Despite the importance of the results of the included studies, we identified several research gaps that limit our understanding of the relationship between internet use and SRH. First, it is important to note that a significant portion of the studies included in this review (25/27) were based on a cross-sectional design, a common methodological approach that, by its nature, limits the ability to infer causal relationships between variables because it captures phenomena at a single point in time [96]. This methodological limitation requires careful consideration when interpreting the findings and generalizing them to dynamic or process-based relationships. Nevertheless, the included studies met most of the key criteria for assessing risk of bias in cross-sectional research, as outlined in the methodological review by Kelly et al [97], including selection (sample representativeness), exposure (measurement validity), outcome (measurement reliability), confounding (control of variables), missingness (handling missing data), selective reporting (complete results disclosure), and conflict of interest (financial or professional influence). The overall methodological quality strengthens the degree of confidence that can be placed in the review's findings, even if conclusions must be drawn with caution. In light of the methodological challenges inherent to this design, there is a clear need to promote longitudinal and interventional studies that allow for a deeper understanding of dynamic relationships and causal pathways over time. Second,

XSL•FO
RenderX

most of the studies did not apply a theoretical framework or model. Only 6 of the 27 studies referred to a theory, such as activity theory, social participation theory, or the social ecological model. The limited use of theoretical frameworks may reflect the lack of models that are specifically tailored to understanding the relationship between internet use and SRH in older adults. Without a guiding framework, it becomes more difficult to interpret the processes underlying this relationship, including possible mediators and moderators. Therefore, future research should aim to develop or adopt theoretical models that can offer clearer conceptual guidance for investigating this association. Third, regarding internet use, the majority of the studies focused primarily on examining use or frequency of use without reference to the purpose of internet use. Therefore, further studies should focus on understanding how the different purposes for which the internet is used may affect older adults' SRH. Finally, this review included only studies from industrialized countries, highlighting the need for future research in developing countries and low- and middle-income countries. In these contexts, internet access is often more limited, and older adults may encounter unique barriers such as lower levels of digital literacy, limited technological infrastructure, and different social and health care systems [98]. In addition, sociocultural factors such as norms surrounding aging, family roles, and attitudes toward technology may also influence patterns of internet use and its impact on SRH [99,100]. Therefore, findings from low- and middle-income countries may differ substantially from those in high-income countries and warrant focused, context-sensitive investigation.

Limitations

This scoping review has several limitations. Although the search strategy followed established guidelines and covered 5 major electronic databases, supplemented by Google Scholar searches and reference list screening, relevant studies published in sources not indexed in these databases may have been missed. In addition, the review was restricted to English-language publications; therefore, relevant studies published in other languages may have been excluded. Finally, the review included only peer-reviewed journal articles and did not incorporate gray literature, despite evidence that gray literature can provide valuable insights in systematic and scoping reviews [101].

Conclusions and Implications for Practice and Policy

This scoping review mapped 27 studies examining the association between internet use and SRH among older adults. Most studies reported a positive association between internet use and better SRH, although the magnitude and consistency of this relationship varied depending on how internet use was measured and on the characteristics of specific subgroups. Overall, the findings suggest that the relationship between internet use and SRH depends substantially on the purpose of use, with socially oriented uses such as communication and social participation appearing particularly relevant and potentially operating through mediating social pathways, including greater perceived support and reduced loneliness. However, because the evidence base is dominated by cross-sectional studies, longitudinal and intervention research is needed to strengthen causal inference, strengthen and extend the evidence on mediating mechanisms, which have been examined in a relatively small number of studies and mainly through social factors, and on moderating mechanisms, and to clarify for whom and under what conditions internet use contributes to SRH.

From a practical standpoint, the findings support advancing digital inclusion as part of healthy aging policy by providing age-tailored training that promotes safe and meaningful use, especially uses that facilitate social connection, access to information and services, and community participation. Digital support should be integrated into health and social care through community-based initiatives and digital navigators who can provide hands-on guidance and ongoing assistance. In addition, improving digital inclusion may also benefit health and social care systems by facilitating timely access to services and support and potentially contributing to greater system efficiency [102]. This may also help reduce health disparities among older adults [102]. At the same time, maintaining nondigital options across service points and information channels is important to prevent exclusion of those who do not use the internet or struggle to do so. These recommendations align with framing digital inclusion as a social determinant of health rather than merely a technological issue [102]. Finally, there remains a notable gap in evidence from low- and middle-income countries, where sociocultural contexts and system-level conditions may shape patterns of internet use and its health implications [99,100]. In these settings, and among socioeconomically disadvantaged groups within high-income countries, digital inclusion efforts may also need to address structural barriers such as affordability, access to connectivity, and the availability of accessible online services tailored to older adults.

Data Availablilty

The datasets used during this study are available from the corresponding author on reasonable request.

Funding

The author received no financial support for the research, authorship, and/or publication of this study.

Authors' Contributions

HA led the conceptualization, methodology, investigation, data curation, formal analysis, visualization, project administration, and the writing of the original draft, as well as the review and editing. FA-R led validation and contributed in a supporting role

Abstract

Background: The use of augmented reality (AR) and virtual reality (VR) to address addictive behaviors such as substance use disorders and gambling disorders has been growing. However, little has been done to explore the use of AR and VR in the treatment of other behavioral addictions.

Objective: This scoping review aims to provide an overview of existing literature on AR and VR interventions for behavioral addictions. Specifically, the research questions are as follows: (1) What behavioral addictions or behavioral harms are being treated using AR and/or VR? (2) What AR and/or VR treatment interventions are being used to treat these behavioral addictions?

Methods: This scoping review was conducted based on the framework first proposed by Arksey and O'Malley, later refined by Levac et al, and further outlined in the Joanna Briggs Institute (JBI) Manual for Evidence. The literature was searched in the following databases: CINAHL, PsycArticles, PsycInfo, PubMed, and Web of Science, with Google advanced search complementing the search on Feb 22, 2023. Studies were screened by 2 independent reviewers based on inclusion criteria (all ages; any behavioral addiction, problematic behavior, or behavioral harm; AR or VR treatments and interventions) and exclusion criteria (pornography, sexual, and paraphilic disorders). Discrepancies were resolved by third and fourth reviewers. As this study is a scoping review, risk of bias was not assessed. Data were extracted and presented in tabular form as well as through conceptual analysis as a narrative summary.

Results: A total of 9 studies were included in this review, 4 studies on video gaming and 5 studies on gambling behaviors. Participants' age ranged from 12 to 65 years. Only the use of VR was identified. VR was used as a platform for cue exposure therapy and skills training in both gaming and gambling disorders. VR therapy was effective alone or in combination with other treatments and was comparable to traditional interventions. No adverse effect was reported in the studies.

Conclusions: VR is efficacious in treating behavioral addictions and can replace or be used in conjunction with traditional methods. Future directions include using VR with other psychotherapy or relapse prevention, applying VR to treat other addictions, and investigating harmful side effects of VR use. The frequency and duration of sessions can also be optimized. A limitation of this study is that there may be other documents beyond those published and searched in gray literature that could not be included in this review due to time and resource restrictions. The use of AR in the treatment of behavioral addictions did not yield any results in this review. However, VR application in behavioral addiction is promising, potentially efficacious, and capable of multiple applications.

Introduction

Background

Behavioral addictions are characterized by repetitive and rewarding behaviors that disrupt an individual's life [1]. Only 2 behavioral "addictions"—gambling disorder and internet gaming disorder—are acknowledged in the *ICD-11* (*International Classification of Diseases, 11th Revision*) [1]. Substance use disorders and compulsive sexual behavior disorders are excluded, as they are classified separately under the *ICD-11* due to their distinct clinical profiles. Other behavioral harms such as exercise-related harms [2], mobile phone harms [3], and social media harms [4] are also widely debated. Systematic reviews and meta-analyses indicate that the worldwide prevalence of gaming disorders is approximately 3.05% [5], while the prevalence of gambling disorder is approximately 1.29% [6]. These findings show similarities to the prevalence of certain substance use disorders, estimated at 2.6% [7]. The World Health Organization (WHO) presentations on addictions at international forums in 2017 and 2019 [8] highlight an increase in attention on behavioral addictions.

Both recognized behavioral addictions have been linked to negative consequences. Internet gaming disorders have been associated with issues such as lower academic achievement, sleep loss [9], difficulties with interpersonal relationships, and effects on career opportunities [10]. While there exist studies that highlight potential benefits of gaming, especially for open-world games [11,12], this study focuses on excessive or problematic gaming behaviors that extend beyond healthy recreational use. These patterns, when persistent, may lead to significant psychosocial and physical difficulties. Gambling disorders may negatively impact personal relationships [13], employment, fitness, sleep [14], and overall health and well-being [15]. Recently, there has been a significant rise in the development of preventative strategies, assessment tools, and treatment methods for gaming and gambling disorders. Other potentially problematic behaviors that are less studied, such as social media use, shopping [16], exercise [17], work [18], general internet use [19], and other behaviors that do not involve substance intake, may also negatively impact psychosocial and physical well-being.

Current treatments like cognitive behavioral therapy (CBT) have proven effective in lessening problematic behaviors by empowering clients with motivational and cognitive tools to initiate change and avoid relapse [20]. Additionally, CBT helps individuals develop skills for regulating their emotions and problem-solving [20]. Other common interventions include mindfulness-based cognitive therapy to help with managing cravings [21] and family therapy and support groups to provide social support for patients [22].

Technological Advances in Treatment Modalities

Mental health interventions have recently welcomed new innovations and experiences that showcase new technologies [23]. Two of these technologies are augmented reality (AR) and virtual reality (VR). AR technology establishes a computer-generated setting that produces a unique reality where real and virtual elements are perceived simultaneously and interactively [24]. One therapeutic application of AR technology is an AR-powered smart training program designed to teach tooth brushing and enhance oral hygiene for individuals with intellectual disabilities [25]. As a more advanced technology, VR uses computer graphics, motion sensors, and 3D display technologies that fully immerse users [26]. VR technology has shown positive outcomes in enhancing functional performance among adults in psychosocial rehabilitation [27]. Until recent years, VR faced limitations due to its high cost and poor quality of graphics and content available. However, growing interest in VR from the video game industry has made VR more accessible by reducing costs and increasing capabilities, resulting in an increasing uptake of VR technology [28].

The use of AR and VR to address mental health issues such as anxiety, substance use disorders, and gambling disorders has also been growing. AR and VR have been used in exposure therapy, where positive results were shown. One study found that an AR exposure app with graded tasks, varying in intensity and duration, effectively reduced the participants' subjective fear and disgust toward spiders [29]. Another study found that VR therapy effectively decreased craving and improved self-control in individuals with substance use disorders by exposing them to stimulating cues, ranging from pictures of items to immersive environments [30]. In addition, VR has proven helpful in the treatment of anxiety through its ability to generate virtual environments that induce anxiety, serving as a form of exposure therapy. Conducting exposure therapy in a virtual setting instead of in real life lowers the risk of worsening symptoms that might occur with direct exposure, making it a safer approach [31]. VR has also been used in providing role-playing opportunities for vocational training for people diagnosed with schizophrenia. Participants who received a 10-hour virtual job interview training had higher blind-rated scores by human resource members and higher self-rated confidence levels [32]. While there is growing interest in AR and VR as treatment modalities, research exploring the use of AR and VR in the treatment of behavioral addictions has not been consolidated. Hence, this scoping review aims to provide a comprehensive overview of existing literature on the use of AR and VR treatment for behavioral addictions or behavioral harms and to synthesize knowledge gaps for future research.

XSL•FO
RenderX

Methods

Overview

A scoping review was performed systematically according to the methodological framework proposed and augmented by Arksey and O'Malley [33], Levac et al [34], and the Joanna Briggs Institute (JBI) Manual for Evidence Synthesis [35]. The scoping review framework has 6 stages as described in the subsequent sections. The protocol for this study was first submitted for publication on January 27, 2023, and published after peer review [36].

Stage 1: Identifying Research Questions

This scoping review aims to provide a comprehensive overview of existing literature on the use of AR and VR treatment for behavioral addictions or behavioral harms and synthesize knowledge gaps for future research. Our review questions were as follows:

1. What behavioral addictions or behavioral harms are being treated using AR and/or VR?
2. What AR and/or VR treatment interventions are being used to treat behavioral addictions?

Stage 2: Identifying Relevant Studies

A comprehensive search was conducted in 5 databases, including CINAHL, PsycArticles, PsycInfo, PubMed, and Web of Science. Additionally, gray literature and Google advanced search were searched (the first 10 pages were screened). The search strategy aimed to identify studies published in English in the last 10 years where full-text publications were available. This was to account for the validity of recent technological advancements and to include a larger number of relevant articles that can be used in this scoping review.

To identify relevant literature, the selected databases above were searched using keywords after consultation with an academic librarian (see protocol [36] for a full list of keywords used). Boolean operators were applied to combine search terms logically. "OR" was used to group synonyms, ensuring the inclusion of all relevant terms. "AND" was used to combine the main keywords, such as "behavioral addiction," "virtual reality," and "intervention," so that only studies addressing all 3 areas were retrieved. Quotation marks were placed around multiword phrases to search for exact matches, while truncation symbols were used to capture variations in word endings. New keywords found in identified articles were included in the final searches across all databases. The full list of search terms used can be found in Multimedia Appendix 1. Finally, reference lists of all articles and reports were hand-searched for additional studies to ensure comprehensive identification of literature [35].

Stage 3: Study Selection

Inclusion and Exclusion Criteria

Studies were selected based on the inclusion and exclusion criteria to meet the scope of the inquiry. The literature included in this review consists of published articles in peer-reviewed journals using all types of methodologies, including protocols. Gray literature is also included to minimize publication bias through Google advanced search. Only literature published in English was screened, reflecting the language expertise of the reviewers; nevertheless, sources of evidence from any country were eligible for inclusion. Inclusion criteria for participants were studies that involved people who exhibit behavioral addictions at all ages. Concepts of AR and VR interventions that can be used in treating behavioral addictions were included, such as assessments, perspectives, and outcomes measured for these interventions. Exclusion criteria were reviews and conference abstracts. Research that studied pornography addiction and compulsive sexual behaviors was excluded due to separate categorizations of compulsive sexual behavior disorder and paraphilic disorders from the *ICD-11* [1].

Study Identification

The study selection consisted first of screening titles and abstracts according to the inclusion and exclusion criteria by 2 independent reviewers (FXRC and GHL). If titles and abstracts matched the inclusion and exclusion criteria of the scoping review, a full-text review commenced. Two reviewers (FXRC and GHL) worked independently to review and extract relevant articles before importing them into Zotero (Corporation for Digital Scholarship), an open-source reference management software that eliminated duplicates of citations retrieved from multiple databases before screening [37]. A third and fourth reviewer (JS and VT) were consulted for ambiguities until a consensus was reached. Reasons for the exclusion of full-text studies that did not meet the inclusion criteria were recorded and reported in this scoping review. The search and screening processes were presented in a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram [38].

Stage 4: Charting the Data

Data were extracted from selected articles and recorded in a data extraction table in accordance with the methodology of scoping reviews [35]. The data extraction table was used to collate the extracted data based on identified data fields. These data fields include type of behavioral addiction, aim of study, treatment details, control groups, outcome measures, results, future directions, and conclusion. The first 2 authors (FXRC and GHL) independently extracted data from all the full texts. The last 2 authors (JS and VT) then cross-checked all the extractions.

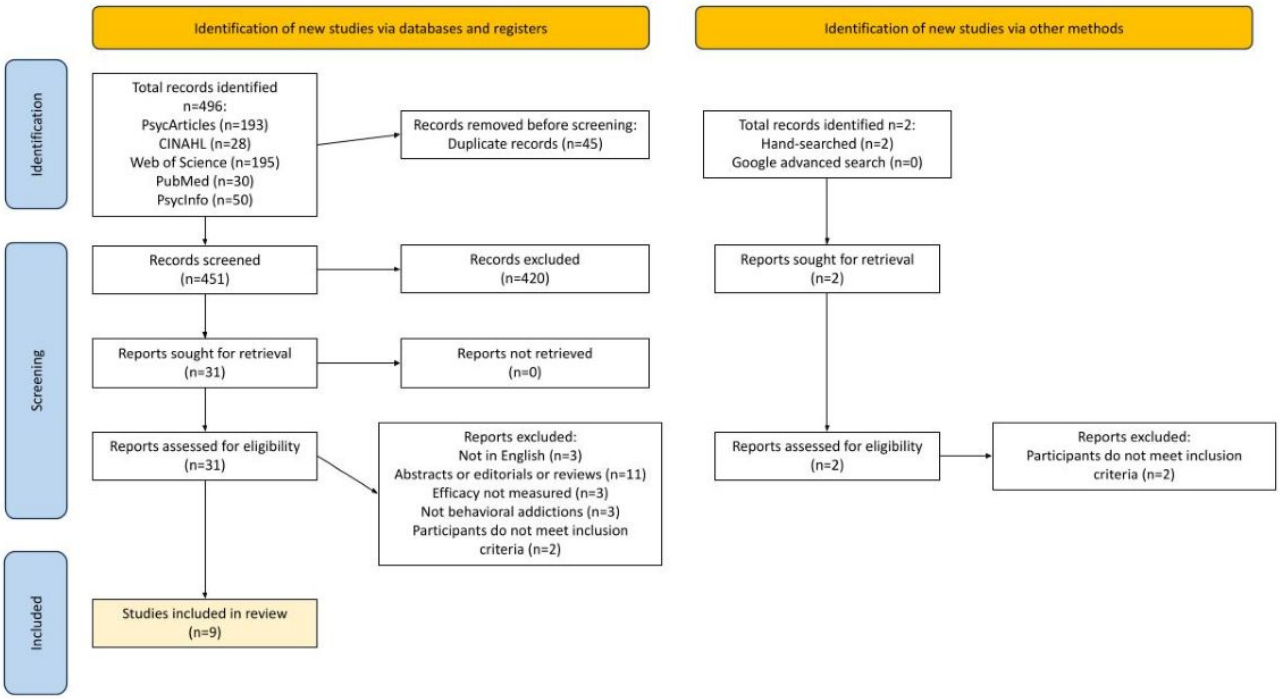
Stage 5: Collating, Summarizing, and Reporting the Results

Results are described and collated according to the PRISMA-ScR checklist [38] and the JBI methodological guide for scoping reviews [35] (Multimedia Appendix 2). A conceptual analysis was then carried out to identify and synthesize the key findings emerging from the included studies into main themes. Common characteristics of included studies were identified, and then comparisons were made between these studies under each identified concept. These were presented as a narrative summary.

Stage 6: Consultation Exercise

The sixth stage is an optional consultation stage of scoping reviews [33]. The purpose of this stage is to gather additional

XSL•FO
RenderX



insights, perspectives, or references from stakeholders. Furthermore, this stage assesses whether findings resonate with real-world experiences to enhance the relevance and applicability of this scoping review. For this review, we reached out to 6 stakeholders—identified based on the research team's established professional networks—including academics, digital developers, and clinicians, about our findings on the identified preliminary literature findings from stage 5. A set of questions, along with a draft of this scoping review manuscript, was emailed to identified stakeholders and consultants for their feedback.

Results

Search Results

Five databases were searched on February 2, 2023. An overview of the data identification and selection process can be found in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart (Figure 1). A total of 496 studies were retrieved, of which 45 were duplicates and 420 did not meet the inclusion criteria. In total, 31 full-text studies were assessed for eligibility, which resulted in 9 studies [39-47] for inclusion in this scoping review.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.

Study Characteristics

Four studies [43-46] were on video gaming, while 5 studies [39-42,47] explored gambling behaviors. All 9 studies explored the use of VR as an intervention, while no studies used AR. The reviewed articles were from Canada (n=3) [39,41,47], Turkey (n=1) [46], Italy (n=1) [40], and South Korea (n=4) [42-45]. Among the studies that provided information on the age range (n=5) [39,40,44,46,47], they covered ages from 12 to 65 years. Studies on gambling behaviors [39-42,47] recruited participants aged 18-65 years, while studies on gaming behaviors [43-46] recruited younger participants aged 12-25 years. Furthermore, when it came to the sex of the participants recruited, 5 of the studies [42-46] exclusively recruited male participants. One study [47] recruited participants who were mainly White, while another [45] carried out its study on Asian participants. The other 7 studies [39-44,46] did not state the ethnicity of participants. Overall, participants across these studies represented a wide age range and were predominantly male. Among the 9 studies, 6 [39,41-43,45,47] were experimental designs, 2 [44,46] were randomized controlled trials, while one [40] was a study protocol for an experimental design. The characteristics and research aims of the 9 articles are presented in the extraction table titled, "Summary of virtual reality applications in behavioral addictions" (Multimedia Appendix 3).

Four themes were identified in the included studies: (1) the application of VR is predominantly for reducing urges, (2) VR therapies are generally efficacious compared to other treatments, (3) adverse effects are not found in the varied uses of VR treatment for behavioral addictions, and (4) further research is needed to support the use of VR in behavioral addictions treatment.

Applications of VR Are Predominantly for Reducing Urges

Across all 9 studies, VR was used either in the treatment of gambling (n=5) or gaming disorders (n=4). No other types of behavioral harms were found. The application of VR varied across the studies. VR was mostly used as a platform for cue exposure therapy (CET) [39-44]. CET is a behavioristic psychological approach where individuals are deliberately exposed to relevant addictive cues with the aim of extinguishing conditioned responses associated with the cue by systematically pairing them with a lack of the addictive substance or behavior [48,49]. When CET is conducted through VR, users are

XSL•FO
RenderX

immersed in an environment where they are exposed to activity-related environmental stimuli. Giroux et al [41] used a virtual environment featuring 5 video lottery terminals along with other gambling-associated stimuli, including people who are gambling on video lottery terminals, a billiard table, and alcoholic beverages. Similarly, Park et al [42] included gambling-related cues such as navigating and playing a casino game, discussing gambling, and witnessing a jackpot scene. Park et al [43] exposed participants to gaming cues that they frequently play in video games, such as scenes of battling, leveling up, or shooting. Whereas Shin et al [44] exposed participants to scenes of video game invitations, the internet café entrance, and conversations on gaming.

VR was also used as a medium to teach specific skills, such as refusal skills and skills on managing game-related family conflicts. This was done by adopting VR as an environment for participants to engage in a role-playing situation to practice the aforementioned skills [44,45]. Shin et al [44] had participants reject gaming invitations through practicing refusal skills. These participants were told to refuse the avatars' invitations to play together in a game. In contrast, Shin et al [45] targeted resolving and minimizing game-related conflict with family through risk-benefit analysis and perspective-taking exercises. In the risk-benefit analysis, participants were asked to consider the benefits and disadvantages of halting the game immediately and to evaluate the impact of each example on them using a visual analog scale embedded in the VR program. In the perspective-taking exercise, they were asked to voice out the parents' behavior from their own perspective, then think about it from the parents' perspective. They were subsequently tasked to rate the extent to which they were able to understand the parents' perspective using the same visual analog scale. VR offers a realistic setting by which to practice real-life scenarios using different avatars and visual environments.

One study adopted VR to play sports games to study the therapeutic effects of VR therapy and aerobic training on fitness, physical activity, and anxiety in those with gaming disorder [46]. The VR therapy group played different sports games, including boxing, hurdles, and beach volleyball, on an Xbox Kinect 360 (Microsoft Corp). The games involved simultaneous body movements of the participants, including jumping and hitting movements. This helped to encourage more physical activity and prevent the worsening of gaming disorder [46]. The last study used VR to evaluate the effect of gambling goals on chasing behavior [47]. Chasing behavior refers to the persistent pursuit of losses through continued gambling, involving a pattern of escalating wagers and increased risk-taking in an effort to recoup money lost during previous gambling activities [47]. Participants played on slot machines and had to decide whether to stop or continue after several rounds. Their behaviors were tracked and compared with their gambling goals, which were assessed through a questionnaire (eg, how much they wanted to win and how motivated they were to win).

VR Therapies Are Generally Efficacious Compared to Other Treatments

The studies in this scoping review either examined the efficacy of VR alone or in comparison to traditional CBT. Comparing pre- and post-effects of VR therapy, VR therapy was found to be effective in reducing the severity of behavioral addictions [39,42-46]. For gaming disorders, the VR therapy group had significantly shorter gaming time (P=.04) and increased weekly physical activity values (P=.03) as compared to a control group that did not receive any treatment [47] and showed significantly reduced scores on the Young's Internet Addiction Scale (YIAS; P<.01) after the treatment [43]. Practicing refusal skills during VR sessions also significantly lowered craving responses (P<.03) [44]. The Internet Gaming Disorder group had a higher frequency of halting the game after the risk/benefit assessment (P=.003) and anger expression task (P=.001) practices using VR as compared to baseline [45].

Similarly, for gambling disorders, VR therapy was effective in controlling gambling problems (P<.05) [39], and participants in the VR therapy group showed significant decreases across sessions in the subjective urge to gamble as compared to baseline (P=.04) [42]. However, one study found no reduction in urges to gamble after a single session of CET in a virtual gambling environment session [41]. It was speculated by the author that this could be due to the study having only one session of 20 minutes as compared to other studies with multiple sessions and longer durations. Overall, all but one study found promising results for the use of VR in the treatment of behavioral addictions.

When compared to other treatment modalities, VR therapy was found to be an effective and viable alternative [39,43,46]. Both CBT and VR therapy resulted in a reduction in the urge to gamble, with similar results regardless of the treatment modality (P<.001) [37]. The VR therapy program was shown to be as effective as the aerobic exercise program in reducing the severity of gaming disorder and anxiety, with both groups having significantly shorter gaming time (P=.04 and P=.04) and sedentary time (P<.001 and P=.03) [46]. Similarly, both CBT and VR therapy groups showed significant effects in reducing YIAS scores with no significant difference in YIAS score change between the CBT and VR therapy groups (P=.52) [43]. VR therapy was also effective when used in combination with CBT (P<.05) or relaxation exercises (P=.04) [39,42]. Furthermore, VR therapy demonstrated effectiveness in reducing the severity of online gaming addiction among individuals with attention deficit/hyperactive disorder symptoms by enhancing their engagement through greater immersion in the therapeutic process using VR. This reduced the challenge of maintaining their attention with conventional therapeutic techniques [43]. Two studies did not evaluate the efficacy of their treatments [40,47].

Varied VR Treatment Programs With No Adverse Effects Reported

Across the 8 studies [39,41-47], with one [40] protocol study excluded, the treatment program varied in terms of type, frequency, duration, and the personnel who conducted the treatment (Table 1). In addition to investigating the use of VR therapy for the treatment of behavioral addictions, some studies [39,41,44,45] considered possible adverse effects, such as cybersickness, also known as simulator sickness. Cybersickness is a syndrome akin to motion sickness and is a potential side

XSL•FO
RenderX

effect during and/or after exposure to various virtual reality environments. While motion sickness is triggered by actual movement, cybersickness is triggered by visual stimulation [50].

Table 1. Program details and cybersickness measurement.

Author (year of publication)	Exposure duration	Facilitated by	Measured cybersickness
Bouchard et al (2017) [39]	20 min	Therapists	Yes
Giroux et al (2013) [41]	20 min	Researcher	Yes
Lister et al (2016) [47]	5 min	Experimenter	No
Maden et al (2022) [46]	30 min	Physiotherapist	No
Park et al (2015) [42]	40 min, 5 separate scenes	Not stated	No
Park et al (2016) [43]	25 min	Psychiatrist	No
Shin et al (2018) [44]	Not stated	Not stated	Yes
Shin et al (2021) [45]	2 scenes, 10-15 minutes each	Therapist	Yes

In terms of duration, 5 studies had participants exposed to VR for at least 20 minutes [39, 41, 42, 43,46], while one study had participants in the VR environment for 5 minutes [47]. In one study, participants were exposed to 5 different scenes in 40 minutes [42]; however, the authors did not state if there were any breaks between the scenes. Similarly, a different study had participants in 2 different scenarios of about 10-15 minutes each [45], without indicating if a break was given in between. One study did not state the duration of virtual environment exposure [44]. Of the studies that specified treatment details, the number of treatments varied from one session [41] to 18 sessions [46].

Despite the varied frequency and duration of treatment, VR used in the treatment for behavioral addictions was not found to induce significant cybersickness. To measure the presence of cybersickness due to VR therapy, 3 studies used the cybersickness questionnaire [39,44,45], while one study used a post-VR exposure questionnaire [41]. The recorded levels of cybersickness did not increase in intensity compared to before VR therapy [39] or remained lower than established norms [44,45], affirming the feasibility of VR immersion for treating internet gaming disorder [44,45] and gambling disorder [39,41]. The other 5 studies [40,42,43,46,47] did not specify measuring cybersickness and did not report any negative side effects associated with VR therapy.

Further Research Is Needed to Support the Use of VR in Behavioral Addiction Treatment

The findings from the included studies in this scoping review highlighted the potential for further exploration of VR in the treatment of behavioral addictions and suggested expanding the use of VR within and beyond the scope of behavioral addictions. All studies should report facilitators of the programs to ensure that adequately trained personnel can administer the intervention. Of the studies that reported this, VR therapy was facilitated by therapists (n=2), psychiatrists (n=1), physiotherapists (n=1), and the researchers themselves (n=2). Two articles did not state the facilitators. Additionally, 2 studies called for improving the efficacy of VR for treatment to address gambling addictions. Park et al [42] suggested investigating the optimal frequency and duration of VR sessions. Similarly, for gaming addictions, Shin et al [44] stated the need to focus on developing VR treatments for internet gaming disorders and comparing them with conventional treatment protocols.

Four studies suggested additional research to assess the effectiveness of combining VR with other types of therapy. Bouchard et al [39] suggested using VR with other forms of psychotherapy or mindfulness. Giroux et al [41] recommended combining VR treatment and relapse prevention with cognitive intervention for gambling problems. Shin et al [45] expressed interest in examining the long-term effects of skill learning in addressing gaming disorders when VR is combined with CBT. Giordano et al [40], whose study protocol aimed to compare combined VR therapy and CBT with traditional CBT, indicated a need for future studies to include a nontreatment control group to better analyze the efficacy of the combined intervention. Beyond behavioral addictions, Bouchard et al [39] recommended exploring the potential of VR applications in addressing other types of addiction. They also cautioned that there is a need for research on the potential of VR addiction [39].

Outside of using VR, Lister et al [47] suggested discovering if there is a better way to reduce problematic gambling outcomes (chasing and losing money), such as redefining goal-setting for gambling achievements. They suggested that setting realistic gambling goals might be more effective in reducing problem gambling compared to the current limit-setting tools such as limiting time or money. Park et al [43] and Maden et al [46] did not mention future research directions.

Consultation Response

Consultation questions, along with an earlier draft of our manuscript, were sent to 6 stakeholders; however, only one responded after the initial email and 2 follow-up emails. Due to the low response rate, no formal analysis was conducted for this stage. The questions and responses are available in Multimedia Appendix 4. Our consultant (Dr. Bhing Leet Tan) has experience working as an occupational therapist and more than 11 years of experience as the head of the department at a mental health hospital. She has also published research on using VR for rehabilitation and AR for people with intellectual and developmental disabilities. She noted that while younger clients may find VR interventions more acceptable due to familiarity, older individuals, particularly those with gambling addictions,

XSL•FO
RenderX

may require adjustment. She suggested grounding interventions within established frameworks like CBT or other frames of reference and providing interventions in multiple languages for psychoeducation. While she found it noteworthy that VR interventions showed positive outcomes in conflict resolution and assertiveness training, this did not come as a surprise to her due to VR's prior effectiveness in social skills training. Nonetheless, she identified gaps in the literature, including specific VR hardware used and the sustainability of urge reduction gains over time.

Discussion

Principal Findings

This scoping review was conducted to provide an overview of existing literature on the use of AR and VR treatment for behavioral addictions. VR was found to be used for the treatment of problem video gaming and problem gambling. However, no AR studies were found. A breadth of studies from 4 countries and participant age ranges (children to older adults) were found; however, participants in the gaming studies were younger than participants in gambling studies. All 9 studies explored either problematic gaming or gambling, with study participants being mostly male, and ethnicity was rarely reported.

CET and skills training were the most common uses of VR in treatment to help with controlling urges and for role-playing to practice specific skill sets. Additionally, it was used as a platform to encourage a healthier lifestyle by introducing alternative activities. VR was applicable for both gaming and gambling disorders. Overall, VR therapy shows promise in the treatment of both gaming and gambling disorders, either as a standalone intervention or in combination with other treatments. It has also shown comparable results to other treatment modalities, showcasing its potential as a viable alternative to traditional treatment approaches. Nevertheless, these findings should be interpreted with caution, as the current body of evidence is still preliminary. A comprehensive systematic review assessing the methodological quality of existing studies is warranted.

Furthermore, most studies in this review tested for adverse effects, but none were identified. Overall, the results indicated that regardless of the treatment type, participants were able to spend up to 40 minutes in the VR environment without experiencing any adverse effects. Additionally, the varied facilitators did not seem to have an impact on cybersickness experienced by participants.

Comparison to Prior Work

Compared to previous literature, this scoping review both supports and extends prior findings in several ways. Consistent with earlier reviews, this review confirms that most research on VR interventions for behavioral addictions is concentrated in a small number of countries [51], notably, Canada (33.3%) and South Korea (44.4%) for this study [28]. Furthermore, 75% of the articles on gaming disorder are from South Korea, possibly due to esports being a prominent culture in South Korea [52]. South Korea also has a very high proportion of gamers among the adolescent population (as high as 91.5%) [53]. This review identified an acute gap in research on the use of AR as an intervention for behavioral addictions, notwithstanding its emerging promise in other fields in mental health rehabilitation [54-56] and in substance use disorders [57,58].

While the practicality of VR in clinical use could be limited by financial constraints [28] and higher production costs [59], AR is an economical and accessible alternative with easy incorporation into smart phones and mobile devices without the need for additional equipment such as headsets for VR environments [60]. Additionally, the ecological validity is higher in AR, as the problematic behavior is embedded in the real environment where the user is allowed to use their own body to interact with virtual objects as opposed to participating via a virtual representation of their body in VR [23]. A possible explanation for the lack of AR treatment approaches could be due to a limited understanding of AR by health care professionals and a lack of awareness of its potential benefits. There may also be more ethical concerns when using AR since it incorporates real-world environments into treatment, potentially making cue induction too realistic with no gold-standard precautions in place to manage clients.

CET and skills training were the most common uses of VR in treatment. These showed mainly positive results, not only in being effective in reducing the symptoms and severity of the addictions but also being comparable to traditional treatment modalities such as CBT. This aligns with the results from studies of patients with panic disorder and agoraphobia where VR exposure therapy was found to be effective and equivalent to CBT alone [61]. In fact, a randomized controlled trial found that self-led VR-based CBT was also found to be effective for panic disorder [62]. Although many other studies using VR, most commonly in the form of CET, found decreased craving and dependence in people with substance use disorders [28], an earlier study found no significant change in craving after VR exposure [63]. Overall, the potential of the use of VR in the treatment of behavioral addictions is promising, especially in combination with CBT. Further research, however, is needed to establish best practices.

A majority of the studies in this review that tested for adverse effects used the Simulator Sickness Questionnaire to test for cybersickness, which is the most widely used measure of sickness in virtual environments [64]. It has been recognized that VR can cause discomfort and cybersickness after prolonged use [65]. However, no adverse side effects were reported in any of the identified studies. In 8 studies, the duration participants spent in the VR environment was within 20 minutes, aligning with studies that confirmed this duration of VR usage did not lead to adverse effects. One study indicated that the VR therapy was 40 minutes, spent in 5 separate scenes [42]. This longer duration also did not lead to adverse effects of using VR, specifically cybersickness. Therefore, in this scoping review, VR is deemed appropriate in the treatment of behavioral addictions, as no significant adverse effects have been reported.

Possible reasons for no reports of cybersickness may be that individuals with gaming and gambling disorders may be spending prolonged periods of time in front of screens, such that they have a higher tolerance to light movements in VR

XSL•FO
RenderX

devices. Dużmańska et al [66] suggested that cybersickness can be avoided when the VR users are allowed enough time to adapt to the simulator conditions. Hence, prolonged periods of screen time during gaming and gambling can be a form of adaptation to the screen rate and locomotion, thus reducing the severity of cybersickness. Nevertheless, studies should screen for participants with known motion sickness, light sensitivities, epilepsy, and schizophrenia.

Future Directions

Overall, the studies included in this review showed that VR was a viable mode of delivering therapy for behavioral addictions (gaming and gambling) and agree that further research is required to optimize the use of VR in treatment to maximize its potential. There is a scarcity of research on the topic of AR and VR in the treatment of behavioral addictions. Future programs that use AR or VR should consider publishing details of their program (eg, what their program was for and what tasks participants were asked to complete) and their effectiveness. Overall, more studies focusing on using AR as a treatment modality for behavioral addictions could be explored.

There is potential for AR and VR to be used in other types of problematic behaviors other than video gaming and gambling. Investigating cue exposure may provide a useful starting point, given that it is the most extensively studied intervention within the existing literature. As Bouchard et al [39] mentioned, combining VR with other psychotherapies is another avenue to explore in future intervention development. An 8-week mindfulness-based program was found to be effective for individuals with gambling problems [67]. A self-directed mindfulness program could be integrated with AR technology in the form of an app to facilitate increased accessibility to treatment. Comparison studies of VR treatment with pharmacological treatments could also be conducted. The ability to configure virtual environments also allows for personalization of treatment, potentially enhancing the effectiveness and receptivity of therapeutic interventions. All in all, VR treatments appear to be efficacious. However, long-term studies and evaluation of the quality of evidence are needed to determine its viability.

This review's consultant points out that the potential of VR interventions among different age groups underscores its potential as a versatile therapeutic tool. She suggested the importance of integrating theoretical frameworks into VR interventions to enhance efficacy and address clients' needs effectively. Further research is warranted to address the identified gaps and refine VR intervention strategies for optimal clinical outcomes.

Strengths and Limitations

As this study was a scoping review, we did not aim to evaluate the risk of bias and quality of the studies found. First, only 9 articles from a small range of countries were found, which greatly limits the amount of evidence in evaluating the actual potential and efficacy of VR in behavioral addictions and in the different contexts. As more articles are published, a future systematic review may be warranted to synthesize the quality of the literature on AR and VR treatments in behavioral addictions. Second, there may be other relevant documents beyond the published articles and gray literature searches, not available in the public domain or published in other languages on this topic, which were not found by our research team and which could not be included in this review due to time and resource restrictions. To overcome this, requests have been made to the library to access full-text articles, and references of included studies were hand-searched for relevant studies. However, the diversity of studies in this review was still limited. Systematic searches of hospital, government, and global agencies may have revealed more studies.

Third, additional limitations based on this review's findings are that only studies on the use of VR with gambling and gaming disorders were identified, despite the wide spectrum of problematic behaviors that are studied (eg, excessive social media use and online shopping). This limits conclusions that can be drawn about AR and VR for other types of behavioral harms relating to technology and internet use. Finally, there were different types of behavioral addictions and varying age groups and sexes of participants. Although it served the purpose of our review, the results may not be as straightforward in providing an accurate picture of the way AR and VR can be incorporated in effecting the treatment of behavioral addictions. On the other hand, this scoping review helps to consolidate available studies and provide an overview and potential directions that may enhance the use of AR and VR in behavioral addiction treatment.

Conclusion

In this scoping review, we consolidated existing literature on the use of VR in the treatment of behavioral addictions, identifying types of behavioral addictions or harms that are being treated and the types of treatments or interventions that are conducted. This review shows that behavioral addictions in gaming and gambling can be effectively treated by using VR. For treatment, VR therapy can be used by itself or in conjunction with CBT for skills training and controlling urges. In research, VR can be used as a modality to simulate real events, such as to study gambling behaviors or the therapeutic effects of physical activities. The range of future research suggested by the studies shows that the full potential of VR therapy is yet to be realized. More research is needed to optimize VR treatment for behavioral addictions in terms of type, frequency, and duration. As further research progresses, this review hopes to encourage the continuous development of treatment options that advances with technology.

Acknowledgments

We would like to acknowledge Prof Tan Bhing Leet for her thoughtful responses in the consultation phase of this scoping review. We would also like to thank Chng Zhi Quan for his diligent work in preparing this manuscript for publication. Finally, we would

Abstract

Background: The use of artificial intelligence (AI) in medical imaging has been growing exponentially. Understanding patient perceptions and factors influencing their views of AI is critical to develop adequate strategies to support implementation and acceptance.

Objective: This study aims to investigate the constructs that influence patients' perceptions and acceptance of AI's use in the analysis of their medical images to support screening and diagnosis.

Methods: A systematic review was conducted to meet the research objective. Relevant articles were found by searching 5 databases. Data were extracted using an iteratively refined framework and synthesized narratively due to heterogeneity in study designs, populations, health care contexts, and outcomes.

Results: A total of 59 relevant studies were included in the review. Patient acceptance of AI in medical image analysis emerged from multiple interacting factors. The most consistently reported determinant in 48 studies was that AI implementation should prioritize human-in-the-loop models, positioning AI as supportive tools, working in conjunction with health care providers rather than as an autonomous decision-maker. Other factors identified were performance of the AI, clarity of accountability, trust, and ethical factors. Patients' individual characteristics such as demographics and health history were also noted to influence acceptance indirectly. The review findings were used to draft a conceptual model to draw attention to the complex relationship among the identified factors.

Conclusions: This review informed the development of a conceptual model illustrating the complex and interactive factors shaping patient acceptance of AI in medical imaging, which can be tested prospectively in future studies. Our results highlight that patients' likelihood of accepting AI cannot be attributed to a few factors. Instead, promoting acceptance will require a holistic approach where multiple factors are considered simultaneously and adapted for each use case.

KEYWORDS

artificial intelligence; patient-centered care; medical imaging; patient engagement; health technology

Introduction

The use of artificial intelligence (AI) to support medical imaging analysis has been growing exponentially [1,2]. AI tools are increasingly used for a variety of tasks, ranging from automated image acquisition, sophisticated image reconstruction, classification, and diagnosis [3]. Initially, AI tools were primarily used for tasks like image segmentation or abnormality detection, whereas recent applications have advanced to deep learning–driven complex medical image classification based on large datasets, with minimal human involvement [4]. For example, AI applications have shown promising results and

XSL•FO
RenderX

capabilities in the early detection of lung [5], skin [6], and breast cancers [7] from various image types such as computed tomography scans, dermoscopic (magnified) skin images, and mammography scans. In experimental studies, AI's performance has been comparable or surpassed human readers, including experienced clinicians [8-10]. In the future, AI is expected to contribute widely to the imaging process, including image analysis and interpretation, and reduce burden on health care professionals, ultimately contributing to improved patient outcomes [1,11,12].

Although the potential benefits of AI in medical image analysis are widely recognized and its implementation is proceeding rapidly, its application in health care remains largely confined to experimental and research settings, with limited integration into clinical practice in some medical imaging applications [13]. Lack of confidence and skepticism among health care providers and patients toward novel health care technologies have been reported as contributing factors [14,15]. As technology improves, understanding if perceptions and views change is essential to develop adequate strategies to support the implementation and acceptance of AI [16].

Most existing studies and reviews to date have addressed health care professional [17] or multi-stakeholder [18] perceptions and the factors influencing their acceptance of AI in medical image analysis. Research has explored patient perceptions of AI implementation across various medical imaging domains, identifying factors such as trust, human interaction, transparency, accuracy, and individual-perceived benefits and risks associated with AI as key influences [19]. However, despite this progress, there remains a gap in understanding the full range of factors and how they interact to shape patients' perceptions of AI. Recognizing the multitude of factors and how they interact can enable implementation scientists to suggest strategies to make the AI more acceptable to patients. Furthermore, this can guide the development of information leaflets and consent forms as well as implementation strategies that are patient-centered and allow informed consent of AI use across future use cases.

The aim of this review was therefore to identify the factors that impact patients' views of AI use in medical imaging applications and to understand how frequently they are reported, how these variables interact, or how contextual elements such as patient demographics, health issues, or the role of AI in the health care process might shape perceptions. The literature was searched with the aim to (1) identify the factors influencing patients' perceptions of AI in medical image analysis and (2) understand how these factors influence patients' acceptance of AI.

