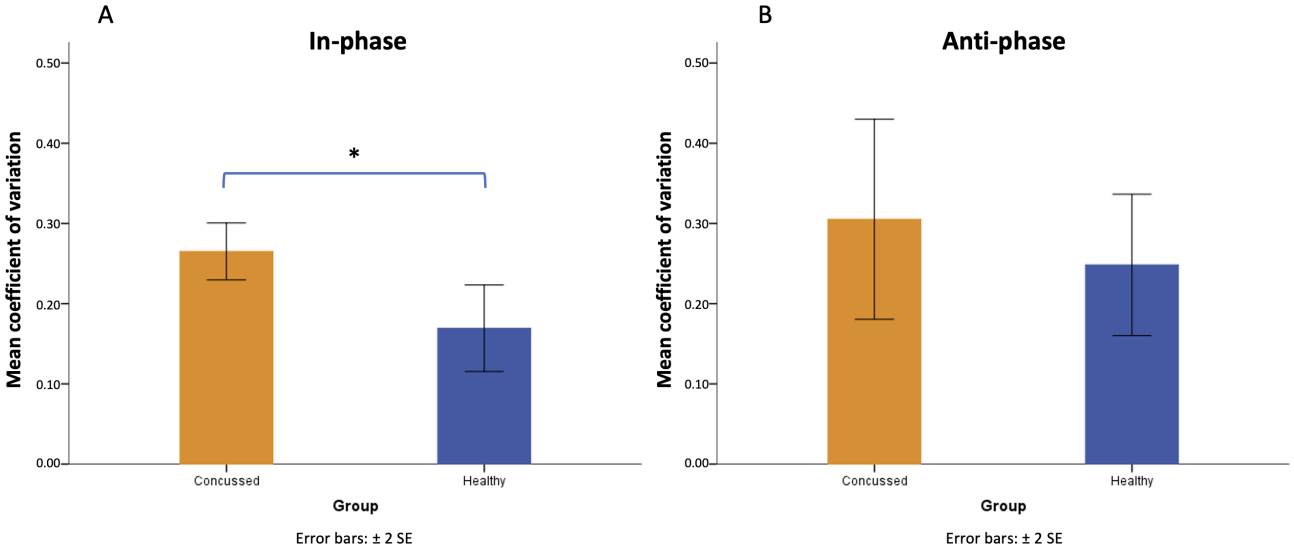
[a]JND: just noticeable difference.

[b]Test 1 vs test 5, P=.05.

[c]Test 1 vs test 6, P<.05.

[d]Test 1 vs test 4, P<.05; test 1 vs test 5, P<.01; and test 1 vs test 6, P<.01.

[e]Test 1 vs test 3, P<.01; test 1 vs test 4, P<.01; test 1 vs test 5, P<.01; and test 1 vs test 6, P<.01.



[f]Test 2 vs test 6, P<.05.

The group difference was detected on CV of JND for in-phase coordination pattern (t_{10}=2.93; P=.02) but not for anti-phase coordination pattern (t_{10}=0.77; P=.46). As seen in Figures 2A and 2B, participants in the group with a history of concussion demonstrated a higher inconsistency in their ability to discriminate the in-phase coordination pattern than the healthy

XSL•FO
RenderX

controls across the 6 assessments ($CV_{Concussed}$=mean 0.27, SD 0.04; $CV_{Healthy}$=mean 0.17, SD 0.07), which was not seen in discriminating the anti-phase coordination pattern. No other main effect or interaction was detected (all other *P* values >.05).

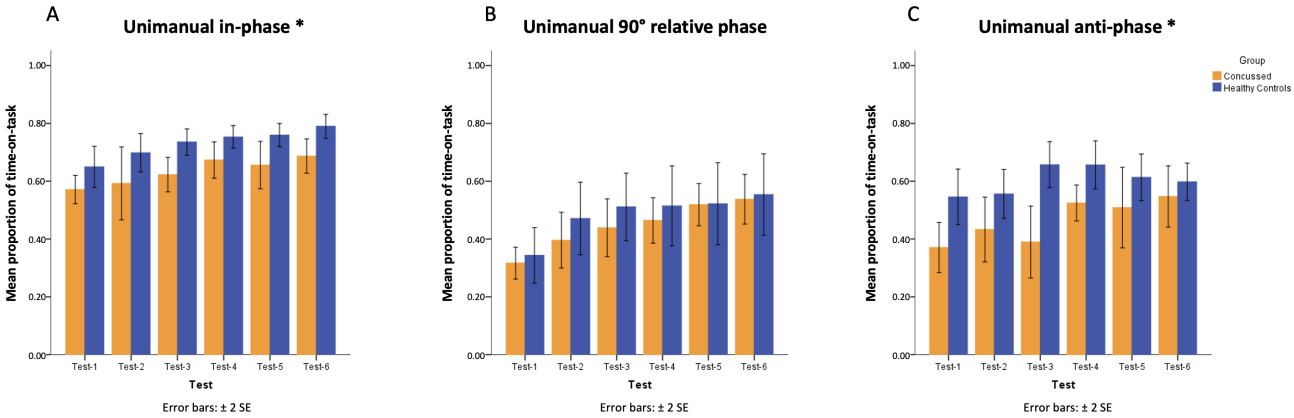


Figure 2. Coefficient of variation of just noticeable difference at in-phase (panel A) and anti-phase pattern (panel B) for participants with a history of concussion and healthy controls. *Significant difference with *P*<.05. Error bars represent the standard error of the mean.

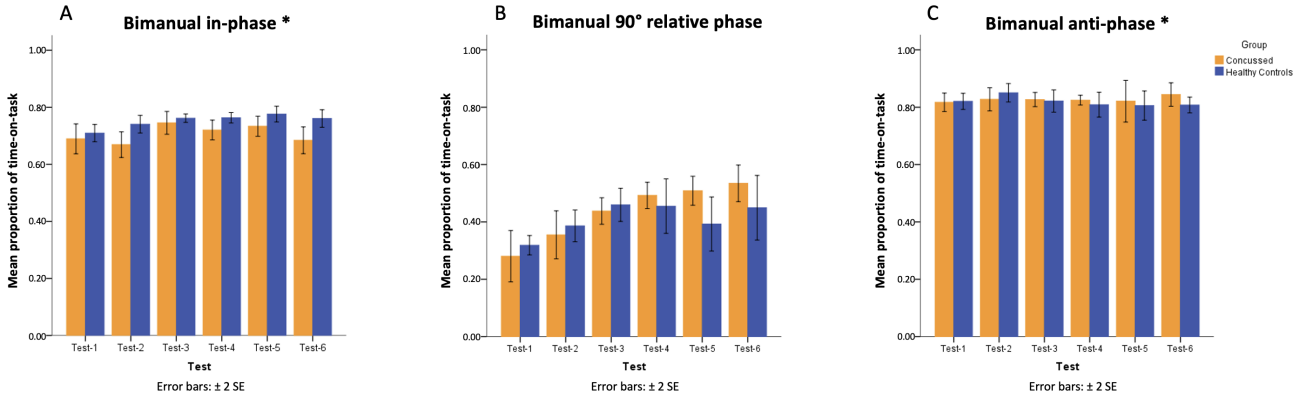
Unimanual Coordination Performance

The main effect of group was detected for performing both in-phase and anti-phase coordination patterns (at in-phase: $F_{1,10}$=8.49, *P*=.02; at anti-phase: $F_{1,10}$=10.67, *P*=.008; Figure 3A-C). Healthy controls overall outperformed participants with a history of concussion in producing the intrinsic coordination patterns (at in-phase: $PTT_{Concussed}$=mean 0.63, SD 0.10, and $PTT_{Healthy}$=mean 0.73, SD 0.08; at anti-phase: $PTT_{Concussed}$=mean 0.46, SD 0.14, and $PTT_{Healthy}$=mean 0.60, SD 0.10). The main effect of testing sessions was detected in performing both intrinsic coordination patterns as well (at in-phase: $F_{5,50}$=7.03, *P*<.001; at anti-phase: $F_{5,50}$=3.16, *P*=.014). In general, healthy controls and participants with a history of concussion both improved their performance of intrinsic coordination patterns in later testing sessions, suggesting that the unimanual coordination task is challenging even for producing the intrinsic coordination patterns (see Table 1 for test means).