Methods

Study Design

We undertook a systematic review of the literature. The SPICE [20] (Setting, Population or perspective, Intervention, Comparison, Evaluation) framework was applied to structure the research question and guide the review process, including the development of the search strategy, establishing the inclusion/exclusion criteria, and selection of relevant articles (Table 1). We followed a 2-phase search strategy (Multimedia Appendix 1), which was developed with the assistance of a university librarian. The protocol of this systematic review was registered with PROSPERO (CRD42024571707) [21]. The finding of this review was reported according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) guidelines [22].

Table 1. SPICE (Setting, Population or perspective, Intervention, Comparison, Evaluation) framework.

SPICE framework	Question	Study details
Setting	What is the context for your question?	Medical imaging AI[a]
Population/Perspective	What is the perspective of your stakeholders or future users of the service or product?	Patient perspectives on medical imaging AI
Intervention	What action is being taken?	Health care practitioner using AI in medical image analysis
Comparison	Are there other/alternative actions or outcomes?	Traditional medical image analysis (if applicable)
Evaluation	What is the outcome measure?	Factors influencing patient perceptions of AI in medical image analysis either independently or in combination with one another

[a]AI: artificial intelligence.

Screening, Selection, Quality Appraisal, and Data Extraction

The final search was conducted in August 2025. Articles from the search results were uploaded to Covidence for title and abstract screening, followed by review of full text articles based on the inclusion criteria (see Table 2). In this review and its inclusion, the term "patient" refers to either participants recruited in a health care setting or individuals from the public who are potential patients or user personas representing patients. The term "AI" refers to both hypothetical and established/applied interventions, incorporated either in the clinic to analyze, interpret, and process medical images and/or support the screening, assessment or diagnosis process. The term "acceptance" refers broadly to patients' willingness for AI to be used in their medical image analysis, commonly assessed through their expectations, preference, or comfort with AI outputs and AI use.

The screening of titles and abstracts was independently conducted by 2 reviewers (PMK and LJC). In the instance of disagreements between the reviewers, conflicts were resolved by discussion and comparison of the article under question

XSL•FO
RenderX

against the predetermined inclusion and exclusion criteria. Full text review, quality appraisal, and data extraction were performed primarily by one reviewer (PMK); a random subset of articles was assessed by a second reviewer (LJC) to ensure accuracy; and any discrepancies in the extracted data were resolved through discussion between the reviewers.

The Joanna Briggs Institute (JBI) critical appraisal checklist [23] was used to assess study quality, with the appropriate tool applied based on each study's design (analytical cross-sectional/qualitative). For mixed methods studies, the analytical cross-sectional and qualitative checklists were combined to evaluate the relevant components. As each checklist varies in length, we calculated the proportion of "yes" and "no" responses relative to the total number of relevant questions, excluding items not applicable to the study to compare study quality. Quality appraisal findings were used to inform interpretation of the results; therefore, no studies were excluded based on the quality scores alone.

The data extraction was conducted using an iteratively developed extraction framework, where the extraction fields were determined inductively as patterns emerged across the included studies. This approach was selected to accommodate the conceptual and methodological diversity of the literature and to ensure the comprehensive capture of patient-reported factors influencing perceptions and acceptance of AI in medical image analysis. Data extraction included the author, year of publication, study location, study type, health care context, AI context, recruitment details, number of participants, and the outcome measures (ie, factors influencing patient perceptions of use of AI in their medical image analysis). In this review, a factor was defined as any reported patient-related perception, attitude, trust, concern, acceptance, or preferences regarding the use of AI in medical image analysis.

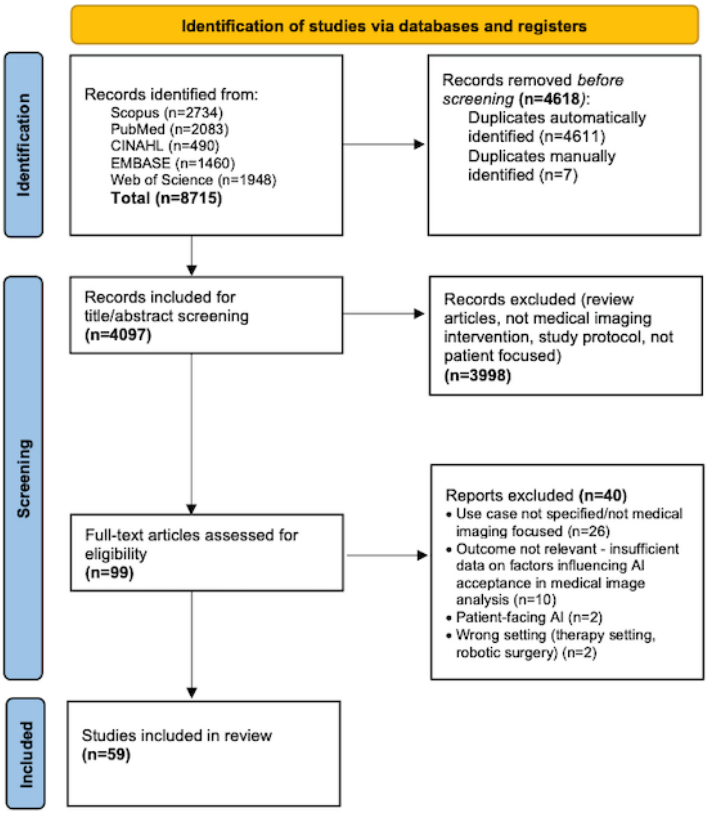
Table 2. Inclusion and exclusion criteria.

Category	Inclusion	Exclusion
General	Peer-reviewed, original research articles in English	Reviews, commentaries, non-English language articles
AI[a] intervention	AI that analyzes medical images for diagnosis or screening (applied AI or hypothetical contexts)	AI for nondiagnostic tasks (eg, automated image capture, radiotherapy treatment planning, surgical automation)
Purpose/use	Used in clinical care and/or by clinicians to support decision making	Patient-facing AI (eg, direct-to-consumer tools, chatbots, mHealth app-based AI)
Patient focus	Examines patient perceptions, attitudes, trust, acceptance, or experience	No patient-reported factors or perceptions. Perceptions of nonpatient groups such as health care providers, health care industry representatives, or medical students
Outcomes of interest	Reports factors influencing patient acceptance or experience of AI	Studies that do not identify influencing factors
Setting and context	Imaging in clinical screening/diagnosis settings (eg, radiology, dermatology, ophthalmology, dentistry)	Nonclinical settings or unrelated applications

[a]AI: artificial intelligence.

Analysis

A narrative synthesis approach was used for data analysis, as the included studies had heterogeneous methods, population groups, health care specialty, and context of AI. Findings were compared across studies and organized into conceptually similar groups, which were summarized and synthesized narratively to address the research question. As no quantitative synthesis of the data was undertaken, the patterns described here should be understood as conceptual.



Results

Screening

In this review, 59 studies [15,19,24-80] were included for data extraction, quality appraisal, and analysis. The results of the screening process are detailed in the PRISMA diagram (Figure 1).

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) flowchart of screening and study selection. AI: artificial intelligence.

Quality Appraisal

The JBI quality score for the articles ranged from 0.5 to 1 (Table S3 in Multimedia Appendix 1), with higher scores indicating higher quality. Qualitative studies scored highly overall, with lower scores mainly reflecting limited reporting of philosophical positioning. Cross-sectional studies showed greater variability where lower scores were most commonly due to use of nonvalidated questionnaires and limited handling of confounding factors.

Study Characteristics

The characteristics of the 59 included studies are summarized in Table 3. All included studies were cross-sectional, and 43 studies were quantitative survey–based, with majority (n=20) utilizing de novo, nonvalidated questionnaires, which were informed from literature reviews, existing nonvalidated questionnaires, or expert consultations. Ten included survey studies also adapted the validated “Patients’ Views on the Implementation of AI in Radiology questionnaire” [19]. The qualitative studies mainly used de novo interview guides, with one using prompts adopted from the Theoretical Framework of Acceptability [32] and another mapping its findings to the Theoretical Framework of Acceptability [45]. The included studies were conducted predominantly in Europe (n=34) and focused on radiology-oriented imaging contexts such as mammography (n=13) and general radiology (n=12). The majority of the studies examined hypothetical AI scenarios (n=49).

[a]AI: artificial intelligence.

[b]Hypothetical AI: studies were classified as hypothetical AI when AI or its output was not shown to patients or did not influence clinical care and perceptions were captured through hypothetical scenarios or questions about AI use.

[c]Applied AI: studies were classified as applied AI when AI results were either shown to patients or used by their health care practitioner to inform clinical decisions, allowing patients to experience its presence and report perceptions in the context of actual AI use.

Results for Aim (a): Factors Influencing Patients' Perceptions of AI in Medical Image Analysis

Eighteen factors that influence patient acceptance and perception of AI in medical image analysis were identified and extracted from the 59 included studies (Table S2 in Multimedia Appendix 1). An overview of the factors identified and the frequency of their reporting is depicted in Figure 2.

Human-in-the-loop was identified as the most frequently reported construct across studies and as a key factor influencing and shaping patient acceptance of AI in their medical image analysis. A sensitivity style examination revealed that for both hypothetical and applied AI contexts individually, the top 5 constructs identified were consistent, although their relative ranking varied slightly in the smaller applied AI sample. This, therefore, suggests that perceptions elicited in hypothetical scenarios broadly reflect those observed in applied clinical settings.

Figure 2. Frequency of the extracted factors across studies with hypothetical and applied artificial intelligence (AI) contexts.

Results for Aim (b): How the Identified Factors Influence Patients' Acceptance of AI

Based on findings from aim (a) and the factors identified, patients' acceptance of AI in medical image analysis appears to arise through a complex interaction among factors, rather than major effects of individual factors.

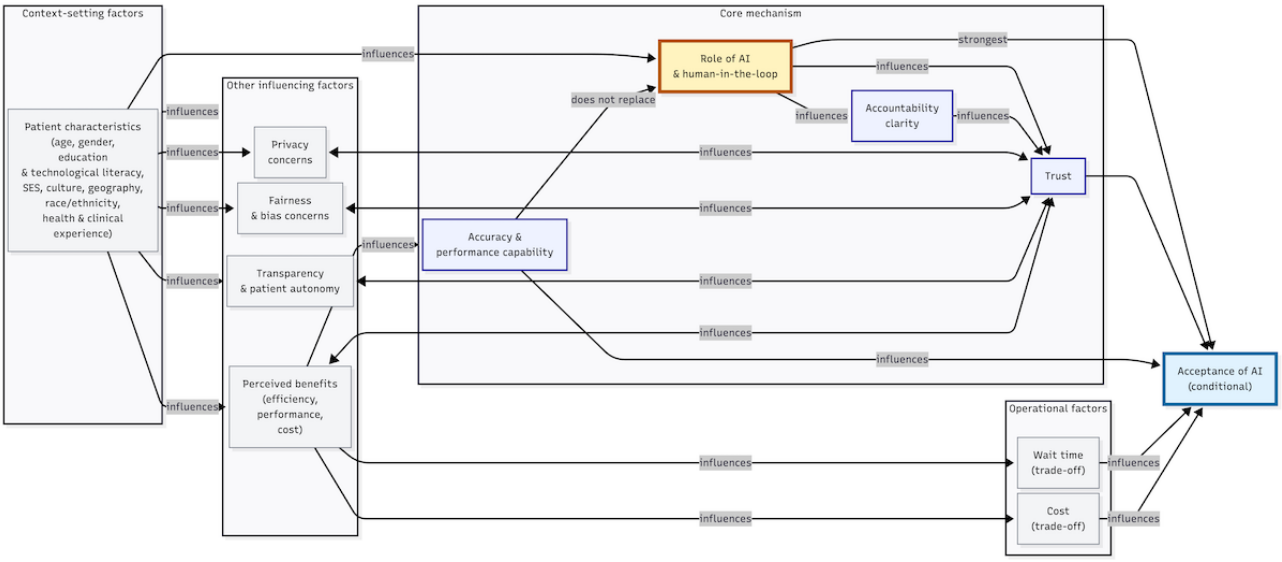

Figure 3 is a visual representation of the multifaceted relationships between factors and serves as a conceptual model grounded in associations reported across the included studies. Arrows represent influences identified through narrative synthesis and reflect patterns in participants' preferences and perceptions rather than empirically tested causal pathways. The model should be interpreted as an author-synthesized framework illustrating how factors discussed across studies may interact in shaping patient acceptance of AI in medical image analysis and viewed alongside the detailed narrative synthesis in the Multimedia Appendix 1 for full context.

Across multiple studies, human-in-the-loop deployment was reported as a central factor associated with higher acceptance of AI. Accountability was frequently discussed alongside human-in-the-loop deployment, reflecting patients' expectations that clinicians retain responsibility and oversight of AI use. Trust appeared central in how patients evaluated AI, shaping how perceived benefits, risks, and implementation features translated into acceptance. The accuracy of the AI system was commonly reported as a necessary factor for acceptance; however, its impact on acceptance is dependent on human involvement and accountable care models.

Studies reported that the preference and importance placed on the human-in-the-loop model was shaped by patients' individual characteristics such as demographic factors, health issues and history, and sociodemographic characteristics. These factors serve as contextual factors and influence elements such as patients' perceived benefits of AI, their privacy, fairness, and bias concerns, and demand for transparency and autonomy, which in turn shapes trust. Operational factors such as cost and wait time were also noted to influence the acceptance of AI, either as perceived benefits or as trade-offs, with some patients willing to compromise on factors such as human involvement, to achieve improvements in operational conditions or to tolerate less favorable operational conditions in return for retaining human involvement.

Figure 3. Synthesized conceptual model of factors influencing patients' acceptance of artificial intelligence (AI) in medical image analysis. SES: socioeconomic status.

Discussion

Patients' acceptance of AI in medical image analysis was observed to be influenced by several interacting factors. How the AI was applied in the health care setting and human involvement (ie, human-in-the-loop) was most consistently reported to shape acceptance. Hence, high acceptance was reported by studies when AI was positioned as a supportive tool assisting clinicians rather than as functioning autonomously. Other common influential factors included AI accuracy and performance, transparency that AI was used, trust in AI, clarity on who is accountable, and ethical concerns such as privacy and fairness. Sociodemographic characteristics, clinical and health experiences, and operational factors such as waiting time and cost shaped acceptance in more variable and context-dependent ways.

The level of human involvement in how AI is used had the most profound impact on patients' acceptance across studies. These findings are consistent with existing ethical guidelines and empirical studies emphasizing the importance of human oversight and accountability in AI deployment [81-83]. For example, the High-Level Expert Group on Artificial Intelligence listed "human agency and oversight" and "accountability" as a key requirement of a trustworthy AI. Furthermore, Australia's AI ethics principles state that "People responsible for the different phases of the AI system lifecycle should be identifiable and accountable for the outcomes of the AI systems, and human oversight of AI systems should be enabled." Furthermore, prior work has shown that acceptance of AI-supported services increases when users are informed that humans remain in control, while fear of human replacement can undermine acceptance [84-88]. This pattern is reflected in many emerging AI applications in medical imaging, where systems are typically designed to support clinician decision-making rather than replace it, such as AI tools developed for ultrasound-based disease classification and magnetic resonance imaging lesion detection [89,90].

AI-based image analysis systems are increasingly capable of high diagnostic performance, reflecting the ongoing emphasis among the emerging AI interventions to enhance diagnostic accuracy [91-93]. However, as identified in this review, although the accuracy of AI was frequently prioritized by patients, it did not override the preference for human involvement in the use of AI. Similarly, the emerging AI systems are typically designed to support clinician decision-making rather than operate autonomously, reflecting that these models account for human-in-the-loop requirement. Furthermore, similar to previous research, this review found that transparency and explainability support acceptance primarily by boosting patients' trust rather than through inducing a detailed technical understanding of AI among them [94-96].

Studies reported that factors such as privacy and fairness influenced how patients interpret the benefits and risks of AI, thereby shaping their trust and accordingly acted as either facilitators or barriers of acceptance. Concerns related to privacy, fairness, and bias among patients mirror growing evidence that these concerns can undermine trust in AI-enabled health care [88]. Age, gender, and education of patients were the most commonly studied demographic factors; however, correlations with patients' optimism toward AI were not consistent. The inconsistent influence observed in this review aligns with literature on technology acceptance, which also found that demographic characteristics do not directly influence acceptance. Studies on technology acceptance more broadly not specific to AI found that demographic characteristics such as education shape an individual's technological familiarity, perceived benefits, and expectations of the intervention, which ultimately influences their acceptance [97]. Despite this, acceptance can be high or low within each demographic subgroup and can change over time, as more information about a new technology becomes available and therefore needs to be assessed in future studies.

Patients' individual characteristics like their medical history, experience with clinical contexts, and personal psychological factors were noted to act as context-setting factors, influencing

XSL•FO
RenderX

expectations and sensitivities around AI. Operational factors such as waiting times and costs were identified as trade-offs, with patients potentially willing to trade-off some of their health care professionals' involvement and accept autonomous use of AI in their screening or diagnosis for shorter wait times and reduced costs, or vice versa.

This study has several limitations. First, the conceptual model is grounded in data extracted from the included studies and informed by the authors' interpretation; however, given the complexity of the relationships identified, not all potential interactions could be exhaustively represented. Second, the heterogeneous nature of the included studies and the use of varying survey tools limited direct comparison and quantitative synthesis. Third, certain factors such as cultural influence, socioeconomic status, and race or ethnicity were underreported across studies. This may limit the depth of conclusions that can be drawn in these areas and bias the findings toward populations and health care settings most commonly represented in the literature. This, therefore, may limit the generalizability of conclusions to more diverse contexts. Fourth, variations in terminology and conceptualization of "acceptance" across studies may affect comparability. Fifth, while the search terms and search strategy was developed with adequate guidance to be as exhaustive as possible, there is potential that some relevant publications may have not made into the search results due to variations in the keywords or controlled vocabulary used. Finally, our review focused on peer-reviewed sources reporting original research, including letters or short reports with sufficient methodological detail. Therefore, the findings may emphasize concerns that are more likely to be published, such as privacy, fairness, or specific medical contexts, and may underrepresent perspectives reported in conference proceedings, regional reports, or grey literature. This limitation should be considered when interpreting the results and designing future studies.

Overall, this review suggests that successful implementation of AI in medical image analysis should prioritize human-in-the-loop designs. Policymakers and health care organizations should focus on building governance frameworks that strengthen trust, address privacy and fairness concerns, and ensure that responsibility for AI-assisted decisions remains clearly assigned to human professionals. Furthermore, considering the complex relationship among these influencing factors, with one impacting the other in most instances, patients' choice of accepting AI cannot be attributed to one or a few factors. Instead, promoting acceptance will require a holistic approach where all influencing factors are considered on a case-by-case basis.

Having a standard set of constructs and variables to assess patients' acceptance may be beneficial and enable the development of a structured approach to enhance patient acceptance of AI. The influencing factors identified in this review can form the basis for the development of standard measurement constructs to understand patients' acceptability of AI in medical image analysis for screening and diagnosis. These constructs can be further explored and substantiated by discussions and interviews with patients.

It is important to note that the relationships represented in Figure 3 should not be interpreted as causal pathways. Most included studies were cross-sectional surveys that assessed reported preferences or perceptions, often using hypothetical scenarios. As such, the model represents an interpretive synthesis of reported associations and patterns in participants' reasoning rather than empirically tested mechanisms. The framework is therefore intended to guide future research that could prospectively examine these relationships.

Acknowledgments

The authors would like to thank the university librarian for their assistance in developing and refining the search strategy for this systematic review.

Funding

This research is partly funded by the National Health and Medical Research Council (NHMRC) Centre of Research Excellence grant (2006551) and NHMRC Synergy grant (2009923). PMK is supported by a research training program scholarship from the University of Queensland. MJ is funded by an investigator research fellowship from the NHMRC (2034422).

Data Availability

This systematic review was a secondary study; therefore, data availability is not applicable to this article. Details of the search strategy are included in the Multimedia Appendix 1.

Abstract

Artificial intelligence (AI) is already fundamentally changing society, with medicine being no exception. AI will impact how we practice, how hospitals operate, and even the practice of medicine itself. The use of AI-based products has already begun, with examples including AI scribes and large language models such as ChatGPT. Work is ongoing to produce models that have specific functions within medicine, such as kidney injury prediction. However, transformative foundational work, such as AlphaFold (for protein structure prediction), also promises to completely change the way we approach medicine. Therefore, clinicians must develop a clear understanding of AI, not as an optional skill, but as a core competency of modern medical practice. This paper serves as a tutorial to guide medical professionals through the basic principles of AI. It will teach clinicians how to build a mental scaffold to understand and springboard into AI. The core parts of this paper are organized in steps, with additional relevant topics addressed in modules at the end of the paper. The core steps are meant to be read sequentially. To prepare the reader for the rest of the paper, this tutorial will first introduce what AI is and then cover some basic definitions needed to understand other concepts. The reader will then be ready to understand what deep learning is and the difference between supervised and unsupervised learning. Finally, the reader will go through how deep learning models learn. Separate modules on safety and clinical applications are also included. This tutorial is relevant to clinicians at all levels but may be particularly useful for practicing clinicians who are encountering AI tools integrated into their practices without previous formal education in the field. Users of this tutorial can refer to specific sections or read the entire paper.

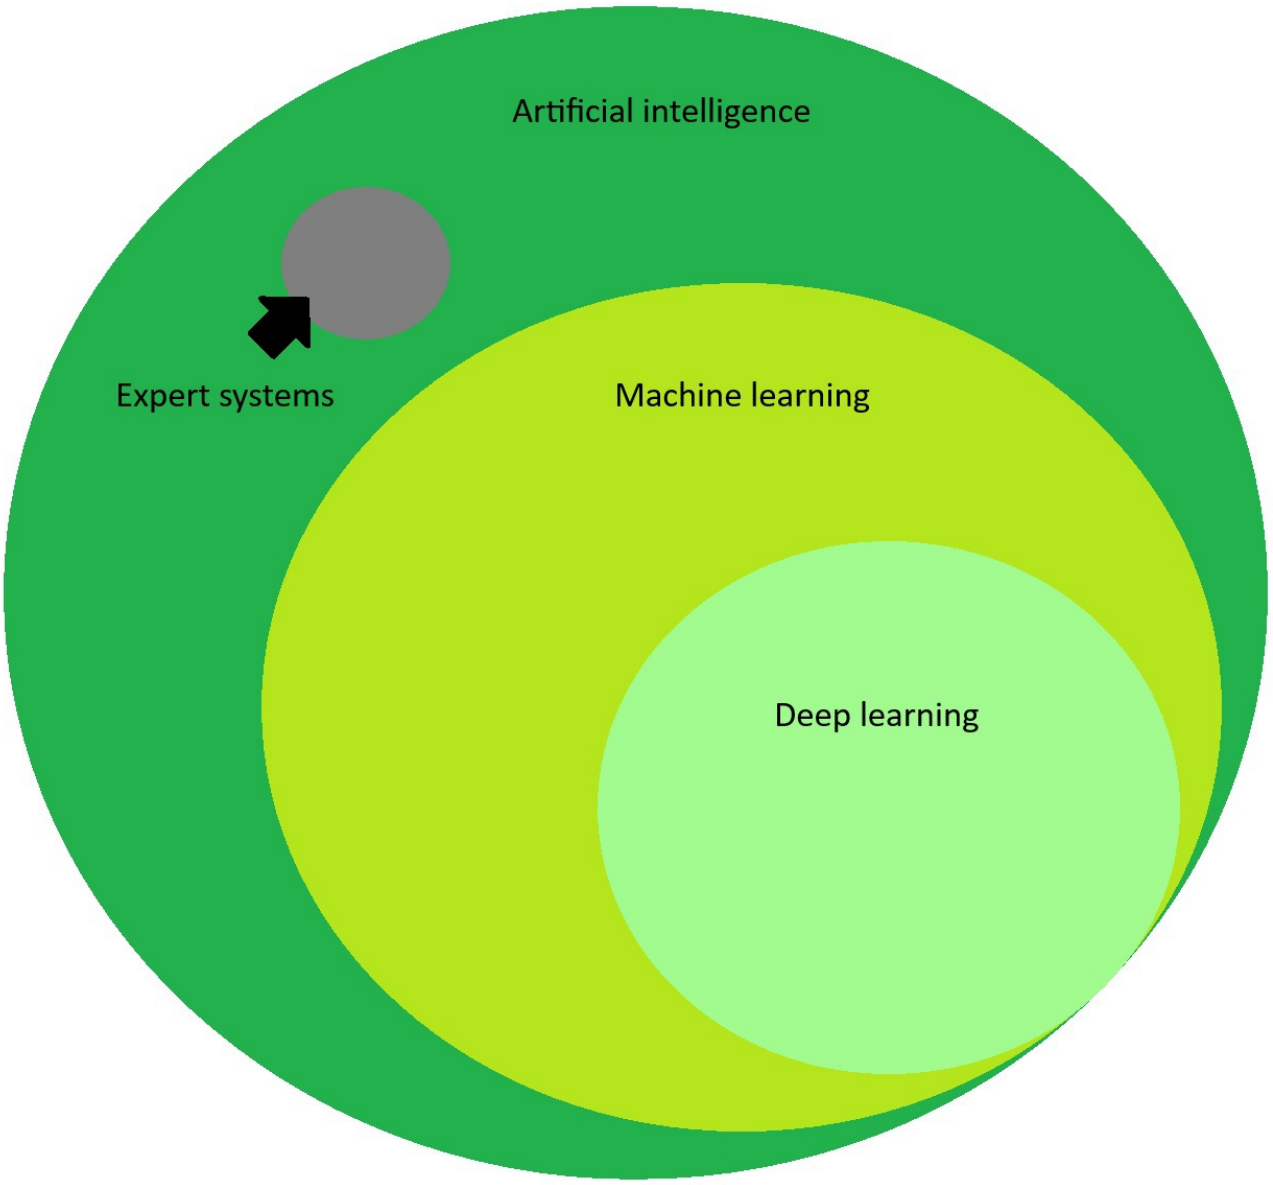
KEYWORDS



medical education; machine learning; artificial intelligence; AI; deep learning

Step 1: Understanding What Artificial Intelligence Is

Before delving into the concepts underlying artificial intelligence (AI), it is important to understand what AI means. AI is a broad term that generally refers to computer systems that can perform complex tasks historically associated with humans, such as human learning, comprehension, problem-solving, decision-making, creativity, and autonomy [1]. In computer science, AI algorithms encompass a variety of methodologies. Most AI in the modern era is machine learning (ML) and even more specifically, deep learning (DL; Figure 1). While all ML is considered AI, not all AI is ML.

XSL•FO
RenderX

Figure 1. Venn diagram of artificial intelligence terminology.

Expert systems are an older paradigm of AI in which a subject matter expert's knowledge is hardcoded into intricate rule-based algorithms to simulate human decision-making (eg, "if x condition, then y result"). Well-known examples include the MYCIN system, designed by Edward Shortliffe in 1974 to predict antibiotic choice [2], and traditional chess AI systems. Even famous examples such as Deep Blue (IBM Corp) relied on hardcoded knowledge [3]. Expert systems and these hardcoded methodologies have been largely abandoned in the modern era due to the incredible effort required to develop them and the brittleness and inflexibility of the resultant systems. Limited examples of expert systems also exist in health care, such as older sepsis and drug interaction clinical decision support systems. AI is primarily ML currently. Rather than relying on hardcoding from experts, ML algorithms are trained to learn relationships and patterns in data. The terms DL and ML are often used interchangeably; however, it is worthwhile mentioning that DL is really a subset of ML. There are many types of ML that are not DL (eg, k-means clustering and decision trees). DL is discussed in depth in a following section.

Step 2: Understanding Basic Definitions

Some level-setting is required to understand ML algorithms and models. ML *algorithms* are tools (eg, logistic regression) that are trained on data to create an ML *model*. ML models that are used for classification are frequently referred to as *classifiers*. The quality of the data used to train an algorithm is critical to the performance of the model. Each record or event in the dataset is referred to as an *instance*. Each aspect of an instance (eg, color, duration, and test result) used to train a model is known as a *feature*. In a simple set of data, instances would be rows in your data spreadsheet, while features would be the column headers. Many ML datasets can have thousands of instances and hundreds of features.

A *label* is the information on a particular feature for a certain instance in the dataset (eg, "red" for a feature of "color," "30 minutes" for a feature of "duration," and "34 mg/dL" for a feature of "glucose level"). A label generally refers to information that has been applied by a human or another

XSL•FO
RenderX

algorithm based on manual or traditional analysis of the data and represents a classification, categorization, ranking, or answer to a question. For example, in a dataset of inpatients hospitalized for at least 30 days with a feature of "patient developed a hospital-acquired infection during admission," the label would be "positive" if an infection was acquired and "negative" if none occurred, bearing in mind that the application of positive or negative would have to be done by a human who was analyzing the patient's data.

Of note is that data that are not manually labeled are simply referred to as data. One may also choose to use only a subset of the data in a dataset for training.

Step 3: Differentiating Between Supervised and Unsupervised ML

A core initial concept is understanding the difference between 2 major categories of ML. In general, ML can be classified into supervised and unsupervised learning, although there are other categories or approaches such as reinforcement and transfer learning.

In *supervised learning*, data that have been labeled are fed into the ML algorithm for training. Once the algorithm has been trained, it is called a *model*. One of the greatest challenges in developing a high-quality model is being able to obtain a substantial amount of data (ie, usually thousands of instances) that have been accurately labeled. An example of supervised learning would be an algorithm trained on a dataset of chest X-rays and corresponding diagnoses [4-6]. In *unsupervised learning*, unlabeled data are fed into an algorithm, and the algorithm discovers relationships and groupings for itself. This difference is illustrated in Figure 2. An example of unsupervised learning is work in which an algorithm identified distinct clusters or groups of patients who had COVID-19 [7,8].

Figure 2. Illustration of (A) supervised and (B) unsupervised learning.

Index	Data	Label
Data point 1		Circle
Data point 2		Square
Data point 3		Circle
Data point 4		Square
Data point 5		Square
Data point 6		Circle

Figure 2(A)

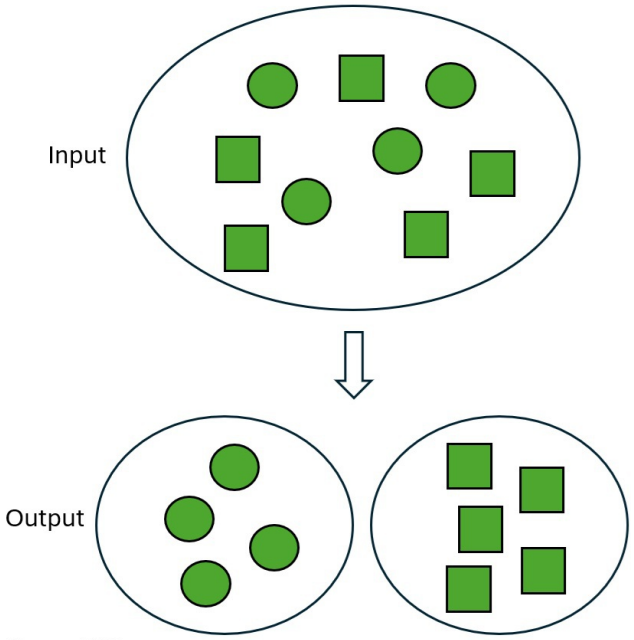


Figure 2(B)

In Figure 2A, the shapes are labeled as circles and squares by a human. The dataset is fed into the algorithm, and through these labels, the machine learns which features contribute most to classifying the shapes. In Figure 2B, the machine is fed raw data without any labels. Through exploration and differences detected in the data among its features, the model learns that there are potentially 2 different categories of objects. Of note is that the model may not inherently recognize them as a circle or a square but rather as 2 distinct categories of objects.

Other forms of learning also exist, such as *reinforcement learning*. In reinforcement learning, an algorithm experiences an environment and takes an action. On the basis of this action, the model is given a reward or a punishment as feedback. The algorithm learns which patterns result in rewards vs punishments and adjusts its behavior accordingly. Furthermore, supervised and unsupervised learning exist on a continuum, and some forms of learning are a mixture of both (ie, some instances are labeled, while others are not). A full description of these concepts is beyond the scope of this paper.

Transfer learning is another method in which an algorithm is first trained on a very large but nonspecific set of data for the desired outcome and then uses the learned patterns on a smaller but more specific set of data to refine the algorithm into a model. Transfer learning is often used where high-quality labeled datasets specific to the subject area are limited, whereas broader, nonspecific datasets are more plentiful.

Step 4: Defining DL and Neural Networks

A subcategory of ML is DL. This branch of ML is heavily focused on neural networks. *Neural networks* were first described in the mid-20th century [9,10] and were designed to emulate neural processes in the human nervous system. While foundational work has been ongoing for decades in the field

XSL•FO
RenderX

[11-13], much early work was constrained by hardware and data availability. The emergence of powerful parallel computing, called graphics processing units; platforms to leverage graphics processing units; and the availability of large datasets have helped overcome these barriers [14].

Artificial nodes, called *neurons*, are connected in layers to form a network. Data are put into the input layer of the network; the network processes the data through one to many hidden layers and then provides results in the output layer.

DL specifically refers to ML done on neural networks with many layers (thus the term “deep”). There is no exact number of layers that is generally agreed upon as a threshold. However, common examples such as ResNet (Microsoft) and the architecture underlying ChatGPT (OpenAI) can contain a hundred layers and billions of parameters [15,16].

Step 5a: Walk-Through on How ML Algorithms Work

Next, this tutorial will lay out the process by which ML algorithms work, describe the process with an example, and then define other key terms. To learn how to properly predict, classify, or rank instances in supervised learning, an algorithm analyzes the data to determine which features contribute the most to the data labels. This learning process is called *training*. During training, the machine learns to adjust internal parameters, called *weights*, to produce the desired outputs. These weights correspond to individual neurons. This occurs through minimizing loss functions, in which the gap between the observed and expected prediction is minimized.

For example, consider a model designed to estimate the risk of candidiasis in hospitalized patients. The model may learn that features such as intensive care admission, fever, abdominal symptoms, or a normal white blood cell count are associated with either a higher or lower risk of candidiasis. Features will often be mapped in a complex fashion across a series of neurons and layers. Modification of the weights applied to each of these features influences the resulting model’s output through complex interactions across many layers of analysis, allowing the model to learn patterns that relate input features to the target outcome. In simpler forms of ML, it is sometimes possible to determine which features most greatly contribute to an outcome; however, in DL, this is often difficult because of the number of nodes and layers involved. Therefore, in DL, the change in importance may not be directly interpretable.

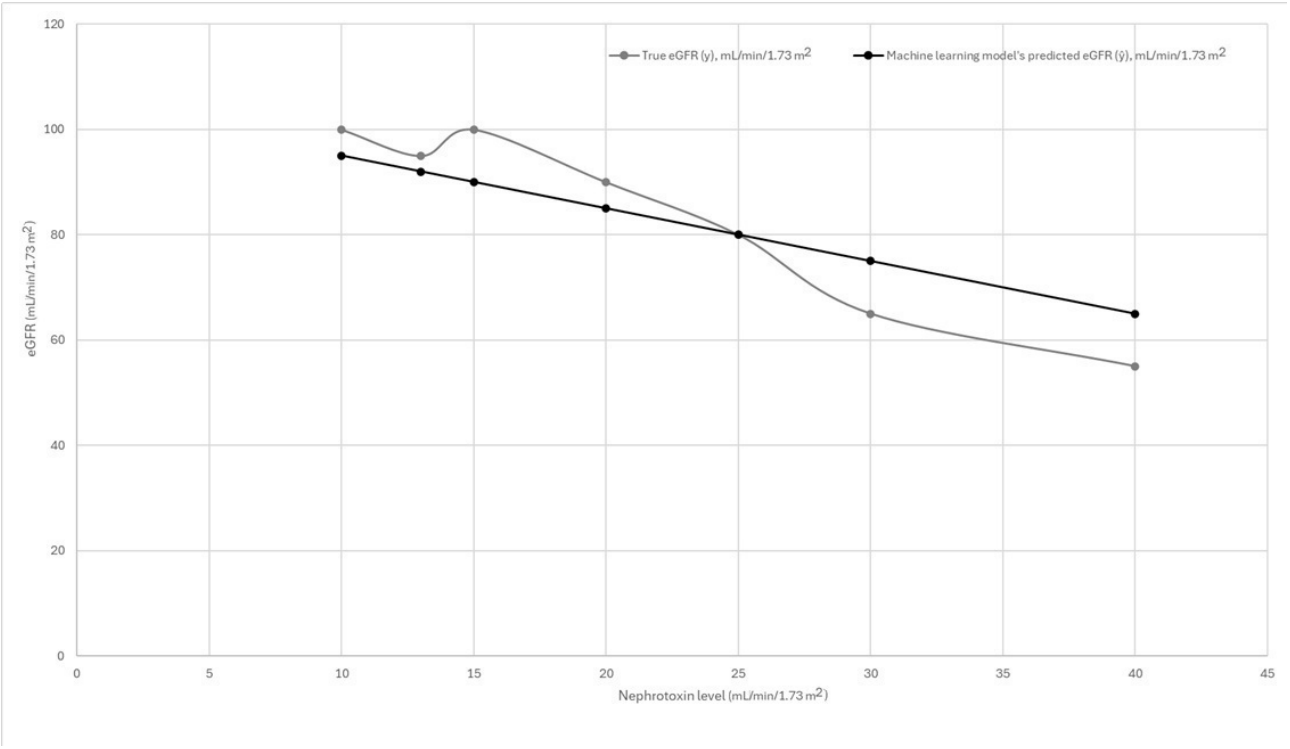
Datasets are often large and contain many features, some of which logically have nothing to do with the outcome being examined. If the data used to train an algorithm contain these completely unrelated variables, the algorithm may make nonsensical associations, which can later result in spuriously wrong results. For example, it may associate the color of a hospital gown and/or patient’s sandwich preference with overall length of stay. However, if there are different colors of hospital gowns or menu choices for patients in intensive care units vs regular floors that are not captured in the data, then the model may miss the confounding variable completely. These errors in model development are hard to detect in all ML and even harder in DL.

Step 5b: Walk-Through of Basic ML Mathematics Using an Example—Loss Function

To illustrate the mathematics of ML training, we can use an extremely simplified example with a continuous variable in supervised learning. It is noted that most modern DL requires massive sets of data. While specifics may change in other forms of ML, this example will illustrate general concepts. In this example, the dataset includes the trough levels of a nephrotoxic drug and the resultant measured (true) estimated glomerular filtration rate (eGFR) in patients. The measured eGFR is the labeled data in this supervised ML. An appropriate ML algorithm is selected that attempts to predict the eGFR based on drug levels (Table 1).

Table . Sample data for a model predicting nephrotoxin toxicity.

Nephrotoxin level (mg/L)	True eGFR[a] (y; mL/min/1.73 m^2)	Machine learning model’s predicted eGFR ($\hat{y}$; mL/min/1.73 m^2)
10	100	95
13	95	92
15	100	90
20	90	85
25	80	80
30	65	75
40	55	65



[a]eGFR: estimated glomerular filtration rate.

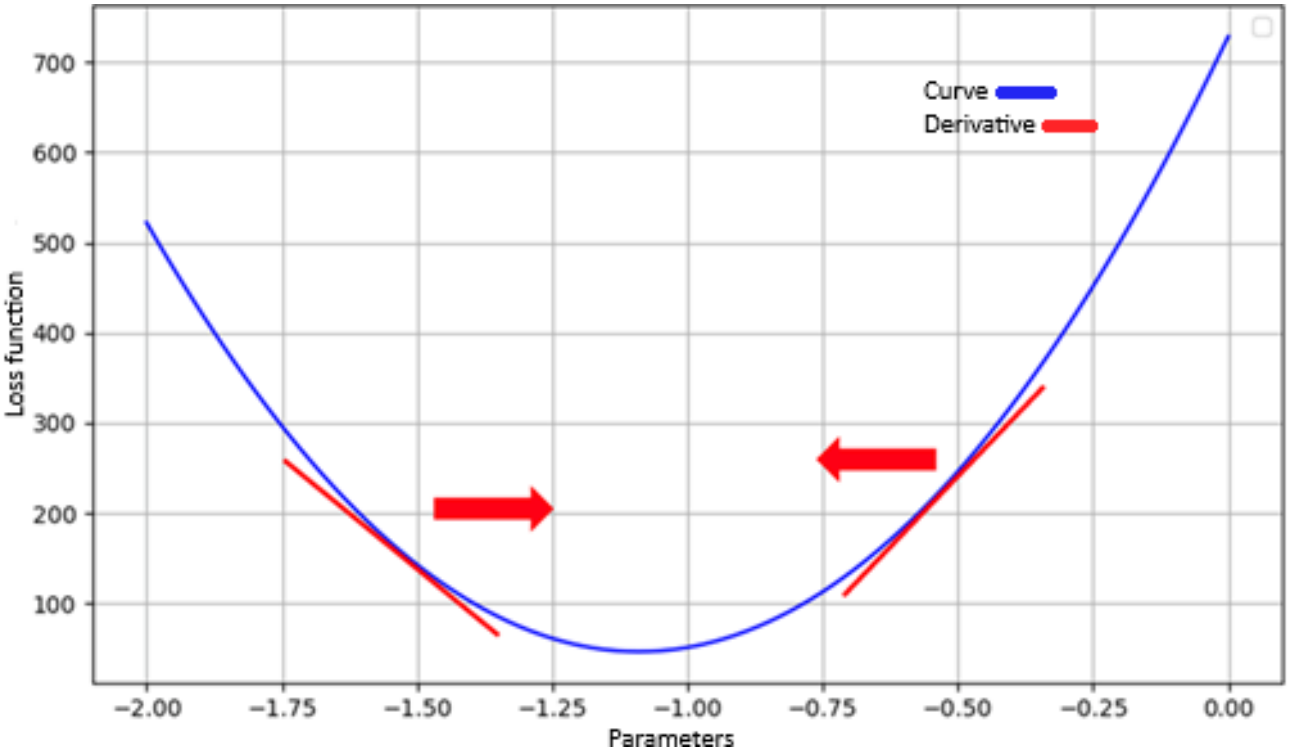
The model produces a prediction ($\hat{y}$) based on the nephrotoxin level (x). The algorithm compares the predicted eGFR ($\hat{y}$) to the real measured value of eGFR (y). Graphically, the predicted values of eGFR (the orange line in Figure 3) are plotted against the true values (the blue line). To determine the pattern between the nephrotoxin level (x) and the measured value of eGFR (y), the algorithm calculates the loss function. Differences might appear small in most regions but noticeable in some. To capture

XSL•FO
RenderX

a model's performance across all data points, we use this loss function, a mathematical function that quantifies the total error between predicted and observed values.

Figure 3. Sample data for a model predicting nephrotoxin level. eGFR: estimated glomerular filtration rate.

By convention, updates are made to the loss function after each batch in training. The model then adjusts the weights and tries again to determine, across all the instances in the dataset, which set of weights will produce the lowest loss function on average for the training data. With high-quality data that represent the full spectrum of possible cases that the model could be given, this helps ensure that the model is trained to perform well on average and does not result in spuriously wrong predictions. The specifics of how the algorithm calculates loss functions vary between algorithm types, with different functions being optimized for different tasks. For instance, the mean squared error, a common loss function, squares the difference between $\hat{y}$ and y. By squaring the difference, it ensures negative loss values do not cancel positive values when summed, and it helps penalize severely wrong predictions.



In a model that performs well when it is fed new data (ie, generalizes well), $\hat{y}$ and y will be similar for any new patient's nephrotoxin level fed into it. Models that do not generalize well may make large, nonsensical errors in prediction for a small subset of patients with a few specific differences in data points. This is why training a model on high-quality data that accurately represent the types of data it may encounter after deployment is critical.