Figure 3. Mean proportion of time-on-task at unimanual in-phase (panel A), 90° relative phase (panel B), and anti-phase pattern (panel C) for participants with a history of concussion and healthy controls across 6 tests. *Group main effect revealed by mixed-design ANOVA. Error bars represent the standard error of the mean.



The main effect of testing sessions was detected in performing the novel coordination pattern at the 90° relative phase ($F_{5,50}$=18.92; *P*<.001). Regardless of the history of concussion, all participants learned and improved their unimanual 90° coordination. No other main effect or interaction was detected (all other *P* values >.05).

Bimanual Coordination Performance

The main effect was detected for both group ($F_{1,10}$=6.49; *P*=.03) and testing sessions ($F_{5,50}$=6.15; *P*<.001) in performing the in-phase coordination pattern with no interaction ($F_{5,50}$=1.65; *P*=.16). As seen in Figures 4A-4C, participants with a history of concussion performed the in-phase coordination pattern worse than healthy controls ($PTT_{Concussed}$=mean 0.71, SD 0.06; $PTT_{Healthy}$=mean 0.75, SD 0.04), and both groups improved their performance throughout the testing sessions (Table 1). No main effect or interaction was detected in performing the anti-phase coordination pattern (all other *P* values >.05).

XSL•FO
RenderX

Figure 4. Mean proportion of time-on-task at bimanual in-phase (panel A), 90° relative phase (panel B), and anti-phase pattern (panel C) for participants with a history of concussion and healthy controls across 6 tests. *Group main effect revealed by mixed-design ANOVA. Error bars represent the SE of the mean.

As for the performance of 90° coordination, the significant main effect of testing session ($F_{5,50}$=19.02; P<.001) and the group by testing session interaction ($F_{5,50}$=3.81; P=.005) were detected, but the group difference was insignificant ($F_{1,10}$=0.35; P=.57). Although participants improved their performance at 90° across the testing sessions, their performance changed differently depending on the group. While the health controls dropped their performance in later sessions, participants with a history of concussion maintained their improved performance in later sessions. As shown by the following simple main effect analysis with post hoc of Tukey HSD analysis, participants with a history of concussion outperformed the healthy controls only in the fifth session ($PTT_{Concussed}$=mean 0.51, SD 0.06; $PTT_{Healthy}$=mean 0.39, SD 0.12).

Cohen d Effect Size of All Coordination Tasks

As seen in Table 2, a large effect size (d>0.80) was detected for CV of JND in discriminating the in-phase coordination pattern, PTT in performing the unimanual in-phase and anti-phase coordination tasks, and PTT in performing the bimanual in-phase coordination task, suggesting that these tasks and task measures are promising for screening participants with a history of concussion.

Table . Cohen *d* effect size for all task measures in experiment 1.

Task measures	Main effect		Interaction	Cohen *d* of group main effect
JND[a] of in-phase	N/A[b]	N/A	N/A	0.689
JND of anti-phase	N/A	Test	N/A	0.373
CV[c] of JND at in-phase	Group	N/A	N/A	*1.362* [d]

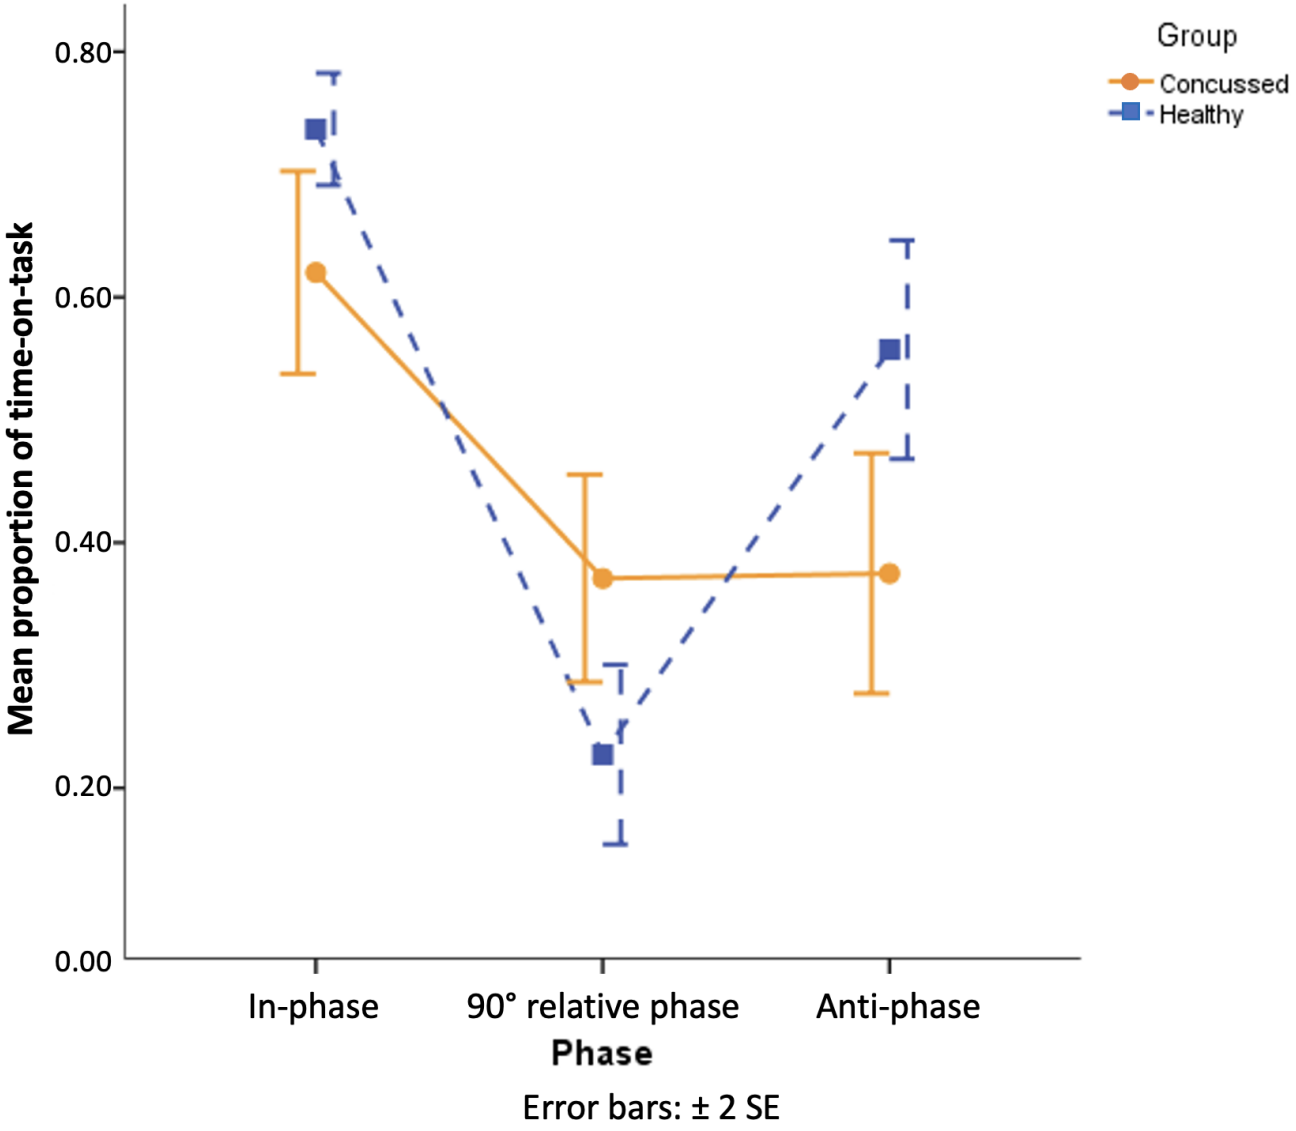
[e]PTT: proportion of time-on-task.