Step 6: Understanding the Concepts of Backpropagation and Gradient Descent

Another set of key concepts to understand is backpropagation and gradient descent. In DL, a model modifies the weights of specific neurons within a neural network to create its predictions. When data are input, they forward pass through the network. The initial run creates random weights, and the prediction ability of the initial model is likely poor. However, after this forward pass, the model evaluates its resultant loss function and attempts to minimize the loss through a process called gradient descent. In gradient descent, we assign a learning rate, which increments our point along the curve of the loss function (Figure 4). If the model discovers that the loss is increasing, it will move backward to decrease the loss. Conversely, if it discovers that the loss is decreasing, it will continue moving in that direction. In doing so, it eventually seeks out the local minima, thus minimizing the loss function and improving the model's predictive capacity.

XSL•FO
RenderX

Figure 4. Graphical illustrations of concepts.

Mathematically, gradient descent can be expressed asw=w−η(dLdw). Remember that the derivative (dLdw) of the loss function gives the gradient at any given point. This allows the model to know if the loss is increasing or decreasing. The learning rate (η) tells the model how much to move in each direction. Recall that the loss function quantifies the difference between the predicted and observed values, with the goal of identifying the lowest point and, thus, minimizing this difference. These concepts are illustrated again visually in Figure 4. The mean squared error of our example model's simple line (Figure 3) is a parabola, creating an easy visualization of gradient descent for illustration purposes. When η is set at too large a value, it is possible that the model will jump very far back, such that it misses the local minima. Conversely, too small a value of η may result in such minimal movement that the minima is never reached.

During the training process, to specifically update the gradient, the model will undergo a process called backpropagation. The trainer algorithm will go through the neural network and alter the weights of neurons with the intention of decreasing loss. This process ultimately results in better prediction ability of the ML model.

Module 1: A Brief Explanation of AI Explainability and Safety

As AI becomes significantly more powerful and integrated into society, various risks and errors have been observed. A brief discussion of safety is outlined here, and there are many other publications available that dive into each of these in detail.

How an ML model determines its output (ie, resultant prediction or result given to a user) from input is often unclear. This refers to the "black-box" nature of all ML but particularly of DL and neural networks. A field called explainable AI has emerged and attempts to not only better understand how models make their predictions but also add components to the ML model that require the model to explain how it arrived at its result (ie, which features had the most impact) [17].

For all AI, especially in medicine, it is imperative that model performance be checked for variations in outcomes that may indicate that human bias in the data has been promulgated or exacerbated by the model. AI algorithms are exquisitely sensitive pattern detection tools. As such, they can detect slight variations in data that resulted from human prejudice and bias. Worse, they can promulgate such bias into the model. Therefore, it is imperative that models be checked for differences in results that can be attributed to race, gender, socioeconomic status, religion, etc, as the presence of these elements in a model will cause the model to produce inaccurate results in certain groups of patients. Concrete examples include models having difficulty diagnosing dermatological conditions in those with darker skin tones [18], and a software program that accidentally referred White patients over African American patients to receive special care [19]. In the latter example, while the goal was to ensure patients received the care required, the algorithm was designed to predict whose care would cost more money, and it was found that less money was spent on African American patients despite having the same level of need [19]. Furthermore, a study found that an AI system could learn to predict ethnicity from radiographs alone [6]. There are now tools that assist in the detection of these elements, and models that include these elements need to be retrained on optimized data or otherwise mitigated to ensure the best care for all patients. Finally, risks associated with the infrastructure of AI also exist. As many models use a cloud-based model for computation and some public commercial large language models (LLMs) use input

XSL•FO
RenderX

data to retrain models, clinicians need to be aware of where sensitive data are being sent and stored.

Now that the use of AI is rapidly becoming more pervasive, it is reasonable to think that the degree to which AI is set to perform autonomously (ie, without a human in the middle) will increase. Some publications have discussed safety measures that are required to mitigate risks as AI becomes more autonomous and integrated into systems. These risks range from tangible risks today to theoretical risks with more powerful models. Experts have classified these risks into 4 categories: misuse, misalignment, mistakes, and structural risks. Misuse occurs when users intentionally instruct an AI tool to behave in harmful ways (ie, the user is an adversary). Misalignment occurs when AI systems knowingly act against human intent (ie, the AI is an adversary). This includes intentional deception by AI. Mistakes occur when AI systems produce incorrect outputs without intentional wrongdoing, often because real-world data are complex and influenced by many contributing factors. Finally, structural risks may emerge whereby pervasive AI systems integrated into society cause harm through the actions of multiple independent agents in a multifactorial, multiagent fashion [20].

A substantial body of ongoing research in AI focuses on ensuring and improving AI safety. For instance, studies focus on the effects of adversarial attacks on models to understand safety. Developers also attempt to build safeguards into models and use red teaming, where security professionals attempt to simulate attacks to determine robustness [4,18]. Equally important are efforts to create nuanced and well-informed regulations and guidelines for development [18,21-26].

Module 2: Contemporary Clinical Applications of AI in Medicine

Health care is one of the most promising industries for AI. While disruptive-level work is underway, such as the ability to understand protein folding [27], AI has numerous applications currently being used routinely in health care.

Documentation is recognized to often be excessive and contributory to physician burnout, with an American Medical Informatics Association survey finding that 73.26% of health care professionals believed the time spent was inappropriate, 77.42% reported after-hours work related to documentation, and 74.83% believed that documentation impedes patient care [28]. Canadian data show similar findings, with physicians spending excessive amounts of time on administrative tasks that result in burnout [29,30].

AI scribes are tools that can ambiently listen to patient interactions and automatically generate notes for physicians, reducing the administrative burden for physicians. Numerous companies have created offerings; however, in general, scribes use LLMs, models based on the transformer architecture (which uses an attention mechanism to process preceding information and learn relationships among them) [31,32]. Within the context of scribes, the LLM uses this mechanism of self-attention to help generate logical text. Thus, the same limitations of transformers and LLMs carry forward onto AI scribes. For example, in many LLMs, hallucinations are a concern, which are theorized to arise because of algorithms being rewarded for correct responses, thereby making guessing a more advantageous response than acknowledging uncertainty. Health care providers must be aware of these limitations of AI scribes and how they may potentially arise.

LLMs have also been used by vendors such as Epic to automatically extract information out of existing notes, such as creating discharge summaries, reading radiology reports, providing summaries, preparing tasks based on the note being created, and providing insights [33]. They have also been used as chatbots to act in clerical roles and as search engines for medical knowledge [34,35]. While LLMs such as ChatGPT (OpenAI), Claude (Anthropic), and Gemini (Google) are commonly used by the general public, OpenEvidence (OpenEvidence LLC) is trained specifically on medical literature, reducing errors and hallucinations [36]. Models intended for use in research and science also exist, such as Perplexity (Perplexity AI) and Elicit (Elicit Research) [36,37]. Open source, medically-focused models without interfaces also exist, such as MedGemma (Google) [38].

Under the broader definition discussed in this paper, AI has been used in diagnostics for decades using simple rule-based algorithms. However, more recently, ML-DL–based approaches have begun to gain traction due to improved performance. Areas that have shown promise for ML-DL performance are radiology and pathology [39,40]. In radiology, a DL software such as CINA-iPE (Avicenna.AI) has shown promise in detecting pulmonary embolisms [41]. In pathology, ML has improved rapid patient diagnostics based on DNA methylation markers [42]. Sepsis and cardiac arrest prediction have been an ongoing area of work [43,44]. While results from this work are promising, due in part to interpretability, accuracy, and the potential for uncovering clinically irrelevant abnormalities (“incidentalomas”), it is unclear how clinicians should react to findings [45]. The volume of AI tool uptake is increasing, and AI will inevitably impact the workflow of clinicians in the near future. AI could also support hospital infrastructure [46].

Despite its potential benefit, AI integration into health care is still an evolving landscape. Regulation and guidance remain an important area of evolving work for health care AI, with numerous national and international bodies producing frameworks and guidelines for AI use [47-49]. Important questions that remain under debate include the responsibility for AI errors, with many institutions holding physicians ultimately accountable for clinical decisions, how to mitigate bias in health care AI propagated by inherent bias in training data, and the importance of privacy [6,18,19,50]. Furthermore, many studies have indicated that implementation into workflows can also be challenging, due to a lack of awareness and engagement by both patients and health care professionals, as well as logistical implementation challenges inherent to any health technology [51].

Future Directions

AI promises to be one of the most critical revolutions of human society, arguably on par with the industrial or even agricultural

XSL•FO
RenderX

revolutions. AI will impact every area of human society, including health care.

While current implementations such as LLMs, predictive models such as convolutional neural networks, and the tools they have created (eg, AI scribes and ChatGPT) are influential, most of the society-changing work is being dedicated to creating artificial general intelligence and artificial superintelligence. While the exact definition of these terms, and even their possibility, is a matter of contention [52], they generally refer to AI systems that are either as intelligent as or more intelligent than human beings across a wide array of domains and tasks.

In achieving this goal, AI will have implications on the role of humans in a post–artificial general intelligence society. While there are critical concerns about human displacement, there is also a potential for creating abundance, reducing scarcity, and an ability to supercharge scientific discovery [53].

Due to its importance, the authors believe it is important that clinicians receive structured educational content on the topic. Leaders could consider integrating formal foundational AI teachings into medical school curricula and, then in later years, providing a chance to discuss its implications and applications in health care. These sessions could also be incorporated into postgraduate education and into continuing medical education sessions offered by workplaces.

Acknowledgments

The authors declare the use of generative artificial intelligence (GAI) in the research and writing process. According to the Generative Artificial Intelligence Delegation Taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision: proofreading; editing; adapting and adjusting emotional tone; and reformatting sentence structure in specific, limited portions of text. On occasion, ChatGPT was used as a search engine to find links to relevant references, with authors further reviewing and ensuring the accuracy of these references. The GAI tool used was ChatGPT (version 5.1; OpenAI). Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Funding

No external financial support or grants were received from any public, commercial, not-for-profit, or other entity for any part of this work.

Conflicts of Interest

None declared.

Abstract

Deduplication across search results is one of the earliest and most critical steps in the systematic review methodological process; yet, existing solutions often lack the transparency, auditability, and reproducibility required by rigorous systematic review standards. Many automated deduplication tools introduce bias through opaque, nonconfigurable algorithmic decisions, while also potentially removing relevant references through false positive identification. We provide a tutorial on the Rayyan Method, including the Systematic Auto Resolver feature for the deduplication process. This method is defined by an enhanced deduplication approach that combines high-sensitivity duplicate detection with user-controlled resolution criteria. Systematic Auto Resolver enables research teams to define, apply, and document their own deduplication standards rather than relying on predetermined automated decisions. Users apply deduplication criteria, iteratively reviewing results after each pass, maintaining complete control over methodological decisions. The Rayyan Method addresses critical limitations in current deduplication approaches by supporting methodological rigor through user-controlled resolution while enhancing efficiency, transparency, and reproducibility. By empowering research teams to define their own deduplication criteria, this approach supports and aligns with the prescribed methodologically rigorous systematic review process. The method provides a citable framework for researchers to comprehensively document their deduplication methodology.

KEYWORDS

systematic review methodology; deduplication; software demonstration; transparency; evidence synthesis

Introduction

The escalating demand for evidence-based decision-making across diverse sectors, notably health care and policy, has amplified the reliance on methodologically rigorous systematic reviews for robust evidence synthesis [1]. The systematic review process begins with a carefully constructed literature search strategy, adhering to predefined, transparent, and registered criteria [2]. Central to maintaining the rigor of systematic reviews is the effective deduplication of search results, a crucial step to minimize reviewer workload, mitigate bias, and ensure the accuracy of findings [3].

While many software platforms offer a deduplication feature, their functionalities can lack the full integration, auditability, transparency, and reproducibility that are essential for regulatory applications [4,5]. With the increasing automation of research workflows, concerns have grown commensurately about the critical need to maintain controlled, transparent processes in regulatory contexts, particularly with the application of artificial intelligence. However, many researchers have adopted deduplication solutions that may inadvertently remove or cause the removal of relevant evidence in pursuit of identifying the most complete set of duplicates. This is inherently contradictory and perilous to the methodology.

The Multidimensional Challenge of Defining Duplicate References

The primary challenge of this stage of the review stems from the absence of a consistent definition of what constitutes a duplicate in an evidence synthesis context. For example, duplicates have been defined as “the same article published in the same place, while the same article published in a different place is not a duplicate” [6]. In contrast, duplicate records have been described as “being the same bibliographic record (irrespective of how the citation details were reported; eg, variations in page numbers, author details, accents used, or abridged titles)” [7,8]. Additional factors that may result in duplicate records include intradatabase and interdatabase duplication due to differences in publication year, volume, or page numbers resulting from early release or online-first

XSL•FO
RenderX

publication [9]. These examples of varied definitions highlight the need for deduplication solutions to address the primary challenge by accommodating the varying criteria used to define duplicate references.

A critical dichotomy has emerged with the increasing number of available solutions: (1) the failure to detect duplicates with single-character deviations or greater (where missing, incomplete, and erroneous data cause duplicates to be missed entirely) and (2) the failure to avoid false positives (where highly similar references are erroneously resolved as duplicates). The result can be significantly impactful when the removal of relevant evidence identified as false positives compromises the integrity of systematic reviews. This can raise concerns about biased conclusions stemming from omitted evidence, where any research produced using such a tool would be suspected of the same. Consequently, there is a critical need for testing, auditing, and validation of deduplication methods and solutions. When solutions offer a single method of deduplication, the method, concerningly, minimizes human expertise in the method's application [7,10].

Rayyan's approach is designed to address this duplication complexity by fulfilling 2 research paradigms. First, convenience, where researchers rely on automated tools for deduplication while recognizing the dependency on the applied method or algorithm and the data assessed. Second, integrity, where researchers follow transparent, auditable, and reproducible procedures to ensure methodological rigor when removing inexact duplicates.

History and Evolution

Rayyan was originally conceived with the objective of supporting the most time-consuming aspects of systematic literature reviews by enhancing the process of deduplication and screening of titles and abstracts for researchers with varying experience and expertise across a broad spectrum of review types (eg, literature reviews, scoping reviews, and systematic reviews). Initially, Rayyan offered automatic duplicate detection; however, after realizing that automatic detection violated the platform's mission to protect full user control, Rayyan updated the design to execute a semiautomated process with a foundational commitment to a level of usability governed by speed, accuracy, and simplicity while maintaining full user control.

We, as the Rayyan team, aimed to design a comprehensive systematic review application enabling human-computer research collaboration where research teams have a solution that conforms to their unique requirements, methods, standards, and even individual preferences. Rayyan's user-centric design philosophy is driven by our commitment to methodological rigor without imposing a single *one-size-fits-all* approach to systematic reviews, including the important and sensitive challenge of deduplication. Further details on the history of Rayyan's inception, architecture, usability, accuracy against manual methods, and the added value of Rayyan's other features are published elsewhere [10].

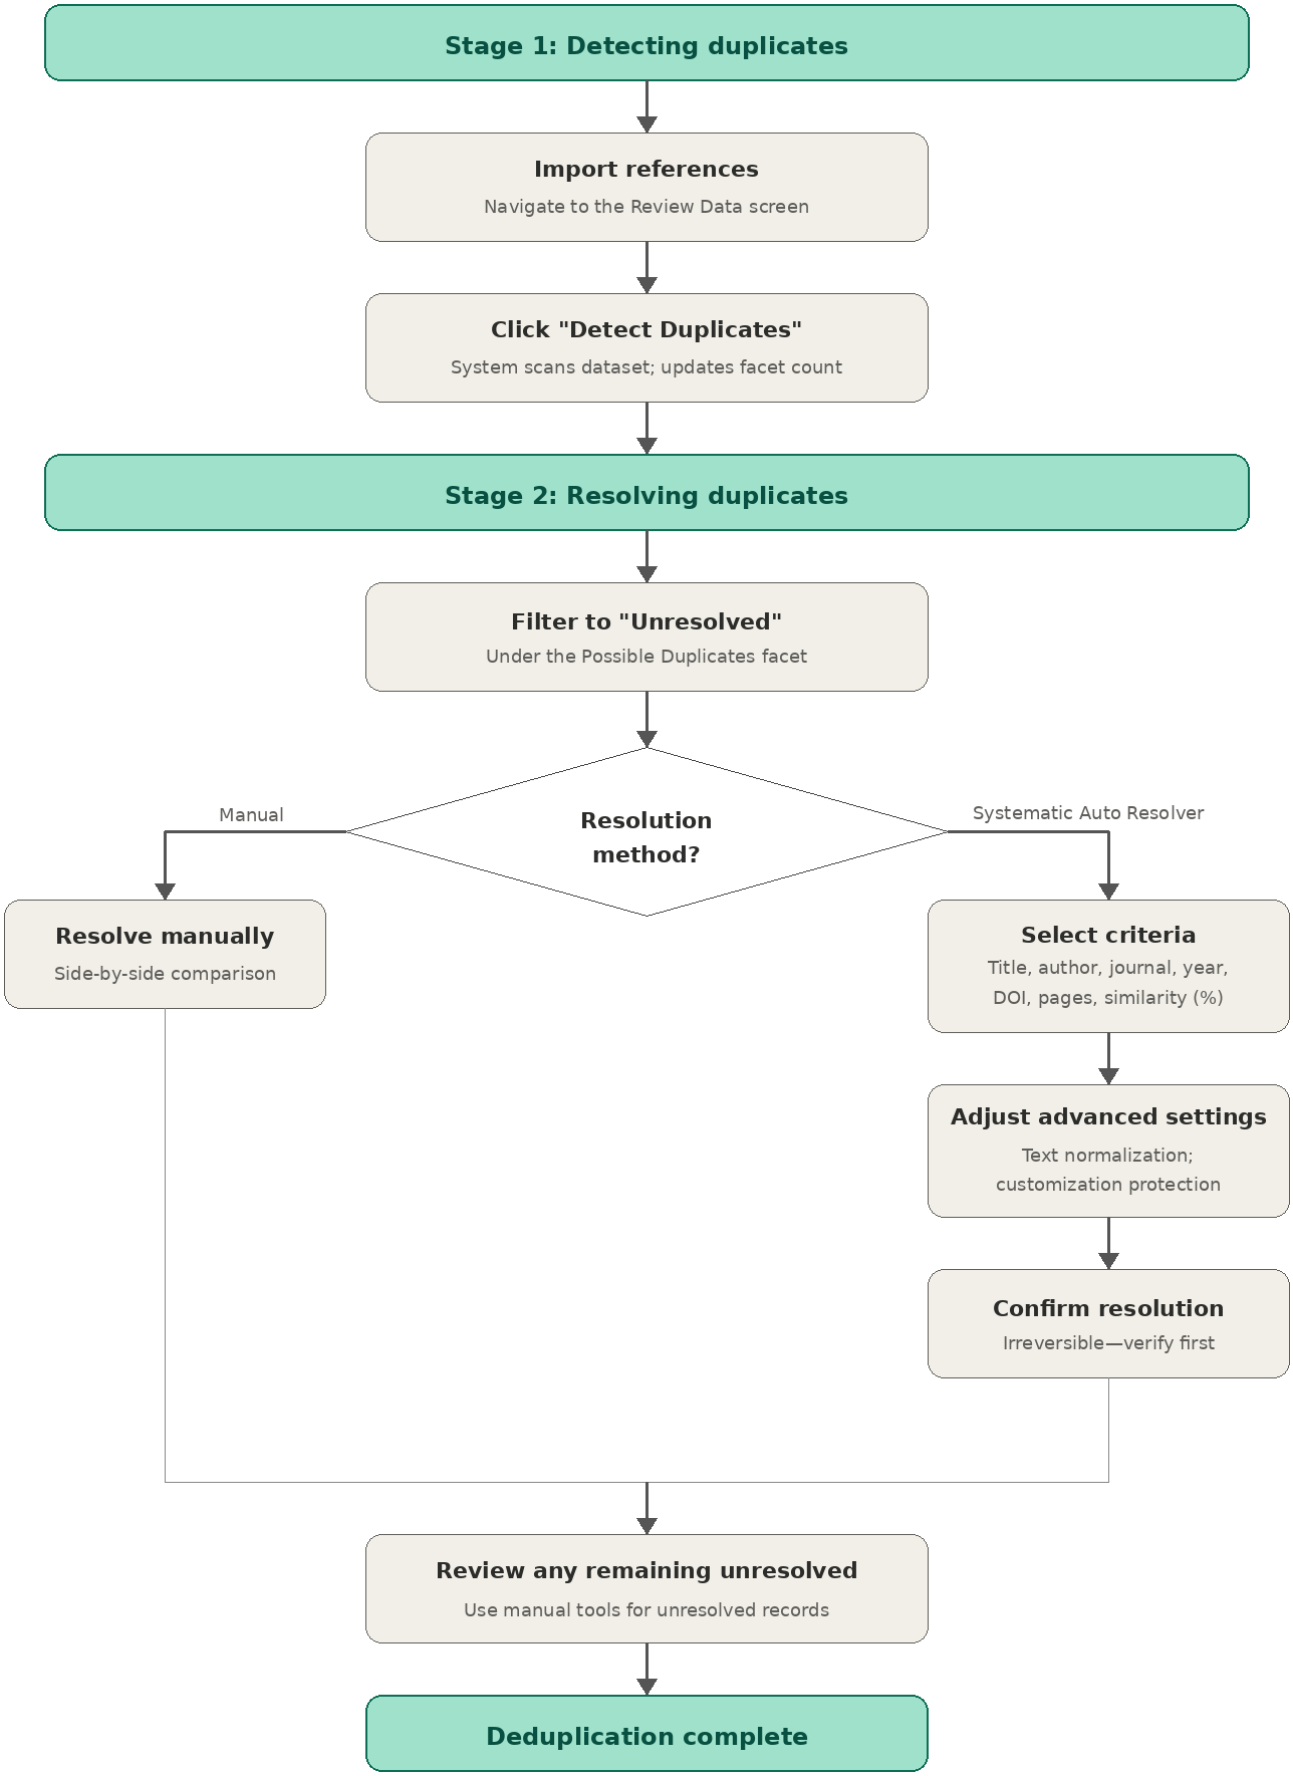
Objective

This tutorial specifically describes the deduplication process using the unique capabilities of Systematic Auto Resolver and its advantages. Together, the capabilities of Rayyan combined with the user-defined deduplication criteria constitute a deduplication method, henceforth referred to as the Rayyan Method.

The Rayyan Method

Background

The Rayyan Method is guided by the principle of implementing human control and oversight rather than a human-in-the-loop paradigm. In human-in-the-loop systems, humans are often informed of the results after automated actions occur [11]. The Rayyan Method instead starts with human initiation and guidance of deduplication decisions, preventing the automated removal of potentially relevant evidence. This distinction ensures that humans initiate the action and guide it with human expertise.



The pioneering work of methodologist Bramer established the concept of a manual series of deduplication criteria to achieve superior deduplication results beyond exact duplicates [4]. The Rayyan Method also meets the same objectives and extends the process by providing researchers with the capability where deduplication criteria are defined by the user, rather than predetermined by software developers. This evolution represents a shift from fixed procedural steps to adaptable, user-controlled criteria that can accommodate the diversity of research contexts and requirements.

Rayyan offers an advanced duplicate detection algorithm within both its web-based and mobile app designed for the systematic review process [10]. Using greater sensitivity, Rayyan detects more possible duplicates than other solutions [7]. Using precision rules, Rayyan minimizes false positives and false negatives by allowing the review team to specify which deduplication criteria to apply to their dataset. The applied deduplication criteria can be reported for transparent, auditable, and reproducible reporting of the deduplication method. Any possible duplicates that are not removed by the application of the deduplication criteria can be manually reviewed and resolved. Manual resolution is most common for instances of multiplicity stemming from high similarity, where the research team is then able to decide whether to keep one or both references.

This is a 2-stage process that separates detection from resolution (Figure 1). This separation is critical because it allows for maximum sensitivity in detection without the risk of false positives in resolution. In stage 1, Rayyan casts a wide net to identify all possible duplicates to delegate precision to stage 2 resolution. In stage 2, research teams apply their own criteria to resolve these duplicates systematically and transparently.

XSL•FO
RenderX

Stage 1: Detecting Duplicates

Research teams start by importing all their search files containing the references that constitute the possible evidence base for their systematic review into the Rayyan platform. Rayyan also offers a *PDF first* import option where the platform creates the references and retrieves metadata based on the initial PDF upload. Rayyan currently supports importing 1 GB for ZIP files, 100 MB for reference files, and 10 MB for PDFs, with support for a large array of industry-standard content formats (EndNote, RefMan, BibTeX, PubMed, Web of Science, PDF, and more) and file formats (.enw, .ris, .bib, .csv, .wos, .txt, .xml, .doc, .zip, and .pdf). The simultaneous import of more than 10 search files may be repeated any number of times to add additional references to a review for processing in real time. Any limitation on the size of the search files, the number of search files that may be simultaneously imported, or the number of references that duplicate detection can handle has been specified as a safeguard to prevent misuse of the platform, given that duplicate detection is a free feature of Rayyan available to anyone. However, users may also overcome the 10-file limit by importing searches from Rayyan's "My Library" to a review.

Once all references are uploaded to Rayyan by the review team, the deduplication process is user initiated with one click of the Detect Duplicates button, returning a set of records identified as "Possible Duplicates" as a filtered index of records. The Detect Duplicates button may be found in several locations, including the Overview page, Review Data page, or the Rayyan mobile app. Initiating the duplicate detection process from any of these interfaces or via the application programming interface has the same effect. Duplicate detection and removal are user initiated, meaning deduplication is neither automatic nor required to use Rayyan to complete an end-to-end systematic review workflow.

Rayyan's detection algorithm identifies similar records [10] to generate "Possible Duplicates," defined as having sufficient similarity to other records. The returned results include a set of possible duplicate records with their individual similarity scores presented in an additional column. In independent third-party evaluations, Rayyan possessed remarkably high and consistent accuracy, sensitivity, and specificity for identifying duplicate references [7,12].

Step 2: Resolving Duplicates

Selecting Deduplication Criteria

After executing Detect Duplicates, the end user is provided with a similarity score (percentage of similarity) for records sharing similarities. The end user is presented with the option to manually resolve or autoresolve these potential duplicates based on the criteria defined a priori. The Systematic Auto Resolver empowers the end user with control over the criteria used to define duplicates within the set of detected possible duplicates. For example, a review team might choose title, author, year of publication, and DOI to ensure accuracy. Once the universe of possible duplicates has been identified, the process of resolving duplicates manually and with the Systematic Auto Resolver is enabled.

The deduplication criteria available for selection include the following:

- Title
- Author
- Journal
- Year
- Pages
- DOI
- Publication type
- Overall similarity score (percentage of similarity based on title, journal, year, and author information)

These criteria can be applied individually or in combination. The end user specifies the deduplication criteria that are applied to resolve duplicates. This level of control allows for tailored deduplication strategies that are not possible with fully automated tools.

Manual Resolution of Duplicates

The first stage of duplicate resolution is manual resolution. By selecting the "Unresolved" filter under the "Possible Duplicates" filter on the "Review Data" screen, a list of possible duplicate records is shown. By selecting a record listed within the Unresolved filter and clicking "Resolve Duplicates," paired combinations of possible duplicates, in plurality for those instances, are presented side by side for the end user to resolve manually. This manual process intends to provide maximum control and human oversight over the verification and removal of duplicates from the systematic review. The steps for manual resolution of duplicates are as follows:

1. Visit the "Review Data" screen
2. Click "Detect Duplicates" to complete duplicate detection
3. Select "Unresolved" from the Possible Duplicates facet
4. Review and resolve duplicates manually by selecting which records to keep (left, right, or both) or marking them as "Not Duplicate"

To export the deleted records, select the "Deleted" filter in the Possible Duplicates facet. Then select "Export" and select "Filtered" to export only the deleted records for reporting.

Systematic Auto Resolver Feature for Duplicate Resolution

The second stage of duplicate resolution is to apply Systematic Auto Resolver and is summarized in the following steps:

1. Access the Systematic Auto Resolver
2. Select the deduplication criteria
3. Adjust advanced settings
4. Confirm autoresolution
5. View notifications and results

Research teams may repeat the application of the Systematic Auto Resolver with a progressive series of rules from the most conservative to the most encompassing or resort to manual resolution to deal with unresolved possible duplicates that are resistant to the application of rules. The ability to control and exercise oversight is intended to minimize the risk of undetected false positives that can occur when single-stage automated tools delete high-similarity possible duplicates as duplicates without

XSL•FO
RenderX

user authorization or visibility. It is important to note, however, that the Systematic Auto Resolver is not immune to false positives, particularly when few criteria are applied without sufficient specificity or methodological grounding. The iterative, criteria-based approach described in this tutorial is designed to reduce this risk, and the auditable record of all resolution decisions ensures that any errors remain traceable and correctable by the research team.

While concerns have heightened over the increasing automation of systematic reviews, with particular sensitivity around the behavior of artificial intelligence, many ignore the seemingly innocuous endorsement of single-stage deduplication tools that may cause the removal of relevant evidence without human control or oversight. Like other early errors in the systematic review process, such as poor protocol development, deficient search strategies, or poor search implementation, deleting relevant evidence using an automation tool jeopardizes the integrity of the systematic review process from the earliest steps. Tool adoption becomes an implicit endorsement of the deduplication method it uses. Unlike single-stage automated tools that remove duplicates without user authorization or visibility, the Rayyan Method ensures that resolution decisions, whether manual or criteria-based, are explicitly authorized, documented, and auditable by the research team. This 2-step deduplication process does not entirely eliminate the possibility of false positives but ensures that any such errors are traceable to specific user-defined criteria rather than opaque algorithmic decisions, preserving the researcher's ability to identify, review, and correct duplicate cases.

However, user control is only as rigorous as the methodological decisions informing it. Transparency in tooling does not substitute for competency in application; instead, it transfers responsibility to the reviewer. This is a meaningful tradeoff: where closed, automated tools make implicit methodological decisions on the user's behalf, the Rayyan Method requires users to make those decisions explicitly and deliberately. For researchers without deep familiarity with deduplication methodology, this degree of control can itself become a source of error if criteria are selected without an understanding of their relative reliability, limitations, or appropriate sequencing (eg, applying DOI as a sole matching criterion can systematically overlook duplicates in records with incomplete or "dirty" metadata). The considerations that follow are designed to address this directly by providing not only procedural steps but also the methodological rationale behind each decision point, including known field-specific limitations that reviewers should consider before proceeding. Readers seeking a broader evidence base for criteria selection are encouraged to consult the methodological literature on deduplication field performance [4,6,7,13].

Additional Considerations

Options for Mitigating Risks of False Positives and False Negatives When Using Systematic Auto Resolver

Optimizing the selection of criteria requires an understanding that no single field is perfectly reliable across all records or databases [4]. There is variation across all the criterion fields in how they are populated and/or formatted, which directly impacts sensitivity (detecting more true duplicates) and specificity (avoiding the removal of unique records). The evidence base includes literature on the tradeoffs between sensitivity and specificity and should be considered when configuring a criterion approach [4,7]. We recommend selecting criteria based on published validation evidence rather than ad hoc testing. The methodological literature provides empirically grounded guidance on the relative reliability of individual matching fields [4,7,8], which reviewers should consult when configuring Systematic Auto Resolver passes. A stepwise approach, beginning with high-specificity combinations and progressively broadening, has been shown to maximize duplicate detection while minimizing the risk of false-positive removal. To inform the definition of this approach, we provide the following considerations for the various criterion fields: Title; Year, Author, and Journal; DOI; Pages and Publication Type; and Overall Similarity Percentage.

Title is a consistently populated and stable field across databases but also has varying representations across databases. With Rayyan, text normalization, which converts text to lowercase and removes punctuation (discussed further below), should be enabled to execute title-based matching and minimize minor formatting differences between database records that can lead to true duplicates being missed.

Year, *Author*, and *Journal* are criteria that can serve as confirmatory criteria used in conjunction with Title rather than as standalone matching fields. Year is a supplement that can reduce false positives from a similar titled but distinct articles, thereby reducing false positives. Author fields commonly have variations across databases (eg, full name vs initials, surname order), which can reduce recall when used alone as an identifier. Journal fields are reliable when well indexed in biomedical literature and less so for gray literature, conference proceedings, or preprints. Overall, these fields are subject to variation across databases that can significantly impact duplicate detection and resolution.

DOI is considered a highly precise criterion but with lower recall. DOIs that are confirmed as matched can be reliably considered true duplicates; however, DOI metadata can be limited or erroneous for a proportion of records [14,15]. Consequently, we recommend DOI as a supplementary confirmatory criterion in later iterations and not as a primary or sole matching criterion.

Additionally, *Pages and Publication Type* are also less reliable as standalone criteria. An important consideration is that the formatting of page numbers frequently varies across databases (eg, first page only vs full range; online-first vs final print pagination). The same is often the case for Publication Type. Therefore, these fields are potentially most useful as supplementary criteria within multifield combinations rather than as primary matching criteria.

Finally, as reported in the Rayyan platform, the *Overall Similarity Percentage* is potentially most useful for capturing duplicates with inconsistent metadata across multiple fields. Higher thresholds of ≥95% approximate exact matching with tolerance for minor variation and carry a lower risk of false

XSL•FO
RenderX

positives. Lower thresholds increase the number of duplicates detected but require more careful manual review of flagged records. We recommend beginning at ≥95% and reviewing the results before considering a lower threshold.

Applying Criteria Iteratively

Rather than applying all criteria in a single pass, we recommend a stepwise approach grounded in the evidence base, as established by Bramer et al [4], among others [15]. Evidence strongly supports that applying a multistep method that begins with high-specificity field combinations and then broadens the criteria can outperform single-pass deduplication approaches [4]. With this evidence-based guidance in mind, Rayyan's Systematic Auto Resolver is designed to support sequential passes with criteria sets. An example of a practical evidence-based methodological sequence for many review types could be as follows:

- Pass 1: Title + Year + Author. This combination captures the majority of exact and near-exact duplicates with minimal risk of false positives. It is the appropriate starting point for most datasets.
- Pass 2: Title + Journal, or Title alone with text normalization enabled. This pass targets records with author field inconsistencies or missing author metadata that may have been missed in Pass 1.
- Pass 3: Previous fields + DOI + Pages + Publication Type. A final high-confidence pass for any remaining unresolved records where additional metadata are present and verified.
- Pass 4: Overall Similarity at ≥95%. Review flagged records before confirming resolution, as this pass is most likely to surface borderline cases requiring judgment.

Rayyan does not take any action specifically not authorized by end users. This means the integrity of the results is entirely in the hands of the researcher, where the application of methodological rigor guarantees integrity. Rayyan's role in this instance is to apply the tools as instructed by the user to produce the results. It is important to note that because Systematic Auto Resolver decisions are irreversible, prioritizing specificity in early passes and reserving broader criteria for later passes, where manual review of flagged results is feasible, reduces the risk of inadvertently removing unique records.

Tool transparency does not guarantee review transparency. Rayyan's Systematic Auto Resolver provides a transparent and auditable process, but this only contributes to a reproducible review record if researchers actively document and report their deduplication decisions. In accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 reporting standards [1] and best practices for deduplication reporting [4,7,13], researchers should document the following elements in their methods section, registered protocol, or supplementary materials:

- Tool and date: The name of the deduplication software used and the date on which deduplication was performed. Software features and criteria may be updated over time, so the date of use contextualizes the methodology for future readers.
- Detection method: Whether duplicate detection was initiated via the Detect Duplicates function and any settings applied at that stage.
- Criteria per pass: For each Systematic Auto Resolver pass, the specific criteria applied (eg, Title + Year + Author; Overall Similarity ≥95%), the sequence of passes, and whether text normalization or customization protection was enabled.
- Resolution counts: The total number of references flagged as possible duplicates; the number resolved via Systematic Auto Resolver; the number resolved manually; and the number remaining unresolved after all passes.
- Criteria rationale: A brief statement of the reasoning behind criteria selection, particularly where choices were informed by dataset-specific factors or deviated from standard stepwise practice.

Research teams that have conducted deduplication partially or entirely outside Rayyan should note that Rayyan's PRISMA flow diagram generator allows *n* values to be manually overridden to ensure the completed diagram accurately reflects the full deduplication process, regardless of where it was performed. This should be documented in the methods section alongside the other deduplication reporting elements listed above. Thorough documentation of these elements ensures that the deduplication process is fully citable, replicable by other research teams, and auditable by journal reviewers and editors.

Advanced Settings

In addition, the following advanced settings may be applied as part of the deduplication criteria.

Select Default Search: The end user may specify which imported dataset to preserve when duplicates are detected across different searches. This setting is applied independently for each Systematic Auto Resolver pass, meaning researchers can select a different default dataset across passes to reflect the relative quality or completeness of metadata from different sources for a given criteria set. For any duplicates that remain unresolved after Systematic Auto Resolver passes, the user retains full control at the individual record level during manual review, where they may choose whichever version is most appropriate regardless of any default dataset previously specified. This flexibility may benefit the overall systematic review workflow, for example, by preserving the better source for a particular database combination or by aiding full-text retrieval from a preferred source.

Text Normalization: It enhances deduplication by standardizing textual inputs before comparison. This includes converting text to lowercase and ignoring punctuation, which mitigates variations resulting from formatting differences, typographical errors, or inconsistent data entry. By reducing discrepancies in titles and author names, normalization improves both sensitivity (detecting true duplicates) and specificity (avoiding false positives). Given these benefits, normalization is enabled by default for title-based matching in most deduplication workflows, consistent with standard practice in citation deduplication. Researchers working with datasets containing non-Latin scripts or extensively abbreviated metadata should

XSL•FO
RenderX

verify that normalization performs as expected in their specific dataset before proceeding with full-scale resolution.

Customization Protection: It protects any articles with customized actions, such as assigned decisions, reasons, or labels, from being accidentally deleted during autoresolution (default: on). Customization Protection logic also checks if the user has taken a manual deduplication decision to keep the article. This feature is beneficial when importing new records after a review has already started.

Discussion

Overview

This discussion provides an overview of Rayyan's integrated deduplication capabilities, as previously reported [10], but with the enhanced feature of the Systematic Auto Resolver to support the Rayyan Method. While several software platforms offer deduplication features, many rely on fully automated algorithms with limited user control [5,7,13]. These tools may be efficient but can lack the flexibility needed to address nuanced deduplication scenarios, such as the problem posed by dirty data, including missing, incomplete, and nonstandardized metadata. Rayyan's Systematic Auto Resolver combines the strengths of more sensitive detection with automation and user control, allowing review teams to tailor the deduplication process to their specific needs.

Understanding the Systematic Auto Resolver Performance in Deduplication

Unlike fully automated deduplication tools that apply fixed, predetermined algorithms without user input, the Systematic Auto Resolver executes only the criteria explicitly selected and authorized by the research team. While Rayyan provides recommended default settings to guide users toward established best practices, the criteria driving duplicate resolution are not fixed; instead, they are configurable, transparent, and documented at the user's discretion. As a result, the Rayyan Method for Deduplication, including the Systematic Auto Resolver, reflects the stringency and appropriateness of the criteria determined by the research team rather than a black-box algorithm. This design ensures that deduplication standards align with each review's specific requirements and that the transparent reporting of user-applied criteria provides for the auditability and reproducibility of the deduplication method used.

Methodological Advantages

With its simple 2-stage process, the Rayyan Method can identify potential duplicates across datasets containing hundreds of thousands of references, leveraging its cloud-based infrastructure to handle large-scale work efficiently. In the detection stage, Rayyan produces a list of possible duplicates, each assigned a similarity score and presented in a clear table view, allowing researchers to assess which records may be duplicates and proceed to the resolution stage.

The resolution stage offers extensive customization, setting it apart from other tools. Researchers can view and manually review suspected duplicates, making decisions based on their specific criteria. They can also apply normalization rules, such as converting text to lowercase or omitting punctuation, to improve matching accuracy. This is particularly valuable when consolidating references exported from multiple databases, where differences in formatting conventions (eg, title capitalization, punctuation style, or author name formatting) can cause true duplicates to appear as distinct records. By applying normalization rules prior to comparison, researchers reduce the likelihood that format-driven inconsistencies across sources will result in missed duplicates or inflated reference counts.

Additionally, users can consider multiplicity by examining publication types or correcting previous record discrepancies. Rayyan's ability to allow for the combination of systematic rule application and manual review enhances accuracy while avoiding the cumbersome, rigid workflows seen in some manual methods or the concerns of false positives of other automated methods. Research teams may apply criteria sequentially, reviewing results after each pass. This allows teams to begin with conservative rules, observe their impact on resolving possible duplicates, and then decide whether to proceed with manual resolution or adjust to a different set of criteria. Ultimately, this approach maximizes both performance and convenience, accommodating the unique characteristics of each dataset and ensuring transparent, reproducible results while preserving ultimate decision-making for the reviewer.

Transparency and Auditability

This tutorial intends not only to provide a step-by-step guide to the enhanced deduplication process in Rayyan but also to highlight the benefits of this feature to review teams. It is important to distinguish between the two stages of the Rayyan Method: duplicate detection, which uses an algorithm to identify and score possible duplicates, and duplicate resolution, which is entirely determined by the end user. While the detection algorithm automates the identification of candidate duplicates, all resolution decisions, including the criteria applied and the final determination for each record, are made exclusively through human control and oversight. This design does not eliminate automation from the deduplication process but ensures that automation is confined to candidate identification rather than final decision-making.

This distinction is critically impactful to 2 overarching objectives of the Rayyan platform: (1) reducing the risk of introducing bias through opaque automated resolution decisions, what we term vendor bias, while acknowledging that user-controlled resolution is only as rigorous as the methodological competency of the research team applying it and (2) providing a reproducible, auditable process that upholds the foundation of systematic review methodology. Transparency and auditability are critical in systematic reviews, particularly in regulatory contexts. Rayyan facilitates this by providing a clear record of all resolution decisions, including the user-specified criteria applied to the Systematic Auto Resolver and the rationale for resolving individual duplicates. This level of documentation is intended to enhance the credibility and defensibility of the review's methodological process.

XSL•FO
RenderX

Limitations and Considerations

While the Rayyan Method provides significant control, this flexibility requires careful consideration by users. Incorrectly configured criteria could result in either false negatives (failing to identify true duplicates) or false positives (incorrectly identifying distinct records as duplicates), limited to the detected candidates. For example, deduplicating by DOI alone is theoretically feasible given the reasons for DOIs in the first place. However, the amount of erroneous, missing, and shared DOIs increases the possibility that this singular deduplication criterion alone can lead to false positives or false negatives. Adding more criteria increases accuracy, while reducing criteria increases sensitivity. Rayyan is under continuous development. Future development of the Systematic Auto Resolver is expected to continuously improve the accuracy, sensitivity, and usability of this capability across diverse use cases. Feedback from the research community serves as a major source of inspiration to address real-world contexts and identify the types of duplicates that are most challenging to resolve.

Conclusion

Rayyan's duplicate detection and Systematic Auto Resolver features offer a unique combination of user control, flexibility, and support for transparent workflows. By empowering review teams to tailor the deduplication process to their specific needs, Rayyan contributes to more accurate, reproducible, and efficient systematic reviews. While this manuscript provides a descriptive overview of Rayyan's deduplication features, further empirical research will help guide future development. We encourage review teams to leverage Rayyan's deduplication features to enhance the rigor and efficiency of their systematic reviews while also contributing to the growing body of evidence on the effectiveness of different deduplication methods.

Acknowledgments

The authors would like to acknowledge all members of the Rayyan team who contributed to the development of the platform features. During the finalization of the last submitted revision, the authors used Claude Sonnet 4.6 to review the manuscript for readability, language, and grammar. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the published article.

Funding

No external funding was provided to support this work.

Data Availability

All data and materials considered in this review are publicly available on the Rayyan website.

Authors' Contributions

MMK conceived the study. MMK, AMS, HH, MA, and RA collected and analyzed software platform data and components. MMK, AMS, and RA defined all components of the manuscript and co-wrote the manuscript. All authors have read and approved the final manuscript. The corresponding author attests that the listed authors meet authorship criteria and that no others meeting the criteria have been omitted.