Experiment 2

The 2-way mixed-design ANOVA on mean PTTs yielded a main effect for target coordination pattern ($F_{2,36}$=61.35, P<.001, and Cohen d=3.52). As seen in Figure 5, in general, performance of in-phase coordination (mean PTT 0.68, SD 0.12) was significantly better than that of anti-phase coordination (mean PTT 0.47, SD 0.17) and then that of 90° coordination (mean PTT 0.30, SD 0.14). Significant 2-way interaction between group and target coordination pattern was detected ($F_{2,36}$=12.60, P<.001, and Cohen d=1.54). Simple main effect analysis showed that healthy controls outperformed participants with a history

XSL•FO
RenderX

of concussion in performing in-phase ($F_{1,54}$=4.20, P=.045, and Cohen d=0.48; mean $PTT_{Concussed}$=0.62, SD 0.13; and mean $PTT_{Healthy}$=0.74, SD 0.07) and anti-phase coordination patterns ($F_{1,54}$=10.26, P=.002, and Cohen d=0.81; mean $PTT_{Concussed}$=0.37, SD 0.15; and mean $PTT_{Healthy}$=0.56, SD 0.14), while the participants with a history of concussion outperformed healthy controls only in performing 90° coordination ($F_{1,54}$=6.36, P=.015, and Cohen d=0.62; mean $PTT_{Concussed}$=0.37, SD 0.13; and mean $PTT_{Healthy}$=0.23, SD 0.12). To be noted, the 2 groups demonstrated different patterns in performing the 3 coordination patterns. As revealed by simple main effect analysis followed by post hoc of Tukey HSD test, healthy controls ($F_{2,54}$=41.20, P<.001, and Cohen d=2.38) performed in-phase coordination (mean PTT 0.74, SD 0.07) significantly better than anti-phase coordination (mean PTT 0.56, SD 0.14), while their performance of 90° coordination (mean PTT 0.23, SD 0.12) was significantly worse than that of both in-phase and anti-phase patterns. However, this differentiated performance between the 3 coordination patterns (as healthy controls showed in Figure 5) was absent for participants with a history of concussion ($F_{2,54}$=12.57, P<.001, and Cohen d=1.27) and their performance of in-phase coordination (mean PTT 0.62, SD 0.13) was better than that of anti-phase (mean PTT 0.37, SD 0.15) and 90° coordination (mean PTT 0.37, SD 0.13), with no difference detected between the latter 2, suggesting that their cognitive-motor system could not differentiate the 2 coordination patterns involving displacement of dots.

Figure 5. Mean proportion of time-on-task at unimanual in-phase, unimanual 90° relative phase, and unimanual anti-phase for participants with a history of concussion and healthy controls. A conventional pattern of performance (V-shape) was demonstrated by healthy controls but not by the group with a history of concussion. Error bars represent the SE of the mean.

Discussion

Principal Findings

In experiment 1, three coordination tasks have been implemented to examine the comprehensive cognitive-motor functions of people with and with no history of concussion, and among the 10 task measures, 4 measures have been identified with a great effect size to capture the group difference (Table 2). The results suggest that participants with a history of concussion demonstrated greater variability in perceptual discrimination of the in-phase coordination pattern and worse motor performance in both unimanual and bimanual coordination tasks than healthy controls. These deficits were consistently seen in the following bimonthly sessions, suggesting persistent cognitive-motor impairments in individuals with prior concussion.

Experiment 2 was conducted using an iterated protocol based on the results of experiment 1 and examined the possibility of using the unimanual coordination task alone to detect the cognitive-motor deficits associated with concussion. Compared with the protocol used in experiment 1, the current testing protocol could be completed within 10 minutes (instead of an hour) with the group difference being captured in just 1 testing session. The results showed that unimanual coordination tasks were sensitive to detecting performance deficits in participants with a history of concussion in that individuals with a history of concussion performed worse on both in-phase and anti-phase tasks and failed to differentiate between anti-phase and 90° coordination patterns.

Visual and Motor Coordination Deficits Revealed Through Comprehensive Assessments

In experiment 1, the visual discrimination task was designed to assess cognitive functions of coordination, which include attending to and tracking the 2 moving dots on the screen, memorizing the spatial-temporal pattern of their movements, and then identifying the target coordination pattern from those distracting patterns. Although these cognitive functions have been reported to be impaired by concussion in previous studies [42-44], participants in this study did not show group differences in discriminating the intrinsic coordination patterns, suggesting that our participants with a history of concussion have recovered the cognitive functions required for perceiving the fundamental coordination tasks such as walking and jumping. This is conforming to the literature that most cognitive dysfunctions associated with concussion spontaneously recover to baseline within 2 weeks [45]. Nevertheless, the analysis on the CV of JNDs revealed that our participants with a history of concussion were more inconsistent in discriminating the in-phase pattern than their healthy counterparts, suggesting that the ability to consistently detect the minor decoupling between 2 oscillators (eg, minor asynchronization of foot takeoff in jumping) was impaired following concussion despite the spontaneous recovery of the ability to perceive intrinsic coordination patterns.

The unimanual coordination task was designed to examine cognitive-motor functions of coordination, specifically, the ability to produce and maintain a rhythmic movement to interact with a computer based on the established perception of coordination pattern. Such an ability not only requires the aforementioned cognitive functions to detect and retain the coordination pattern but also demands motor functions to move one hand in coordination with the moving dot on the screen and correct any perceived movement error to maintain the coordination pattern. The group difference was captured when motor functions were demanded together with cognitive functions. Our healthy controls outperformed participants with a history of concussion in performing both intrinsic coordination patterns. Such a finding conforms to a previous study [46] suggesting that the deficits of dynamic motor functions (eg, visuomotor tracking and walking under various conditions of attention) persist following the concussion despite the spontaneous recovery of cognitive functions. As for the performance of the novel coordination pattern, both participants with a history of concussion and healthy participants improved over the testing sessions without showing any group difference, suggesting that the unimanual coordination task was quite challenging in nature, and the ability to learn new coordination pattern remained intact postconcussion.