Conflicts of Interest

All authors (MMK, AMS, HH, MA, and RA) have completed the ICMJE Disclosure Form to disclose that they are employees of Rayyan Systems, Inc, the company that develops Rayyan. AMS, HH, MA, and RA are shareholders of Rayyan Systems, Inc.

Abstract

Background: Major depressive disorder (MDD) and treatment-resistant depression (TRD) are heterogeneous conditions in which key clinical details are split across structured fields and free-text notes in electronic health records (EHRs), constraining population-level insight and timely audit of care quality.

Objective: This study aims to present a clinician-oriented, artificial intelligence-supported real-world evidence (RWE) methodology integrating structured and unstructured EHR data to profile MDD and TRD, and report comorbidity patterns from a 2-site pilot. This analysis reports the first objective of the MOOD project, which is to characterize the real-world clinical and disease severity profile of patients with MDD and treatment-resistant depression, providing a necessary foundation for subsequent evaluations of treatment patterns and outcomes.

Methods: We conducted a retrospective study in 2 Belgian hospitals (September 2021-June 2023). Adults (aged ≥18 years) with MDD were identified via *DSM-IV* (*Diagnostic and Statistical Manual of Mental Disorders* [Fourth Edition]) and *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) codes or natural language processing-detected note mentions; bipolar depression was excluded. TRD was defined as initiation of a third distinct antidepressant, supplemented by explicit mentions of TRD in notes. Structured data (demographics, diagnoses, medications, and hospitalizations) were harmonized in an Observational Medical Outcomes Partnership warehouse. Free-text notes were processed with a natural language processing pipeline to capture symptoms, psychiatric comorbidities, and contextual events.

Results: We identified 1147 adults with MDD, of which 46% (524/1147) met TRD criteria. Females comprised 62.9% (722/1147) and mean (SD) age was 57.8 (18.4) years. Mortality was 13.3% (152/1147) overall (57/1147, 10.9% TRD vs 95/1147, 15.2% non-TRD). Common medical comorbidities were central nervous system diseases (477/1147, 41.6%) and heart diseases (349/1147, 30.4%). Dementia was more frequent in TRD (42/1147, 8% vs 32/1147, 5.1%), whereas obesity was higher in non-TRD (70/1147, 11.2% vs 46/1147, 8.8%). Anxiety disorder occurred in 35.4% (406/1147) overall and was more prevalent in TRD (229/1147,

XSL•FO
RenderX

43.7% vs 177/1147, 28.4%); personality and panic disorders also trended higher. Severity was sparsely documented (severe MDD 170/1147, 14.8%) and standardized scales were rarely recorded.

Conclusions: We present a step-by-step artificial intelligence-supported methodology tailored for clinicians, discussing challenges in integrating RWE into psychiatry, and identifying opportunities to enhance data collection with minimal workflow changes, which emphasizes the transformative potential of RWE systems in mental health research.

KEYWORDS

major depressive disorder; treatment-resistant depression; real-world evidence; natural language processing; symptom clusters; longitudinal data; clinical practice

Introduction

Major depressive disorder (MDD) affects a considerable portion of the global population, often leading to significant disability [1]. Meanwhile, treatment-resistant depression (TRD), where patients do not respond adequately to at least 2 standard antidepressant treatments, remains an especially difficult clinical challenge [2]. Studies have shown that patients with TRD often face poorer outcomes, which amplifies the need for tailored therapeutic approaches [2]. Beyond treatment nonresponse, TRD is also characterized by substantial clinical heterogeneity (eg, comorbidity profiles, symptom expression, and illness course), which complicates comparisons across cohorts and health systems and makes baseline characterization clinically relevant in its own right [3]. Large-scale electronic health record (EHR)—based studies have previously used TRD as a model phenotype and highlighted the need for reliable approaches to define outcomes and longitudinal status in routine care [4]. The MOOD project focuses on a comprehensive description of this patient population, aiming to elucidate the demographics, medical history, and psychiatric patient history among MDD and TRD cohorts.

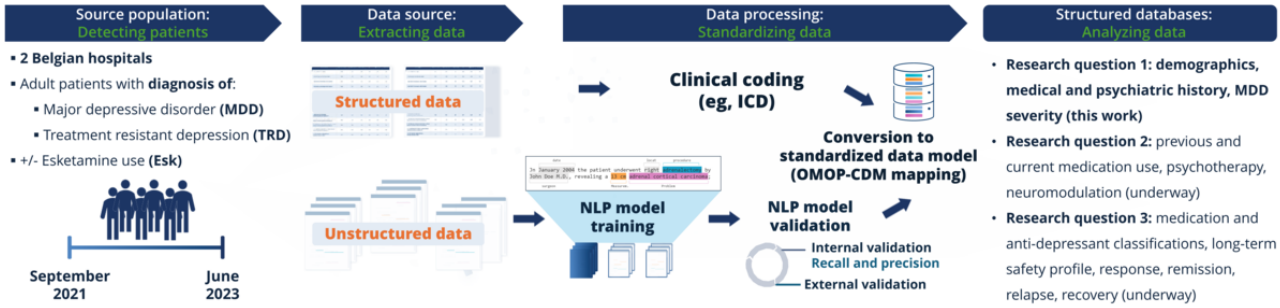
Real-world evidence (RWE) has become increasingly important to complement or expand upon findings from controlled trial settings and fill data gaps on new treatments, for example, patient profiling [5]. Furthermore, natural language processing (NLP) offers a time-efficient means to mine free-text fields, which are abundant in psychiatric reports [6]. This is particularly relevant in mental health EHRs because clinically decisive information such as symptom clusters, course specifiers, contextual triggers, and clinician-assessed status frequently appears in narrative documentation rather than in standardized structured fields [4,6,7]. Moreover, psychiatric research is hindered by a lack of standardized documentation, particularly for severity levels and outcomes, which are often inconsistently captured or absent in structured data [8-10]. Empirical work has also shown that even when severity indicators exist (eg, patient health questionnaires), their availability can be incomplete or uneven across encounters [11], reinforcing the need to combine structured fields with information from clinical text when feasible. This work showcases the methodology of a pilot project in psychiatry aimed at streamlining the comprehensive analysis of MDD and TRD patient populations.

We present a detailed methodology of a preliminary study conducted at 2 Belgian hospitals. The study leverages NLP as an artificial intelligence approach to analyze unstructured data alongside structured data from EHRs in psychiatry [12-15], generating RWE that seeks to offer a nuanced understanding of patient experiences and treatment trajectories even in the absence of depression scale scores. In doing so, the approach aligns with broader developments in mental health informatics, where NLP has been used to structure depression-related information from large EHR repositories to support observational research at scale [7]. Given the clinician-facing orientation of this manuscript, the NLP workflow is described step-by-step with emphasis on interpretability, validation, and how outputs map back to clinical concepts, consistent with clinician-oriented guidance on the development and implementation of AI methods in medicine [16]. Initial results on patient demographics and comorbidities are included here, and future analyses will address patterns of care. The ultimate goal is to inform clinical practice and guide future research into the complexities of treating depression in diverse patient cohorts.

The MOOD project comprises three overarching objectives focused on patients with MDD, with particular emphasis on those meeting criteria for TRD. The first objective is to characterize patient demographics, medical history, and psychiatric disease burden, including MDD severity, in these populations. The second objective is to assess real-world treatment patterns, encompassing pharmacological therapies, psychotherapy, and neuromodulation approaches used in MDD and TRD. The third objective aims to address data gaps for emerging treatments, with a specific focus on treatment patterns associated with esketamine nasal spray in patients with TRD [3]. While the MOOD project encompasses multiple objectives, the comprehensive real-world characterization of patients with MDD and treatment-resistant depression represents an important scientific objective in its own right. Despite the clinical relevance of TRD, contemporary data describing disease severity, comorbidity burden, and longitudinal clinical profiles in routine care remain limited [8-10]. The present manuscript addresses this gap by reporting the results of the first project objective, thereby establishing a baseline understanding of the studied population prior to analysis of treatment patterns and outcomes, which are ongoing.

Methods

Study Design and Data Sources



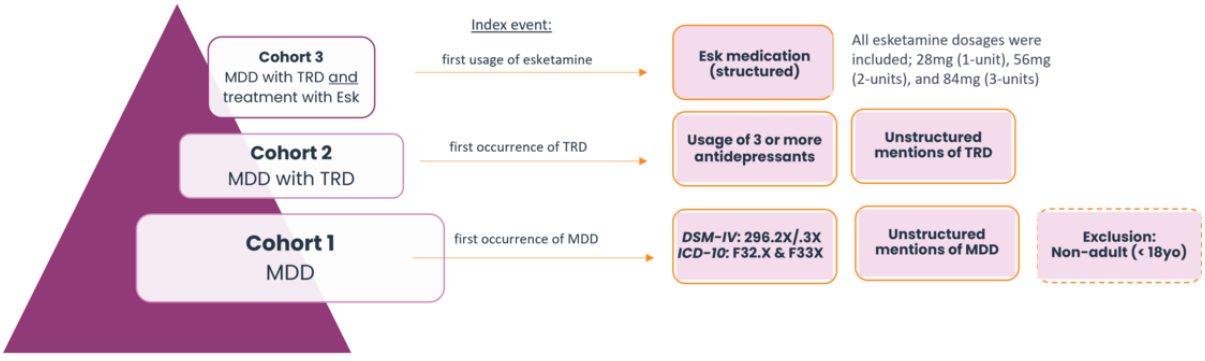
This study was a preliminary multicenter analysis conducted at 2 Belgian hospitals (University Hospital Brussels and Psychiatric Center Ariadne) from September 2021 to June 2023. Data were

XSL•FO
RenderX

extracted from both structured and unstructured sources within the EHRs of the hospital. Structured data encompasses demographic details, treatment dosages, frequency of administration, and hospitalization information, whereas unstructured data comprised clinicians' notes, pathology reports, and other textual documentation that captured patient histories and treatment responses.

The integration of data sources facilitated a thorough analysis of patient characteristics and enabled the study to capture information frequently overlooked in traditional research settings, such as nuanced clinical observations noted only in free-text fields. As the available data originate from two Belgian hospitals, the findings reflect the clinical documentation structure of these settings, with potential for broader generalizability as additional sites are incorporated in future work. A schematic of the overall study design is provided in Figure 1.

Figure 1. Schematic of the study design and methodology. Results for Research question one are included in this work, while analyses for Research questions 2 and 3 are underway. Esk: esketamine; *ICD*: *International Classification of Diseases*; MDD: major depressive disorder; NLP: natural language processing; OMOP-CDM: Observational Medical Outcomes Partnership-common data model; TRD: treatment resistant depression.



Participants and Cohorts

Patients eligible for inclusion were those aged 18 years or older with any record of MDD or TRD, and some had documented esketamine (Esk) use. Treatment-resistant depression is defined by the European Medicines Agency (EMA) as MDD with inadequate response to at least 2 different antidepressant treatments administered at adequate dose and duration [17]. Likewise, EMA approved esketamine specifically for adults with TRD [18], such that patients with TRD were assumed to have a diagnosis of MDD, and patients with esketamine use were assumed to have both MDD and TRD. This operational definition prioritizes sensitive real-world identification of TRD in EHR data; reasons for treatment changes (eg, nonresponse vs intolerance) are not consistently documented in structured records and could not be reliably distinguished. This definition is also consistent with prior large-scale TRD studies such as STAR*D [19], which similarly rely on sequencing of antidepressant trials in the absence of systematically documented reasons for change [20-22].

Three nested cohorts were established (Figure 2), including a MDD cohort (diagnosed through *ICD-10* [*International Statistical Classification of Diseases, Tenth Revision*] codes F32.X or F33.X, as well as *DSM-IV* [*Diagnostic and Statistical Manual of Mental Disorders* {Fourth Edition}] and *DSM-5* [*Diagnostic and Statistical Manual of Mental Disorders* {Fifth Edition}] codes 296.2X, 296.3X, excluding bipolar depression), a TRD cohort (individuals with three or more distinct antidepressants during the study period, or explicit mention of TRD in unstructured notes), and an esketamine (Esk) cohort (patients with esketamine treatment events of any dose). The index date for the MDD cohort was defined as the first occurrence of either MDD, TRD, or Esk, for the TRD cohort as the first occurrence of either TRD or Esk, and for the Esk cohort as the first recorded esketamine administration. Maximum follow-up (censoring) was applied based on the latest recorded date for any event per patient, defined as any recorded date for medication, diagnosis, or treatment in both structured and unstructured data.

Figure 2. Schematic of the nested cohorts included in the study, their index events, and definitions. *DSM-IV: Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*; Esk: esketamine; *ICD-10*: *International Classification of Diseases*, Tenth Revision; MDD: major depressive disorder; TRD: treatment resistant depression.

Variables

The variables were grouped according to the MOOD study's primary objectives, with corresponding timeframes and patient cohorts of interest (Table 1). This study presents the results for demographics, medical history, and psychiatric history, which constitute the first objective (shown as "this work" in Table 1). Future analyses will cover the additional variables linked to pharmacological and psychotherapeutic interventions, esketamine treatment patterns, and long-term outcomes (shown as "ongoing" in Table 1). Specific medications and antidepressant classifications can be found in Table S1 in Multimedia Appendix 1.

Table 1. Variables used in the study per objective, with their respective cohorts and timeframe.

Objective	Variables extracted	Cohorts	Timeframe
Patient demographics, medical, and psychiatric history (this work)	• Demographics: age, sex, death status. • Medical history: Parkinson disease, obesity, cardiac arrhythmia, rheumatoid arthritis, kidney disease, COPD[a], stomach disease, heart disease, anemia, central nervous system diseases, dementia, liver disease, HIV, diabetes, thyroid disease, cancer, stroke, CVS[b] or fibromyalgia, hypercholesterolemia, autoimmune disease, infectious diseases, and hypertension. • Psychiatric history: borderline personality disorder, bulimia nervosa, obsessive-compulsive disorder, circadian rhythm disorders, anxiety disorder, addiction (composite), personality disorder, panic disorder, posttraumatic stress disorder, anorexia nervosa, suicidal tendencies. • MDD[c] severity: mild, moderate, and severe MDD, MADRS[d], CGI-S[e].	• MDD and TRD[f] (this work), Esk[g] (ongoing)	• On or before index date
Medication, psychotherapy, and neuromodulation treatments (ongoing)	• Medication use: SSRIs[h], tricyclic antidepressants, atypical antipsychotic augmentation, serotonin and noradrenaline reuptake inhibitors, monoamine oxidase inhibitors, anxiolytics, selective noradrenaline reuptake inhibitors, antidepressants acting on neuroreceptors, noradrenaline and dopamine reuptake inhibitors, other antidepressants. • Psychotherapy: CBASP[i], cognitive behavioral therapy, psychoanalytic therapy, crisis intervention, psychodynamic psychotherapy, problem-solving therapy, mindfulness, relationship or family therapy, interpersonal psychotherapy, general psychotherapy. • Neuromodulation: transcranial magnetic stimulation and electroconvulsive therapy.	• TRD and Esk	• On or before index date
Esketamine treatment patterns (ongoing)	• Treatment characteristics: Frequency, duration, dosing, switching, and cessation. • Efficacy: Response, remission, relapse, recovery. • Safety: Adverse events. • Psychiatric hospitalization.	• Esk	• Within esketamine treatment period

[a]COPD: chronic obstructive pulmonary disorder.

[b]CVS: cyclic vomiting syndrome.

[c]MDD: major depressive disorder.

[d]MADRS: Montgomery-Åsberg Depression Rating Scale.

[e]CGI-S: Clinical Global Impression - Severity Scale.

[f]TRD: treatment-resistant depression.

[g]Esk: esketamine.

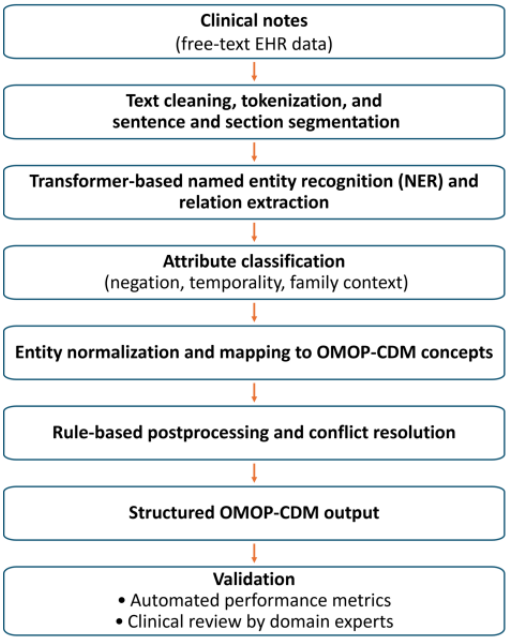
[h]SSRI: selective serotonin reuptake inhibitor.

[i]CBASP: cognitive behavioral analysis system of psychotherapy.

Database Generation

Following data extraction, the processed information was systematically integrated into a research-grade Observational Medical Outcomes Partnership (OMOP) Common Data Model (CDM) data warehouse, which promotes consistent data storage and reproducibility [23]. Data mapping used the *ICD* (*International Classification of Diseases*) codes for structured data and their equivalent Unified Medical Language System (UMLS) Concept Unique Identifiers (CUIs), while unstructured

XSL•FO
RenderX



data were directly encoded to CUIs (see full data point list in Table S2 in Multimedia Appendix 1).

NLP pipeline as an initial step, the underlying clinical notes were characterized by determining the total number of records, the number of patients with at least one record, and the allocation of documents to the predefined note-type categories. These data informed the preprocessing stages of the NLP pipeline.

NLP was used to handle unstructured text derived from clinical notes, pathology reports, and other sources. In this pipeline, text preprocessing involved splitting documents into sentences and words, followed by entity recognition to identify clinical terms such as “remission” or “relapse.” Entity linking was performed to map recognized entities to standardized medical concepts in the UMLS. An attribute extraction phase was then used to capture further details such as negation (eg, “no suicidal ideation”) or speculation. Model training and fine-tuning leveraged extensive medical datasets, with adjustments made for the psychiatry context, as shown for other therapeutic areas in detail (see [12-15,24,25]).

Figure 3 provides an overview of the end-to-end workflow, from free-text EHR documentation to structured, analysis-ready OMOP-CDM outputs, and situates each NLP component within the overall data-generation process. In line with the accepted methodological description of our platform and prior validated implementations in other disease areas [12-15,24-26], the pipeline was implemented as a cascade of transformer-based models complemented by rule-based interventions defined by domain experts to support robust extraction in real-world clinical text.

Figure 3. Overview of the clinical natural language processing pipeline used to convert free-text electronic health record documentation into structured Observational Medical Outcomes Partnership-common data model outputs. The workflow begins with clinical notes and applies text cleaning and segmentation, transformer-based named entity recognition and relation extraction, and attribute classification (eg, negation, temporality, and family context). Extracted mentions are then normalized to standardized Observational Medical Outcomes Partnership-common data model concepts, followed by rule-based post-processing and conflict resolution. The resulting structured Observational Medical Outcomes Partnership-common data model dataset is evaluated using automated performance metrics and clinical review by domain experts. EHR: electronic health record; NER: named entity recognition; OMOP-CDM: Observational Medical Outcomes Partnership-common data model.

Text cleaning, tokenization, and sentence and section segmentation were first applied to standardize heterogeneous document formats and to support downstream extraction within meaningful clinical contexts (Figure 3). Transformer-based named entity recognition (NER) and relation extraction were then applied to identify clinically relevant entities (eg, symptoms, diagnoses, and medications) and their relations (eg, date or dosage). In the pipeline, NER and relation extraction are framed as a sequence-to-sequence structured prediction task, which generates a structured representation of entities and relations directly from raw text [25,26]. This approach supports joint extraction of entities and relations in a single step and allows nested or compositional mentions to be represented in the model output.

After entity extraction, attribute classification was used to capture the contextual status of each extracted mention, including negation, temporality, and family context (Figure 3). This step distinguishes affirmed findings from negated or uncertain statements (eg, “no suicidal ideation,” “possible relapse,” “history of depression,” or “family history of bipolar disorder”), thereby reducing false positives that can arise when narrative documentation contains ruled-out symptoms or historical information. The attribute model is fine-tuned for multiple Boolean or contextual attributes, enabling classification of mentions into categories such as absent or negated, hypothetical, historical, or family-related [25,26].

Entity normalization and mapping to standardized OMOP-CDM concepts were subsequently performed (Figure 3). Structured data elements retained their source coding (eg, *ICD* where

XSL•FO
RenderX

applicable) and were aligned to standardized concept identifiers, while extracted unstructured mentions were normalized to UMLS-linked concepts and mapped to the OMOP-CDM vocabulary. Normalization is implemented via transformer-based entity linking (eg, SapBERT-style metric learning over UMLS) with nearest-neighbor retrieval and threshold optimization; concept mapping covers relevant clinical vocabularies used within OMOP (eg, SNOMED CT [Systematized Nomenclature of Medicine – Clinical Terms], *ICD-10*, Logical Observation Identifiers Names and Codes [LOINC], and RxNorm) [25,26].

Finally, rule-based postprocessing and conflict resolution were applied to improve data fidelity and address recurrent real-world documentation artifacts (Figure 3). These interventions include pattern-based extraction for semistructured mentions, exclusion of nonclinical document sections, filtering of incompatible NER label-semantic type combinations, resolution of conflicting attributes (eg, historical labels paired with inconsistent dates), and default date assignment when timing is not explicitly documented, using a predefined cascade of rules [25,26].

Training Data and Annotation Framework

The NLP models, used for initial processing of the corpus, rely on a continuously expanding proprietary corpus of manually annotated clinical text in Dutch. This annotated resource includes approximately 33897 sentence-level annotations across 5954 sentences (for NER, relation extraction, and attribute detection) and 4716 concept-level annotations from 3777 documents (for coding and attribute classification). For this study, model performance was estimated using a separate set of 2638 clinician-validated annotations derived from 1921 documents, which serve as an out-of-the-box (OOTB) evaluation sample. These validation annotations were subsequently reintegrated into the training pool as part of an iterative continuous-learning process, in which corrected model outputs inform further fine-tuning. This workflow reflects our standard development approach, prioritizing broad clinical coverage and iterative refinement rather than fixed, project-specific data partitions.

Validation

Validation involved a multistep process to confirm data quality and clinical reliability (Figure 3). First, automated evaluation was performed by comparing NLP-extracted concepts against a clinician-curated gold standard, with precision, recall, and F_1 scores calculated at the datapoint level; where relevant, performance was also assessed separately for specific subtasks such as attribute handling (eg, negation and temporality) and concept normalization. Second, clinical review by domain experts was conducted on sampled patient records and on aggregated outputs to confirm that extracted concepts were clinically meaningful, internally consistent, and aligned with expectations from routine practice. This review step explicitly targeted common failure modes in psychiatric documentation, including ambiguous phrasing, historical versus current symptom mentions, and "rule-out" statements, and it served as an iterative quality check to identify systematic extraction errors that could affect downstream analyses. Findings from automated metrics and expert review informed targeted refinements of extraction logic and postprocessing (eg, resolving conflicting attributes or excluding nonclinical document sections), followed by reassessment to ensure that updates improved fidelity without introducing new inconsistencies [25,26].

Statistical Analysis

Descriptive statistics were used to summarize findings related to the first objective (patient demographics, medical history, and psychiatric history). Means, medians, SDs, and minimum-maximum values were used for continuous variables such as age at index, whereas categorical variables, including comorbidity status, were presented as frequencies and percentages. Statistical analyses were performed using R environment software (version 4.1.0; R Foundation for Statistical Computing). No inferential analyses were included because the objective was descriptive cohort characterization rather than hypothesis testing. Counts below five were suppressed as "<5" (<x%), and when this alone still allowed back-calculation, the complementary subgroup was shown as a symmetric count and percentage range.

Ethical Considerations

Ethical approval was obtained from the relevant Institutional Review Boards (Commissie Medische Ethiek, Universitair Ziekenhuis Brussel, BUN1432023000167, EC-2023-199, Project ID=23162_RWE Mood). The ethics evaluation resulted in approval for the secondary use of routinely collected health data. The study was conducted following the Declaration of Helsinki, ethical standards of the responsible institutional and national committees on human experimentation, and applicable regulations. Patient privacy was safeguarded according to Belgian Privacy Law and General Data Protection Regulation articles 6, 9, and 89. Data were pseudonymized prior to analysis. Patient consent was waived by the approving ethics committees due to pseudonymization of the data and the retrospective nature of the study, in accordance with Belgian legislation. No financial or other compensation was provided to patients.

Results

NLP Pipeline and Metrics

A total of 56,396 records across both hospitals were included in the dataset, where 1262 patients presented at least one record. Clinical assessment notes constituted the majority of all extracted records (32,075/56,396, 56.9%). Admission, intake, and hospitalization notes (13,109/56,396, 23.2%), together with consultation notes (5605/56,396, 9.9%, including client, referrer, bedside, psychiatric, and telephone contacts), accounted for most of the remaining documentation. The other note types, including multidisciplinary meeting reports, administrative or system-generated communications, diagnostic or procedural documents, risk and safety assessments, and treatment-plan notes, each represented a smaller proportion of the dataset (< 4% each).

Performance against a clinician-annotated gold standard, reported as precision and recall for OOTB pipeline versus the postmitigation pipeline (ie, after rule-based postprocessing and conflict resolution), is summarized in Table S3 in Multimedia Appendix 1. Overall, postmitigation precision was high, with values ranging from 66.7% to 100% (96.6% mean), while

XSL•FO
RenderX

postmitigation recall ranged from 91.7% to 100% (98.1% mean). In contrast, OOTB recall was notably more variable (range 10%-100%, 72.3% mean), supporting the importance of the mitigation layer for reliable extraction.

Performance gains were most visible for clinically central symptom and outcome concepts that are frequently documented in narrative form. For example, recall improved from 39.3% to 95.2% for depressed mood, from 42.4% to 93.9% for anxiety, and from 35.4% to 95.8% for suicidal mentions. Similarly, the concept Major Depressive Disorder increased from 10% to 95% recall after mitigation, indicating that postprocessing materially reduced missed detections for key diagnostic constructs when expressed variably in free text (Table S3 in Multimedia Appendix 1).

Across variable classes, medication entities and medication-class groupings tended to perform best after mitigation (typically near-perfect precision and recall for commonly observed treatments or classes in the annotated sample), as did many diagnosis or comorbidity concepts (postmitigation precision typically in the high-90% range with recall approaching 100%). Symptom or context concepts also reached strong postmitigation recall overall, but they represented the main area where OOTB performance was lower, consistent with the greater linguistic variability of symptom documentation in psychiatric notes.

Routine documentation sometimes indicated different intended uses for the same medication, which is not consistently recoverable from structured medication records alone. For example, trazodone and benzodiazepines were frequently mentioned in the context of sleep rather than antidepressant or anxiolytic use, and this indication context was captured from unstructured notes by the NLP extraction layer.

Patient Demographics

Table 2 summarizes key demographic characteristics of patients with MDD, stratified into not-treatment-resistant (Not TRD, 623/1,147, 54%) and treatment-resistant (TRD, 524/1,147, 46%) subgroups. Among patients with TRD, 2% (n=8) had an explicit TRD mention in clinical notes; the remaining patients met the TRD definition based on medication information (≥3 distinct antidepressants). Females comprise 62.9% (722/1,147) of the overall MDD population, with a higher proportion in the TRD group (349/524, 66.6%) compared to Not TRD (373/623, 59.9%). The mean age is 57.8 years, and the median age is slightly higher in the TRD group (60 years) than in not TRD (58 years). Most patients are alive (995/1,147, 86.7%), with a slightly higher mortality rate in the Not TRD group (95/623, 15.2%) compared to TRD (57/524, 10.9%).

Table 2. Patient demographics.

Characteristics	MDD[a] (Overall), n (%)	MDD (N=1147; 100%)	
		Not TRD[b], n (%) (N=623; 54% of MDD)	TRD, n (%) (N=524; 46% of MDD)
Sex, n (%)			
Female	722 (62.90)	373 (59.90)	349 (66.60)
Male	425 (37.10)	250 (40.10)	175 (33.40)
Age at index			
Mean (SD)	57.8 (18.4)	57.2 (18.7)	58.4 (18)
Median (min-max)	59 (18-101)	58 (19-96)	60 (18-101)
Status, n (%)			
Alive	995 (86.70)	528 (84.80)	467 (89.10)
Dead	152 (13.30)	95 (15.20)	57 (10.90)

[a]MDD: major depressive disorder.

[b]TRD: treatment-resistant depression.

Medical and Psychiatric History of MDD and Patients With TRD

Table 3 summarizes the medical and psychiatric history of patients with MDD, with or without TRD. Among medical comorbidities, central nervous system diseases, infections, and heart diseases are the most common, with similar prevalence across both subgroups. Notable differences include higher rates of dementia in patients with TRD (42/524, 8% vs 32/623, 5.1%) and obesity in individuals without TRD (70/623, 11.2% vs 46/524, 8.8%). Psychiatric comorbidities reveal more pronounced differences, with anxiety disorders found at higher proportions for patients with TRD (229/524, 43.7% vs 177/623, 28.4%), along with higher rates of personality disorders and panic disorders. Alcohol and drug-related issues are prevalent in both groups, with slightly higher alcohol abuse (148/623, 23.8%) and drug dependence (152/623, 24.4%) in patients without TRD. In terms of depression severity, detected on or at the index date, severe MDD is observed in 14.8% (170/1147) of the overall population, with comparable rates across subgroups. Severity was only well captured in a minority of patients (see the Discussion section). This data underscores the complex clinical profiles of MDD and highlights key differences between treatment-resistant and nontreatment-resistant cases.

Discussion

Overview, Scope, and Importance of the MOOD Project

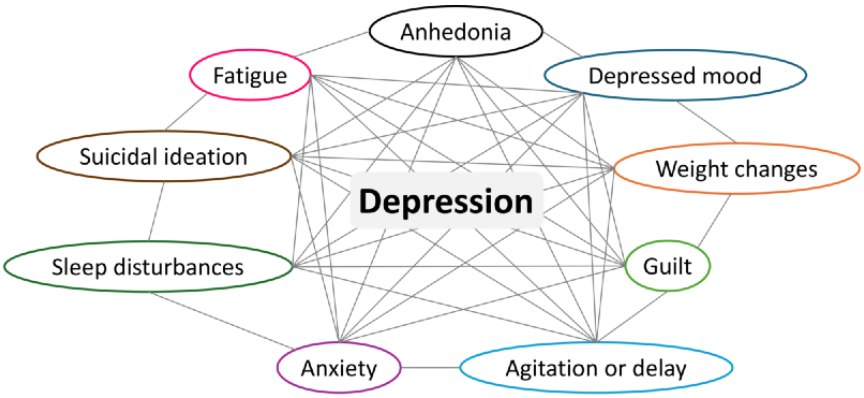
The MOOD project highlights the growing need for RWE in psychiatry, particularly for understanding complex disorders such as MDD and its treatment-resistant form [8,27]. The findings presented here provide an essential real-world baseline of disease burden and patient complexity in MDD and TRD, enabling more informed interpretation of subsequent treatment-focused analyses from this project. By integrating structured and unstructured data, the study addresses key gaps in psychiatric research, where conventional methods often overlook contextual details captured only in free-text notes [12,13]. This approach is vital given the global prevalence and significant disease burden of depression, as well as the unique clinical and economic challenges posed by TRD [2,3]. Building upon existing literature that highlights the limitations of traditional datasets, the MOOD project aims to generate comprehensive insights that can inform a more patient-centered and evidence-driven model of psychiatric care [5,6,8].

Main Findings and Link to Previous Work

Results regarding NLP metrics support the contribution of unstructured text augmentation: variables that are often absent or inconsistently represented in structured fields (symptoms, clinical course descriptors, response language) can be extracted with high postmitigation performance, aligning with prior evidence that NLP improves ascertainment beyond structured claims data alone in large-scale psychiatric EHR studies [4]. The first analyses from the MOOD project reveal how NLP-based extraction of free-text data complements structured clinical fields, leading to a richer depiction of patient trajectories in MDD and TRD. The systematization of clinical experience results in a holistic overview that avoids confirmation bias based on individual cases. [6,7]. For instance, the project's NLP pipeline successfully extracted a dashboard overview of clinical experience in TRD.

Automation of data extraction through NLP further reduces the burden on clinicians, allowing them to spend more time with patients while still generating valuable research insights [6]. This aligns with the broader goal of enhancing both research and clinical practice in psychiatry. These findings align with prior large-scale investigations showing that real-world data capture a heterogeneous array of patient experiences and outcomes [8,27]. The capacity to identify these factors using textual data sources resonates with studies showing that TRD can have varying definitions and multistep strategies commonly are recommended, which may involve switching, augmentation, or combination regimens [3]. Consequently, the MOOD findings expand on this literature by illustrating how robust informatics frameworks can overcome the inconsistent or complex documentation required for psychiatric research.

As extensively discussed in major TRD reviews and large real-world cohorts [20-22], heterogeneity in TRD definitions and reliance on retrospective EHR documentation contribute to variability in reported prevalence; our findings therefore align with expectations for hospital-based MDD populations [22], where TRD proportions typically approach 45%-50% rather than the approximately 30% seen in general MDD populations [3]. In addition, the descriptive differences observed in our cohort, such as higher rates of dementia, anxiety disorders, personality disorders, and panic disorder among patients with TRD, are broadly consistent with patterns described in published European TRD cohorts, which similarly report greater psychiatric and medical complexity in TRD than non-TRD populations [28-30].



Disentangling the Depression Symptom Cluster Using Unstructured Data

The study highlights the importance of a structured framework for understanding the "nine pillars of depression," or "depression

XSL•FO
RenderX

symptom cluster" that defines MDD in the *DSM-V* [31], which encompasses key domains such as diagnosis, symptom severity, and quality of life (Figure 4). While structured data sources offered a baseline for documenting diagnoses and comorbidities, unstructured data provided critical insights into the nuanced clinical profiles of patients. Indeed, patient profiles within MDD can vary widely depending on symptom patterns [32]. Through the use of the NLP pipeline, descriptions of symptom clusters, such as anhedonia, psychomotor retardation, and psychosocial stressors, can be more easily extracted, offering a more comprehensive understanding of patient experiences. This approach addresses the challenges inherent in psychiatric data, where nonstandardized language can obscure critical details about each patient's depression severity or clinical features. By extracting and categorizing these domains via NLP, researchers gain a more nuanced view of how depression manifests and evolves in real-world settings, supporting calls for thorough documentation in clinical practice.

Figure 4. Schematic representing a network of the "nine pillars of depression". Each node represents a key symptom or domain—such as anhedonia, depressed mood, weight changes, and sleep disturbances—which collectively define depression as a clinical syndrome. The network schematic emphasizes how these interconnected elements comprise the overarching concept of depression [26].

The depression symptom cluster includes the following symptom domains:

1. Anhedonia
2. Depressed mood
3. Changes in weight or appetite
4. Sleep disturbances
5. Psychomotor agitation or retardation
6. Feelings of anxiety
7. Feelings of guilt or worthlessness
8. Fatigue or diminished concentration
9. Suicidal ideation or thoughts of self-harm

Challenges in Real-World Psychiatric Research

Despite its advantages, leveraging RWE in psychiatry presents notable challenges. A primary issue is the inconsistent documentation of critical clinical parameters [6]. Depression severity, for example, is often recorded in free-text notes without the use of standardized scales such as the Montgomery-Åsberg Depression Rating Scale (MADRS) or the Clinical Global Impression - Severity (CGI-S) scale [8]. This lack of standardization complicates the extraction and analysis of severity data [9,10]. With minimum extra work on behalf of the physicians, that is, noting down CGI-S scores, the clinical added value to be gained from patient records would be notable.

Unstructured clinical notes, while rich in contextual information, pose additional difficulties for data extraction. NLP tools must contend with variability in language, medical jargon, and incomplete or ambiguous entries. Recent advancements in NLP have improved the accuracy of concept extraction, yet challenges remain, particularly in capturing nuanced information such as reasons for treatment changes or patient-reported outcomes [6,33].

The integration of structured and unstructured data also requires careful attention to data quality and consistency. Discrepancies between these sources can lead to errors in analysis or misinterpretation of findings. For example, structured data may indicate a medication switch, but unstructured notes may reveal that the switch was due to adverse effects rather than lack of efficacy [6,8,27].

Our findings also revealed significant variability in the documentation and conceptualization of TRD [3]. We defined TRD as the initiation of a third antidepressant during the study period, as identified through structured data sources. However, unstructured notes frequently included additional nuances, such as mentions of partial response, adverse effects, or patient-reported discontinuation reasons. While the EMA's definition of TRD relies on two failed antidepressants in one same depressive episode [3], medication failure (eg, due to side effects or inefficacy) was not reliably captured in structured data alone. NLP contributed by identifying unstructured mentions of TRD that provided context for treatment changes, supporting the ongoing refinement of TRD criteria for clinical use.

Limitations of the MOOD Project

While the MOOD project represents a significant step forward, several limitations must be acknowledged. First, the study relied on data from two hospitals in Belgium, so future expansions to include additional sites and more diverse datasets could broaden the extent of the findings. Second, the accuracy of the NLP pipeline, while robust, is contingent on the quality and completeness of the underlying data. Missing or ambiguous information in clinical notes can affect the reliability of extracted concepts, and variability in clinician terminology limits the accuracy of NLP tools, a challenge noted across studies

XSL•FO
RenderX

leveraging NLP for mental health interventions [6]. For instance, this analysis did not attempt to algorithmically infer or predict depression severity scores when not documented; severity capture was descriptive and limited to explicitly recorded severity descriptors and scale measurements identified in structured fields or narrative notes. Efforts to standardize documentation practices and improve data curation are critical for addressing these issues [9]. Finally, the lack of patient-reported outcomes in the study highlights a gap in understanding the subjective experiences of patients with MDD and TRD. Incorporating patient-reported measures in future studies could provide a more comprehensive view of treatment efficacy and quality of life [33].

Conclusions

The findings from the MOOD project underscore the importance of continued innovation in RWE methodologies for psychiatry. Expanding the study to additional hospitals and incorporating standardized documentation practices will enhance the generalizability of the results. RWE studies also have the potential to improve clinical decision-making. By uncovering patterns in real-world treatment use, such as the adoption of esketamine for TRD, these studies can guide the development of more effective and personalized care strategies [8,34,35]. Moreover, the ability to analyze patient trajectories in diverse populations can help address disparities in access to and outcomes of psychiatric care [9,34]. Furthermore, integrating patient-reported outcomes and exploring the use of novel data sources, such as wearable devices or mobile health applications, could enrich future research [33,36]. Collaboration between clinicians, data scientists, and policymakers is essential to ensure that RWE studies address the most pressing challenges in psychiatric care. By leveraging advancements in artificial intelligence and NLP, future projects can build on the foundation laid by the MOOD project, ultimately improving outcomes for patients with MDD, TRD, and other mental health conditions. Therefore, the MOOD project can be a first cornerstone for cross-border collaboration on a structured RWE network for mental health.

Acknowledgments

We thank Prof Giovanni Briganti for his thorough revision and editing of the manuscript, as well as Clara L. Oeste for medical writing.

Funding

This study was funded by Johnson & Johnson.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to them being property of each participating hospital and therefore subject to strict privacy laws, but are available from the corresponding author on reasonable request.

Abstract

Background: Long COVID, or postacute COVID-19 syndrome, presents with persistent cognitive and psychological symptoms such as *brain fog*, anxiety, depression, and fatigue, significantly impacting quality of life and daily functioning. Digital health interventions offer a scalable, accessible solution to bridge care gaps, especially where conventional neuropsychological support is limited. However, evidence regarding their effectiveness for neuropsychiatric symptoms in long COVID remains fragmented.

Objective: This scoping review aimed to systematically identify and map the existing evidence on digital interventions targeting cognitive and psychological symptoms in individuals with long COVID. The review also sought to categorize intervention types, assess reported outcomes, and identify methodological gaps to inform future clinical and research priorities.

Methods: The review followed the Arksey and O'Malley framework and adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. Comprehensive searches were conducted in 4 databases (PubMed, Scopus, Web of Science, and ScienceDirect) from December 2024 to February 2025. Eligible studies included peer-reviewed and gray literature published in English or Spanish since 2020. Studies were screened and selected based on predefined inclusion and exclusion criteria. Data were extracted using a standardized charting form and synthesized narratively, with thematic grouping by intervention type.

Results: Of 888 records identified, 25 (2.82%) were included. Intervention types encompassed telehealth platforms, mobile health apps, virtual reality, online cognitive and psychological therapies, game-based cognitive training, neuromodulation (transcranial direct current stimulation), and multicomponent programs. Most studies reported improvements in psychological well-being, emotional regulation, and cognitive domains such as attention and memory. However, findings varied, with some interventions showing no significant cognitive gains or sustained effects. Common limitations included small sample sizes, lack of control groups, heterogeneity in outcomes and intervention protocols, and short follow-up durations. The underrepresentation of older adults and underserved populations was also noted.

Conclusions: Digital interventions show promise for addressing cognitive and psychological symptoms in long COVID, particularly when delivered as multicomponent programs. Nonetheless, the evidence base remains preliminary. Future research

XSL•FO
RenderX

should prioritize high-quality randomized trials with standardized outcome measures, long-term follow-up, and diverse participant samples. Addressing barriers related to digital literacy and access will be essential to ensure equity and real-world effectiveness.

KEYWORDS

long COVID; postacute COVID-19 syndrome; digital health interventions; cognitive symptoms; psychological symptoms; telehealth; eHealth

Introduction

The COVID-19 pandemic has resulted in an unprecedented global health crisis, with more than 700 million confirmed cases worldwide to date. Beyond the acute phase [1,2], a substantial number of individuals experience persistent symptoms, collectively referred to as *long COVID* or *postacute COVID-19 syndrome* [3,4], which can persist for weeks or months after initial recovery. Among the most reported and debilitating effects are cognitive and psychological impairments [5,6], which significantly impair daily functioning, employment, and overall quality of life.

Cognitive symptoms, colloquially referred to as *brain fog*, include problems with attention, memory, executive functioning, and information processing [7,8]. These manifestations can severely impair daily functioning, work performance, and social participation [9,10]. Concurrently, psychological symptoms such as anxiety, depression, posttraumatic stress, sleep disturbances, and fatigue are highly prevalent in individuals with long COVID, further compounding the burden of disease. These neuropsychiatric sequelae often persist long after the resolution of respiratory symptoms and may occur even in individuals who experienced only mild acute illness [11,12].

Emerging evidence suggests that the mechanisms underlying these symptoms are complex and multifactorial, including neuroinflammation, microvascular damage, immune dysregulation, and psychosocial stressors [13,14]. The unpredictability of symptom progression and the lack of clear diagnostic markers pose challenges for clinical management and rehabilitation planning. Furthermore, many patients report difficulties in accessing appropriate care, particularly neuropsychological and mental health services, due to geographical, logistical, or systemic barriers [15,16].

In this context, digital health interventions have gained considerable attention as innovative and scalable tools to bridge gaps in care. These interventions encompass a wide range of modalities, including mobile health (mHealth) apps, telehealth consultations, online therapy platforms, virtual reality (VR) tools, and other web-based cognitive or behavioral training programs [17]. Digital interventions offer the potential for continuous, remote, and personalized support, which is particularly valuable for populations affected by chronic illness and mobility limitations [18].

Although there is a growing body of research exploring the use of digital health tools in the context of long COVID, most studies to date have addressed general management or physical recovery. Fewer have specifically focused on interventions targeting the cognitive and psychological symptoms that are among the most disabling and persistent sequelae of the condition. As such, health care professionals lack a synthesized and focused body of evidence to inform clinical decision-making in this domain, and researchers face uncertainty regarding which digital approaches show the most promise for addressing neuropsychological aspects of long COVID [17,19,20]. Given the rapid evolution of digital health technologies and the fragmented nature of the current literature, a comprehensive mapping of existing evidence in this area is urgently needed [21]. This is particularly important given the increasing prevalence of long COVID and the growing demand for accessible, nonpharmacological support strategies.

This scoping review aims to address this knowledge gap by systematically identifying, mapping, and synthesizing the existing evidence on digital interventions targeting cognitive and psychological symptoms in individuals with long COVID, while categorizing intervention types, evaluating reported outcomes, and identifying key methodological gaps to inform future research and clinical practice.

Methods

Study Design

We conducted a scoping review to examine the evidence on digital interventions addressing cognitive and psychological symptoms in individuals with long COVID. This methodology was chosen due to the exploratory nature of the research question and the heterogeneity of the available evidence in terms of study designs, intervention types, and outcome measures. Scoping reviews are particularly suited to emerging research areas, as they allow a comprehensive overview of the literature and the identification of key knowledge gaps, rather than a narrowly focused assessment of effectiveness.

This review followed the framework proposed by Arksey and O'Malley [22], which comprises 5 key stages: identifying the research question; identifying relevant studies; selecting studies; charting the data; and collating, summarizing, and reporting the results. To enhance transparency and methodological rigor, the review was conducted in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [23]. The completed PRISMA-ScR checklist is provided as Checklist 1. Additionally, a publicly accessible study protocol was registered in the Open Science Framework on December 11, 2024 [24].

XSL•FO
RenderX

Research Questions

To structure the research question, we used the population, intervention, comparison, outcomes, and study design framework [25], summarized in Textbox 1.

Textbox 1. Population, intervention, comparison, outcomes, and study design (PICOS) criteria for the research question.

Population

- Individuals with long COVID who experience cognitive or psychological symptoms

Intervention

- Digital interventions (eg, mobile apps, virtual reality, telehealth, and online cognitive or psychological therapies)

Comparison

- No comparison was required for inclusion; comparators, when present, were reported

Outcomes

- Cognitive outcomes (eg, attention, memory, and executive function) and psychological outcomes (eg, depression, anxiety, fatigue, and well-being)

Study design

- Randomized controlled trials, observational studies, protocols, qualitative studies, and reviews (including scoping, systematic, and narrative reviews), as well as gray literature

The secondary research questions were as follows:

- What digital interventions are available and effective for managing cognitive and psychological symptoms in individuals with long COVID?
- What types of digital interventions are most commonly used?
- What evidence supports their efficacy?
- What methodological limitations and knowledge gaps exist?

Identifying Relevant Studies

A comprehensive search strategy was designed and peer-reviewed by a research librarian. The following databases were searched between December 2024 and February 2025: PubMed, Scopus, Web of Science, and ScienceDirect. Search terms combined concepts related to long COVID (eg, “Long COVID,” “post-COVID,” “post-acute COVID-19 syndrome,” and “chronic COVID”), digital interventions (eg, “teletherapy,” “digital intervention,” “mobile app,” “telehealth,” “eHealth,” and “virtual reality”), and neuropsychiatric symptoms (eg, “cognitive symptoms,” “*brain fog*,” “anxiety,” “depression,” and “mental health”).

In addition to peer-reviewed records, our search strategy included gray literature available within the databases consulted—particularly ScienceDirect—which indexes materials such as book chapters, conference proceedings, and scientific reports. These records were screened using the same inclusion and exclusion criteria applied to peer-reviewed studies.

The search was limited to studies published in English or Spanish from 2020 onward to capture literature emerging during the COVID-19 pandemic. These languages were selected based on the language competencies of the review team and the high likelihood of relevant literature being published in these languages during the COVID-19 pandemic.

The complete search strings for each database are available in Multimedia Appendix 1 [26,27].

Although hand-searching of reference lists is commonly used as an additional step to identify relevant studies, it was not performed in this review. This decision was based on the comprehensiveness of the database search strategy, which was developed in collaboration with a research librarian and included multiple major databases and gray literature sources. This approach was considered sufficient to capture the relevant body of evidence.

Study Selection

Study selection was conducted in 2 stages. Initially, 2 reviewers independently assessed titles and abstracts to evaluate their potential relevance. Studies deemed potentially eligible were then examined in full text. Disagreements between reviewers were addressed through discussion based on predefined inclusion criteria (Textbox 2), and a third reviewer was involved when necessary to achieve consensus.

No restrictions were placed on study design or sample size. All identified relevant studies were included to provide a comprehensive overview.

XSL•FO
RenderX

Textbox 2. Eligibility criteria for the study.

Inclusion criteria

- Original studies (quantitative, qualitative, and mixed methods), reviews (including systematic, scoping, and narrative reviews), or study protocols
- Studies involving digital interventions targeting cognitive and/or psychological symptoms in patients with long COVID, either exclusively or as part of a broader multicomponent approach
- Studies published from 2020 onward in English or Spanish

Exclusion criteria

- Studies focusing solely on physical symptoms or nondigital interventions
- Studies not reporting outcomes related to cognitive or psychological health
- Studies published in languages other than English or Spanish

Data Charting

Data from the selected studies were charted using a standardized data extraction table designed to capture key information related to the research questions. The extracted data included authors, year of publication, study design and setting, population and sample size, type and description of the digital intervention (including duration and frequency), cognitive and/or psychological outcomes assessed, key findings, and reported limitations. The data extraction form was piloted on a subset of 3 studies and refined to improve consistency and capture all relevant variables.

Data were extracted by one reviewer and verified by a second reviewer. Discrepancies were resolved by consensus. The charting process remained iterative, allowing for the inclusion of additional variables as needed.

Data Synthesis

A narrative synthesis was performed to describe the digital interventions, their outcomes, and methodological characteristics. A descriptive thematic analysis was used to classify interventions into key categories (eg, VR, teletherapy, and mobile apps). Outcomes were synthesized narratively according to their effects on cognitive and psychological domains. The interventions were grouped thematically and compared based on their reported effects on cognitive and psychological symptoms.

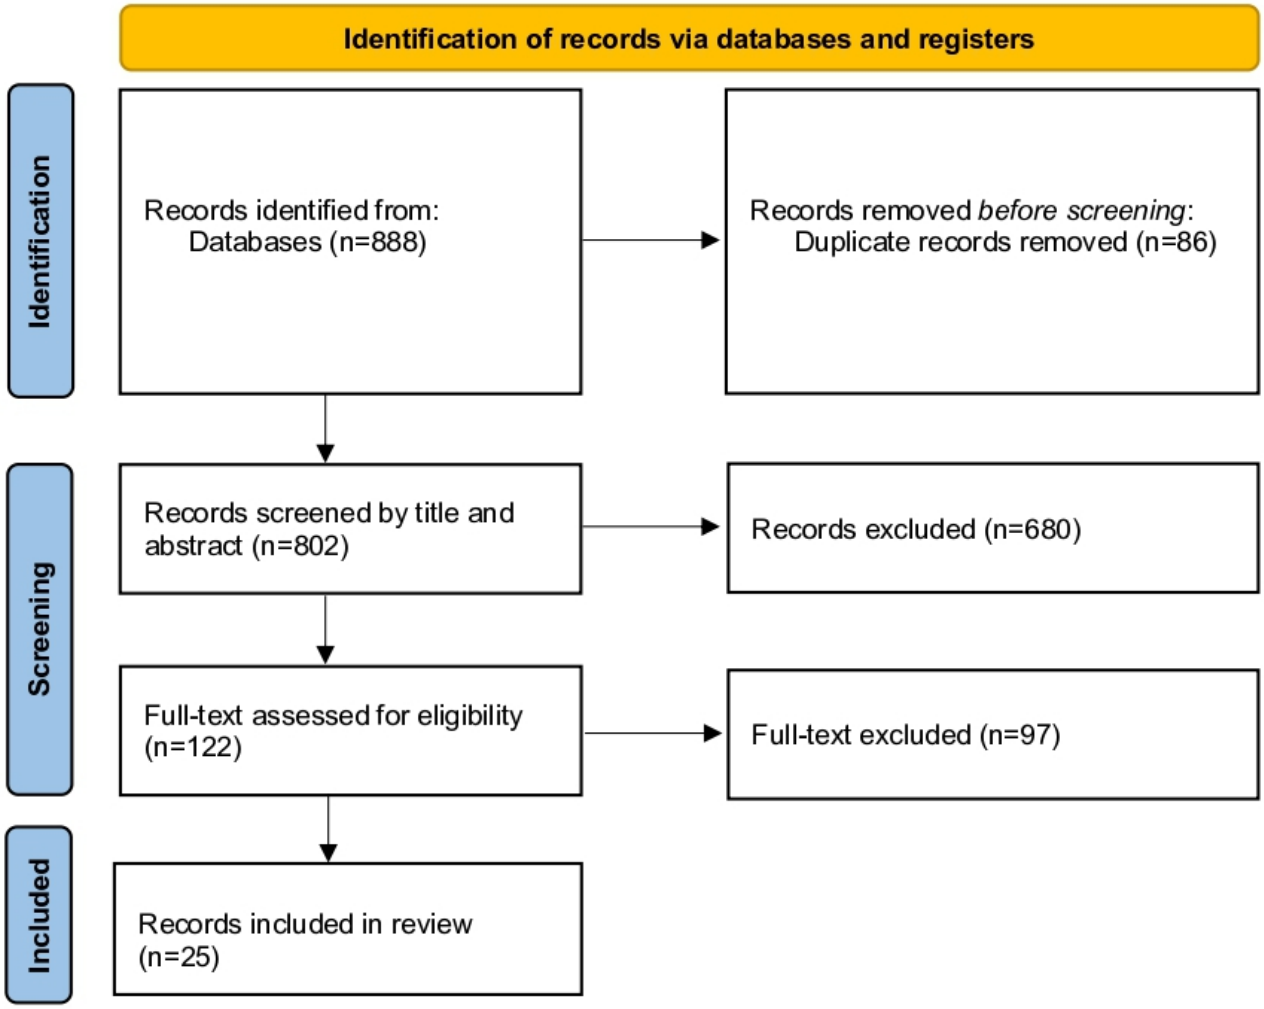
Findings are presented in tabular format and complemented by descriptive summaries. Additionally, key gaps in the literature and recommendations for future research were outlined based on patterns identified during synthesis.

Because this is a scoping review, no formal quality assessment or meta-analysis was conducted, in line with best practices for this review type. However, reported limitations and methodological concerns were documented.

Ethical Considerations

This study involved the review of publicly available literature and did not require ethics approval. No human participants or personal data were involved. This study complies with ethical standards for secondary research and adheres to the principles outlined in the Declaration of Helsinki, where applicable.

Results



Sources Selection and Characteristics

The initial database searches yielded 888 records. After removing duplicates, 802 (90.32%) unique records remained for title and abstract screening. Of these, 680 (76.58%) records were excluded based on predefined inclusion and exclusion criteria. In total, 122 (13.74%) full-text records were retrieved and assessed for eligibility, leading to the exclusion of 97 (10.92%) records for reasons such as irrelevance to cognitive or psychological symptoms, lack of a digital intervention, or publication in an unsupported language. Following full-text screening, 25 (2.82%) records were included in this scoping review. These records included peer-reviewed research papers, book chapters, and other relevant literature. Although gray literature (eg, commentaries, editorials, and policy statements) was considered, only the abovementioned records met the inclusion criteria.

The selection process is illustrated in the PRISMA-ScR flow diagram (Figure 1), summarizing the records identified, screened, included, and excluded. In total, 8 (32%) studies were study protocols and had not yet reported outcome data at the time of the review.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.

To improve readability and facilitate comparison across records, a simplified summary of the included interventions is provided in Table 1. This table groups the records by type of digital intervention, lists the corresponding authors, and highlights the main reported effects on cognitive and psychological symptoms. Detailed methodological characteristics and outcome measures for each study can be found in Multimedia Appendix 2.

Population Characteristics

The studies included in this scoping review investigated individuals with persistent post–COVID-19 symptoms across various countries, including Germany, Spain, the United Kingdom, the United States, Canada, Greece, Italy, the Netherlands, and Taiwan. Most included studies were conducted in Europe and North America, indicating a geographic concentration of research and limited evidence from low- and middle-income countries. Populations commonly presented with a mix of cognitive symptoms (eg, *brain fog*, memory impairment, and concentration difficulties) and psychological symptoms (eg, anxiety, depression, fatigue, and sleep disturbances), along with impaired physical function and reduced quality of life.

Sample sizes varied significantly, from as few as 11 participants in a pilot telehealth group therapy study [44] to >600 participants in a blended digital rehabilitation program [32]. Some studies focused on specific age groups—for example, the CICERO trial [35] limited participants to adults aged 30 to 60 years—while others explored experiences across younger and older adults [42]. A common trend was the overrepresentation of women, with some studies noting that digital tool acceptance was higher among women and those with prior digital experience [47]. Although some studies reported participants' age, gender, and previous digital experience, comprehensive demographic data, such as digital literacy and socioeconomic background, were not systematically reported, limiting subgroup analysis and generalizability.

Types of Digital Interventions

Digital health interventions varied widely in format, intensity, and content. The most common approaches included telehealth and online rehabilitation platforms, mHealth tools, VR, game-based cognitive therapies, digital psychotherapy, multicomponent programs, and neuromodulation techniques.

Telehealth and online rehabilitation platforms typically combined cognitive training, physical exercise, and mental health support delivered via weekly video calls and digital resources [28,29]. mHealth tools were also frequently implemented; for example, an immersive VR-based app integrating mindfulness and cognitive training was used [37], alongside mobile apps and wearable monitoring tools [19].

VR interventions were explored in several records, showing benefits in physical recovery and emotional well-being [36,38,39], although some users reported side effects such as dizziness and headaches. Game-based cognitive therapy was also represented by a video game designed to enhance cognitive function, which led to improvements in processing speed and executive function.

Digital psychotherapy approaches were also identified, including trauma-focused cognitive behavioral therapy (CBT) delivered online [40] and telehealth group CBT incorporating verified COVID-19 information and peer support [44]. In addition, multicomponent programs combined web-based exercise classes, symptom education, and in-person community support [32]. Finally, neuromodulation techniques, including remotely supervised transcranial direct current stimulation, were reported to improve fatigue and depression in a small case series [46].

XSL•FO
RenderX

The duration and frequency of interventions ranged from 2 weeks to 3 months, with varying intensity and adherence strategies, such as weekly sessions or daily app use.

Intervention Efficacy

Outcomes evaluated across records spanned several domains. Cognitive function was frequently assessed, including memory, executive function, attention, and processing speed [35,37,45]. Psychological health outcomes were also commonly reported, particularly depression, anxiety, posttraumatic stress disorder, sleep quality, and fatigue [28,40].

In addition, several records examined physical health indicators such as breathlessness, exercise tolerance, sleep quality, and overall physical performance [29,38]. Broader measures of quality of life and functioning—including self-efficacy, daily activities, occupational performance, and health care use—were also assessed [31,32]. Finally, usability and acceptability outcomes, such as satisfaction, adherence, and technological barriers, were reported in a subset of sources [39,47].

Many records reported positive effects across multiple outcome domains. Cognitive improvements were observed in several studies, including enhanced processing speed and attention [45], global cognition [37], and memory performance [28]. However, these effects were not consistent across all studies, with some reporting no significant cognitive gains [38]. Variability in intervention type, duration, and assessment tools likely contributed to these mixed findings.

Psychological benefits included reductions in depression and anxiety [28,40], as well as improvements in emotional well-being. Physical outcomes also improved in several trials, including enhanced sleep quality [29], decreased breathlessness [38], and increased physical activity [32]. Additionally, quality of life and self-efficacy improved, particularly in studies integrating behavioral support and health education [19,28].

Nonetheless, effects were not universally sustained, and several studies reported limited or nonsignificant changes in certain domains, such as sustained attention or long-term mental health outcomes.

Methodological Limitations and Knowledge Gaps

The methodological quality and design heterogeneity of the included studies present important considerations for interpreting the findings of this review. Although several randomized controlled trials [28,29,45] contributed robust evidence, a substantial proportion of the literature consisted of pilot studies, observational designs, or study protocols without reported outcomes [30,34,48]. This variability limits the overall strength of conclusions and underscores the early, exploratory nature of research in this domain.

Sample sizes were frequently small, particularly in feasibility or case studies [44,46], reducing statistical power and generalizability. Several studies lacked control groups or used nonrandomized designs, making it difficult to establish causal relationships between interventions and outcomes. Blinding—both of participants and researchers—was often absent or not reported, introducing a potential risk of bias.

Additionally, many studies relied heavily on self-reported outcome measures to assess cognitive and psychological symptoms. Although these tools provide valuable patient-centered data, they are subject to recall bias and may not accurately reflect clinical change. The use of diverse instruments across studies also complicates cross-study comparisons. Furthermore, follow-up periods were generally short, limiting insights into the sustainability of treatment effects over time. Overall, although early findings are promising, methodological constraints suggest that current evidence should be interpreted cautiously.

Despite growing interest in digital health interventions for long COVID, important gaps remain that hinder the development of standardized, scalable treatment approaches. One key limitation is the lack of long-term follow-up data. Most studies evaluated outcomes immediately after the intervention or within a few weeks, leaving unanswered questions about the durability of effects, relapse rates, and maintenance strategies.

Intervention protocols were highly heterogeneous in terms of content, delivery mode, duration, and intensity, making it difficult to identify the most effective components or to compare results across studies. The absence of standardized outcome measures further complicates synthesis and meta-analysis efforts. Moreover, although digital interventions are often assumed to be widely accessible, few studies addressed issues related to digital literacy, internet access, or usability challenges—factors particularly relevant for older adults and underserved populations.

Certain groups, including older adults, individuals with severe or complex post–COVID-19 symptoms, and those from lower socioeconomic backgrounds, were underrepresented in most samples. Cultural and gender-specific factors affecting the acceptability and efficacy of interventions were also largely unexplored. Finally, few records examined the mechanisms through which digital interventions exert their effects, leaving open important questions about how improvements in cognitive or emotional functioning are achieved and whether they translate into functional recovery.

Collectively, these gaps highlight the need for well-designed, adequately powered trials with longer follow-up, consistent outcome measures, and inclusive recruitment strategies. Future research should also explore how to personalize digital interventions and integrate them sustainably into health systems to meet the needs of diverse populations affected by long COVID.

Discussion

Principal Findings

This scoping review synthesized the current landscape of digital interventions targeting cognitive and psychological symptoms in individuals with long COVID. The findings reflect a field in active development, with diverse intervention types, from telehealth to VR, showing potential benefits across cognitive, emotional, and functional domains [6,49]. Although symptoms such as *brain fog*, memory deficits, fatigue, and anxiety were consistently addressed, intervention efficacy varied widely,

XSL•FO
RenderX

underscoring the need for more tailored, evidence-based approaches.

A notable strength of this emerging field is the international scope of research, encompassing studies conducted across Europe, North America, and Asia. Despite differences in study design and health care infrastructure, there was considerable consistency in the reported symptom burden among participants. Cognitive dysfunction and psychological distress, such as anxiety, depression, and fatigue, were prevalent across cohorts. These findings are consistent with prior research that has identified neurological and psychiatric effects as central and disabling features of long COVID [50,51].

Digital interventions were diverse in format, encompassing telehealth platforms, mobile apps, VR, digital cognitive therapies, and online behavioral support programs. Interventions often addressed multiple domains simultaneously, incorporating physical, psychological, and cognitive components. This multimodal approach aligns well with the multisystemic nature of long COVID and reflects a growing emphasis on integrative, patient-centered care [52]. For example, programs like those described by León-Herrera et al [28] and Smith et al [32] combined exercise, cognitive rehabilitation, and education, yielding improvements in quality of life and mental health outcomes.

Despite these promising findings, the effectiveness of digital interventions was not uniform. Although several studies reported improvements in processing speed, attention, emotional well-being, physical activity, and sleep quality, other outcomes—such as sustained attention and long-term psychological recovery—showed inconsistent or nonsignificant effects. These mixed results may reflect the variability in intervention type and intensity, as well as individual differences in symptomatology, baseline functioning, and engagement levels. Previous research has consistently highlighted the heterogeneous nature of long COVID symptoms, with some individuals experiencing more persistent and debilitating effects than others. This variability in symptom severity, along with differences in how patients engage with interventions, may explain the inconsistencies observed across studies. Moreover, the complexity of long COVID, involving multiple systems of the body, suggests that a one-size-fits-all approach to digital interventions may not be equally effective for everyone [53].

The methodological quality of the included records varied widely. Although this scoping review did not conduct a formal risk of bias assessment, a substantial number of included studies used nonrandomized or uncontrolled designs, limiting the strength of causal inferences and contributing to heterogeneity in findings. Although randomized controlled trials provided valuable insights (eg, Victoria et al [45], León-Herrera et al [28], and Lai et al [29]), many studies were limited by small sample sizes, lack of control groups, or reliance on self-reported measures. In particular, the short follow-up periods commonly used across studies limited the ability to assess the durability of observed improvements. Furthermore, the reliance on subjective outcome measures, often without objective neurocognitive or physiological assessments, raises concerns about measurement reliability and the potential for response bias.

In terms of equity and access, several important gaps remain. Many interventions assumed a basic level of digital literacy and reliable access to internet-enabled devices—assumptions that may not hold true for older adults, people with disabilities, or those in socioeconomically disadvantaged settings [54,55]. Notably, long COVID and digital access disparities often intersect with age, socioeconomic status, and geography, especially as digital interventions are intended to bridge, rather than widen, these gaps. Few studies systematically addressed these barriers, and older adults were often underrepresented despite being disproportionately affected by both COVID-19 and digital exclusion. Studies have shown that older adults, individuals from low-income households, and those in rural areas are significantly less likely to have consistent access to internet-enabled devices or the digital literacy needed to engage with these tools. Designing low-bandwidth applications, providing user training, and incorporating hybrid support models may help mitigate these disparities and expand reach [56,57].

Importantly, the mechanisms through which digital interventions exert their effects remain poorly understood. Whether improvements in cognitive or emotional domains result from specific therapeutic content, increased social engagement, improved physical fitness, or a combination of these factors is still unclear. Recent investigations have begun exploring these mechanisms, although definitive conclusions remain elusive [58,59]. Understanding these mechanisms will be essential for refining and targeting future interventions.

Overall, this review reveals a rapidly developing but still nascent field. To build a more robust evidence base, future research should prioritize high-quality randomized trials with adequate sample sizes, long-term follow-up, and standardized outcome measures [60,61]. Equally important is the inclusion of diverse populations and the evaluation of implementation factors such as usability, adherence, and cost-effectiveness. Addressing these gaps will be essential to integrate digital health solutions into routine care pathways and to ensure that they are accessible and effective for all individuals affected by long COVID.

Strengths and Limitations

This scoping review offers a comprehensive and up-to-date synthesis of digital interventions aimed at addressing long COVID, encompassing a wide range of technological approaches and international contexts. A major strength is the breadth of included study designs, which enables the mapping of both experimental and exploratory initiatives, as well as emerging clinical protocols. By including various forms of digital care—such as telehealth, mobile apps, VR, and neuromodulation—this review captures the evolving landscape of post–COVID-19 rehabilitation and highlights the multidisciplinary nature of digital health innovation.

However, several limitations must be acknowledged. First, the heterogeneity of study designs, populations, and outcome measures limited the ability to perform direct comparisons or draw definitive conclusions about intervention efficacy. Second, as with many scoping reviews, the aim was to map available

XSL•FO
RenderX

evidence rather than evaluate quality in depth; thus, a formal risk of bias assessment was not conducted. Finally, the inclusion of ongoing trials and study protocols, while useful for identifying research trends, means that many findings are preliminary and not yet peer-reviewed.

Clinical and Policy Implications

Physicians and health care systems may consider testing scalable, low-cost digital solutions such as online CBT, symptom tracking apps, or telerehabilitation platforms as complements to conventional care. To ensure successful implementation, it is essential to provide patients with support for uptake, address barriers to access, and align digital interventions with existing service delivery pathways. Integrating these tools can expand the reach of health care and maintain its continuity, especially in underserved populations.

Future Directions

Future research should build on these early insights by prioritizing well-powered randomized controlled trials that include diverse, representative populations and longer follow-up periods to assess the sustainability of intervention effects. There is a clear need for standardized outcome measures that capture the multidimensional nature of long COVID, including validated tools for cognitive, emotional, and physical health, as well as functional status and quality of life. Research should also explore adaptive and personalized digital interventions that can respond to individual symptom profiles and levels of digital literacy.

In addition, future research should consider mixed methods approaches, as qualitative studies can provide insights into patient experiences and inform the design of well-powered randomized controlled trials. Conversely, trends and patterns observed in large trials can guide research exploring the lived experiences of underrepresented or marginalized populations, including older adults, individuals living in rural or remote areas, and people with disabilities.

Moreover, implementation science approaches are needed to evaluate how digital interventions can be integrated into real-world health care systems, addressing barriers such as technological access, health care professional training, and user engagement. Cost-effectiveness analyses and health equity assessments will be crucial to ensure that digital solutions do not widen existing disparities. Finally, investigating the mechanisms of action—such as whether improvements stem from behavioral change, neuroplasticity, or social support—can help refine digital treatment strategies and optimize outcomes for individuals living with long COVID.

Conclusions

This scoping review highlights the growing use of digital interventions—such as telehealth, mobile apps, VR, and online therapies—for managing cognitive and psychological symptoms in individuals with long COVID. Although early evidence suggests potential benefits across domains such as mood, attention, and quality of life, findings remain heterogeneous, and sustained improvements are inconsistently reported.

Current evidence is limited by methodological weaknesses, small sample sizes, and short follow-up periods. Additionally, there is a lack of standardized outcome measures and insufficient representation of older and underserved populations.

Future research should prioritize well-powered, methodologically rigorous trials that examine long-term effects, address equity and accessibility challenges, and explore how digital tools can be sustainably integrated into health systems. Personalized, multicomponent digital approaches may offer the most promise for supporting recovery in this complex and heterogeneous condition.

Abstract

Background: Children's eating habits are formed at an early age, making childhood a crucial period for introducing novel foods, such as pulse-based food products. Pulse Discovery Toolkit (PDTK) intervention was designed to increase familiarity with pulses and to eventually contribute to the consumption of pulse-based foods among preschool children in childcare centers (CCs).

Objective: To determine PDTK's impact on knowledge, acceptability, and consumption of pulse-based foods among preschool children attending CCs, and to assess its feasibility and acceptability by early childhood educators (ECE) and cooks. The nutrient contents and food group servings of pulse-based intervention recipes in the PDTK were also compared with regular CC recipes.

Method: The PDTK intervention was delivered over a 3-month period in 2 CCs in Saskatoon (50 children, 8 staff). The intervention, which integrated taste exposure and nutrition education, consisted of 12 child-friendly weekly lessons, a food service guide for cooks, 15 recipes for pulse-based foods, 4 intervention recipes incorporated in the CC menu, and 4 parent newsletters. Mixed methods were used with pre- and postintervention knowledge tests, plate waste measurement, sensory evaluation, ECE and cook's perspective, and nutrient content comparison of the intervention and control foods from the regular childcare menu to evaluate the intervention's impact.

Result: Improvements in correct identification of chickpeas (2/21 [10%] at preintervention to 7/21 [33%] at postintervention, *P*=.074), beans (8/21 [38%] to 11/21 [52%], *P*=.68), and peas (6/21 [27%] to 8/21 [38%], *P*=.61) were not statistically significant. Children consumed higher amounts of the regular recipes (293.54, SD 27.65; 178.46, SD 24.33) than the intervention recipes (211.56, SD 25.61; 108.83, SD 21.97) at both times, respectively. However, at the end of the intervention, significant differences were only observed in the amount of total food consumption (*P*=.049) and the protein content (*P*=.04) when consumption proportion was examined, with both being higher for the control recipes in comparison to the intervention recipes. The majority (92% and 72%) of the children rated the refried bean wrap and lentil smoothie, "yummy," respectively. Most of the intervention recipes have lower energy, fat, and sodium content compared with the regular CC recipes. Findings from ECE semistructured interviews and the lesson plan evaluations revealed that the ECEs reacted favorably to the curriculum. The cooks from the participating CCs did not report any barriers to cooking pulses in their facility. However, the need for modification to make the recipes easier to cook in CCs was noted in our study.

Conclusions: With a few modifications to make some of the lessons more age-appropriate and some of the recipes easier to cook, it is feasible to implement the PDTK in CCs in order to promote regular consumption of pulses.

Introduction

Children's eating habits are formed at an early age, making the first 5 years of life a crucial period for introducing novel healthy foods. A growing body of evidence supports the need for repeated exposure to ensure liking and preference of novel foods [1-3]. Many researchers contend that childcare centers (CCs) are useful for the delivery of nutrition interventions as they provide continuous and intensive contact with children at an age when they develop life-long dietary preferences and eating patterns [4]. The fact that children often consume about 70% of their daily nutrient intake in this environment [5] and 52% of children younger than 6 years old attend CCs increases the significance of childcare institutions for nutrition intervention.

Sustainability, cost, nutrition, and health value make pulse-based foods (foods made with beans, chickpeas, peas, and lentils) a suitable dietary choice for establishing healthy eating habits among preschool children in CCs. Young children who consumed beans were found to have greater protein, fiber, potassium, and magnesium intake compared with those who did not [6]. Despite these benefits, the consumption of pulse-based foods is low in Canada [7]. Further, Canada is a global leader in pulse crop production. An increase in awareness through repeated exposure and skill in cooking pulses can potentially lead to liking of pulse-based dishes and more pulse-based dishes being offered in CCs [1,8], which can, in turn, lead to an increase in the consumption of these foods.

While much effort has been dedicated to improving fruit and vegetable intake in CCs [9-12], interventions promoting pulse-based dishes in CCs are scarce. Built on social cognitive theory and taking Piaget's cognitive development into consideration, the Pulse Discovery Toolkit (PDTK) intervention was developed to promote consumption of pulse-based foods in CCs [13]. The PDTK is designed to offer multiple opportunities for children to taste and learn about pulses either through lessons or through pulse-based snacks and lunches. This pilot study aimed to compare knowledge, willingness to taste, and consume pulse-based foods in preschool children in 2 CCs pre- and post-PDTK intervention. In addition, nutrient contents and food group servings of the pulse-based intervention recipes were compared with the regular CC recipes. The feasibility and acceptability of the intervention from early childhood educators' (ECE's) and cooks' perspectives were also assessed.

Method

Overview

A pre-post design pilot study with a community-based approach was carried out in 2 CCs in Saskatoon. ECEs, staff, and children in CCs were engaged in revising the PDTK before its rollout. A detailed description of the method is published by Haileslassie et al [13]; this study used a multimethod approach with both quantitative and qualitative data collection.

Ethical Consideration

Ethical approval was obtained from the University of Saskatchewan Behavioral Research Ethics Board, and a certificate of approval was issued (Beh # 15 - 388). Prior to data collection, consent and verbal assent were obtained from parents and children, respectively. As a pilot study designed to assess feasibility, 50 children were recruited from 2 CCs, a sample size consistent with recommendations in Teresi et al [14].

The Intervention and Study Population

The PDTK was developed using principles of intervention mapping, and it was delivered over the course of 3 months in 2 CCs in Saskatoon (50 children, 8 staff) in 2016. Both centers are located in the city and provide food prepared on-site by their cook. The children in these centers are offered a morning snack, lunch, and an afternoon snack. Prior to implementation, each of the 2 facilities received copies of the PDTK manual, and ECEs and cooks received training on using the manual and the overall objectives of the project. The PDTK manual consisted of 12 lesson plans, a food service guide, 15 recipes, and 4 parent newsletters. One of the participating CCs was English-speaking, and one was French-language only. The latter required the PDTK manual to be translated into French. Trained graduate nutrition students and ECEs participated in the delivery of the lessons.

Knowledge Assessment Questionnaire

Pre- and posttest assessment of the children's pulse knowledge was carried out at each intervention site. A pictorial data collection questionnaire was adapted and pretested for this purpose. A similar type of pictorial tool has been previously validated and used with children [15,16].

Plate Waste Assessment and Comparison of Nutrient Composition and Food Group Servings of Intervention and Control Recipes

The 12 weeks of the intervention were divided into 3 cycles: time-point 1 (the first 4-wk cycle), adjustment period, and time-point 2 (the last 4-wk cycle). Recipes that could possibly serve as a control for the intervention recipes were selected from the regular recipes offered in each CC (Table 1). The matching of the intervention recipes was based on their similarity to control menu items, likelihood of adaptability, and cooking time. In addition to the pulse-based foods prepared at CCs, commercially purchased products, such as puffs (extruded light and airy snacks), lentil pasta, and biscuits, were also evaluated by the children. The puff flavors were particularly developed in consultation with food science experts, educators, and children. These foods were incorporated to increase plant-based snack and meal options as opposed to the regular high-salt processed foods.

XSL•FO

Table . Intervention recipes and their corresponding controls in the participating childcare centers in Saskatoon.

Intervention recipes	Control recipes
Lentil pizza	• Mexican Pizza • Chicken Pizza
Chickpea spread	• Hummus • Cream Cheese
Stir fry chickpea, vegetables	• Stir Fry Vegetables with Beef • Kidney Beans, Beef, and Vegetables
Three bean quesadillas	• Chicken and Cheese Quesadillas • Tuna Wrap

Plate waste measurement of the intervention and the regular recipes was taken twice during the 12-week intervention. A digital photography-enhanced application validated in previous studies captured the weight of the foods before and after consumption [17]. Food Processor Nutritional Analysis Software (Esha version 10.10.00) was used to compute the energy, nutrient breakdown (protein, total fiber, fat, saturated fat, calcium, potassium, sodium, and iron), and food group servings (meat and alternative, milk, grain, vegetable, and fruit) in order to compare the nutrient composition and food group servings of intervention and control recipes.

Sensory Evaluation

Three types of sensory evaluation were carried out to assess the acceptability of the pulse-based intervention recipes. First, sensory evaluation was carried out as part of the lesson on 3 occasions. The children were asked to taste and report their liking using a 3-point facial hedonic scale with the options of "Yummy," "Yucky," and "Ok" [18]. Second, sensory evaluation of selected recipes was conducted at 2 time points to compare the degree of liking after exposure. The first was closer to the beginning of the intervention, and the second was taken at the end after several exposures to pulse-based dishes. Third, preference tasting was carried out by presenting 2 pulse-based foods at the same time and requesting the children to indicate which of the two they like the most. This was particularly used for tasting spreads, and participants were offered a choice of trying it with and without accompanying vegetables. Further details are available in the protocol by Haileslassie et al [13].

Qualitative Data Collection: Lesson Plan Evaluation, ECE, and Cook Interviews

Weekly lesson plan evaluation using questions adapted from Sharma et al [9] was carried out at the end of each lesson. One-on-one semistructured interview guides were used to gather information from cooks and ECEs. A semistructured postintervention interview adapted from Sharma et al [19] was used to further explore the acceptability and feasibility of the PDTK educational resource by the ECEs. The cooks' interview focused on the perceived benefits and barriers of cooking pulses and the feasibility of cooking the recipes included in the PDTK. Interviews were recorded, transcribed, and analyzed into themes [20]. The participants were given a chance to review their transcripts to validate their views or opinions.

Data Analysis and Quality Control

To ensure a standardized procedure was followed for data collection, research assistants were trained on administering the pre-post questionnaire, conducting sensory evaluation, and plate waste measurement. Furthermore, each assistant was trained on how to instruct and prepare the participating children for sensory evaluation. A one-day training session, along with practice in a pretest CCs using data not included in the final analysis, was conducted to ensure that research assistants fully understood the data collection protocols and were proficient in applying them.

Quantitative data were analyzed using SPSS (version 24; IBM Corp; Armonk, NY, USA) and SAS (version 9.4; SAS Institute Inc. Cary, NC, USA). Results were considered statistically significant if a P value <.05 was obtained. SPSS was used to generate descriptive statistics and for paired comparisons. Each item on the Knowledge Assessment Questionnaire was scored as a binary categorical variable (1=correct identification; 0=incorrect identification). For each pulse item, we calculated the proportion of children answering correctly at pre- and postintervention. Chi-square and McNemar tests were used for paired nominal data to compare the pre and post pulse knowledge scores. A paired sample t test was also conducted on spreads (green split pea vs red bean) to determine if there was any difference between sensory acceptance at the beginning and at the end of the intervention. SAS was used to generate t test and generalized estimating equation (GEE) model results for plate waste measurements. The GEE model was developed to analyze the relationship between control recipes and intervention recipes, along with the co-covariates age, sex, and center across the 2 time periods (baseline and endpoint) using aggregate data. The outcome variable was the amount of food consumed, and a fixed effect was selected. The independent variables included the type of recipe (intervention vs control), time (baseline and endpoint), and covariates (age, sex, and center). The GEE model analysis is a widely used statistical model for data collection for repeated measurements, as it allows analysis for missing and unbalanced data. Since the distribution of all responses (outcomes) is from the gamma distribution family, we were required to choose gamma distribution and "power (-1)" as link function for conducting "pro Genmod" in SAS. While the GEE model accounts for missing data, a sensitivity analysis was not conducted. Using aggregate data, an independent t test was performed to compare the mean

XSL•FO
RenderX

consumption and the mean consumption proportion of both the intervention and control recipes. Consumption proportion (proportion of food consumed to food served) was calculated for each intervention and control recipe using the formula provided below:

Consumption proportion = Proportion of food consumed / Proportion of food served

The qualitative data analysis followed thematic analysis, consistent with the coding reliability approach described by Braun and Clarke [21]. The validated transcripts from ECE and cook interviews were analyzed separately to reflect their distinct perspectives. In the first phase, transcripts were reviewed line by line to identify recurring ideas and patterns. In the second phase, initial codes were independently reviewed by a second researcher to verify consistency and refine theme development. In the third phase, emerging themes were discussed collaboratively to ensure coherence and resolve discrepancies through consensus. Relevant participant quotes were organized under final thematic categories to illustrate and support the findings. To enhance trustworthiness and rigor, the team used researcher triangulation, peer debriefing, and an audit process. Themes were refined iteratively to ensure they accurately represented the data.

Ethical Consideration

Ethical approval was obtained from the University of Saskatchewan Behavioral Research Ethics Board. Prior to data collection, consent and verbal assent were obtained from parents and children, respectively.

Result

Overview

A total of 50 children between the ages of 2 and 5 years from 2 CCs participated in the study. All ECEs (n=5) from both schools completed the lesson plan evaluation forms. In addition, the ECEs and cooks in each center participated in a postintervention interview.

Pre and PostIntervention Pulse Knowledge of Preschool Children

Pre and postintervention pulse knowledge of the preschool children is presented in Table 2. No statistically significant improvements in children's pulse knowledge from pre to postintervention across all items were noted, though the increase in correct identification of chickpeas approached significance (P=.07).

Table . Pre and postintervention pulse knowledge of preschool children in 2 childcare centers in Saskatoon (n=21). The number of children who have a complete set of pre-post knowledge assessment data in a McNemar's test.

Questions	Pretest, n (%)		Posttest, n (%)		*P* value
	Correct	Incorrect	Correct	Incorrect	
Distinguishing between lentils and beans	14 (67)	7 (33)	13 (62)	8 (38)	≥.99
Identification of chick-peas	2 (10)	19 (91)	7 (33)	14 (67)	.07
Identification of lentils	1 (5)	20 (95)	2 (10)	19 (90)	≥.99
Identification of beans	8 (38)	13 (62)	11 (52)	10 (48)	.68
Identification of peas	6 (27)	15 (71)	8 (38)	13 (62)	.61

Plate Waste Measurement of Pulse-Based Foods

The amount of food consumed from the intervention and the control recipes at time-point 1 and time-point 2 is described in Table 3. Significant differences in mean consumption between the control and intervention recipes were noted among most of the variables at both times, except for the fruit and vegetable servings, meat and alternative servings, and fiber content. The GEE Model analysis showed significantly lower mean consumptions in time-point 2 for all the variables of interest, except for the fruit and vegetable servings. The mean consumption proportion from the intervention and the control recipes at time-point 1 and time-point 2 is presented in Table 4. At time-point 1, no significant difference was observed in the mean consumption proportions of all the nutrients of interest between the intervention and control recipes, except for the higher saturated fat from the control recipes and the higher trans-fat from the intervention recipes. At time-point 2, significant differences were only observed between the mean consumption proportion of the quantity (P=.049) and the protein content (P=.04); both of which were higher among the control recipes in comparison to the intervention recipes. In terms of the consumption proportion, the GEE model revealed significant differences in the total quantity and most nutrients, except for the servings of fruit and vegetables, meat, whole grain, trans-fat, and sugar content.

Sensory Evaluation of Pulse-Based Foods

The results obtained from sensory evaluation of lentil pasta, refried bean wrap, lentil smoothie, and 2 types of extruded snacks (puffs) are presented in Table 5. Majority (92% and 72%) of the children rated the refried bean wrap and lentil smoothie “yummy,” respectively. Some children (9.4%, 17%, and 15%) refused to taste the lentil smoothie, red pepper and lime flavor puff, and white cheddar puff, respectively.

Comparison of the Nutrient Composition Between Intervention and Control Recipes

The nutrient composition of intervention and control recipes is provided in Table 6. The comparison revealed higher energy, lower fat, and lower sodium content in most of the intervention recipes.

Qualitative Findings: Educator and Cook Perspectives on the PDTK Intervention

The qualitative data are presented in three distinct sections: (1) open-ended lesson plan evaluations, (2) ECE interviews, and (3) cook interviews. These are presented separately to reflect the distinct data collection and analysis processes used for each group.

Lesson Plan Evaluations

ECEs rated the clarity of the instructions of most lessons as "good" on a 5-point scale that ranges from poor, fair, good, very good, to excellent. They indicated that most of the learning objectives were appropriate for this age group. However, ECEs also reported that some of the activities were difficult for the children in this age group to comprehend. One of the ECEs mentioned particularly in lesson 12 (mystery bucket).

> *I think it was difficult for children to identify food groups.*

The ECEs also noted children's reactions to the lessons and reported that most children were engaged in the PDTK activities. Examples of responses are as follows:

> *They had smiles on their faces as they were eager to answer the questions correctly to show what they already knew.* [Lesson 1- Healthy Eating]
>
> *They were engaged and enthusiastic and seemed to have fun.* [Lesson 2- Meet the pulses]
>
> *Dramatic play is one of the children's favorite games. They couldn't wait to have a turn being a server, customer or cook.* [Lesson 10- Let's Play Restaurant]
>
> *They loved it. They concentrated on their menus and had a lot of fun playing restaurant.* [Lesson 10 - Let's Play Restaurant]

Recommendations on improving the acceptability and feasibility of these lesson plans included breaking down the lesson plan activities into smaller components, as well as dividing the children into smaller groups to reduce wait times and the risk of loss of interest. The following quotes are responses related to the acceptability of PDTK activities for implementation in their CCs.

> *Yes, anything promoting active lifestyle is always acceptable.* [Lesson 9 Pulse Bowling]
>
> *Yes, having children be part of the meal preparation encourages healthy eating.* [Lesson 10 - Let's Make Our Own Food]
>
> *Yes, we can insert [the program] into the curriculum for the health of the Canadian children and to avoid obesity in children.* [Lesson 11- Let's play restaurant]

Educators' Perception of the PDTK

Key themes were collated from ECE responses about their PDTK experiences. The primary themes identified from the interviews were as follows: (1) feasibility and acceptability of the PDTK, (2) barriers to implementation, and (3) recommendations for the PDTK. Table 7 provides a snapshot of themes developed and examples of corresponding quotes from the educators' observations and experiences throughout the intervention.

XSL•FO
RenderX

Table . A snapshot of the themes and corresponding quotes identified from interviews.