Finally, the bimanual coordination task was used to examine the motor functions of coordination. Compared with the unimanual task, the bimanual task demands the motor production of the coordination pattern entirely by requiring participants to move 2 hands rhythmically; therefore, the independent visuomotor control and hemisphere cross talk are both challenged. The results showed the group difference only in performing the in-phase pattern with healthy controls outperforming the participants with a history of concussion. Such a finding not only supported previous studies suggesting that bimanual coordination deficits are associated with concussion [47] but also indicated that the concussion-induced malfunction of CC might have caused the problem for spatial and temporal coupling of 2 hands, which is typically seen in patients with split brain or callosotomy [48]. Compared with the anti-phase and novel coordination patterns, the in-phase pattern demands more spatial and temporal coupling of 2 hands. Therefore, people with a history of concussion are more likely to be screened out by the in-phase bimanual coordination task.

In sum, all 3 coordination tasks have been proven effective for discriminating people with a history of concussion with at least 1 task measure that could be used. Interestingly, most effective task measures are related to the ability to perceive or perform the in-phase pattern, suggesting that the cognitive-motor deficits associated with concussions may be specifically tied to the inability to detect and maintain spatiotemporal coupling in performing eye-hand coordination tasks. The unimanual task emerged to be a good candidate for screening people with a history of concussion because (1) half of effective task measures were found in the unimanual task with the largest effect size to detect group difference, (2) it examines the cognitive-motor functions required for both perceiving and performing coordination patterns, and (3) the performance can be quickly assessed and used for evaluation. Consequently, experiment 2 was designed to examine whether the unimanual task alone can serve as a quick and efficient tool for detecting the chronic cognitive-motor deficits following concussion.

RenderX

Perception-Action Coupling Disruptions in Simplified Unimanual Coordination Task

In experiment 2, the unimanual coordination task entails the integration of cognitive-motor functions including attention, memory, and visuomotor tracking, for which one needs to successfully detect the spatiotemporal relationship between the 2 moving dots on the screen and then adjust the manual movement to maintain that pattern. According to the perception-action theory of coordination [29,49], the relative direction of 2 oscillators is used in perceiving and performing both in-phase and anti-phase coordination patterns, while the relative position of 2 oscillators is used for the 90° coordination. Since in-phase and anti-phase patterns represent the coordination movements with the relative direction always being identical (ie, in-phase) or opposite (ie, anti-phase), they are distinctive and easy to be perceived and produced. In contrast, the relative position is ambiguous in 90° coordination due to the fluctuations in the movement direction, which makes it difficult for both perception and production [50]. Both perceptual and motor studies on rhythmic coordination using healthy participants [31,35,38,51] have shown that the performance of 90° coordination is worse than that of in-phase and anti-phase, with the former outperforming the latter (the differentiated performance between 3 coordination patterns as seen in Figure 5 for healthy controls).

In both experiments when unimanual coordination performance was assessed, we found consistently that healthy controls outperformed participants with a history of concussion in producing both in-phase and anti-phase patterns while maintaining the differentiated performance between all 3 coordination patterns, suggesting that they were sensitive to the information of relative direction that is required for perceiving and performing the intrinsic coordination patterns, although having difficulty in finding the information of relative position for successful perception and production of the novel coordination pattern due to lack of practice. As for the participants with a history of concussion, they showed a significantly degraded performance at both in-phase and anti-phase while losing the performance difference between anti-phase and 90°, suggesting that the previous concussion might have limited their ability to discriminate and use the appropriate spatiotemporal information for successful production of both intrinsic and novel coordination patterns. As shown in experiment 1, the participants with a history of concussion did not have a problem with visual discrimination of in-phase and anti-phase patterns; therefore, their degraded performance in performing unimanual in-phase and anti-phase patterns had to do with the deficit in perception-action coupling. Although their performance at 90° was seemingly better than the healthy controls, such a performance was not different from their performance in producing the anti-phase pattern, suggesting that anti-phase and 90° coordination patterns may have been treated as the same by the individuals with a history of concussion since they both involve the displacement and opposite relative direction of moving oscillators. Hence, their seemingly better performance at 90° was a false positive, stemming from their confusion between 90° coordination and anti-phase coordination.

Although more studies are warranted to prove the impaired ability to discriminate and use spatiotemporal information for coordination by the participants with a history of concussion, experiment 2 overall showed that participants with a history of concussion demonstrated deteriorated cognitive-motor functions in performing the unimanual in-phase and anti-phase patterns, which could be attributed to the dissociation between perception and action. In addition, the conventional differentiated performance between the 3 coordination patterns (in-phase > anti-phase > 90°) was not seen for participants with a history of concussion, which suggests that the differentiated performance between the intrinsic and novel coordination patterns in the unimanual coordination task could potentially serve as a useful indicator for screening concussion.

Limitations and Future Directions

This study has several limitations that should be acknowledged. First, although 2 experiments were conducted, the sample size in each was relatively small, which may limit the generalization of both study findings. While several outcomes demonstrated large effect sizes for group main effect (Cohen d>0.80), which suggest a possibility of using a combined approach for assessment and screening, a larger sample size is warranted in future studies to prove the effectiveness and reliability of using eye-hand coordination tasks to detect the chronic or subacute cognitive-motor deficits associated with concussion.

Second, there was a wide range of the reported time from the last concussion. The reported last concussion occurrence ranged from 2 to 96 months in experiment 1 and from 4 to 54 months in experiment 2. As a result, participants could be at different stages of spontaneous recovery from concussion. Also, during that time, participants could be reinjured by concussion that was not medically examined. Future studies could improve on this by focusing on participants within narrower postinjury time frames or by using recovery stage as a covariate in analyses.

Finally, poor eye-hand coordination could result from neurocognitive disorders other than concussion (eg, posttraumatic stress disorder and attention-deficit/hyperactivity disorder). Although all participants in this study were college students with ongoing study programs, and they self-reported to have no history of substance abuse, peripheral neuropathy, and neurological disorders, there is still a possibility for undiagnosed neurocognitive disorders other than concussion to impact the eye-hand coordination performance. In future work, standardized screening tools or neuropsychological assessments could be included to help isolate the impact of concussion from other potential influences on cognitive-motor performance.

Conclusions

This study provides preliminary evidence for using the computerized eye-hand coordination tasks to detect the chronic cognitive-motor dysfunctions associated with concussion. In developing neurobehavioral tools to capture the postconcussion chronic cognitive-motor deficits, the unimanual coordination task should be considered, and the differentiated performance between intrinsic and novel coordination patterns should be examined.

Abstract

Obstetrics and gynecology journal impact factor trends during the COVID-19 pandemic were similar to those seen among other medical specialties, and our findings further highlight the ongoing need to implement a metric of research impact that is not as easily manipulated by selective publication.

(Interact J Med Res 2025;14:e70554) doi:10.2196/70554

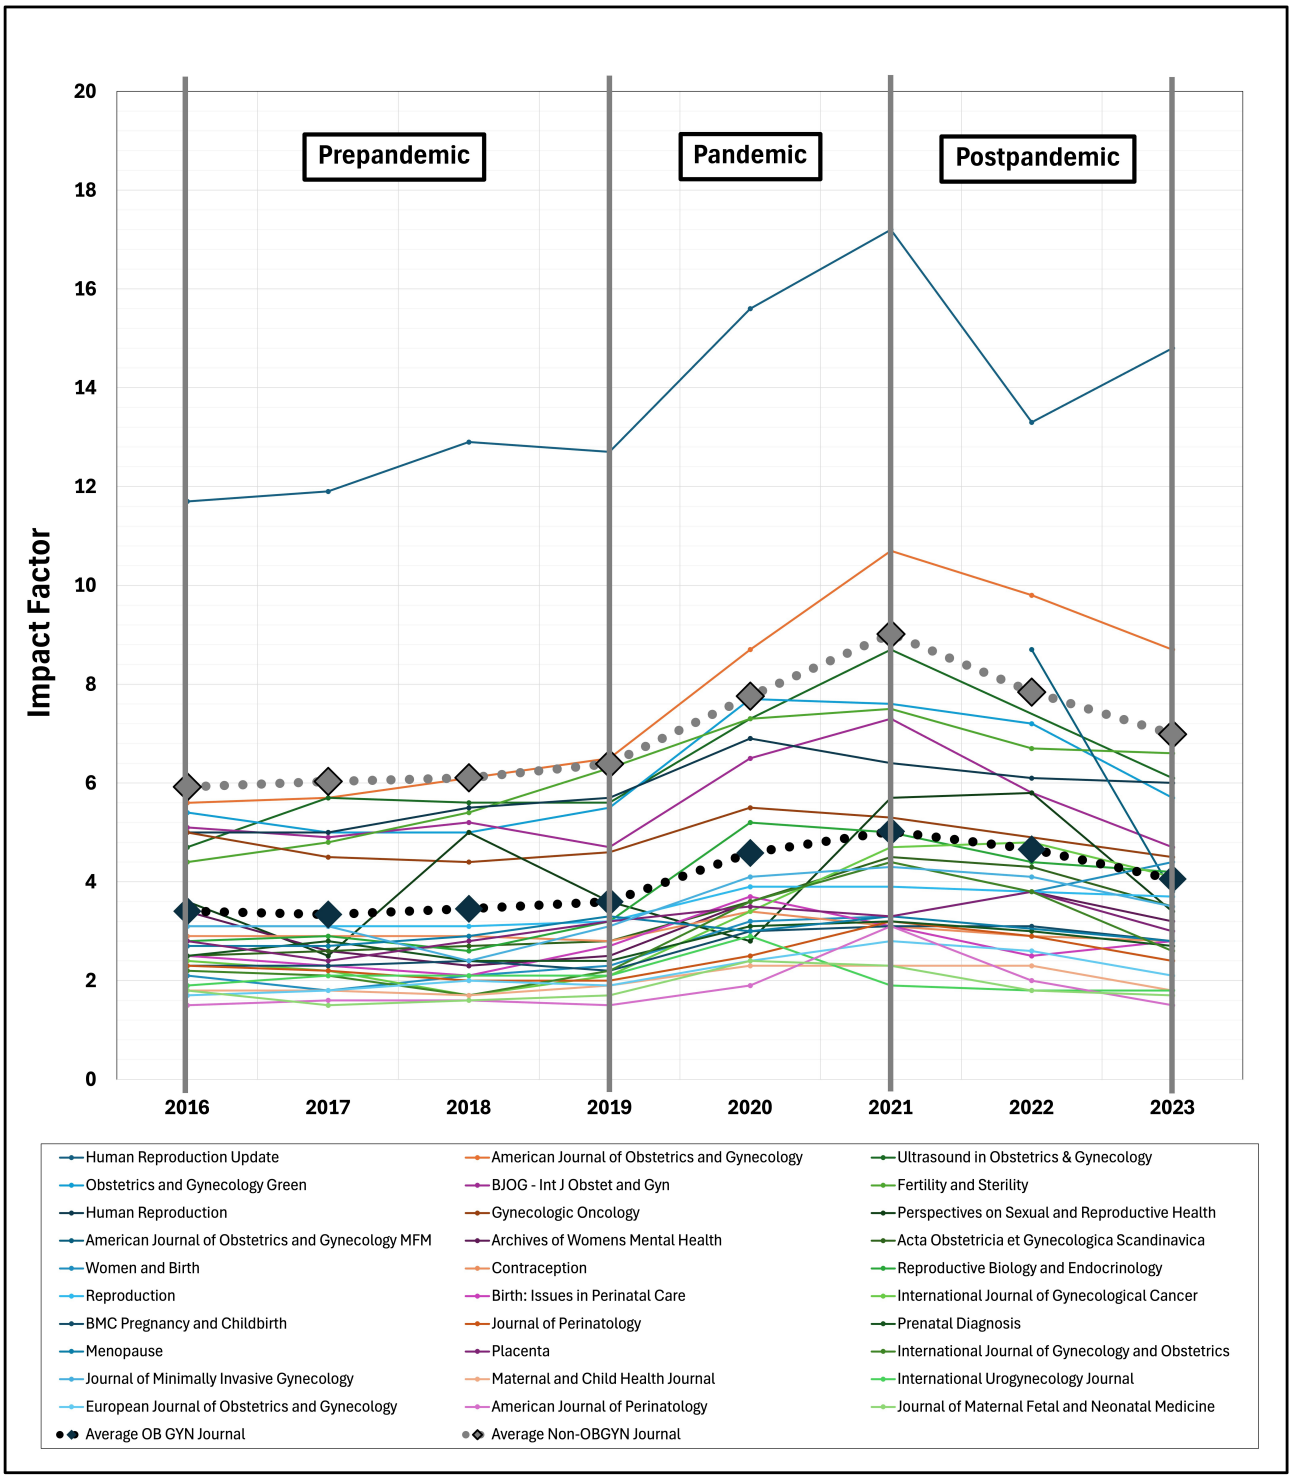
KEYWORDS

impact factor; COVID-19; research impact

Introduction

The impact factor (IF), originally introduced as a metric to aid librarian purchasing decisions, has quickly become a marker for journal prestige [1]. Over the years, the concept of IFs has been highly criticized, as they are susceptible to manipulation and may be a disservice to science and their readers [1-4]. While temporal changes may provide insight into journal growth, IFs are also uniquely affected by publication trends. Studies have shown that the COVID-19 pandemic created an unprecedented surge of highly impactful publications increasing IFs [5-8]. Whether an IF uptrend was appreciated among obstetrics and gynecology (OBGYN) journals during COVID-19 and whether the changes reflect a COVID-19 "blockbuster" effect or genuine advancement in women's health research remains unknown. We aimed to determine the IF trends of the top OBGYN journals and compare them to representative journals for other medical specialties (non-OBGYN).