Themes	Quotes
1.Feasibility and acceptability of the PDTK	• *Since you guys started, I found every day was a positive influence on the kids. I really enjoyed that you guys came and did these. We don't often have the opportunity to have something like this to encourage healthy eating. We do it on our own and make up our own. So, to have someone come in that already has something set up and in place was awesome, because I love encouraging kids to eat healthy food.* [ECE # 1] • *For this place, the people are not moving too much and the kids are not moving too much. It is not like, I came from [name of country] and the kids they can walk and we don't have a problem with winter. They stay at home and they are not moving. Sometimes I see what there are eating too much is giving them obesity. But, when you have food that control it. Like your program it will help them to stay healthy. It will help them. I would like to put it that way. If I had my own center, like this I would put in my own program as quickly.* [ECE #2] • *I think we can try some activities. So, for example, we made taco with beans and I think it is a good curriculum for children. Because, the activities included sensory activities. So we could taste it, smell it and feel. All sensory were included in these activities. Also, children they are interested in making food and touching something. So, we can do them next time.* [ECE #3] • *They were engaged because sometimes they would ask normally when you people are coming…even the kids would ask, what they are going to give us to eat today. They will ask like that or maybe they will ask … (the cook)…. what are you going to cook for us today? Beans and what, they need to know.* [ECE #3]
2.Barriers to implementation	• *Not, that I didn't enjoy that is not the word. I think some activities were very, not difficult but were not really appropriate for their age, is appropriate the word? (Yea). They were very young for the kind of activities. It wasn't really for them. It wasn't really helpful.* [ECE #1] • *don't think it's important to know about food groups and guide. We don't need for children. We just can explain that milk is for teeth and meat is for our health and just explain simply and they can accept. If we added some information it it's for first group and some food include in the first group….. They are just 2 and half years old, it's difficult for them.* [ECE #2] • *Actually, we didn't have time to do the activity. We have 20 children and plus we have two teachers with the 20 children. For me I think it was difficult to do these lessons. Because, before starting these activities we need to explain what we are going to do and what kind of things I do with some stuff. But, actually, sometimes when I was alone with many children it was so difficult.* [ECE #3]
3. Recommendation for the PDTK	• *What I enjoyed was when they had to see the different kind of peas, the different colors and when we had to do the smoothies. Because they have to count, measure and they have to taste, they have to touch. It was really physical; you know sensory for them and when they have to grow all the seeds.* [ECE #4] • *We need more big charts, big pictures, not just the small paper to show exactly what it actually is. Also, we need, more time to explain what it is. So, I prefer, one day we can do about the first food group and the next day the second group ….…..…* [ECE #5]

Recommendations for Enhancing the PDTK Resource

The educators had several suggestions for strengthening the sustainability of the PDTK resource. These include (1) more training for ECE; (2) separate group lesson plan activities according to specific age groups; (3) introduction of concepts one at a time, thus breaking the lesson plan into smaller components; (4) large demonstration charts to increase the level of engagement; and (5) constant repetition of the pulse-related concepts. It was also discussed that the educator's level of interest and level of experience were key to increasing buy-in within centers. Overall, educators perceived that the PDTK has significant potential in increasing acceptance of novel food at an early age. One of the ECE's stated,

XSL•FO
RenderX

> *It's awesome. It's exactly what Saskatchewan needs right now. More people are advocating and starting young.* [ECE # 2]

Cooks' Perceptions of the PDTK Recipes

The cooks in both CCs indicated they had prepared at least one pulse-based food every 2 weeks prior to the intervention. Neither cook saw any barrier to cooking pulses in their facility. When asked about opportunities for including more pulse-based food products, they indicated that having them on their menus and keeping cooked pulses in the freezer would increase their use in regular dishes. They indicated that it is feasible to include recipes from the PDTK resource in their menus. One of the cooks mentioned that the nutrition intervention provided more opportunities and experience in cooking new pulse recipes. They reported that most of the recipes are easy to follow and to shop for, and the food tastes good. One of the cooks indicated that she liked the lentil pizza as the children enjoyed it, and it was good for the children's health. She further mentioned that this dish can be added to their menu. The 3-bean quesadilla recipe was the favorite of one of the cooks. She said it was fun to make, whereas the other cook said that, while it was a good recipe, it was hard to cook. They both believed that the children were receptive to the recipes that they tried. Overall, they both said that they liked all the recipes, with some needing modifications.

Discussion

Principal Findings

This study presents findings from Phase 2 of a 3-phase project evaluating PDTK, a 12-week multicomponent nutrition intervention designed to promote consumption of pulse-based foods among preschool children in CCs. As outlined in the protocol [13], Phase 2 was conducted as a pilot study with a primary focus on assessing implementation processes and determining whether the intervention could be delivered as intended within real-world childcare settings. Accordingly, feasibility was operationalized through process-oriented outcomes, including cooks' and educators' perceptions of PDTK recipes, lesson plan evaluations, and recipe tasting activities, with particular emphasis on the practicality of recipe preparation and alignment with existing curricula. The impact of the intervention on knowledge, acceptability, and consumption of pulse-based foods was assessed. Feasibility and acceptability of the PDTK intervention for implementation in CCs were captured through lesson plan evaluations and interviews with ECEs and cooks.

To our knowledge, no recent studies have specifically examined pulse consumption in childcare settings for this age group in Canada. While the data for our study were collected a few years ago, it remains pertinent given the lack of significant interventions or policy changes that could have altered pulse consumption trends. The only notable changes are the release of the new Canada's Food Guide in 2019 and the increased promotion of plant-based diets. Evidence from a study by Hank et al [22] explored the potential impact of the 2019 Canada's Food Guide on the eating environments and food provided in early learning and CCs across Canada. This study found that representatives from CCs faced challenges in interpreting and implementing the new guidelines. As a result, no significant changes to children's dietary patterns in these settings were observed. This suggests that, despite the shift in dietary recommendations, pulse consumption in childcare environments has likely remained stable. While isolated case studies of transitions toward plant-based menus [23] have been reported in Canadian CCs, these appear to be the exception rather than the norm. Recent studies in Canada further reinforce the importance of childcare-based interventions in shaping children's dietary behaviors and daily nutrient intake [24,25].

Although some improvement was noted in the percentage of preschool children who correctly identified pulses in this study, the improvement was not noted for all pulses. This could be partly explained by the longer duration of some lessons, preschoolers' short attention span, and the small sample size. These findings contradict similar studies that introduced other food items, such as fruits and vegetables, to preschoolers [26,27]. Many of these studies indicated a significant increase in knowledge of fruit and vegetables between the pre and posttests. The differences in the findings between this pulse intervention and the fruit and vegetable interventions could be attributed to the familiarity of households with fruit and vegetables or the novelty of exposing young children to pulses.

A significantly greater amount of the regular recipes was consumed at time-point 1 than the intervention recipes; however, this difference was not seen when the consumption proportion was considered. Unlike the finding at time-point 1, the children consumed a higher quantity of the regular recipes than the intervention recipe at time-point 2, even when the consumption proportion was considered. These results contradict findings of increased consumption of lentils after repeated exposure [1]. In contrast to our study, the children in Ramsay et al [1] study were exposed to lentils 1 to 2 times per week for a total of 13 weeks. Though the children in our study were exposed to different pulse-based foods at least twice a week, the same dish was only offered every 3 weeks. In addition, Ramsay et al [1] let the children taste unseasoned lentils, while our study exposed children to a variety of pulse-based foods. These findings highlight the possibility of higher effectiveness of repeatedly exposing to one specific pulse-based dish at a time than exposure to a series of pulse-based dishes to increase intake and acceptability of pulses among young children. In addition, the pulse-based dishes introduced in this study were mixed dishes, unlike most of the studies [28,29] that reported a significant increase in acceptability and intake after repeated exposure to food. The use of mixed dishes in PDTK may have limited the positive impact of the repeated exposure on the intake and acceptability of the pulse-based dishes in our study.

The comparison between the intervention and regular recipes, which revealed lower total kilocalories and fat content in most of the intervention dishes, is not surprising given the low energy, fat, and sodium contents of pulses [30-32]. In addition, most of the regular recipes selected for comparison contain animal source foods, which could contribute to the higher fat and energy content of the regular recipes.

XSL•FO
RenderX

Unsurprisingly, some children were not willing to taste the pulse-based dishes offered to them during the sensory evaluation activities. Similar reactions have been reported before, where novel food products served to children were rejected, a phenomenon described as neophobia, which refers to the fear or avoidance of new or unfamiliar foods [33]. The children in our study were at the peak age of neophobia [34]. Food reluctance has been reported as a key challenge to offering plant-based meals in Canadian CCs [22], and food neophobia remains a well-documented barrier in early childhood nutrition, as highlighted in a recent multicountry systematic review demonstrating that neophobia contributes to children's reluctance to try unfamiliar foods and limits dietary variety [35]. The recipes with the highest rating of "Yummy," refried bean wrap and lentil smoothie, were interestingly recipes that children took part in preparing as part of the lesson activities. Similarly, though the study population was older children (5 - 7 y-old) and the finding could not solely be linked to their participation in the preparation, children rated foods they prepared "more yummy" than foods served to them [36].

Findings from ECE semistructured interviews and the lesson plan evaluations revealed that the ECEs reacted favorably to the curriculum, especially to lesson plan activities that had both sensory and hands-on components. The ECEs stated that the children particularly enjoyed preparing the snacks, role-playing, and gardening, and were highly engaged when performing these activities. The educators in this study also discussed a few factors that could potentially act as barriers to the feasibility and acceptability of the nutrition curriculum. Key barriers identified were the length of time to complete each activity and the suitability of some of the activities to meet the children's cognitive level. These findings are similar to a pilot study conducted by Sharma et al [9], a healthy nutrition and a physical activity program in 2 CCs.

In our study, the cooks from the participating CCs did not report any barriers to cooking pulses in their facility, contrary to a previous study that examined the barriers and opportunities to serving pulses in school meals, which includes time for cooking dry beans [37]. In our study, the PDTK recipes use canned pulses or dry lentils, which do not take as long as dry beans to cook. However, the need for modification to make the recipes easier to cook in childcare settings was noted in our study.

To better suit different developmental stages of preschool children, the intervention's lesson plans could be adapted by varying the complexity of activities based on cognitive and motor skills. For instance, in Lesson One, "Naming Pulses," the lesson could be tailored as follows: For younger preschoolers (ages 3 - 4 years), the lesson plan can focus on sensory exploration, where children touch and sort different pulses (eg, beans, lentils, peas) by size or color, enhancing their fine motor skills and hand-eye coordination. Teachers can also encourage language development by labeling the pulses and asking children to repeat their names, introducing basic vocabulary. For older preschoolers (ages 4 - 5 years), the activity can include problem-solving tasks such as sorting pulses by categories or counting them, along with more precise motor tasks like transferring pulses using scoops, while also fostering cognitive skills through matching games. Though our study looked at specific pulse-based dishes, we can speculate that including a wider variety of pulse-based recipes in the intervention could increase its appeal and effectiveness for children by offering more fun, diverse, and flavorful options that cater to different tastes and preferences, making the learning experience more engaging. The results were instrumental in guiding the subsequent roll-out of the intervention in phase 3 in 4 CCs. Revisions include lesson plan modifications to better align with developmental stages and age-appropriate learning, and simplified activities for younger children to emphasize sensory exploration and basic identification tasks, rather than more complex components that require higher levels of cognitive processing. These findings informed practical adjustments to the intervention design, recipe selection, and PDTK lesson plans. The lessons learned were also used to expand the program to elementary school [38]. The growing interest in plant-based dietary patterns for both health and environmental sustainability further underscores the continued relevance of interventions such as the PDTK. The growing interest in plant-based dietary patterns for both health and environmental sustainability further underscores the continued relevance of interventions such as the PDTK, particularly in light of Canadian evidence demonstrating both the feasibility of plant-based menu implementation in childcare settings and the significant role these environments play in shaping children's dietary behaviors [24,25].

Limitations

First, due to the convenience sampling technique used and the small sample size, the generalization of the findings is limited. Second, the 2 CCs have different meal practices; in one of the centers, children are encouraged to portion their own food, whereas in the other center, food is served prior to mealtime. Additionally, children not attending all sessions during data collection or when lessons are offered may have reduced the impact of the PDTK intervention. Lack of control groups limited the study's ability to draw strong causal inferences, and future studies with a control group will better isolate the intervention's effects by comparing recipients to nonrecipients. The inclusion of cooks was limited to those working at the center, which resulted in a smaller sample size.

Conclusions

The PDTK intervention resulted in an increase in the percentage of preschool children who correctly identified pulses, but not their intake of pulse-based foods. The findings from the pilot testing also revealed that modifications are necessary to make some of the lessons more age-appropriate. Cooks found most of the PDTK pulse-based recipes to be acceptable and were willing to include them in the centers' menus while noting that some need adjustments to make them easier for batch cooking. Further research may be necessary to determine what effects a modified PDTK intervention will have on preschool children's pulse knowledge, acceptability, and intake of the intervention pulse-based foods. In addition, a follow-up assessment can determine if behavioral changes are sustained, the durability of the intervention's effects, and whether further support is needed for long-term sustainability.

Abstract

Background: The use of dietary supplements (DSs) can lead to an excessive intake of certain nutrients, posing potential health risks. However, studies are scarce on whether DS users adhere to recommended doses provided by the manufacturer and what factors are associated with overconsumption of DS.

Objective: By leveraging purchase history data to estimate DS use precisely, this study aimed to investigate the factors associated with DS consumption exceeding manufacturer-recommended doses and examine the prevalence of excess nutrient intake among DS users.

Methods: An online survey was conducted from November to December 2024 among 2002 adults (aged 18 - 74 years) with a history of buying one of the 25 major DS products and who had used it in the previous month or regularly. Self-reported daily DS consumption was assessed using a questionnaire and compared to the manufacturer-recommended doses indicated in the package. Using multivariate logistic regression analysis, the associations between DS consumption exceeding the manufacturer-recommended doses and sociodemographic factors were examined.

Results: The prevalence of DS users exceeding tolerable upper intake levels (ULs), defined according to the Dietary Reference Intakes for Japanese, was calculated based on vitamin and mineral intake from DS only. Consequently, 371 (18.5%) of the 2002 participants consumed DS above the manufacturer-recommended dose. Consumption of DS above the recommended dose was associated with middle-aged, part-time or full-time employment, use of tablet-form DS, especially single water-soluble vitamin tablets, use of DS for 6 months or more, and intentional consumption above the recommended dose. For 1705 individuals consuming DS with UL nutrients, 17.4% (n=297) exceeded the manufacturer-recommended dose. Of these, 61.9% (184/297) surpassed UL by ≥1 nutrient.

Conclusions: Middle-aged, part-time or full-time jobs, using tablet-form DS, and using DS for 6 months or more were associated with DS consumption exceeding the manufacturer-recommended dose, which may lead to excessive nutrient intake.

KEYWORDS

dietary supplement; Japanese; risk factors; nutrients; dietary reference intake

Introduction

Over the last few decades, the use of dietary supplements (DSs) has been increasing in many countries [1-4]. For example, the proportion of DS users in the United States increased from 51.8% in 2011 - 2012 to 61.4% in 2021 - 2023 [3], while in Australia, it increased from 28.5% in 2011 - 2012 to 33.6% in 2023 [4]. Although DSs are widely used to promote health and prevent nutrient deficiencies, concerns have emerged regarding their safety due to DS overuse and the risk of excessive nutrient intake [5,6]. Since primary sources of vitamins and minerals are a normal diet [7], having nutrients from DS in addition to diet might increase the risk of exceeding the tolerable upper intake level (UL). Excessive nutrient intake could bring adverse health effects such as liver dysfunction by vitamin A and hypercalcemia by vitamin D and calcium [8]. Therefore, understanding the behaviors and factors that contribute to DS overuse and excessive nutrient intake is a pressing public health issue.

Previous studies have investigated the prevalence [6,7,9-15] and risk factors [16] of exceeding the ULs when considering DS consumption. For instance, approximately 10% of DS users surpass the UL for iron or zinc, and <5% exceed the UL for calcium or magnesium among adults in the United States [9].

XSL•FO
RenderX

In Ireland, the risk of excess was most notable for iron and vitamin B_6 among women taking DS [12]. Although high-dose DS (ie, containing higher content of nutrients in one tablet or capsule) itself constitutes a risk for excessive nutrient intake [17], one possible cause of excessive nutrient intake among DS users is the overconsumption of DS products. In the United States and European countries, regulations mandate that DS product labels display the manufacturer-recommended dose (written as "serving size" or "recommended daily intake") to safeguard consumers [18,19]. However, studies on whether DS users adhere to manufacturer-recommended doses are scarce. For example, a 2012 survey by the Consumer Commission, Cabinet Office, Japan, reported that 2.4% of 8064 DS users consumed DS exceeding doses recommended by the manufacturer [20]. The prevalence of adherence to manufacturer-recommended doses may have been underestimated because the survey relied on self-reports to assess adherence to DS use, namely asking participants whether their consumption aligned with, below, or above the recommended dose.

Most previous studies [2-4,7,9-16], as well as the aforementioned Japanese survey [20], relied on self-reported data to collect information on the consumption of DS products and their use. This approach has several limitations. Participants may misreport or forget the details regarding DS use, making it challenging to identify the exact products used [21]. Furthermore, DS databases have rapidly become outdated because of the rapid turnover of products in the market [21]. These methodological weaknesses hinder the accurate estimation of DS consumption and compliance. To address these issues, purchase history data can be useful for precisely identifying DS products. Using purchase history data enables us to ask about the usage habits of specific products among participants without self-reporting the product names. This prevents the generation of data that is unanalyzed due to unknown product names. By leveraging purchase history data, this study aimed to address these gaps, with the following objectives: (1) to investigate the factors associated with DS consumption exceeding the manufacturer-recommended doses indicated on the product label or manufacturer website and (2) to examine the prevalence of nutrient intake exceeding the tolerable upper limits among DS users. This study provides a methodologically robust alternative to traditional self-reporting approaches. Since no previous study has investigated factors associated with overuse of DS, we analyzed, as a first step, variables related to sociodemographic and socioeconomic status and dietary supplement use habits.

Methods

Participants and Overview of Study Design

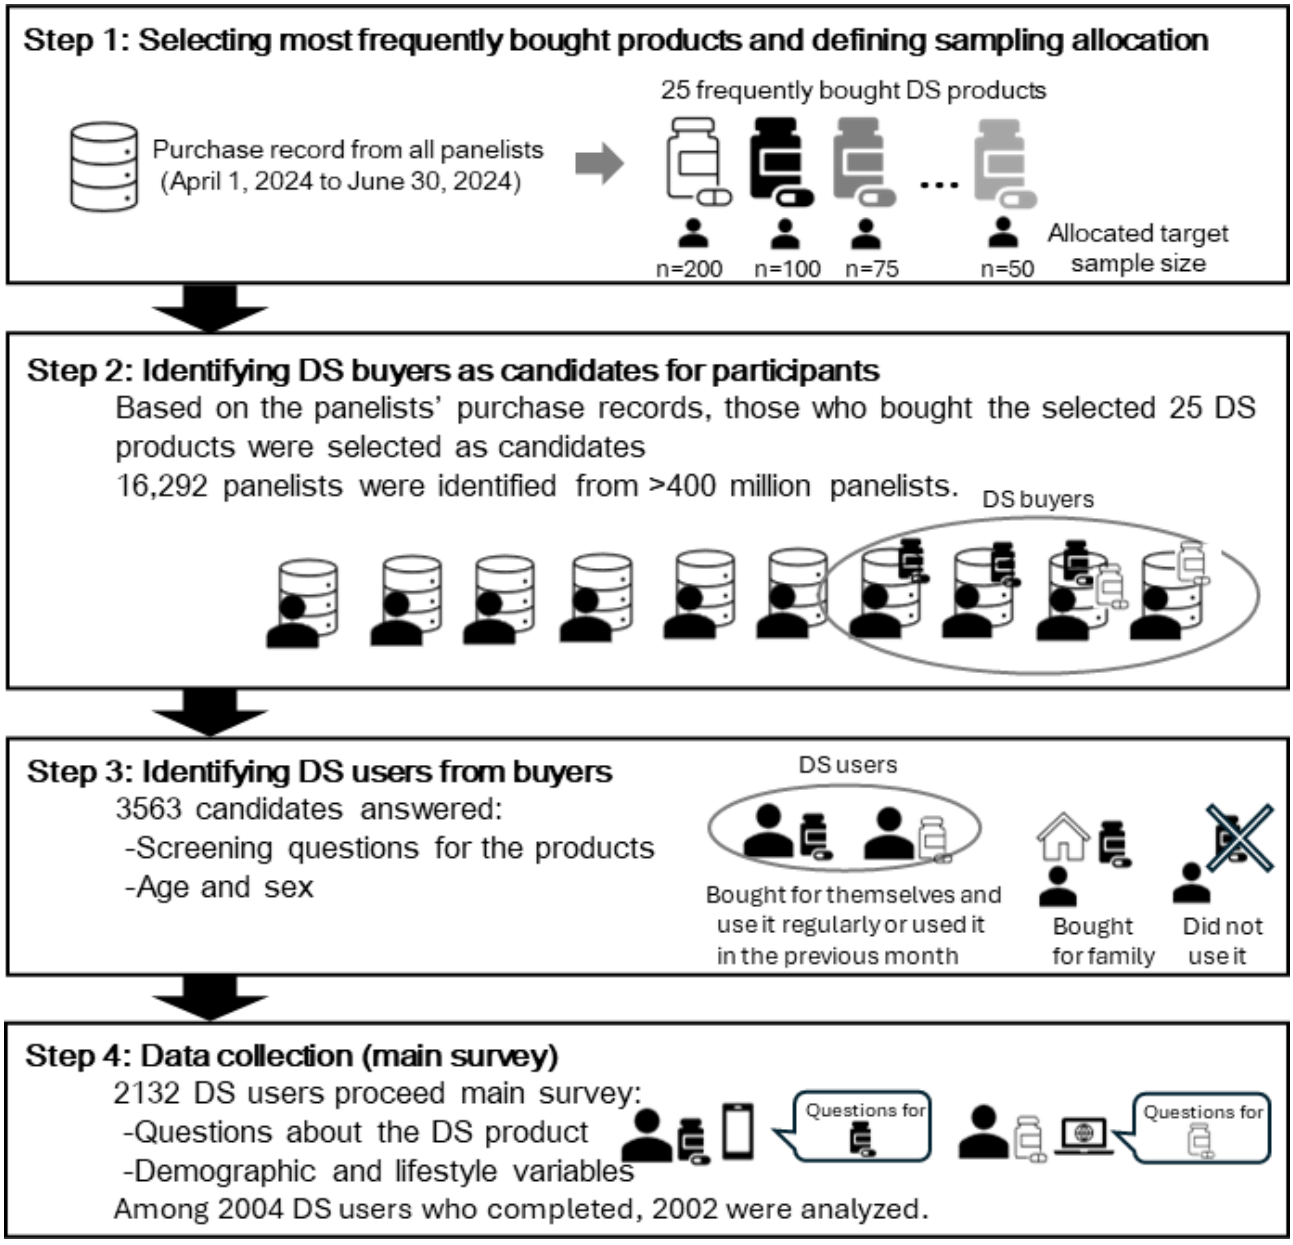
This cross-sectional study used data obtained through a web-based questionnaire survey. Data were collected between November 14 and December 1, 2024. This study was prepared according to the Checklist for Reporting Results of Internet e-Surveys (CHERRIES) [22]. The process of participant selection included identifying commonly used DS and subsequently selecting participants who reported using them. The survey procedure is detailed in the following sections. Target participants were Japanese adults (≥18 years) who consumed at least one DS product in the previous month. The target sample size was set at 2000 adults. This sample size allowed for reasonably precise estimates of the prevalence of nutrient intake exceeding the ULs, while also remaining feasible within financial constraints.

Survey participants were recruited from a registered consumer panel. The panelists routinely recorded their purchased products (such as food, daily necessities, and DSs) through a dedicated smartphone app. This consumer panel comprised primary shoppers in each household, with 70% being females and 75% being in their 20s to 40s. The panelists were distributed across Japan, closely reflecting the national population distribution.

Although the consumer panel was managed by Research and Innovation Co. Ltd., the data collection process (including participant invitation, survey distribution, and data management) was conducted using the research infrastructure of INTAGE Inc., a major market research company in Japan and the parent company of Research and Innovation Co. Ltd. This was because Research and Innovation Co. Ltd. did not have a system for asking users detailed questions, whereas INTAGE Inc. did.

Ethical Considerations

This study was approved by the ethics committee of the Toho University Faculty of Medicine (approval no. A24059; approved on October 7, 2024). Informed consent was obtained from all the participants on the website. To ensure privacy and confidentiality, the research team received only anonymized data from the survey company (INTAGE Inc.), and no personally identifiable information was accessible to the researchers. All data were handled in accordance with institutional ethical guidelines. The participants were compensated with standard incentives from Research and Innovation Co. Ltd, after completing the survey.



Survey Procedure

Overview

Data were collected in 4 steps (Figure 1). The first and second authors (MS and KA) prepared the questionnaires. Each participant reported information about one of the selected DS products.

XSL•FO
RenderX

Figure 1. Survey procedure. DS: dietary supplement.

Step 1: Selecting the Most Frequently Bought Products and Defining Sampling Allocation

Due to the lack of comprehensive and nationwide statistical data on the consumption of DS products, the most frequently purchased DS products are unknown. Thus, using purchase record data from all panelists for the past 3 months (April 1, 2024, to June 30, 2024), the second author (KA) identified the most frequently purchased DS products across the following 5 categories: liquid form supplements, multivitamin tablets, water-soluble vitamin tablets, fat-soluble vitamin tablets, and mineral tablets. The anticipated number of respondents was first allocated to each of the 5 categories to ensure accurate estimation of the prevalence of excessive intake. Considering the actual sales volumes, the anticipated number of respondents was allocated as follows: 300 for liquid-form DSs, 400 for multivitamin tablets, 600 for water-soluble vitamin tablets, 200 for fat-soluble vitamin tablets, and 500 for mineral tablets. To meet the target sample sizes, products were selected in descending order of sales volume within each category. The number of products selected in each category was as follows: 2 liquid-form DS, 6 multivitamin tablets, 6 water-soluble vitamin tablets, 7 fat-soluble vitamin tablets, and 4 mineral tablets, totaling 25 products. The names of the selected 25 DS products and the expected number of respondents for each product are presented in Table S1 in Multimedia Appendix 1.

Step 2: Identifying DS Buyers as Candidates for Participants

The buyers of the 25 DS products selected in step 1 were identified from over 4 million panelists by INTAGE Inc as candidates for participants. Panelists were selected as buyers of DS if they had at least one purchase history of ≥1 DS among 25 selected DS products in the past 3 months. To avoid duplicate responses from individuals, those with a record of purchasing 2 or more selected DS products were randomly assigned as potential respondents to one of the selected DS products. INTAGE Inc. operates a random allocation. Consequently,

XSL•FO
RenderX

16,292 panelists were identified as DS buyers (ie, candidates for participation).

Step 3: Identifying DS Users From Buyers (Screening)

INTAGE Inc. sent invitation emails to candidates. Participants completed the questionnaire via a survey platform provided by INTAGE Inc using their own smartphone, tablet, or PC. Through identity authentication, access to the questionnaire was restricted to the individual panelist surveyed. During the survey, the collected data were encrypted and stored in a database at INTAGE Inc. To screen DS users, the candidates were asked the following questions after a question about their sex and age:

- Question 1: We would like to ask you about the dietary supplement [product name] you have purchased in the past 3 months. Did you purchase this product for your use? (options: yes, for myself; no, for my family)
- Question 2: Do you still use this product regularly? (options: yes or no)
- Question 3: Have you taken this product in the last month? (options: yes or no)

Those who answered "yes" to question 1 and also responded "yes" to either or both questions 2 and 3 were identified as DS users. Among the 16,292 candidates, 3563 (21.9%) panelists answered the screening questions. After screening the questions, 1431 panelists were excluded, and 2132 (13.1%) of the 16,292 panelists were identified as DS users and proceeded to the main survey.

Step 4: Data Collection (Main Survey)

A total of 2132 participants were asked about the use of one of the 25 selected DS products. Among them, 106 participants did not complete the questionnaire, and 22 panelists were excluded because of unreliable data and an extremely short response time. Overall, 2004 participants completed the main survey at a completion rate of 94% (2004/2132). The main survey comprised 50 questions. The number of items per page was set to one to increase readability on the screen. Thus, the survey consisted of 50 screens in total.

Assessment of DS Use

The participants were asked to respond to a series of questions regarding one of the 25 DS products purchased. To simplify the survey procedure, we did not ask questions about the use of other products. To help participants accurately identify the product in question, the survey screen displayed an image of the product package for each set of questions and referred to a specific product name in the text. If the product package shows the manufacturer-recommended dose, this information was masked in the image provided.

To estimate DS consumption per day, they were first asked for their consumption at one time with the following question, with the appropriate unit of measurement (such as tablet or milliliter) automatically displayed depending on the product:

- We would like to ask you about the dietary supplement [product name] you have purchased in the past 3 months. Please answer the subsequent questions without looking at the product container or packaging. How much do you consume at one time? If you take it multiple times a day, please report the amount for a single intake, not the daily total.

The participants entered the quantity as an integer. Next, they were asked about their consumption frequency: "How frequently do you consume [product name]?" The frequency was selected from the following predefined 12 categories, from "more than six times per day" to "less than once per month," as shown below. The reference period (ie, consumption in the last month) was not specified in these questions because we had already asked the participants whether they had used the DS in the previous month and whether they had used it regularly in the screening.

DS consumption per day was calculated by multiplying the number of tablets or milliliters of liquid consumed at a time by the consumption frequency. The multiplied numbers according to the consumption frequency were as follows: more than six times per day=6, five times per day=5, four times per day=4, three times per day=3, two times per day=2, once per day=1, four to six times per week=5/7, two or three times per week=2.5/7, once per week=1/7, two or three times per month=2.5/30, once per month=1/30, and less than once per month=0.5/30.

Furthermore, the duration of use, checking the manufacturer-recommended dose before use, and self-perception of their DS consumption were asked via the following questions, respectively:

- For [product's name], how long have you been using it for? (options: <3 months, 3 months to <6 months, 6 months to <1 year, or ≥1 year)
- For [product's name], before you started using the product, did you check the manufacturer-recommended doses of the product? (options: yes or no)
- For [product name], compared to the manufacturer-recommended doses, your consumption is… (options: more, same, or less than the manufacturer-recommended doses, unsure, or no manufacturer-recommended doses provided)

The Manufacturer-Recommended Doses of Products

All 25 selected products indicated the manufacturer-recommended dose, although labeling of the manufacturer-recommended dose is not mandated for DS in Japan, with some exceptions [23]. Among the 25 selected products, 18 are labeled as "food with nutrient function claims (*Eiyo-Kino-Shokuhin* in Japanese)," which are required to display a manufacturer-recommended dose [24]. The other 2 products are approved as "designated quasi-drugs" by the Ministry of Health, Labour, and Welfare and are required to indicate the approved dosage and administration on the label [25]. They can be bought at a drugstore, grocery store, or convenience store without a prescription and are usually used as DS. The other 5 products were voluntarily shown the manufacturer-recommended doses. Table S1 in Multimedia Appendix 1 shows which products were labeled as "food with nutrient function claim," "designated quasi-drugs," or neither. The manufacturer's website was searched using the product's

XSL•FO
RenderX

name and package image. The names and package images used in the survey were provided to researchers by INTAGE Inc. When searching the manufacturers' websites, we ensured that the packaging images on the sites matched the packaging images of the products used in the survey. The manufacturer-recommended doses of each product were extracted from the website of the first author (MS). Although evaluating the appropriateness of the manufacturer-recommended doses was outside the scope of this study, no product exceeded the UL for any nutrient at the manufacturer-recommended doses.

Estimation of Nutrient Intake From DSs

Nutrient intake was calculated for the following 16 nutrients using the UL established in the Dietary Reference Intakes (DRIs) for Japanese 2025 [8]: vitamins A, D, E, B_6, niacin, folic acid, calcium, magnesium (for intakes derived from DS only), phosphorus, zinc, copper, manganese, iodine, selenium, chromium, and molybdenum. In Japanese DRIs, UL was defined based on "lowest observed adverse effect level" or "no observed adverse effect level" and uncertainty factor by the committee for DRIs composed of researchers regarding nutrition, medicine, and public health [8]. Nutrient intake from the DS was estimated by multiplying the daily DS consumption (number of tablets or mL) by the nutrient content of the products (per tablet or mL). The contents of these vitamins and minerals per tablet or milliliter in each product were obtained from the product's website. There were no products providing phosphorus content. Thus, intakes of 15 nutrients were calculated.

Assessment of Demographic and Lifestyle Variables

Sex and age were assessed during the screening. Other information regarding demographic and lifestyle factors was provided in the main survey. The sex at birth was selected as either male or female. Age, body weight, and body height were determined using numerical values and integers. When filling in their body weight and height, the participants were instructed to round to the nearest whole number. To prevent participants from discontinuing the survey due to their reluctance to disclose their body weight or height, these two items were not designated as mandatory responses. The following information was also collected by the questionnaire (categorization shown in parentheses): education level (junior high school, senior high school, 2-year college or technical professional school, university or higher, others, refusal to answer), employment status (unemployed, student, part-time job, full-time job), medical history (hypertension, stroke or cerebral hemorrhage, dyslipidemia, diabetes mellitus, hyperuricemia/gout, fracture or osteoporosis, liver disease, kidney disease, lung disease, heart disease, gastrointestinal disease, cancer, other, refusal to answer; multiple choice allowed); smoking status (never, past, current [<20 cigarettes per day], current [≥20 cigarettes]), drinking habit (not at all, hardly, sometimes, every day), pregnant (yes, no, refusal to answer), breastfeeding (yes, no, refusal to answer). In Japan, alcohol consumption and smoking are legally permitted from the age of 20. Therefore, following INTAGE Inc.'s policy, questions regarding drinking and smoking habits were not asked of participants aged <20 years (n=3).

Age was then categorized into 4 groups (18 - 34, 35 - 49, 50 - 64, and ≥65 years). The ≥65-year group was classified separately to reflect the older adult population, while those aged 18 - 64 years were categorized into 3 groups, approximately 15-year intervals, to capture distinct developmental and lifestyle stages. BMI (kg/m^2) was calculated as body weight (kg) divided by the square of body height (m). Weight status was categorized as underweight (<18.5 kg/m^2), normal (18.5 - 24.9 kg/m^2), overweight or obese (≥25 kg/m^2) [8], or missing (who did not answer body weight, height, or both). Educational level was categorized into 4 groups: junior or senior high school, 2-year college or technical school, university or higher, and other or refusal to answer. Medical history was categorized into 3 categories: yes (having any medical history), no, and refusal to answer. Pregnancy and breastfeeding were categorized into 2 groups: yes and no/refusal. The 3 participants aged <20 years were classified as "never smokers" for smoking habits and "not at all" for alcohol consumption.

Food literacy associated with adherence to the manufacturer-recommended regimen was assessed using the Japanese version of the Self-Perceived Food Literacy Scale [26]. The Japanese version was developed and used in a previous study [27]. This scale is an expert-based, theory-driven, and validated tool for measuring food literacy in healthy eating that focuses on 8 domains. Participants were asked to respond on a 5-point Likert scale (1=not at all or never; 5=yes or always). The food literacy score was calculated as the average of all 29 items. Negative items were reversed in the calculation. Therefore, the higher the score, the higher the food literacy. Possible scores ranged from 1 to 5. Participants were categorized into 2 groups based on their scores: those below the median and those at or above the median.

Analyzed Participants

Participants were excluded from the analysis if their amount of DS consumption was extremely high due to the possibility of incorrect responses, specifically those who reported taking a 60- or 90-day package more than 6 times or more per day (ie, ≥360 or ≥540 tablets per day) (n=2). Daily consumption of DS compared to the recommended dose was calculated as the dietary consumption of DS (ie, the number of tablets or mL of liquid per day) divided by the manufacturer-recommended daily dose of the product. When the daily consumption of DS compared to the recommended dose (%) was over 100, the participants were categorized into the "exceeding–manufacturer-recommended-dose" group (who consumed DS exceeding the recommended dose). Others were classified into the "within–manufacturer-recommended-dose" group (who consumed DS at the same or below the recommended dose).

Statistical Analysis

All statistical analyses were performed using the SAS statistical software (version 9.4; SAS Institute Inc). Significant results were defined as 2-tailed *P* values <.05. Variables of demographic and lifestyle factors and food literacy scores are presented as frequencies and percentages for categorical variables and means and SDs for continuous variables. First,

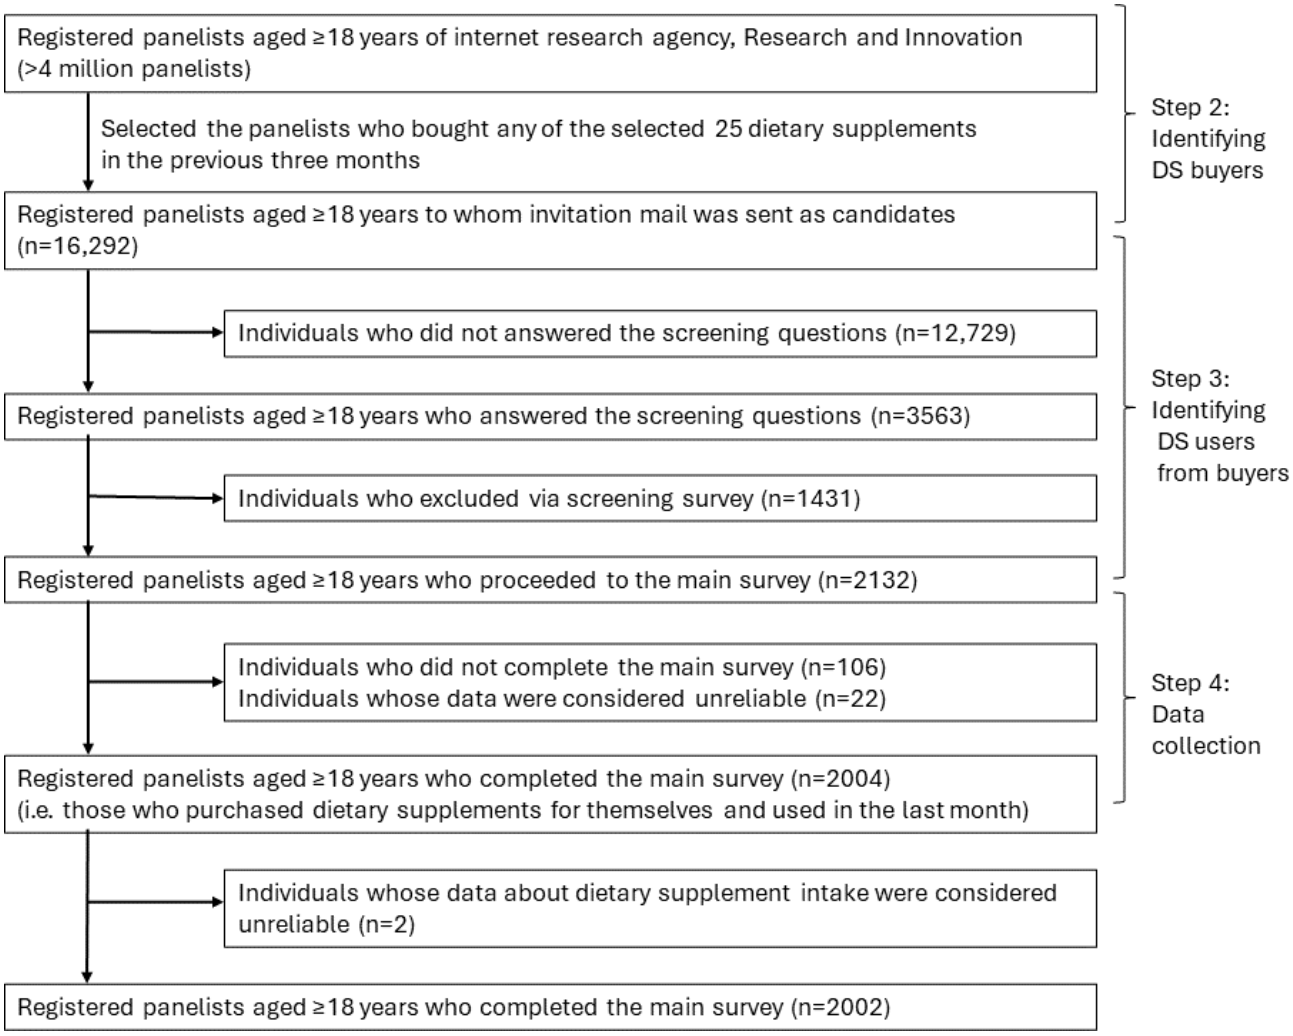
XSL•FO
RenderX

these variables were compared between 2 groups: the within–manufacturer-recommended-dose group and exceeding–manufacturer-recommended-dose group. Statistical differences were analyzed using the Student *t* test for continuous variables and the chi-square test for categorical variables.

Univariate and multivariate logistic regression models were used to evaluate the factors associated with DS consumption exceeding manufacturer-recommended doses. Individuals in the manufacturer-recommended-dose group served as the reference group. The explanatory variables were demographic and lifestyle variables, namely, age, sex, weight status, educational level, employment status, medical history, smoking status, and drinking habits. In addition, the following variables were examined as explanatory variables: form of DS, featured nutrients of DS tablets, duration of use, checking of the manufacturer-recommended dose before use, self-perception of DS consumption, and food literacy score. Featured nutrients of tablet form DS were categorized as follows: "multivitamin/multimineral" containing 3 or more vitamins or minerals; "folic acid and iron" containing folic acid and iron as the primary nutrients; "single fat-soluble vitamins" containing <3 fat-soluble vitamins as the primary nutrients; "single water-soluble vitamins" containing <3 water-soluble vitamins as the primary nutrients; and "single mineral" containing <3 minerals as the primary nutrients.

In the multivariate model, the following covariates were mutually adjusted for: sex, age (18 - 34, 34 - 49, 50 - 64, or ≥65 years), weight status (<18.5 kg/m^2, 18.5 - 24.9 kg/m^2, ≥25 kg/m^2, or missing), educational level (junior or senior high school, 2-year college or technical professional school, university or higher, or others or refusal to answer), employment status (unemployed, student, part-time job, or full-time job), medical history (yes, no, or refusal to answer), smoking status (never, past, current [<20 cigarettes a day], or current [≥20 cigarettes a day]), drinking habit (not at all, hardly, sometimes, or every day), and form of DS (liquid or tablet). The form of the DS was adjusted for differences in user characteristics, including consumption compared to the manufacturer-recommended doses, sex, weight status, and whether users checked the manufacturer-recommended doses before use (Table S2 in Multimedia Appendix 1). When one of the main variables, such as the duration of DS use, checking the manufacturer-recommended dose before use, and self-perception of DS consumption compared with the manufacturer-recommended dose, or food literacy score, was included in the model, it was analyzed alongside 9 covariates. When the featured nutrients of tablet form DS were the main variables, the form of DS was not adjusted because this analysis only included participants who consumed tablet-type DS. Additionally, linear trends of odds ratios were tested for age, educational level, employment status, smoking status, drinking habit, and duration of DS use. In the regression analysis, ordinal variables (ie, 1, 2, 3, and 4) were used as explanatory variables for educational level, employment status, smoking status, and drinking habit. The median value of each category was used for age and duration of use.

Nutrient intake from DS was described as the median and 25th and 75th percentiles for those with ULs. The medians and 25th and 75th percentiles were calculated for those who consumed DS containing each nutrient with ULs. For example, vitamin A intake was described in participants who consume DS containing vitamin A. In other words, participants who consumed DS without vitamin A were excluded from the calculation of vitamin A intake. In addition, the number and proportion of participants who exceeded the UL were calculated for all participants and within– or exceeding–manufacturer-recommended-dose group.



For sensitivity analysis, the same analysis was conducted after excluding participants who reported consuming DS five times or more than the manufacturer-recommended dose. Overall, 1821 participants were analyzed after excluding those who consumed DS five times or more than the manufacturer-recommended dose (n=183).

Results

A flow diagram of the participant selection process is shown in Figure 2. The mean age was 43.7 (SD 10.7) years, and half of the participants were aged 34 - 49 years (Table 1). The mean BMI was 21.6 (SD 3.6) kg/m^2 (n=1755, for those who answered both body weight and height); 59.5% (1192/2002) of the participants were categorized as having normal weight, while 12.3% (247/2002) did not answer their body weight, height, or both. The participants were predominantly female (1514/2002, 75.6%). The mean age and BMI were not significantly different between the within– and exceeding–manufacturer-recommended-dose groups (43.6 [SD 10.6] vs 44.2 [SD 11.1] years; 21.6 [SD 3.6] vs 21.8 [SD 3.4] kg/m^2, respectively). The exceeding–manufacturer-recommended-dose group had a higher proportion of participants aged 51 - 64 years and with drinking habits "every day." There were no statistically significant differences in other demographic and lifestyle variables between the within– and exceeding–manufacturer-recommended-dose groups.

[a]Participants were panelists who bought one of the 25 selected dietary supplements in the previous 3 months and used it within the past month or regularly. Information was collected from one of the 25 dietary supplements used by each participant.

[b]Those whose daily intake of the dietary supplement was equal to or below the manufacturer-recommended dose.

[c]Those whose intake exceeded the manufacturer-recommended dose.

[d]*P* values by chi-square test for categorical variables. Statistical significance was set at $P<.05$.

[e]"Multivitamins" contained 3 or more vitamins or minerals. "Folic acid and iron" contained folic acid and iron as the primary nutrients. "Single fat-soluble vitamins" contained <3 fat-soluble vitamins as the primary nutrients. "Single water-soluble vitamins" contained <3 water-soluble vitamins as the primary nutrients. "Single mineral" contained <3 minerals as the primary nutrients.

[f]The median score among the participants was 3.17, with possible scores ranging from 1 to 5.

Among 2002 participants, 18.5% (371/2002) exceeded the manufacturer-recommended dose. Regarding the variables related to DS use, the exceeding–manufacturer-recommended-dose group had a higher proportion of individuals who used tablet-form DS, especially single water-soluble vitamin products, and those who used the products for ≥6 months. In addition, the proportion of participants who checked the manufacturer-recommended doses was higher in the exceeding–manufacturer-recommended-dose DS group than in the within–manufacturer-recommended-dose group (90.3% [335/371] vs 82.8% [1351/1631]). The proportion of participants who thought their consumption was "more than the manufacturer-recommended dose" was higher in the exceeding–manufacturer-recommended group (57/371, 15.4%) than in the within–manufacturer-recommended group (25/1631, 1.5%). Moreover, 57.1% (212/371) and 10.8% (40/371) of those in the exceeding–manufacturer-recommended-dose group thought that their consumption was the same or below the recommended dose, respectively. In the exceeding–manufacturer-recommended-dose group, the daily DS consumption compared with the manufacturer-recommended dose (%) ranged from 394% for single water-soluble vitamin tablets to 543% for folic acid and iron tablet DS (Table S3 in Multimedia Appendix 1).

The unadjusted and adjusted odds ratios (AORs) for exceeding the manufacturer-recommended dose are presented in Table 2. From the multivariate logistic regression analysis, participants aged 50 - 64 years (AOR 1.45, 95% CI 1.10-1.92), those with part-time jobs (AOR 1.58, 95% CI 1.13-2.21), or those with full-time jobs (AOR 1.49, 95% CI 1.09-2.03) were likely to consume DS exceeding the manufacturer-recommended doses compared with those aged 18 - 34 years and those who were unemployed. In addition, participants who used a tablet form DS (AOR 6.02, 95% CI 3.46-10.47), especially a single water-soluble vitamin tablet DS (AOR 1.51, 95% CI 1.11-2.06), were likely to exceed the manufacturer-recommended doses compared to those using liquid-form DS and multivitamin/multimineral tablets. Moreover, using DS for 6 months to <1 year or ≥1 year, and those who thought they took "more than" the manufacturer-recommended doses were associated with exceeding the manufacturer-recommended doses.

Variables	Crude model[b]		Adjusted model[c]	
	OR[d] (95% CI)	*P* for trend	AOR[e] (95% CI)	*P* for trend
Same as median score or more	1.09 (0.87 - 1.37)		1.07 (1.07 - 0.84)	

[a]Participants were panelists who bought one of the 25 selected dietary supplements in the previous 3 months and used it within the past month or regularly. Information was collected from one of the 25 dietary supplements used by each participant.

[b]Derived from univariate logistic regression models.

[c]Derived from multivariable logistic regression models mutually adjusted for sex, age, weight status, educational level, employment status, medical history, smoking status, drinking habit, and form of dietary supplement; excluded for main variables.

[d]OR: odds ratio.

[e]AOR: adjusted odds ratio.

[f]"Multivitamins/multimineral" contained 3 or more vitamins or minerals. "Folic acid and iron" contained folic acid and iron as the primary nutrients. "Single fat-soluble vitamins" contained <3 fat-soluble vitamins as the primary nutrients. "Single water-soluble vitamins" contained <3 water-soluble vitamins as the primary nutrients. "Single mineral" contained <3 minerals as the primary nutrients.

[g]The *P* for trend was not calculated, since a linear relationship between categories could not be assumedor because only one exposure category (in addition to the reference group) was included..

[h]Users of the liquid-form dietary supplement were excluded from the analysis. The form of the dietary supplement was not adjusted.

[i]The median score among participants was 3.17, with possible scores ranging from 1 to 5.

Table 3 describes the intake of 15 nutrients with UL as defined in the DRIs for Japanese, along with the number of participants taking DSs containing these nutrients. Among 2002 participants, 1705 adults took DS containing ≥1 nutrient with UL. Among 371 adults in the exceeding–manufacturer-recommended-dose group, 297 adults took DS containing ≥1 nutrient with UL. No participant in the within–manufacturer-recommended-dose group exceeded the UL for their DS intake. In the exceeding–manufacturer-recommended-dose group, 61.9% (184/297) exceeded the UL for at least one nutrient. For vitamin A, niacin, folic acid, and zinc, the proportion of users who exceed UL was more than 40% in the exceeding–manufacturer-recommended-dose group using DS containing the nutrient with UL, namely, 50.7% (37/73) for vitamin A, 57% (73/128) for niacin, 48.1% (76/158) for folic acid, 59% (26/44) for magnesium, 52.9% (46/87) for zinc.

[a]UL: tolerable upper intake level.

[b]Participants were panelists who had bought one of the 25 selected dietary supplements in the last 3 months and used it within the past month or regularly. Information was collected from one of the 25 dietary supplements used by each participant.

[c]UL is defined by the Dietary Reference Intakes for Japanese, 2025.

[d]Those whose daily intake of the dietary supplement was equal to or below the manufacturer-recommended amount.

[e]Those whose intake exceeded the manufacturer-recommended amount.

[f]Number of participants taking nutrient-containing dietary supplements in the leftmost column.

[g]Amount of nicotinamide.

[h]ULs were defined for intakes derived from dietary supplements only.

For sensitivity analysis, 10.4% (190/1821) of patients were categorized into the exceeding–manufacturer-recommended-dose group. The results for the factors associated with DS consumption exceeding the manufacturer-recommended doses were almost unchanged from the original analysis of the 2002 participants (Tables S4 and S5 in Multimedia Appendix 1). The number of participants who consumed DS containing ≥1 nutrients with ULs was 134 adults. Of these, the number of participants who exceeded UL for at least one nutrient with ULs was 44 (32.8%). These numbers were much smaller than those included in the main analysis (Table S6 in Multimedia Appendix 1).

Discussion

Principal Findings

To the best of our knowledge, this is the first study to examine the factors associated with DS consumption exceeding the manufacturer-recommended doses among Japanese adults. Among 2002 DS users, 371 (18.5%) consumed DS that exceeded the manufacturer-recommended doses indicated on the package. Consumption of DS above the recommended dose was associated with middle age, part-time or full-time employment, use of tablet-form DS, especially single water-soluble vitamin tablets, use of DS for 6 months or more, and conscious consumption above the recommended dose. Among 1705 individuals consuming DS containing nutrients with ULs, 17.4% (n=297) exceeded the recommended dose. Of these, 61.9% (184/297) of individuals surpassed the UL by at least one nutrient. The results will contribute to a more accurate understanding of DS overuse behaviors, their associated factors, and possible health outcomes.

In this study, the proportion of participants who exceeded the manufacturer-recommended dose was 371 (18.5%) out of 2002, which is substantially higher than that previously reported (2.4%) [20]. When the proportion was calculated based on the self-perception of DS consumption, 4.1% ([25+57]/2002) exceeded the manufacturer-recommended dose, which is close to that previously reported. Among the 371 participants, only 15.4% (57/371) were aware that their consumption exceeded the recommended dose. These findings suggest that self-perception of adherence to the recommended dose is not a reliable indicator of actual dose consumption. To accurately assess compliance with the recommended doses, identifying the specific product used and comparing the reported consumption with the corresponding manufacturer-recommended dose are essential.

Previous research on DS overuse has focused on the use of multiple DS products [28,29], and to our knowledge, no studies have specifically examined DS consumption exceeding the manufacturer-recommended dose. Therefore, although the reasons for the observed associations with the abovementioned factors remain speculative, several possible explanations can

XSL•FO
RenderX

be considered. Among older adults, a higher prevalence of multiple DS use has been reported in the US population [28,29]. As health deterioration associated with aging may increase interest in diet [30], older individuals may consciously or unconsciously consume higher amounts of DS. Regarding employment status, individuals with part-time or full-time jobs may rely on DS as a convenient means of supplementing their nutrition due to busy schedules, which could lead to excessive DS intake. A previous study has reported that individuals working long hours often perceive barriers to consuming healthy meals [31]. Since only 31.4% (627/2002) of participants reported a medical history in this study, and 70% of DS users among patients did not disclose DS use to their physicians in a previous study [32], it was unlikely that participants had exceeded the manufacturer-recommended dose of DS based on specialists' recommendations.

Users of the DS tablet form, especially those using a single water-soluble vitamin tablet, were more likely to exceed the manufacturer-recommended dose. In addition, use of DS for 6 months or more, and conscious consumption above the recommended dose were also associated. With respect to the form of DS, liquid DS may be used more episodically and may be less likely to result in use above the recommended dose, as a previous study suggested that energy drinks are used episodically rather than regularly among college students [33]. According to a US study, DS of water-soluble vitamins were used to expect that it would boost the immune system, prevent colds, and improve overall health [34]. Some participants may have intentionally consumed more than the manufacturer-recommended dose regularly, believing that it would yield greater health benefits, even when they were aware of the manufacturer-recommended dosages. Moreover, a considerable proportion of individuals may have either misinterpreted or failed to retain the correct information regarding the recommended intake even after reviewing it. For such individuals, even if dosage guidelines are clearly indicated on labels, the information may not be effectively used. Notably, no significant differences in food literacy scores were found between those who adhered to appropriate dosage levels and those who consumed higher dosage levels. This finding implies that general food literacy scales may not adequately capture the literacy specific to DS use. Alternatively, factors beyond literacy, such as health beliefs, perceived efficacy, and trust in DS, may contribute to excessive intake. To prevent overconsumption of DSs, it may be necessary to improve the clarity and accessibility of dosage-related information and increase public awareness of the potential harm associated with excessive intake.

In this study, among 1705 participants who consumed DS containing nutrients with UL, 10.7% (184/1705) of participants exceeded the UL for at least one nutrient. They were asked about their consumption of only one DS product. Although some participants may have obtained nutrients from other DS sources, this was not captured in the survey. Previous studies in the United States reported that the concurrent use of multiple DS was common [28,29]. For example, middle-aged and older DS users use an average of more than 3.2 different DS, with 41.9% using 4 or more products [28]. Another US study on adults found that all individuals whose usual daily folic acid intake exceeded the UL consumed folic acid from multiple sources [16]. Consequently, among our study participants, the proportion of individuals exceeding the UL for specific nutrients may have been higher if nutrient intake from multiple concurrently used DS had been considered.

Previous studies have reported the proportion of individuals exceeding the UL. In the United States, approximately 20% - 40% of adults use vitamin DSs, with reported rates of exceeding UL at 7% for folic acid, 3% for vitamin A, 3.5% for vitamin B_6, and 1.6% for vitamin C [13]. Approximately 7% - 12% of DS users exceeded the UL for iron or zinc, and less than 3% - 7% exceeded the UL for calcium or magnesium [11]. In the Netherlands, although the nutrient intake from both DSs and fortified foods exceeded the UL for some participants, the proportions were <3% for calcium, iron, vitamins B_6, vitamin A, and folate [14]. In Canada, when intake from DS was included, ≥10% of individuals in certain age and sex groups had intakes of vitamins A and C, niacin, folic acid, iron, zinc, and magnesium that exceeded the UL [15]. However, few studies have provided detailed descriptions of how individuals use DS, such as whether they use multiple DS concurrently or whether they consume doses exceeding the manufacturer-recommended dose. Therefore, future studies should not only report the proportion of individuals exceeding the UL but also examine the behavioral patterns of DS use to better understand the factors contributing to excessive nutrient intake.

Strengths and Limitations

The strength of this study lies in the use of purchase history data to recruit participants. We targeted panelists who purchased and used specified DS products. This approach helped minimize misreporting related to product identification, such as when respondents were unable to recall or report product names accurately. In addition, presenting the specific unit for the product in the questionnaire might reduce the misreporting of the dosage, although some misreporting appeared. Consequently, this enabled a reliable comparison between the participants' reported DS consumption and the recommended dosage for each product. However, this study has some limitations. First, the participants were limited to panelists registered as online survey monitors, which may compromise the generalizability of the findings owing to potential sampling bias. Our participants had higher education levels than the nationally representative sample aged 20 - 74 years (43.2% for junior or senior high school, 15.6% for 2-year college or technical school, 24.2% for university or higher; education level reported in the Population Census of Japan 2020 [35]). Second, the extent to which the DS included in this study represents the full range of products consumed by Japanese DS users remains unclear and may be due to the lack of comprehensive and nationwide statistical data on the consumption of DS products. However, as the items were selected based on their high purchase frequency in transaction records, they were considered to ensure a certain level of representativeness. Third, data on daily DS consumption and frequency of consumption were self-reported, which introduces the possibility of reporting errors. Although the survey was

XSL•FO
RenderX

designed to facilitate accurate responses by clearly specifying the units of each product on the response screen, some participants likely misreported their consumption quantities. We excluded those who consumed extremely high doses of DS (≥360 tablets per day) from the analysis because they were likely to have overreported it; however, some participants in the analyzed group may have also overreported it. However, when we excluded participants who consumed 5 times the manufacturer-recommended doses, the results were similar (Table S1 in Multimedia Appendix 1). Fourth, this study did not assess participants' concurrent use of multiple DS. To ensure the feasibility of the survey and obtain accurate responses regarding the selected products, participants with purchase histories of multiple DS products were randomly assigned to answer questions about only one of those products. Consequently, information on the use of multiple DS and their contributions to overall nutrient intake and the adequacy of nutrient intake remains unknown. If the concurrent use of multiple DS is also considered, the proportion of participants exceeding the UL may increase further, indicating the need for greater public awareness and caution regarding DS use. Further studies are required to better understand the patterns of multiple DS use and their implications for total nutrient consumption.

Conclusions

In conclusion, middle-aged, part-time or full-time jobs, using tablet-form DS, and using DS for 6 months or more were associated with DS consumption exceeding the manufacturer-recommended dose, which may lead to excessive nutrient intake. Some individuals consume excessive doses of DSs, highlighting the need to raise awareness about the potential health risks associated with overconsumption.

Acknowledgments

The authors would like to express their sincere gratitude to the research staff of the University of Tokyo for their assistance in extracting nutrient content data from the manufacturer's website. The authors declare the use of generative AI (GAI) in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision: proofreading and editing. The GAI tool used was ChatGPT 5.1. Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Abstract

Background: Inclusive health education content has been shown to increase acceptability and accessibility for lesbian, gay, bisexual, transgender, queer, intersex, and asexual, as well as other sexual and gender minority (LGBTQ+) individuals. However, there has been some backlash among general audiences, with claims that such inclusive content is "woke" or otherwise problematic.

Objective: The goal of this study was to test whether individuals across the political spectrum notice when sexual and reproductive health content is written with inclusive language in order to demonstrate the acceptability of inclusive content to a broader audience.

Methods: This study included 454 adults assigned female at birth from the United States, one-third of whom identified as LGBTQ+, reviewed 2 sets of reproductive health educational handouts designed for adolescents, with 1 gender-inclusive and 1 gender-specific version in each set, randomized in order. Individuals were asked to rate each document and state a preference within each pair (implicit preference). They were then debriefed on the study's purpose and asked if they had an explicit preference for gender-specific or gender-inclusive content.

Results: Preferences for explicit content tended toward gender-specific content: always gender-specific (n=184, 40.5%), sometimes gender-specific (n=59, 13%), no preference (n=131, 28.8%), sometimes gender-inclusive (n=39, 8.6%), and always gender-inclusive (n=41, 9%). However, most people (n=273, 59%) did not notice differences between the first pair of documents they viewed or rate them differently (mean difference −0.19, SD 2.17, range −10 to 12). Furthermore, the majority of individuals who had a stated preference for gender-specific health education documents did *not* choose the gender-specific document as their preferred version for either the first (n=45, 24%) or second pair of documents (n=69, 38%). Individuals who preferred content to always be gender-inclusive were significantly more likely to choose the concordant version of their document (n=20, 49% for the first pair; n=24, 58% for the second pair). A total of 58% (n=262) of the participants stated they did not notice the study design until the debrief.

Conclusions: Most participants did not notice when sexual and reproductive health educational content had been made gender-inclusive—even when they had an explicit preference for gender-specific content. This suggests that when inclusive language is not directly called to readers' attention, inclusive sexual and reproductive health content is broadly acceptable to individuals across a range of political beliefs. The use of inclusive language may therefore be a means of increasing the accessibility and applicability of educational materials to diverse recipients, including LGBTQ+ individuals.

Introduction

In the early 2000s, as acceptance for lesbian, gay, bisexual, transgender, queer, intersex, and asexual, as well as other sexual and gender minority (LGBTQ+) individuals was growing across the population of the United States, there was increasing awareness of the need to create sexual and reproductive health education content that would be more inclusive of sexuality and gender [1-3]. One way to accomplish this is by enhancing patient educational materials through reducing or removing assumptions about the gender identity of individuals being discussed, and for sexual health materials, also removing assumptions about the genders of discussed sexual partners, that is, making the content inclusive. This approach has also been described as degendering health content. Over time, language options were developed for these materials to be more inclusive of a broad range of gender identities and sexual orientations (eg, pregnant person, birthing parent, lactating parent, sperm-producing partner, person with a uterus, ovaries, vagina, penis, etc). This often involved focusing on anatomy or experience rather than identity, as those aspects of life tended to be more relevant to the health question or behavior of interest [4]. Inclusive language makes sexual and reproductive health content more relevant to and actionable for lesbian, gay, bisexual, and transgender individuals rather than reinforcing notions that these aspects of a healthy life are only accessible and attainable to those who are cisgender and heterosexual [5-7].

The development of inclusive content has frequently been accompanied by opposition, often politically and/or religiously driven [8-10]. This opposition is often based on inaccurate beliefs that all individuals who have the same anatomy (eg, uterus) will have the same gender (eg, woman). This is problematic not just because up to 2% of the population identify as transgender [11], but because other women may have been born without a uterus or had it removed. In recent years, there has been an exponential growth in attacks on gender and sexual diversity across media and government [12-14]. This has peaked under the second Trump administration, with numerous executive orders and policy initiatives designed to erase transgender and other gender diverse individuals from public life [15-17]. There is also sometimes a perception that it is necessary to safeguard women-centric health care with women-centric language [18,19]. This is particularly true in obstetrics and gynecology—even though not all aspects of women's health are nested within obstetrics and gynecology and not all patients who see obstetricians and gynecologists are women

For many individuals whose sexuality, anatomy, and/or gender differ from expected binary norms, including those who may have been born with variations in their sexual and reproductive anatomy (eg, without a uterus) or have undergone surgeries to alter it (eg, a hysterectomy), health education content that assumes gender based on anatomy, or anatomy based on gender, may not come across as accurate, relevant, or useful, and thus fail to meet their needs. As such, it may be helpful to develop sexual and reproductive health content that is anatomy and behavior-specific and not reliant upon assumptions about gender or sexuality [20]. However, that usefulness is dependent on inclusive medical content not being off-putting, offensive, or considered unrelatable, to heterosexual individuals whose anatomy and gender do reflect binary norms.

In response to community calls for greater uptake of inclusive content, some individuals have expressed strong feelings and beliefs about the dangers or offensiveness of such content [21]. However, to date, no studies have examined whether those opposed to inclusive language notice when such language is present but not specifically brought to their attention. This randomized controlled trial was therefore designed to test the hypothesis that most individuals do not notice when sexual and reproductive content has been changed to use inclusive language, with the exception of those for whom inclusive language is more personally relevant. It was also designed to test whether political identity and/or LGBTQ+ identity were associated with explicit preferences for gender-specific versus inclusive content and/or the likelihood of noticing and preferring such content.

Methods

Study Population

The Prolific survey platform [22] was used to recruit individuals assigned female at birth who lived in the United States for a study in which they were informed that they would be shown 2 different versions of online health content and asked which they preferred. In order to ensure respondents are genuine, potential participants must provide a photo taken with a state or federal ID when registering for the platform. The site validates IP addresses to prevent duplication, uses machine learning to screen for potential automation, and allows studies to withhold payment for suspicious responses, including those completed substantially faster than the average time for completion.

The Prolific quota function was used to recruit a population that was approximately half LGBTQ+-identified and equally divided among conservative, moderate, and liberal political orientations based on the site's built-in demographic questionnaires. Individuals were also asked to self-identify within the survey, and those identifications were used in the analysis. Because of this, the actual sample demographics were not identical to the planned quota sample, reflecting the fact that individuals may have completed initial screeners for the Prolific platform up to several years prior to any given survey participation and some of their answers may have changed.

Study Design

Individuals were asked to review 2 versions of 2 sets of patient-educational materials that were originally designed for adolescents assigned female at birth—the first on polycystic ovarian syndrome and the second on birth control. Within each set, 1 document was made inclusive, while the other used gender-specific language. Two study team members reviewed language differences in the documents to ensure consensus on language choice. The documents were otherwise identical, except that one (redundant) figure in the inclusive birth control document was removed due to the use of images of pregnant women in the figure (changes are listed in Table 1). Individuals were randomized using an allocation table generated in Excel,

XSL•FO
RenderX

so that half received the inclusive document first in each set, while the other half received the explicitly gendered material first.

Table . Text changes made from gender-specific to gender-inclusive document versions.

Context for change (if needed)	Gender-specific version	Gender-inclusive version
PCOS[a] (~1550 words)		
PCOS is a common problem among…	• girls and young women	• people who have ovaries

[a]PCOS: polycystic ovary syndrome, name since changed to PMOS (polyendocrine metabolic ovarian syndrome).

After reading each document, individuals were asked to rate the content on a 5-point Likert scale (−2 to +2) across the following domains: easy to understand, reliable, biased, meant for people like me, and relevant to people like me. These scores were then summed to provide an overall score for each document, with the bias question reverse scored. Individuals were also allowed to comment on each rating. After reviewing each pair of documents, individuals were asked if they had a version preference and to explain their reasoning. A separate comparison score was generated by subtracting individuals' gender-inclusive score from the gender-specific score, so that higher comparison scores were associated with stronger implicit preferences for the gender-specific version.

XSL•FO
RenderX

Finally, after reviewing both sets of informational material, individuals completed a demographic survey that concluded with a question about whether sex education should be required as part of public K-12 education. They were then presented with a debrief that explained the purpose of the study, which included asking whether they had noticed that they were being presented with gender-inclusive material and if they preferred material to be gender-specific or gender-inclusive (explicit preference). Individuals were also given the opportunity to provide their closing thoughts. The questions are provided as a supplementary document. Individuals were not able to return to previous sections of the study or revise their answers to questions. All materials were accessed via Research Electronic Data Capture [23,24].

Ethical Considerations

This study was approved by the Boston Children's Hospital IRB (IRB-P00047950).

Analysis

Power Calculation

The study was powered based on the use of a parallel 2-group design to test whether group A (gender-inclusive first) mean (μ1) was equivalent to group B (gender-specific first) mean (μ2), with difference equivalence bounds of −1 and 1 (H0: $\delta \leq -1$ or $\delta \geq 1$ vs H1: $-1<\delta<1$, $\delta = \mu1-\mu2$), with an overall type I error rate (α) of .05. The common SD was assumed to be the fixed value of 2, with the actual SD for the 2 comparison scales ranging from 2.2 to 2.3. To detect a mean difference ($\delta = \mu1-\mu2 = \mu T-\mu R$) of 0 with sample sizes of 225 for group 1 (treatment) and 225 for group 2 (reference), the power was .9997. With the actual sample breakdown of 176 in the LGBT+ group and 278 in the cisgender-heterosexual group, the power was calculated as .9996 to determine equivalence between those groups. The power was computed using PASS 2023 (version 23.0.7).

Quantitative Analysis

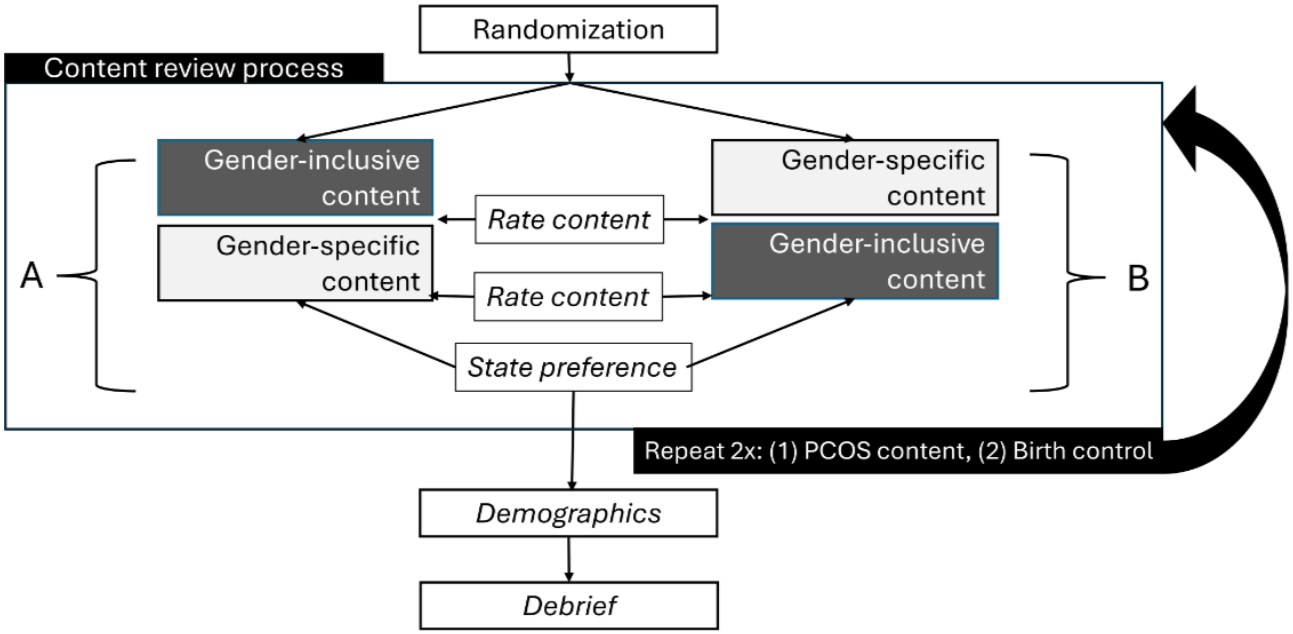
Quantitative analyses were performed in Stata 18.0 (StataCorp LLC). Demographic variables are presented as numbers and percentages. Differences across categories of explicit, stated preferences for gender-inclusive information were calculated using the chi-square test.

For each document, pair preferences for those with varying explicit preferences were categorized as concordant (ie, states they prefer gender-specific information, chose gender-specific document as preferred) or discordant or do not notice (ie, either stated there was no difference between the documents or chose the type of document they said they did not prefer). Differences across explicit preference categories were calculated using the chi-square test as well as for when individuals stated they noticed that 1 document in each pair was gender-inclusive. Differences in calculated preference scores for each pair of documents were analyzed using ANOVA.

Qualitative Analysis

Open-ended answers were analyzed in the Dedoose cloud app for managing, analyzing, and presenting qualitative and mixed method research data (Version 9.2.22: Sociocultural Research Consultants, LLC). Excerpts were excluded from analysis if they did not provide additional information (ie, were a repeat of the answer from a numeric field, or contained a one-word answer such as "no," "yes," or "useful"). They were also excluded if they stated a fact unrelated to the question of interest (eg, "This content is not relevant to me because I do not use birth control pills"). Due to the brevity of responses, inductive content analysis was used to identify commonalities between comments, as well as whether this varied by politics and/or stated (explicit) preference for gender-inclusive information [25,26]. Codes were first generated inductively and then grouped by frequency to provide an overview of types of responses. Summative or frequency information is additionally provided to demonstrate between-group differences.

Results



Overview

In total, 494 individuals participated in the study, 227 in the version that received the gender-inclusive documents first and 227 in the version that received the gender-specific documents first. There were 40 people who started the study but did not complete it, resulting in a response or completion rate of 92% (n=454). The study flow is outlined in Figures 1 and 2.

XSL•FO
RenderX

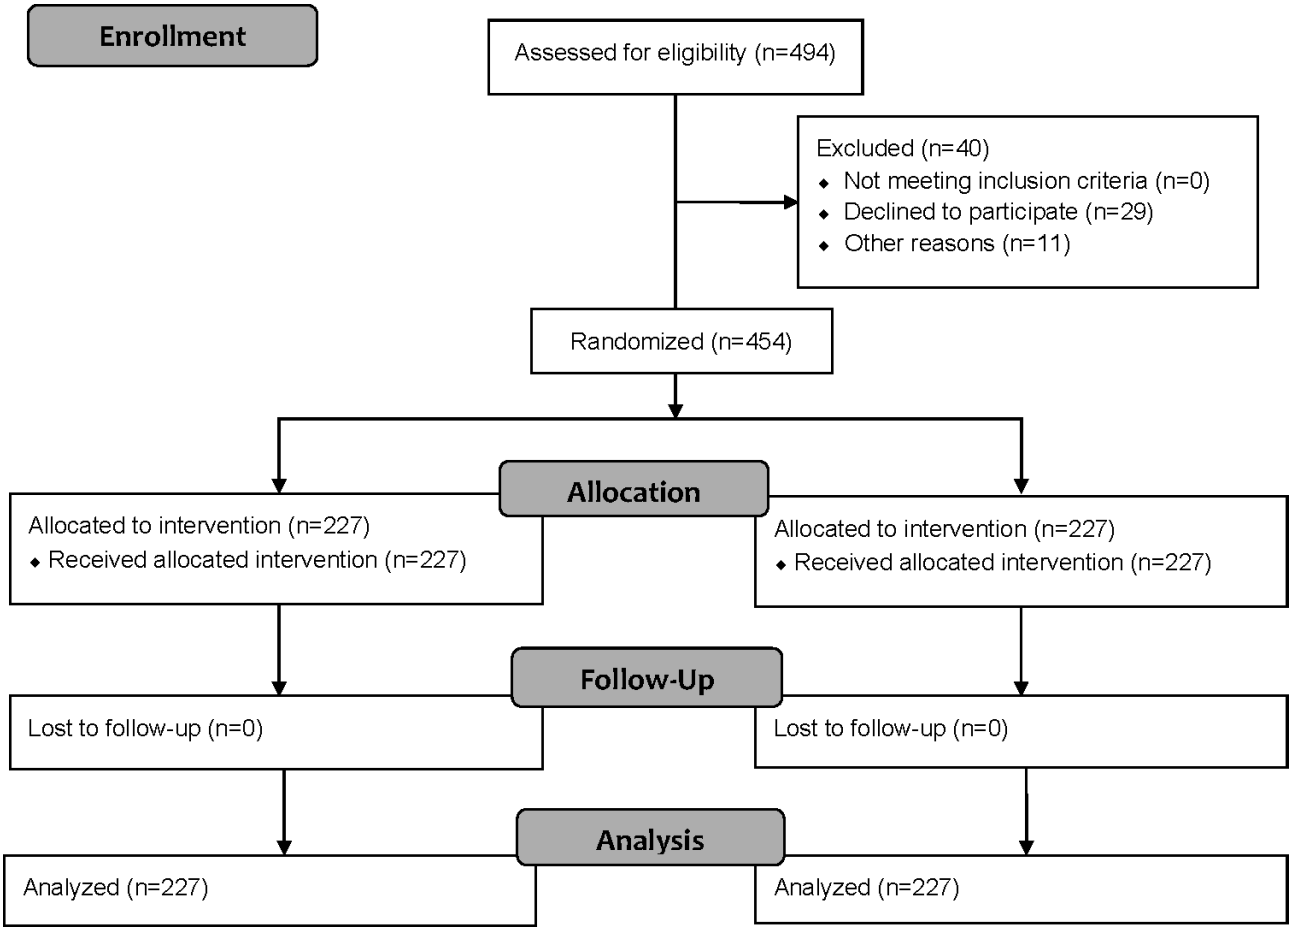


Figure 1. Study flow design. Each assessment is listed in italics. Simultaneously attempting to make quotas on both LGBT identity (1:1) and political identity (1:1:1) led to slightly unbalanced samples, although with sufficient diversity for analyses. LGBT: lesbian, gay, bisexual, transgender; PCOS: polycystic ovary syndrome.

LGBT (n=176)	Non-LGBT (n=278)
Liberal (n=84, 47.7%)	Liberal (n=103, 37.0%)
Moderate (n=47, 26.7%)	Moderate (n=63, 22.7%)
Conservative (n=45, 25.6%)	Conservative (n=112, 40.3%)

XSL•FO
RenderX

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) 2010 diagram. Checklist is available as Checklist 1.

Participants were 41% (n=187) liberal, 24% (n=110) moderate, and 35% (n=157) conservative; 39% (n=176) were LGBTQ+, with 18% (n=32) identifying as transgender and/or nonbinary. These numbers do not match the intended quotas because individuals' self-identification in terms of politics and/or sexual orientation and gender identity may have changed since they filled out the screeners on the survey platform. (Table 2; Figure 1)

[a]The column headings represent the options for the following item: "When thinking about the health information that you read online or get from a health care provider, do you like it to be:". Differences across these categories were calculated using the chi-square test.

[b]Statistically significant at $P<.05$.

[c]LGBTQ+: lesbian, gay, bisexual, transgender, queer, intersex, and asexual, as well as other sexual and gender minority.

Participants Stated (Explicit) Preferences Around Gender-Inclusive Language

After individuals were debriefed, and the purpose of the study was explained, they were asked, "When thinking about the health information that you read online or get from a health care provider, would you like it to" and then given the choices of "always be gender-specific (eg, women's health, pregnant women, mother, etc)" (n=184, 40.5%), "sometimes be gender-specific" (n=59, 13%), "no preference either way" (n=131, 28.8%), "sometimes be degendered (eg, reproductive and sexual health, pregnant people, parent, etc)" (n=39, 8.6%), or "always be degendered" (n=41, 9%). We refer to this as their stated or explicit preference for the remainder of the analysis.

Individuals who stated they preferred inclusive language tended to be younger ($\chi^2_{16}=28.9$; $P=.02$) and more liberal ($\chi^{21}_{16}=154.3$; $P<.001$) and also considered religion less important ($\chi^2_{16}=96.8$; $P<.001$) than those who preferred gender-specific language. They were also more likely to be LGBT ($\chi^2_8=27.7$; $P<.001$) and specifically transgender or nonbinary ($\chi^2_8=28.3$; $P<.001$). Most strikingly, the differences in preference were strongly associated with differences in perspectives on sex education in public schools, which was used as a proxy for people's overall beliefs on reproductive health education ($\chi^2_{16}=62.4$; $P<.001$). Every person who preferred inclusive language supported comprehensive sex education in public schools, while no one who thought sex education should not be allowed in public schools had an explicit preference for inclusive language.

People's Awareness of Inclusive Language

Of the people who saw the inclusive versions first, 56.9% (n=132) stated they did not notice a difference between the documents in the first pair, and 41.4% (n=94) stated they did not notice a difference between the documents in the second pair. These numbers were 61.6% (n=141) and 42.2% (n=96) for those who saw the gender-specific versions first. After the debrief, when asked explicitly about when they noticed that some of the documents were inclusive, 57.7% (n=262) stated that they did not notice until the debrief, 21.1% (n=96) stated that they noticed after the first pair, and 21.1% (n=96) stated that they noticed after the second pair. This did not differ by version ($\chi^2_2=0.6$; $P=.75$). Individuals with the strongest preferences (ie, always) tended to notice sooner than those with weaker (ie, sometimes) or no preference ($\chi^2_8=56.3$; $P<.001$; Table 3).

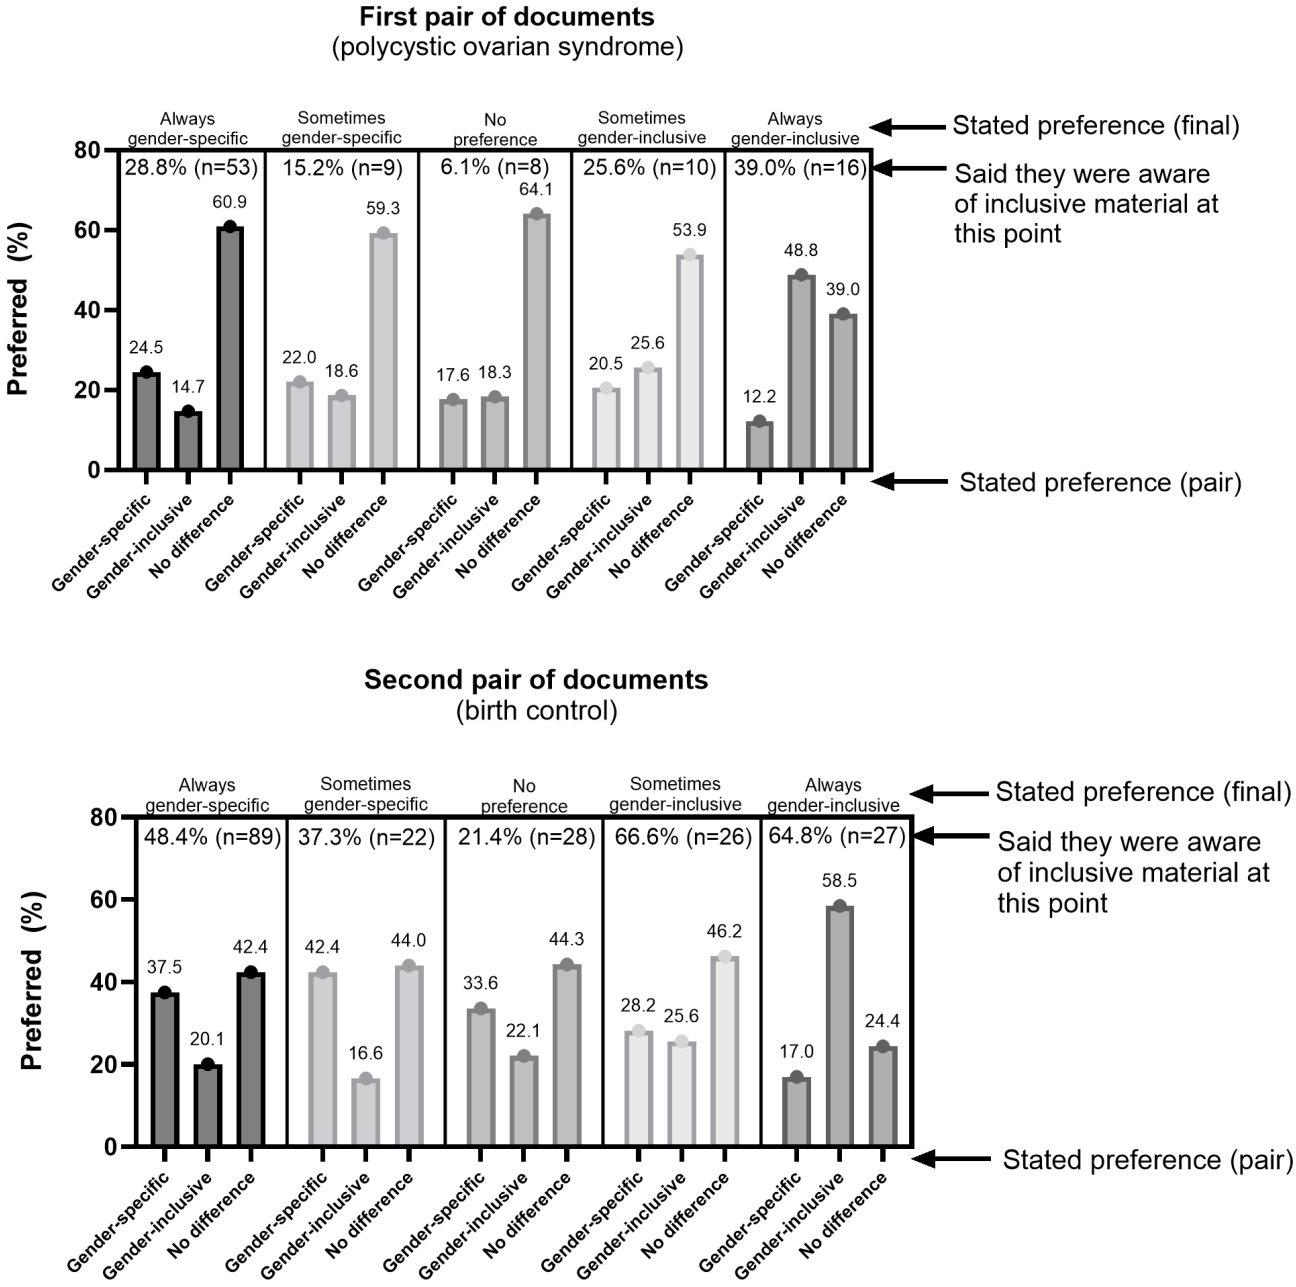
[a]The column headings represent the options for the following item: “When thinking about the health information that you read online or get from a healthcare provider, do you like it to.”

[b]PCOS: polycystic ovary syndrome.

[c]Chi-square.

[d]For always or sometimes gender-specific, a concordant preference was defined as preferring the gender-specific document. For always or sometimes gender-inclusive, a concordant preference was defined as preferring the gender-inclusive document.

[e]Not applicable, individuals who did not have an explicit preference were excluded from this portion of the analysis.



[f]ANOVA F.

People’s Version Preferences in Relation to Their Stated (Explicit) Preferences

Looking just at individuals who had a stated preference for gender-specific or gender-inclusive documents (ie, excluding those who chose “no preference”), the majority of individuals who had a stated preference for gender-specific health education documents *did not choose* the gender-specific document as their preferred version for either the first or second pair of documents, although the number of individuals with a concordant preference did increase for the second document pair. The individuals who preferred content to always be inclusive were substantially more likely to choose the concordant version of their document than those from other stated preference groups (n=20, 48.8% for the first pair; n=24, 58.5% for the second pair). This pattern was also evident in the preference scores generated by questions asked after each individual document, where the only group with large differences in rating scores between the paired versions was those who wanted content to always be inclusive (Table 3, Figure 3).

XSL•FO
RenderX

Figure 3. Stated preferences for each pair of documents (bars) organized by the final explicit preference stated for gender-specific versus gender-inclusive content (sections). The percentage of individuals who stated, at the end of the study, that they were aware of degendering after viewing the document pair is shown at the top of each section.

Qualitative Analysis of Open-Ended Responses

We hypothesized during study design and data collection that most participants who preferred gender-specific language would not notice inclusive language, even when they wanted the language to always be gender-specific. While this was true in the quantitative responses, analysis revealed that some people felt strongly about minor differences between the documents. This manifested qualitatively in the free-text responses, which were categorized using inductive content analysis (Multimedia Appendix 1).