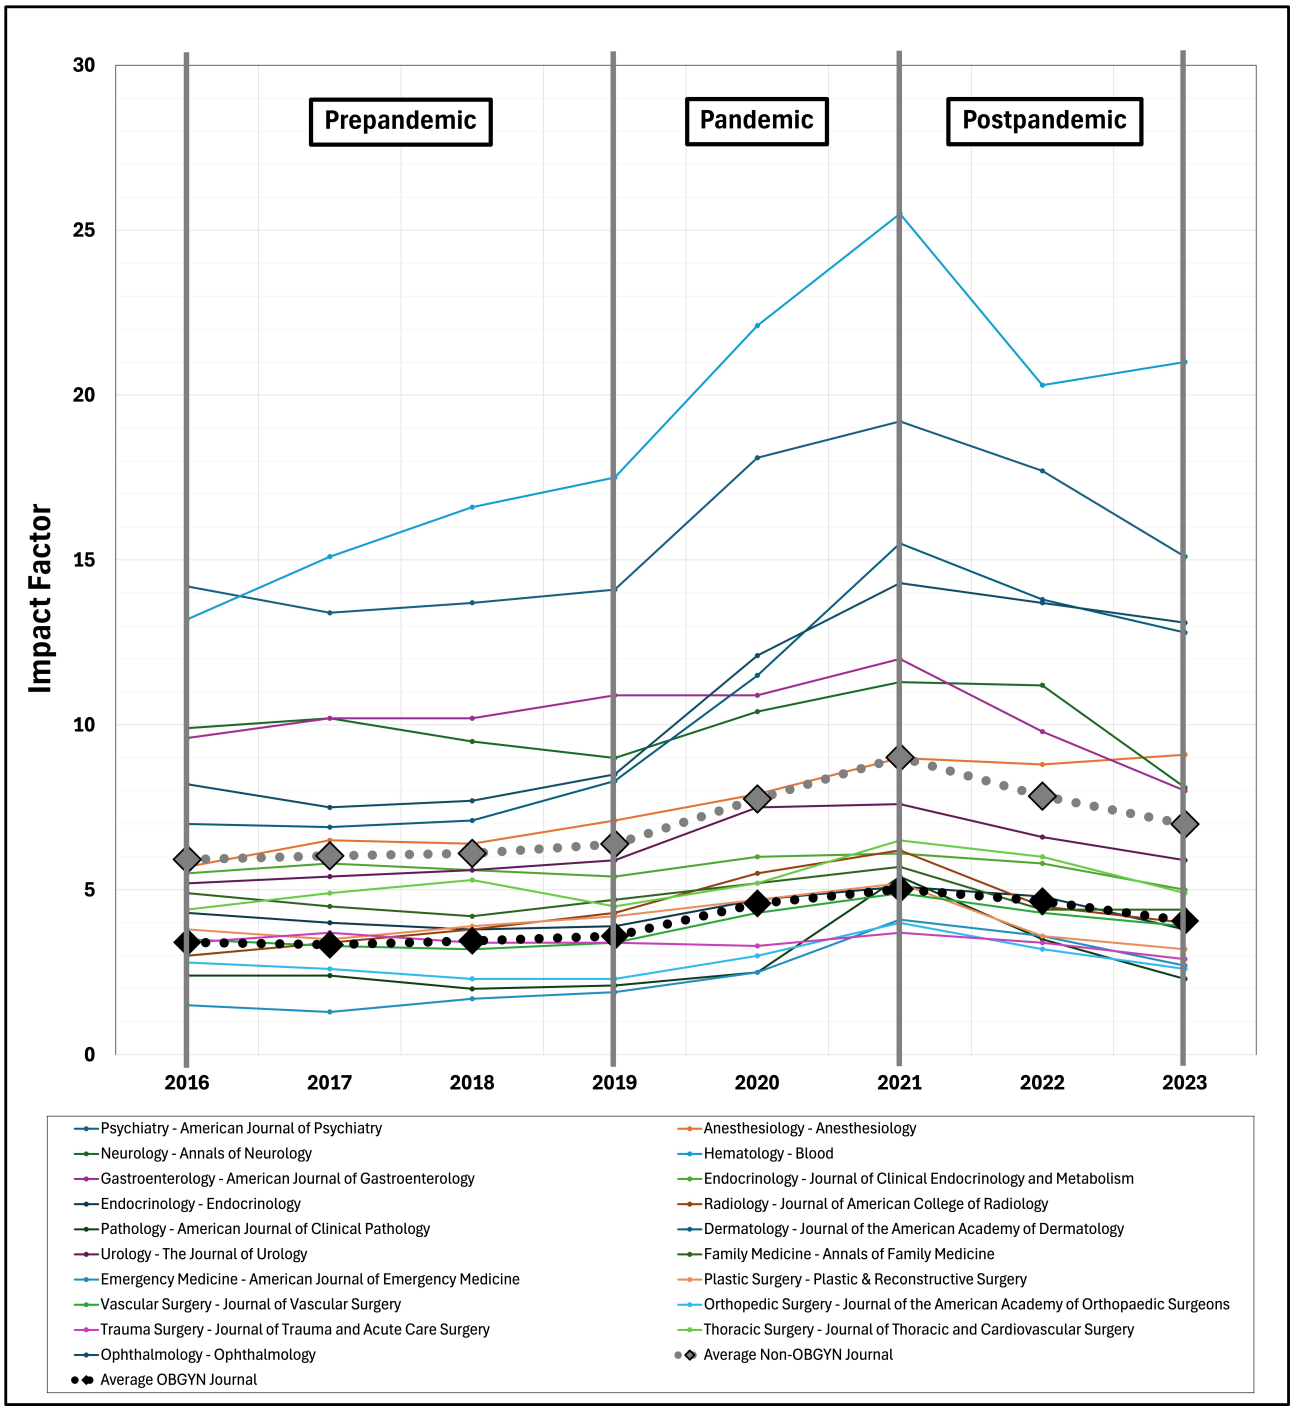
Methods



Using the SCImago Journal Rank database, we identified the top 30 broad scope women's health journals (Multimedia Appendix 1). Non-OBGYN national societies were queried to highlight each subspecialty's representative journal. Annual IFs were identified using a web-based searchable database, and temporal trends were assessed over three time periods: (1) prepandemic (2016 - 2019), (2) COVID-19 pandemic (2019 - 2021), and (3) postpandemic (2021 - 2023) [9]. IF trends by individual journal and composite journal type were assessed using the National Cancer Institute's Joinpoint Regression Program, with measures of association expressed with annual average percent changes (AAPCs) and 95% CIs [10]. The average IF percent changes between composite journal types were compared using Student *t* test. Institutional review board approval was not required for this study.

Results

IF data obtained from the top 30 OBGYN journals were compared to 19 non-OBGYN journals. From 2016 to 2023, the mean OBGYN journal IF increased from 3.4 to 4.1 (AAPC 4.1%, 95% CI 0.8%-4.1%) compared to 5.9 to 7.0 (AAPC 3.6%, 95% CI 0.4%-7.5%) for non-OBGYN journals with an average percent change of 18.8% compared to 16.3%, respectively (*P*=.91; Figures 1 and 2).



XSL•FO
RenderX

Figure 1. Impact factor trends among the top 30 OBGYN journals. The dotted black line represents the average impact factor among OBGYN journals, while the dotted gray line represents the average impact factor among non-OBGYN journals. OBGYN: obstetrics and gynecology.

XSL•FO
RenderX

Figure 2. Impact factor trends among 19 non-OBGYN medical specialty-specific journals. The dotted black line represents the average impact factor among OBGYN journals, while the dotted gray line represents the average IF among non-OBGYN journals. OBGYN: obstetrics and gynecology.

In the prepandemic period, the mean OBGYN journal IF increased from 3.4 to 3.6 (AAPC 8.9%, 95% CI 4.7%-18.1%) compared to 5.9 to 6.4 (AAPC 8.8%, 95% CI 5.0%-17.8%) for non-OBGYN journals with an average percent change of 4.4% compared to 6.9%, respectively (*P*=.57). During the pandemic, the mean OBGYN journal IF increased from 3.6 to 5.0 (AAPC 8.9%, 95% CI –1.1% to 13.6%) compared to 6.4 to 9.0 (AAPC 8.8%, 95% CI –1.8% to 13.4%) for non-OBGYN journals with an average percent change of 42.7% compared to 47.6%, respectively (*P*=.63). Finally, in the postpandemic period, the mean OBGYN journal IF decreased from 5.0 to 4.1 (AAPC –7.2%, 95% CI –18.2% to 4.3%) compared to 9.0 to 7.0 (AAPC –8.3%, 95% CI –19.0% to 2.9%) for non-OBGYN journals with an average percent change of –18.3% compared to –25.7%, respectively (*P*=.16).

Discussion

Our findings indicated significant increases in overall IF trends from 2016 to 2023 among OBGYN journals, though not statistically different from non-OBGYN journals. When analyzing prepandemic, during the pandemic, and postpandemic periods, both OBGYN and non-OBGYN journals exhibited a similar pattern of small increases prepandemic, robust uptrends during the pandemic, then a steep but less pronounced decline post pandemic (Figures 1 and 2). Given these results, it is likely

XSL•FO
RenderX

that IF uptrends were an artificial COVID-19–related "blockbuster" effect rather than genuine advancements in women's health research.

The COVID-19 trends shown here among OBGYN journals have similarly been seen among medicine, global health, and infectious disease journals during the pandemic [5,6,8]. On one hand, the rapid surge in publications shows how strongly we can mobilize and disseminate research early and effectively to quickly improve health outcomes. On the other hand, there was pressure among journals to publish COVID-19 literature given its highly impactful and citable nature. Beyond being used for an indication it was not intended for, the IF has now repeatedly been highly criticized by many studies yet remains the most mainstream metric to discuss journal importance or prestige.

Our study has limitations. We are unable to comment on authors' research funding changes or each journal's editorial policies and shifts in publication practices during the pandemic. Additionally, our analysis was unable to adjust for journal size, scope, or publication frequency.

Using IFs alone in their current capacity may lead to wrongly concluding genuine research advancement in OBGYN. Among the public, this misunderstanding of the IF has the potential to create further distrust of medical literature. Our study further highlights the ongoing need to implement a different metric of research impact such as a composite using the IF, the *h*-index, and altmetrics that are not as easily manipulated by selective publication.

Acknowledgments

MS's time is supported by a National Institutes of Health T32 HD007203 grant. Funding bodies had no input in study design or interpretation. This study is not a clinical trial. This work has never been presented. Generative artificial intelligence was not used for any portion of this manuscript.

Abstract

This letter shows that an estimated 31 million and 44 million adults self-report near-daily experiences of depression or anxiety, respectively. Of these, nearly a third have never spoken to a health care provider about it.

(Interact J Med Res 2025;14:e70626) doi:10.2196/70626

KEYWORDS

depression; anxiety; survey

Introduction

Mental health conditions, including depression and anxiety, have been on the rise in the United States over the past several years [1]. Data from the 2022 National Health Interview Survey indicate that the percentage of adults with anxiety and depression symptoms increased from 15.6% to 18.2% and 18.5% to 21.4%, respectively, between 2019 and 2022 [2]. Depression and anxiety can manifest as fatigue, difficulty concentrating, problems sleeping, or changes in appetite and negatively affect daily life [3,4].

Despite these impacts, people may not talk to their health care provider (HCP) due to stigma, cost, lack of access, or lack of insurance coverage [5]. In particular, stereotypes and prejudice can prevent people from discussing their mental health experiences with friends, family, or even HCPs, which could prevent them from receiving needed care [6].

In this paper, we estimate the number of people experiencing depression and anxiety almost daily based on a recent nationally representative survey. We also estimate how many of these people have never spoken to an HCP about their mental health. To the best of our knowledge, we are the first to report population-level estimates of self-reported experiences of depression and anxiety. While these results do not correspond to clinical diagnoses or a definite need for treatment, they provide timely information on an important issue and highlight the need to address mental and emotional health.

Methods

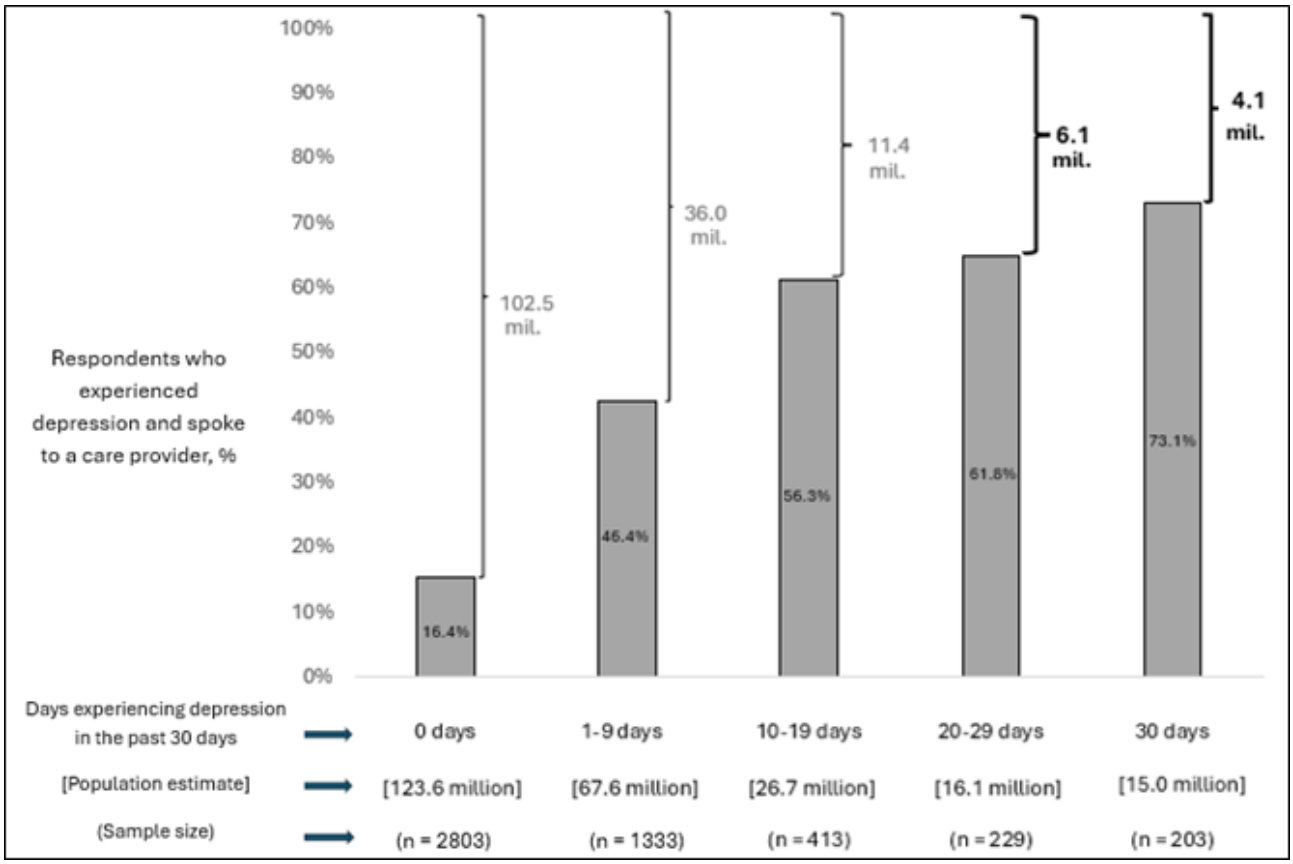
Ethical Considerations

The data for this cross-sectional study were obtained from a nationally representative West Health–Gallup web and mail survey conducted from November 2023 to January 2024; 5149 adults aged ≥18 years were sampled from the Gallup panel using stratified sampling spanning all 50 states and the District of Columbia. The survey response rate was 38%. Ethical approval was granted by Gallup's internal institutional review board. Participation was voluntary, and responses were deidentified. No personal health information or other sensitive information was disclosed to the authors. Multimedia Appendix 1 provides details.

Statistics

Percentages were estimated as the count of responses divided by the number of respondents, multiplied by 100. Probability sampling weights provided by Gallup were used to calculate the population estimates.

Outcomes



Survey questions focused on perceptions about health care. Our 2 main outcomes were self-reported experiences of depression and anxiety. The survey asked respondents how many days they experienced either condition in the past 30 days and if they had ever discussed depression or anxiety with their HCP. Multimedia Appendix 1 provides more details.

Results

We estimate that 31.1 million US adults experienced symptoms of depression on 20 or more days in the past month at the time of this survey. Of these people, an estimated 10.2 million never spoke to an HCP about their mental health (Figure 1).

XSL•FO
RenderX

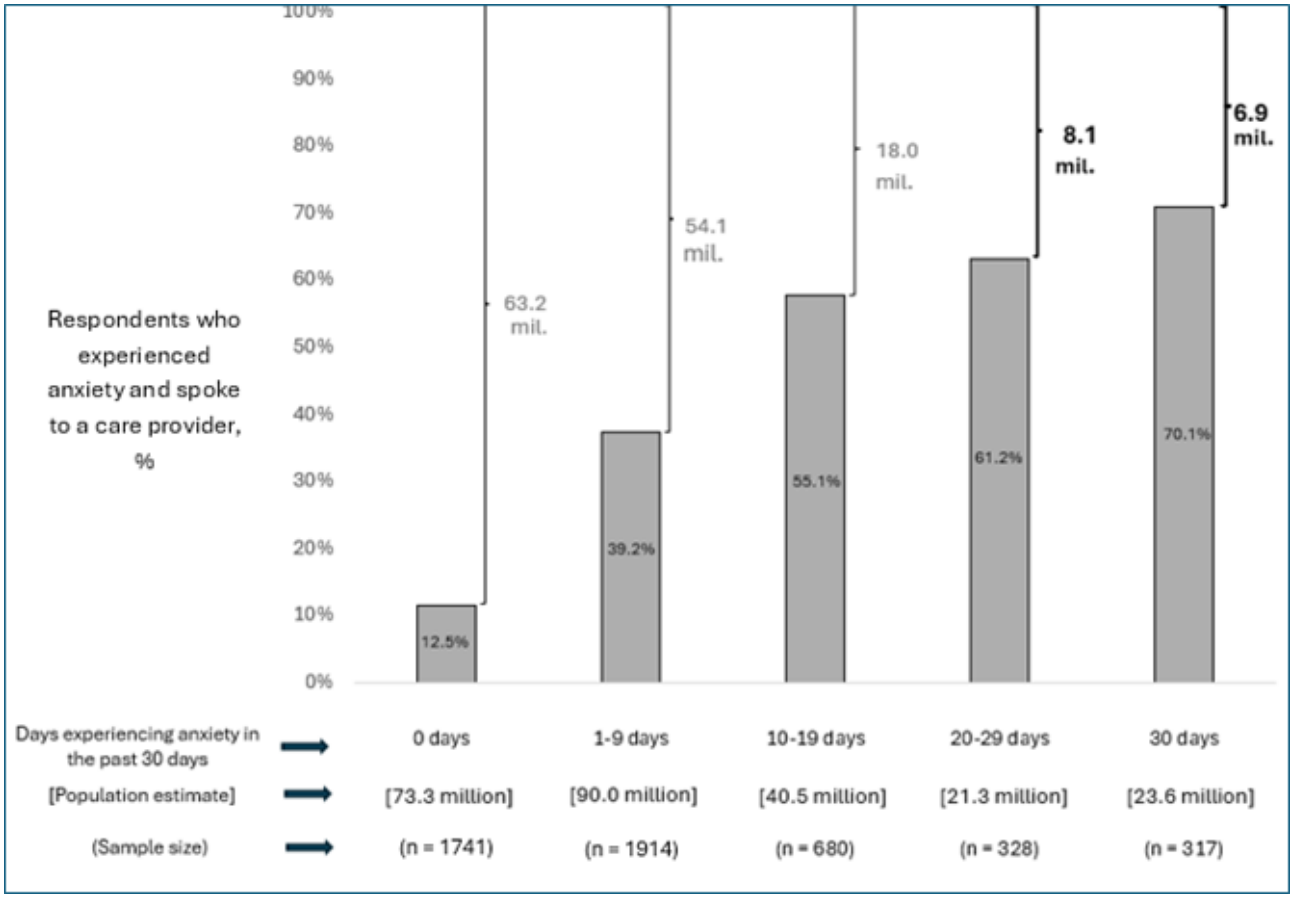


Figure 1. An estimated 10.2 million adults experienced feelings of depression almost every day but had never spoken to a health care provider about it. The figure plots the percentage of people who reported ever talking to a health care provider about depression on the y-axis against the number of days (category) they self-reported experiences of depression. The estimated population size and sample size, broken down across number of days reported (categorical variable), are displayed below the x-axis. The population estimates at the top of the figure, to the right of the curly brackets, represent the population estimates of the number of people who reported experiences of depression by number of days (categorical variable) but never talked to their health care provider about it. Percentages may not add up to 100 as some respondents may not have responded to one or both questions. Full details are available in Multimedia Appendix 1.

Additionally, we estimated that 44.9 million adults experienced anxiety on 20 or more days in the past month. Of them, an estimated 15 million had never spoken to an HCP about it (Figure 2).

XSL•FO
RenderX

Figure 2. An estimated 15.0 million adults experienced feelings of anxiety almost every day but had never spoken to a health care provider about it. The figure plots the percentage of people who reported ever talking to a health care provider about anxiety on the y-axis against the number of days (category) they self-reported experiences of anxiety. The estimated population size and sample size, broken down across number of days reported (categorical variable), are displayed below the x-axis. The population estimates at the top of the figure, to the right of the curly brackets, represent the population estimates of the number of people who reported experiences of anxiety by number of days (categorical variable) but never talked to their health care provider about it. Percentages may not add up to 100 as some respondents may not have responded to one or both questions. Full details are available in Multimedia Appendix 1.

Discussion

Principal Findings

We found that an estimated 53.8 million people have near-daily experiences of depression, anxiety, or both, and an estimated 18.6 million of them have never spoken to an HCP about these experiences.

Limitations

Our findings are based on self-reported data, and we cannot assess if people (1) have a mental health diagnosis, (2) need professional care, or (3) have sought or received care. However, the findings provide useful population-level information about people's self-reported experiences with depression or anxiety even though the results are not prevalence estimates.

Comparison to Prior Work

The Substance Abuse and Mental Health Services Administration reports that 58.7 million adults had any mental illness in 2023 [7]. Based on the National Health Interview Survey, the US Centers for Disease Control and Prevention reports that 18.2% and 21.4% of adults experienced symptoms of anxiety and depression, respectively, in 2022. In comparison, we find that 53.8 million adults (18.5% of the adult population in 2024, as per author calculations) self-reported near-daily experiences of depression, anxiety, or both.

Future Directions

This paper shows that millions of US adults experience depression, anxiety, or both on a near-daily basis but have never sought care from an HCP. The magnitude of these self-reported experiences, while alarming, does not correspond to a clinical diagnosis. Future research should aim to better understand the clinical needs of these people and build on the recent work showing a high degree of unmet need for mental health care [8].

Acknowledgments

EM-F had full access to all the data from the survey and takes responsibility for the integrity and accuracy of the data analysis. No artificial intelligence was used in the creation of this letter.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

Both YP and EM-F contributed equally to this letter and had full access to the survey and results.

Conflicts of Interest

YP is an employee of Gary and Mary West Health Institute. EM-F is an employee of Gary and Mary West Health Policy Center. Both organizations are committed to addressing the need for mental health care.

Multimedia Appendix 1
Sampling strategy, list of questions, and detailed tabulations.