When reviewing the comments on why individuals preferred their chosen versions, the category with the greatest number of comments was “perception versus reality,” dominated by those who appeared to perceive substantially more differences than were actually present between document versions (n=82), which they used to justify their preferences (ie, citing things such as different layouts, flow, and comprehensiveness). That category also included individuals commenting during the debrief, usually with surprise, that they had not noticed the difference between the pairs of documents (n=21). The next most common category of comment was those related to discourse including comments mentioning inclusiveness (n=33), bioessentialism (n=26), and the use of specific language from media tropes (n=11). Finally, there were groups of comments evaluating specific types of language (gender-inclusive, n=27; gender-specific, n=14; problems with inclusive, n=12; pros and cons of both, n=8), personal preferences for gender-specific (n=14) versus gender-inclusive (n=13) content, and comments mentioning identity or writing quality (Multimedia Appendix 2).

RenderX

Discussion

Principal Findings

Confirming our primary hypothesis, the majority of study participants who were opposed to the use of inclusive language either did not notice a difference between gender-specific and gender-inclusive materials or preferred the materials with inclusive language. Those individuals who had a strong preference for inclusive information were significantly more likely to both notice the differences and choose the concordant document than those with other preferences. Nonetheless, it is important to acknowledge that half of that group still did not notice a difference between the materials when the first pair was presented to them.

The study results also confirmed our secondary hypothesis. Individuals had stronger explicit or stated preferences about gender-inclusive language than were represented by their actual ratings and choices of different types of content. In other words, it appeared that people had opinions about this issue even when the presence of inclusive language did not affect them in practice. This was demonstrated by the fact that what people stated as their explicit preference for gender-specific information did not actually predict the content they said they preferred, but it did predict their political views.

Our data suggest that individuals may hold beliefs about the concept of inclusion that differ from the reality of how they experience it. For some people, this may reflect their having been influenced by media and other forms of social polarization to be upset about the concept of inclusion rather than the reality of it. It is also possible that outside of the echo chamber of highly polarizing virtual communities, the importance or performance of highly gendered and explicitly anti-inclusive preferences is reduced. The act of engaging with potentially applicable health content about the *real self* may support different attention to that content than the *virtual self* who may be more engaged with anti-inclusion rhetoric [27]. That said, there were a minority of participants who did appear to be primed for identifying inclusive content, some of whom reproduced common, inaccurate comments about gender and sex in their open-ended responses.

The fact that most people did not appear to perceive a difference between gender-inclusive and gender-specific content when they had not been primed to look for it suggests that discourse in the United States about the potential harms of inclusive language, often amplified by self-described ultra-conservatives or right-wing groups, does not reflect the lived realities of most Americans. Hyper-politicization of diversity, equity, and inclusion (DEI) can lead to discussions of these concepts in the context of health care inducing stronger emotional reactions than their actual implementation would [21,28,29]. Our research suggests that, in the coming months and years, it may be important to universally adopt inclusive language as a change in nomenclature that promotes accuracy and does not have significant bearing on the way in which critical health information is perceived by the majority of patients, rather than as an explicitly DEI approach.

Future Directions

In the future, we hope to analyze the use of inclusive language in real-world situations and in populations of younger patients and their caregivers. Our intention is to decouple the perception of inclusive language from DEI efforts and instead focus on it as a way of accurately and nonjudgmentally describing the bodies of individuals receiving care—similar to the use of accurate anatomic terminology. We also intend to test whether inclusive language is received differently when used in combination with gender-specific language versus on its own (eg, *women and other* people with ovaries vs *people with ovaries*). We hypothesize that combination language will have broader acceptability but possibly also lead to stronger negative reactions in a small minority of people at both ends of the political spectrum—who could become primed to notice and respond to the presence of inclusive language. Our next step in doing so will involve focus groups with a diverse range of people—exploring their reactions to these research results to understand their interpretation and the implications for dissemination. We would also like to use this method to examine people's responses to changing sex and gender language in information unrelated to health—for example, information on the benefits of sports participation for people of *all sexes* versus *all genders*. We hypothesize that subject matter, salience, and valence may all play a role in an individual's response.

Strengths and Limitations

The strengths of this study include a robust study design and a large, diverse respondent sample. The sample also clearly engaged with the research. This could be seen in the extensive comments across open-ended fields.

The main limitation of this study is that it is impossible to rule out rendering differences that may have contributed to the perception of some users that there were substantial differences between the 2 sets of virtually identical documents. The open-ended responses both confirmed and disconfirmed this. Some participants reported that they had believed the 2 documents in each set to be largely identical. Others seemed to believe that the content was completely different, describing different formatting, different lengths, 1 version being much easier to understand, and so forth.

Because the perception of difference among some users was so substantial, care was taken to replicate the study on multiple machines, varying device types (eg, phone, computer), operating systems, and browsers. Across systems, the only identifiable differences between the materials were the minor differences detailed in Table 1.

The study was also, potentially, limited by the sociopolitical environment in which it took place. Participants completed the study in late December 2024, after the election of Donald Trump but before his inauguration. This may have contributed to experiences of polarization among participants. The study was also specifically designed to capture a politically broad range of the US population and cannot be extrapolated to populations outside the United States.

Because of the sampling choice to purposively recruit for political and LGBTQ+ diversity over other forms of diversity,

XSL•FO
RenderX

the sample is not an accurate representation of the full diversity of the United States. For example, looking at the racial and ethnic makeup of the United States, the proportions of the White (67% vs 59%), Black (20% vs 13%), and multiracial (4% vs 2%) populations were higher in this sample than reported in 2022 Census data, while the Hispanic (4% vs 19%) and Asian (2% vs 6%) populations were lower, and that of American Indian or Alaskan Native population (0.8% vs 0.7%) were similar [30].

Conclusions

Despite substantial conservative discourse about the ways in which gender-inclusive sexual and reproductive information is offensive and harmful to women, the majority of individuals assigned female at birth do not appear to notice when such content has been made inclusive—even when they state an explicit preference for gender-specific content. The exception is those individuals for whom inclusive content is explicitly relevant or preferred, who both notice and choose content that is concordant with their preferences at much higher rates than those who prefer content to be gender-specific. This suggests that, by and large, inclusive health education is broadly useful and acceptable.

Abstract

Background: The association between depressive symptoms and cardiovascular diseases is well established. However, their impact on the incidence of stroke in individuals with cardiovascular-kidney-metabolic (CKM) syndrome remains unclear.

Objective: This study aims to investigate the impact of depressive symptoms at different stages of CKM syndrome on the incidence of new-onset stroke.

Methods: This study used data from the China Health and Retirement Longitudinal Study. Depressive symptoms at baseline were assessed using the Center for Epidemiologic Studies Depression Scale, with stroke incidence determined through standardized follow-up questionnaires. Cox regression and restricted cubic spline regression were used to evaluate the association between depressive symptoms and stroke risk.

Results: The analysis included 9593 participants (n=5180, 54.92% male; mean age of 60.89, SD 9.39 y), classified into CKM stages 0 to 3. Fully adjusted Cox regression showed that each 1-point increase in depressive score was associated with a 3% higher stroke risk (hazard ratio 1.03, 95% CI 1.02 - 1.04; *P*<.001). Restricted cubic spline regression confirmed a significant positive linear relationship between depressive symptoms and stroke incidence (*P*<.001).

Conclusions: This cohort study demonstrates a positive linear association between depressive symptoms and increased stroke incidence in individuals with CKM syndrome (stages 0 - 3). These findings highlight the importance of emotional health management, suggesting that effective depression treatment may help reduce stroke risk through inflammation reduction and lifestyle improvements.

Introduction

In the October 2023 Presidential Advisory, the American Heart Association (AHA) defined cardiovascular-kidney-metabolic (CKM) syndrome as a systemic condition characterized by complex pathophysiological interactions among metabolic risk factors (eg, obesity and diabetes), chronic kidney disease (CKD), and cardiovascular disease (CVD). These interrelated processes contribute to multiorgan dysfunction and significantly increase the risk of adverse cardiovascular events. Investigating CKM syndrome as an integrated condition offers a strong scientific foundation for developing comprehensive diagnostic and therapeutic strategies aimed at improving patient outcomes [1]. Metabolic disorders, by reducing insulin sensitivity, elevate the risk of dyslipidemia in patients with CKM, often leading to early cardiovascular complications such as coronary atherosclerosis [2,3], myocardial infarction [4], and heart failure [5]. Additionally, the interaction between CKD and CVD can trigger inflammatory responses [6], oxidative stress [7], and endothelial dysfunction [8]. Moreover, extensive evidence indicates that CVD constitutes the primary clinical burden associated with CKM syndrome, with a disproportionately high impact [9]. Compared to healthy individuals, patients with CKM experience more complex pathophysiological changes.

Conventional medical practice often diagnoses and treats CVD, CKD, and metabolic disorders separately, overlooking their

XSL•FO
RenderX

interrelationships. AHA emphasizes the importance of early detection of CKM staging in the preclinical phase [1]. Previous studies have shown that adults in the United States have concurrent cardiovascular, kidney, and metabolic diseases, with this prevalence on the rise [10]. Roth et al [11] observed that in patients undergoing noncardiac surgery, the risk of postoperative adverse outcomes increases with higher CKM staging. Certain pharmacological interventions, such as angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers, sodium-glucose co-transporter 2 inhibitors, and nonsteroidal mineralocorticoid receptor antagonists, not only slow the progression of CKD but also reduce mortality from CVD [12]. These findings suggest that the 2 conditions may share common biological pathways. A growing body of evidence suggests that the disproportionate clinical burden of CKM syndrome is strongly linked to CVD [1,13]. Stroke is the second-leading cause of death and the third-leading cause of disability globally [14]. Additionally, it is estimated that 2 million new cases of stroke occur annually in China, with 70% to 80% of affected individuals experiencing disabilities that render them incapable of independent living [15]. Studying the incidence of stroke in populations at different stages of CKM syndrome holds significant clinical and public health value.

In 2013, depression accounted for more than 10 million disability-adjusted life years in China, which is projected to rise by approximately 10% by 2025 [16]. Negative emotional states, such as anxiety, depression, or chronic stress, trigger hyperactivation of the hypothalamic-pituitary-adrenal axis, resulting in elevated cortisol levels that exacerbate metabolic imbalances [17]. This physiological disturbance can lead to increased blood pressure, endothelial dysfunction, and the development of atherosclerosis [18]. Moreover, individuals with depression often exhibit systemic low-grade inflammation, which impairs insulin signaling and contributes to dysregulated glucose metabolism [19]. This condition further promotes vascular endothelial inflammation and oxidative stress, accelerating vascular stiffness and plaque formation [20]. Previous studies have shown a strong association between depression and elevated proinflammatory cytokines (eg, interleukin-6 and C-reactive protein [CRP]) in patients with CKD, potentially increasing the risk of cardiovascular events and overall mortality [21]. A 2-year observational study reported that persistent depressive symptoms elevate the risk of stroke, while improvements in these symptoms reduce its incidence [22]. However, the relationship between depressive symptoms and stroke incidence in the population with CKM remains inadequately explored.

Clarifying the association between depressive symptoms and stroke incidence in this group could inform targeted psychological interventions and disease management strategies, ultimately improving patient outcomes and overall health. This study aims to investigate the impact of depressive symptoms at different stages of CKM syndrome on the incidence of new-onset stroke. Since clinical criteria for CVD are present in CKM stage 4, we selected individuals in CKM stages 0 to 3 as the target population for this study.

Methods

Ethical Considerations

The studies involving human participants adhered to the principles of the Declaration of Helsinki and were reviewed and approved by the ethics review committee of Peking University (IRB00001052-11015). The participants provided their written informed consent to participate in this study. To ensure privacy and confidentiality, all data accessed from the China Health and Retirement Longitudinal Study (CHARLS) database were deidentified and analyzed anonymously.

Data Source and Study Population

The data for this study were obtained from the CHARLS, a national cohort study covering urban and rural areas across 28 provinces in China. CHARLS is representative of the population aged 45 years and older in China. All participants provided written informed consent before participating in the study. The baseline survey for CHARLS began in 2011, including approximately 17,000 respondents from over 10,000 households. A stratified sampling method was used to ensure national representativeness. Follow-up surveys were conducted in 2013, 2015, and 2018. All field staff underwent systematic and professional training and conducted face-to-face interviews using standardized questionnaires. The CHARLS database includes information across 5 key domains: demographic and household characteristics, health status, economic status, health care use and expenditures, and social participation and psychological well-being. In this study, the baseline was set in 2011, with the follow-up period ending in 2018.

Exposure

The Center for Epidemiologic Studies Depression Scale is a widely used self-report instrument designed to assess depressive symptoms in the general population [23]. The scale contains 10 items measuring depressive symptoms experienced over the past week, including mood states, somatic symptoms, interpersonal difficulties, and positive affect (reverse-scored). Each item is rated on a 4-point Likert scale: 0 (very little or none of the time), 1 (not much; 1 - 2 d), 2 (sometimes or about half the time; 3 - 4 d), and 3 (most of the time; 5 - 7 d). The total score ranges from 0 to 30, with higher scores indicating more severe depressive symptoms. Participants were categorized into four groups based on quartiles of depression scores: the first group ranged from 0 to 3, the second group from 3 to 7, the third group from 7 to 12, and the fourth group from 12 to 30.

Outcome

The primary outcome of our study was the incidence of new-onset stroke events. A confirmed diagnosis of stroke during the follow-up period was classified as the first event, with the reported date recorded as the onset date. The timing of the stroke was determined by calculating the time interval from the baseline assessment to the reported onset date. For participants who did not report a stroke, the follow-up time was calculated as the interval between the baseline assessment and the date of their last survey. Alternatively, if data loss occurred during this

XSL•FO
RenderX

period, the year in which the loss was first detected was considered the follow-up year.

Definition of CKM Syndrome Stages 0 to 3

The classification of CKM syndrome stages 0 to 3 is based on the guidelines outlined in the AHA Presidential Advisory Statement on CKM Syndrome [1], while also referencing the CKM classification criteria from the study by Zheng et al [24].

Stage 0 is defined as individuals with no CKM risk factors, characterized by normal BMI, waist circumference, blood glucose levels, blood pressure, and lipid levels, as well as the absence of CKD and CVD.

Stage 1 includes individuals with an elevated BMI (≥23 kg/m² for Asian populations) and an elevated waist circumference (≥80 cm for women; ≥90 cm for men), or prediabetes (defined as a glycated hemoglobin of 5.7% to <6.5% or a fasting blood glucose of 100 mg/dL to <126 mg/dL) without the presence of CKD.

Stage 2 is defined as individuals with metabolic risk factors (eg, hypertriglyceridemia [≥135 mg/dL], hypertension, metabolic syndrome [MetS]) or CKD of moderate-to-high risk and diabetes. MetS is defined by the presence of three or more of the following: (1) ≥80 cm for women and ≥90 cm for men; (2) high-density lipoprotein (HDL) <40 mg/dL for men and <50 mg/dL for women; (3) triglycerides ≥150 mg/dL; (4) elevated blood pressure (systolic blood pressure ≥130 mmHg or diastolic blood pressure ≥80 mmHg and/or use of antihypertensive medications); and (5) fasting blood glucose ≥100 mg/dL.

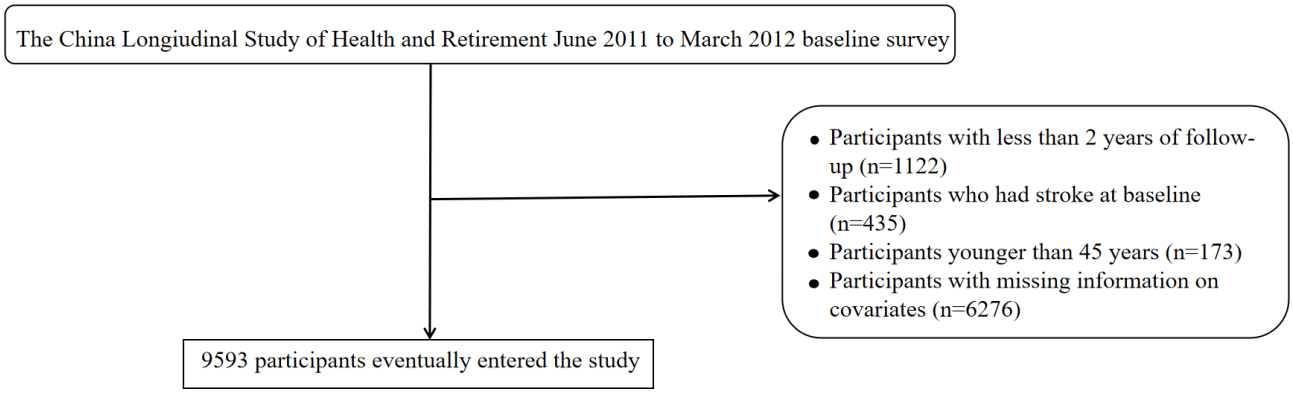
Stage 3 is characterized by individuals with very-high-risk CKD stages or subclinical atherosclerotic CVD with a predicted 10-year CVD risk of less than 10%. Following the methodology of Deng et al [24], atherosclerotic CVD risk was determined using the Framingham risk score. The estimated glomerular filtration rate (eGFR) was calculated via the Chinese Modification of Diet in Renal Disease equation [25].

Covariates

We collected data on various independent variables, including demographic characteristics such as age, gender, educational level, BMI, smoking status, alcohol consumption, and place of residence. Blood test parameters such as CRP, uric acid (UA), blood urea nitrogen (BUN), glucose, hemoglobin A_{1c} (HbA_{1c}), HDL, non-HDL, low-density lipoprotein (LDL), total cholesterol (TC), triglycerides, eGFR, and platelet count were collected. Additionally, we gathered information on disease conditions, including hypertension, diabetes, CVD, chronic liver disease, sleep disorders, lung disease, and kidney disease. Sleep quality was assessed using the question, “My sleep in the last week was restless,” with 3 response options: little or no time (<1 d), some of the time (1 - 2 d), and occasional or moderate time (3 - 4 d). Participants who answered ≥1 were identified as having a sleep problem. The selection of covariates in this study was based on established theoretical frameworks and prior epidemiological evidence regarding risk factors for both depression [26,27] and CVDs [24].

Statistical Analysis

Participants in this study were categorized into 4 quartiles (Q1-Q4) based on baseline depressive scores: Q1 (0 - 3), Q2 (4-7), Q3 (8-12), and Q4 (13-30). Continuous variables with a normal distribution were presented as mean (SD), while categorical variables were expressed as frequencies and percentages. Differences between groups were evaluated using the chi-square test and the independent 2-sample 2-tailed *t* test for continuous variables. To explore the association between depressive symptoms and stroke across various demographic characteristics, subgroup analyses were performed for categorical variables such as education level, gender, smoking status, drinking status, and CKM syndrome stages (stages 0-3). The univariate and multivariate Cox regression models were applied to estimate hazard ratio (HR) and 95% CIs for stroke risk associated with baseline depressive scores. Additionally, restricted cubic spline (RCS) regression was used to assess potential nonlinear relationships between depressive scores and stroke incidence in the overall population with CKM syndrome (stages 0 - 3) and specifically within CKM stage 2 and stage 3 subgroups. All statistical analyses were performed using R software (version 4.4.0; R Foundation for Statistical Computing), with a 2-sided *P* value<.05 considered statistically significant.



Results

Baseline Characteristics of Participants

In the 2011 baseline survey, 17,705 participants were initially included. After excluding individuals with missing stroke data, 17,596 participants remained. Further exclusions were made for those with less than 2 years of follow-up (n=1122) and those with a history of stroke at baseline (n=435), leaving a total of 16,039 participants, of whom 12,852 were classified in CKD stages 0 to 3. Subsequently, 173 participants under the age of 45 years were removed. After removing individuals with missing covariate data, 9593 participants were retained for the final analysis (Figure 1).

Figure 1. Flowchart illustrating the inclusion and exclusion criteria for the study population.

Among them, 54.92% (n=5268) were male individuals. Baseline characteristics, as shown in Table 1, are presented according to the quartiles of the depressive score. The analysis revealed that women, married individuals, and those with lower educational attainment were more susceptible to depression compared to men, unmarried individuals, and those with higher levels of education. Specifically, there was a stark contrast in the distribution of education levels across depression quartiles: individuals with primary school education or below accounted for 82.18% of the most severe depressive group (Q4), whereas those with a college degree or higher represented only 0.95% of the same group. As depressive symptoms increased, the proportion of women also increased, while the proportion of men decreased (χ^2_3=186.7; *P*<.001). Similarly, the proportion of individuals with lower educational attainment rose, while the proportion of those with higher education decreased (χ^2_3=186.70; *P*<.001), with these differences being statistically significant. Furthermore, individuals with chronic conditions such as CVD, liver disease, kidney disease, and lung disease were more likely to experience depressive symptoms than those without these conditions. Additionally, these individuals were more frequently represented among those with the most severe depressive symptoms (Q4). Specifically, individuals with newly diagnosed stroke exhibited significantly more severe depressive symptoms (mean 9.49, SD 6.53) at the 2011 baseline compared to those without stroke (mean 8.16, SD 6.17). Patients with newly diagnosed stroke had significantly higher levels of age, BMI, LDL, HDL, glucose, triglycerides, TC, UA, CRP, and HbA_{1c} compared to healthy controls. In contrast, their sleep duration and eGFR were significantly lower in patients newly diagnosed with stroke compared to healthy controls (Table 2).

The original model examined the relationship between depressive symptoms and the incidence of stroke. In this study, a total of 1044 participants were identified as having experienced a stroke. To evaluate the association between depressive scores and stroke incidence across CKM syndrome stages 0 to 3, 4 Cox proportional hazards models were constructed. Model I was adjusted for age, sex, marital status, educational level, and residential location. Model II expanded upon model I by incorporating additional variables, including smoking status and alcohol consumption. Model III further adjusted for

XSL•FO
RenderX

laboratory parameters such as BUN, platelets, CRP, UA, HDL, LDL, triglycerides, and TC. Model IV extended model III by including comorbid chronic diseases such as hypertension, chronic liver disease, diabetes, and sleep problems. The study found a significant positive association between depression severity and the risk of stroke. When depression severity was treated as a continuous variable, the model yielded an HR of 1.03 (95% CI 1.02 - 1.04; *P*<.001) in the fully adjusted model V.

Further clarifying the relationship between depressive score and stroke incidence, depressive score was categorized into quartiles. In a stratified analysis, the population was divided into 4 groups based on depression severity scores. The second group (scores 3 - 7) showed no significant association with stroke incidence (HR 1.16, 95% CI 0.97 - 1.40; *P*=.10), and this result remained unchanged after adjusting for covariates. In contrast, the third group (HR 1.54, 95% CI 1.29 - 1.84; *P*<.001) and the fourth group (HR 1.69, 95% CI 1.41 - 2.02; *P*<.001) both demonstrated significant associations, with the risk of stroke increasing as depression severity worsened. In the fully adjusted model V, compared to Q1, the HR for Q2, Q3, and Q4 were 1.13 (95% CI 0.94 - 1.35), 1.49 (95% CI 1.24 - 1.79), and 1.63 (95% CI 1.35 - 1.96), respectively.

This indicates that participants in Q2, Q3, and Q4 experienced a 13%, 49%, and 63% higher risk of stroke compared to those in Q1 among the population with CKM syndrome stages 0 to 3. Except for the Q2 stage, the results for the other 2 stages were statistically significant (Table 3).

Table . Adjusted hazard ratios (HRs) for stroke incidence across depressive symptom quartiles in a population with cardiovascular-kidney-metabolic (CKM) syndrome stages 0 to 3.

[d]Model 3: depressive scoreQ, adjusted for age, sex, marital status, education, location, smoking status, drinking status, blood urea nitrogen (BUN), C-reactive protein (CRP), uric acid (UA), total cholesterol (TC), triglycerides, low-density lipoprotein (LDL), and high-density lipoprotein (HDL). *P* for trend (character2integer)<.001; *P* for trend (median value)<.001.

[e]Model 4: depressive scoreQ, adjusted for age, sex, marital status, education, location, smoking status, drinking status, BUN, CRP, UA, TC, triglycerides, LDL, HDL, hypertension, sleep problem, liver disease, lung disease, and diabetes. *P* for trend (character2integer)<.001; *P* for trend (median value)<.001.

RCS regression models were used to further examine the association between depressive score and the risk of stroke among participants with CKM syndrome. The fully adjusted RCS regression model revealed a significant positive linear association between depression scores and stroke risk across participants with CKM syndrome stages 0 to 3 ($P_{overall}$<.001; $P_{nonlinear}$=.20). Similarly, this positive linear correlation was evident in individuals at CKM syndrome stage 2 ($P_{overall}$<.001; $P_{nonlinear}$=.50) and stage 3 ($P_{overall}$=.03; $P_{nonlinear}$=.30; Figure 2). To further explore the relationship between and the incidence of stroke, subgroup and interaction analyses were conducted across different genders, smoking status, drinking status, chronic diseases, and CKM syndrome stages (stages 0-3) with no interactions observed in other subgroups (*P* for interaction >.05; Table 4 and Figure 3).

Discussion

Principal Findings

This study extends current knowledge by establishing for the first time a significant association between depressive symptoms and stroke incidence in individuals with CKM syndrome—a condition marked by the intricate interplay of cardiovascular, kidney, and metabolic dysfunctions. Through multivariable-adjusted Cox proportional hazards regression analyses controlling for demographic characteristics (age, sex, and education), lifestyle factors (smoking and physical activity), and clinical parameters (blood pressure, glycemic status, and renal function), we observed a 3% incremental stroke risk per 1-point increase in depressive symptom severity (adjusted HR 1.03, 95% CI 1.02 - 1.04; P<.001). Notably, quartile-stratified analyses revealed a striking dose-response gradient. Participants in the highest depressive symptom quartile exhibited 63% greater stroke risk compared to the lowest quartile (HR 1.63, 95% CI 1.35 - 1.96; P_{trend}<.001), with intermediate quartiles demonstrating proportionally elevated risks (Q2: HR 1.13, 95% CI 0.94-1.35; Q3: HR 1.49, 95% CI 1.24-1.79). This monotonic risk escalation suggests a potential threshold effect where severe depressive symptoms may constitute a clinically meaningful cerebrovascular risk marker in populations with CKM.

This potential bidirectional relationship highlights the complex interplay between depression and stroke, suggesting that while depressive symptoms may precede stroke, the physiological and psychological impact of a stroke event may also exacerbate depressive states. In depression, disruptions in the serotonin system [28] and hyperactivation of the hypothalamic-pituitary-adrenal axis [29], characteristic of depression, may lead to elevated levels of inflammatory cells and proinflammatory cytokines such as IL-6 and IL-10 [30], both of which are closely associated with an increased risk of stroke. Chronic inflammation accelerates vascular injury and promotes atherosclerosis, significantly elevating the risk of both ischemic and hemorrhagic stroke. Additionally, excessive reactive oxygen species–induced oxidative stress further amplifies this risk by damaging endothelial cells and compromising vascular integrity [31]. Conversely, the inflammatory response following a stroke can deplete L-tryptophan, the precursor of serotonin [32], thereby worsening serotonin system dysfunction and contributing to depressive symptoms such as anhedonia [33]. Regarding the relationship between depression and kidney disease. A systematic review and meta-analysis found that in patients with CKD, depressive symptoms are significantly associated with higher levels of inflammatory markers, suggesting that inflammation may be a shared underlying mechanism linking depression with both CKD and stroke [34]. A study on patients with hypertension found that higher serum cortisol levels are associated with lower eGFR and poorer renal function [35]. Similarly, the pathological mechanisms of the CKM syndrome involve persistent chronic inflammation, oxidative stress, and endocrine dysfunction [36]. Abnormal fat accumulation in CKM serves as a major source of proinflammatory cytokines, exacerbating systemic inflammatory responses and further impairing cardiovascular and renal function [37]. However, this study did not observe a significant positive correlation between the severity of depressive symptoms and stroke incidence in patients with CKM stage 0. Chronic inflammation associated with CKM, along with substantial alterations in individual metabolic or cardiovascular risk factors, may play a pivotal role in mediating this relationship. Further research is warranted to elucidate these

XSL•FO
RenderX

complex interactions and to identify potential intervention targets to mitigate stroke risk in this population.

Our analysis revealed that participants experiencing severe depressive symptoms in the CKM syndrome group had an increased risk of stroke compared to those with less severe symptoms. Stratified subgroup analyses (eg, age and gender) further confirmed that depressive symptoms significantly correlate with new-onset stroke incidence. These findings emphasize that depression is an independent risk factor for stroke, even when other systemic diseases are present. Addressing mild-to-moderate depressive symptoms early to prevent progression could significantly reduce the risk of stroke in populations with CKM syndrome, potentially mitigating both individual and systemic health burdens.

While numerous studies have documented a connection between depression and stroke, these investigations often overlook the broader systemic interactions underlying this relationship. Most previous studies have focused on the impact of poststroke depression on patient outcomes. Sun et al identified that disruptions in neurovascular coupling following a stroke may be a key mechanism underlying the development of depressive symptoms [38]. Approximately 27% of individuals who had a stroke experienced depression, with early-onset depression often persisting [39]. While research on the impact of depression on stroke incidence remains limited, most studies are cross-sectional. Persistently high depressive symptoms and remitted depressive symptoms were associated with increased stroke risk in a large cohort of US adults [40]. A meta-analysis encompassing 28 prospective cohort studies found that depression is associated with a 55% increase in the risk of stroke-related mortality [41]. Using the CHARLS database and logistic regression methods, Cui et al [42] identified a strong association between persistently high levels of depressive symptoms and increased stroke risk. However, the study overlooked the time-dependent relationship between depressive symptoms and stroke onset. In this study, we used a Cox proportional hazards model to examine the association between baseline depressive symptoms and the incidence of stroke, which accounts for time-dependent covariates and is better suited to complex clinical research scenarios.

This study offers several strengths. First, by using data from a large-scale prospective longitudinal study, we used Cox regression models to establish a positive association between depressive symptoms and stroke incidence. Notably, this is the first study to consider the influence of time-dependent variables on outcomes within a syndrome-specific population, thereby improving its clinical relevance. Second, we investigated both the overall relationship between depressive symptoms and stroke risk and the association across different quartiles of depressive symptom severity, allowing for a more nuanced understanding of how varying levels of depression impact stroke occurrence. Finally, subgroup analyses were performed to confirm the robustness and reliability of our findings.

This study has several limitations. First, previous research, including the China Kadoorie Biobank study [43] and other studies on Chinese populations, highlights the low proportion of individuals with depression who receive treatment [44]. As a result, the impact of antidepressant therapy on the study outcomes is likely minimal. Second, the diagnoses of stroke, diabetes, and hypertension in this study were based on self-reported information from consultations with medical professionals, which may introduce reporting bias. To address this limitation, future research should incorporate more objective diagnostic measures. Additionally, depressive symptoms were assessed using a single baseline Center for Epidemiologic Studies Depression Scale score, which may not capture dynamic longitudinal changes during the follow-up period. However, baseline measurements are validated as independent predictors in large-scale cohorts and represent a critical window for early clinical screening and risk stratification. Moreover, the incidence of stroke, as well as diagnoses of hypertension and diabetes, relied on self-reported data, which could lead to recall and misclassification biases. Finally, despite adjusting for a wide range of covariates, residual confounding may still exist due to unmeasured factors, such as specific dietary patterns, physical activity, and the use of medications like antidepressants or antihypertensives. While previous research suggests that antidepressant treatment rates are particularly low in Chinese populations, minimizing their potential impact on our findings, future studies should integrate more objective diagnostic measures and longitudinal data to further strengthen the robustness of these associations.

Conclusions

This cohort study provides evidence of a significant association between depressive symptoms and an increased risk of stroke in individuals with CKM syndrome stages 0 to 3. The new AHA definition underscores the impact of emotional management on systemic, multisystem diseases. Effective treatment of depression may indirectly reduce the risk of stroke by lowering inflammation levels and promoting healthier lifestyle changes.

Abstract

Background: Lung transplantation (LTx) is an established treatment for patients with end-stage lung diseases and can substantially improve survival. However, posttransplant recovery involves complex physical, psychological, and functional challenges, making quality of life (QoL) an important outcome beyond survival alone. Evidence on early longitudinal QoL changes after LTx remains limited, particularly in Chinese recipients and when assessed using disease-specific patient-reported outcome instruments.

Objective: This study aimed to assess QoL and track its longitudinal changes in patients who underwent LTx using a disease-specific patient-reported outcome instrument.

Methods: This single-center prospective cohort study screened 66 patients for enrollment who underwent LTx at the Xi'an Jiaotong University Lung Transplantation Center in China from June 2023 to December 2025. QoL was assessed using the Chinese version of the Lung Transplant Quality of Life questionnaire at baseline (preoperative) and serially at 1, 2, 3, 4, 5, and 6 months after surgery. The Lung Transplant Quality of Life questionnaire comprises 40 items across 7 domains, and each domain score was calculated as the item mean (range 0‐4). Random-intercept linear mixed models (LMMs) with both categorical and linear time specifications were fitted separately for each domain to evaluate longitudinal changes, accounting for repeated measures and incomplete follow-up under the missing at random assumption.

Results: A total of 203 interviews from 51 eligible patients were included in this study, with a median of 5 (IQR 2-6) interviews for each patient. LMM analysis revealed significant overall time effects in 6 of 7 domains (likelihood ratio test: $P<.01$ in all cases). Health perceptions showed the earliest and largest improvement (LMM-adjusted mean difference [MD] −1.58 at month 6; β=−0.23 points per month; $P<.001$), followed by respiratory symptoms (MD −0.95 at month 6; β=−0.15 per month), anxiety and depression (MD −0.82 at month 6; β=−0.13 per month), digestive symptoms (MD −0.50 at month 6; β=−0.10 per month), and cognitive limitations (MD −0.51 at month 6; β=−0.09 per month; $P<.001$ in all cases). Global well-being was the only domain with a positive trajectory (MD 1.18 at month 6; β=0.13 per month; $P=.002$), with significant improvement already evident at month 1 (MD 0.71; $P=.23$).

Conclusions: LTx significantly improved QoL in patients with end-stage lung diseases, with the most substantial gains in health perceptions and respiratory symptoms. Patient-reported outcome–based monitoring can capture clinically meaningful QoL changes and should be integrated into routine posttransplant care to identify critical intervention time points and optimize long-term recovery.

KEYWORDS

lung transplantation; quality of life; patient-reported outcomes; PROs; symptoms

Introduction

Lung transplantation (LTx) is the definitive treatment for end-stage lung diseases, including chronic obstructive lung disease, idiopathic pulmonary fibrosis, and cystic fibrosis [1,2]. With advancements in surgical techniques and perioperative care, the 1- and 5-year survival rates have exceeded 80% and 70%, respectively, although outcomes vary across transplantation centers [1]. Despite these improvements in survival, patients after LTx continue to face multiple physical and psychological complications at various time points, including primary graft dysfunction [3], acute kidney injury [4], atrial arrhythmias [5], anastomotic fistulas [6], fungal infections [7], airway hemorrhage [8], and delirium, all of which severely undermine postoperative survival and quality of life (QoL) [9]. Current clinical practices predominantly focus on reducing

XSL•FO
RenderX

postoperative complications, improving survival rates, and prolonging survival time [10,11], which may overlook the patient perspective on life quality.

This study was motivated by concerns raised by patients and their families, who frequently asked whether their symptoms and functional impairments would resolve and how these would change over time after surviving surgery. A limited body of literature has documented psychosocial and mental health outcomes after transplantation, but these studies have primarily focused on liver, heart, or kidney transplantation [12-14]. Furthermore, the assessment of QoL in patients undergoing LTx has largely relied on generic scales such as the 36-Item Short Form Health Survey or EQ-5D [15,16], which may not adequately capture the specific symptoms, functions, and lived experiences following LTx. Singer et al [17] developed the Lung Transplant Quality of Life (LT-QoL) scale in 2019, a disease-specific instrument that was subsequently translated and validated for the Chinese cultural context, thereby facilitating more accurate QoL assessment in this population.

Patient-reported outcomes (PROs) have been increasingly applied in clinical practice to monitor patient symptoms and experiences [18], improve clinical care [19], and support drug development evaluations by regulatory agencies [20]. However, very little is currently known about longitudinal QoL changes and trajectories in patients undergoing LTx based on PROs. Therefore, we conducted a prospective cohort study to assess QoL changes in patients undergoing LTx at our center using the Chinese version of the LT-QoL questionnaire and characterize the temporal patterns of recovery across multiple QoL domains.

Methods

Study Design and Patients

This was a single-center prospective cohort study conducted at the Xi'an Jiaotong University Lung Transplantation Center (First Affiliated Hospital of Xi'an Jiaotong University, China). A total of 66 patients who underwent LTx from June 2023 to December 2025 were screened for enrollment. Of these 66 patients, 58 (87.9%) patients or their families were fully informed about the study procedures, whereas 8 (12.1%) declined participation. Of the 58 initial patients, 7 (12.1%) were subsequently excluded (n=1 due to retransplantation and n=6 who withdrew due to being too weak to self-report), producing a final analytic cohort of 51 (87.9%) patients who contributed 203 valid interviews across 7 time points.

Inclusion criteria were (1) age of 18 years or above, (2) having undergone LTx, and (3) ability to understand the study content. Patients were excluded if they (1) underwent retransplantation or multi-organ transplantation, (2) were too weak to self-report outcomes, or (3) were diagnosed with active psychosis or severe cognitive impairment during follow-up.

Ethical Considerations

This study was approved by the institutional review board of the First Affiliated Hospital of Xi'an Jiaotong University, China (approval number: LLSBPJ-2023-474), was exempted from clinical trial registration as it was an observational study, and was conducted in accordance with the Declaration of Helsinki. A total of 49.0% (25/51) of the patients provided written informed consent before surgery, whereas the remaining patients provided verbal informed consent due to the urgency of surgery and subsequently supplemented it with written consent at the earliest appropriate time.

Procedures

All enrolled patients were invited to complete the LT-QoL scale at each scheduled assessment. The LT-QoL is a disease-specific questionnaire developed for the assessment of QoL in patients undergoing LTx [17]. A Chinese version was authorized and demonstrated adequate validity, reliability, and internal consistency. It consists of 40 items assessing 7 domains grouped under 4 overarching categories: symptoms (respiratory symptoms: 9 items; digestive symptoms: 8 items), health perceptions (5 items), functional impairment (sexual problems: 3 items; cognitive limitations: 4 items), and well-being (anxiety and depression: 9 items; global well-being: 2 items). Each item is quantified on a 5-point Likert scale (0 - 4), with higher scores indicating greater symptom burden or impairment for all domains except global well-being, where higher scores represent better outcomes. For each domain, a composite score was calculated as the arithmetic mean of its constituent items (item mean score; range 0 - 4). Further details are provided in Multimedia Appendix 1.

For each patient, assessments were scheduled before surgery (T0; baseline) and at 1, 2, 3, 4, 5, and 6 months after LTx (T1-T6). For patients who were unable to self-report, family members or caregivers completed the questionnaire based on the patient's actual condition. Assessments were conducted in the LTx specialized outpatient clinic or via WeChat by a trained study team comprising 2 specialized nurses, 2 researchers, and 2 clinicians. Each visit could take place within a window of –7 days to +7 days from the actual scheduled appointment. Data collection was performed by a nurse under the supervision of a researcher and a clinician to ensure accuracy and completeness.

Data Collection and Management

In this longitudinal study, data were collected and managed using the REDCap (Research Electronic Data Capture; Vanderbilt University) platform hosted at Xi'an Jiaotong University Health Science Center [21]. REDCap is a secure, web-based application designed to support data capture for research studies [22]. Patients could choose to complete either an electronic or paper-based questionnaire. Paper-based questionnaire data were entered into REDCap and verified by an independent nurse.

Demographic information and clinical characteristics were obtained from medical records supplemented by self-reported information about demographics, health behaviors, and medical history. All data were double-checked and cleaned by a professional statistician and a clinician to ensure accuracy and maintain high data quality.

Statistical Analysis

Descriptive statistics, including means with SDs and medians with IQRs, were used to summarize patient characteristics.

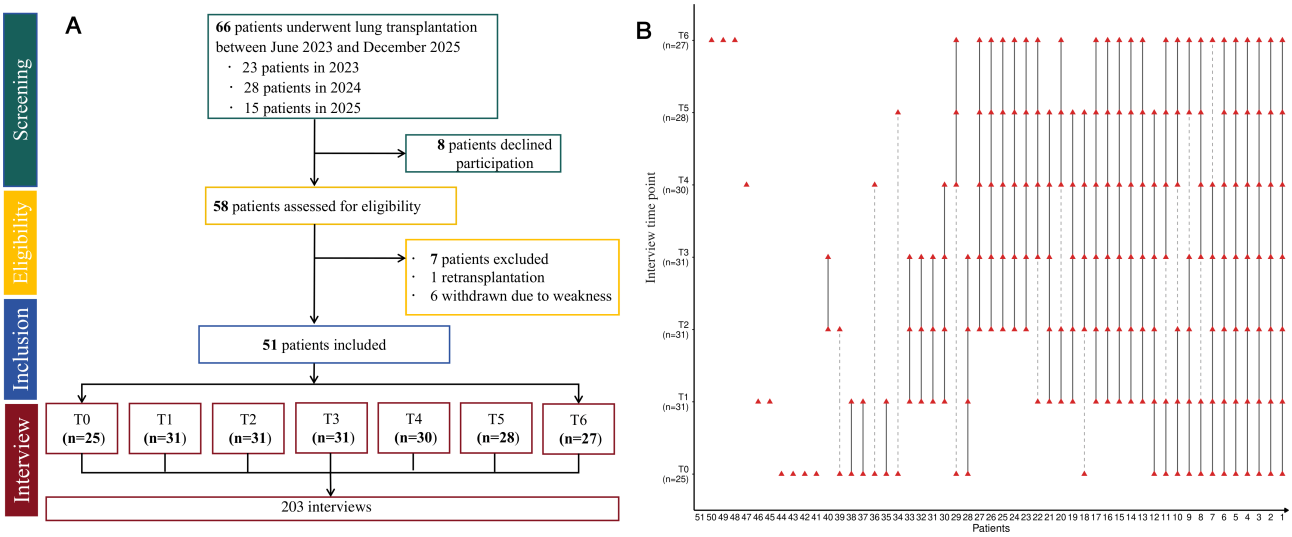
XSL•FO
RenderX

Continuous variables were compared using unpaired 2-tailed Student *t* tests or Wilcoxon signed-rank tests for normally and nonnormally distributed data, respectively. Categorical variables were presented as frequencies and percentages and compared using Fisher exact tests or chi-square tests as appropriate. A 2-sided *P* value of less than .05 was considered statistically significant.

To evaluate longitudinal changes in QoL scores, we used random-intercept linear mixed models (LMMs) fitted separately for each of the 7 QoL domains using restricted maximum likelihood estimation. Two complementary model specifications were used for each domain. In model 1 (categorical time), score was modeled as a function of time point + (1 | participant), where time point was treated as a categorical fixed effect with T0 (baseline) as the reference level. This model yielded the LMM-estimated marginal mean at each time point and the adjusted mean difference (MD) vs baseline with 95% CIs and Satterthwaite-approximated *P* values for each pairwise contrast. In model 2 (linear time), score was modeled as a function of month + (1 | participant), where month was treated as a continuous fixed effect (0, 1, 2,..., 6). This model estimated the average linear slope (β) per month with its 95% CI, quantifying the overall rate of change across the 6-month follow-up period.

The random-intercept specification accounted for within-patient correlation due to repeated measures and accommodated the unbalanced longitudinal design (51 patients contributing 203 interviews). All available observations were used under the missing at random (MAR) assumption, thereby mitigating potential bias from incomplete follow-up data. Individual patient trajectories overlaid with the LMM population fit are shown in Figure S1 in Multimedia Appendix 1, illustrating the heterogeneity among patients and the pattern of missing data that motivated the mixed-effects approach. The intraclass correlation coefficient (ICC; $\sigma^2_u/[\sigma u^2_u + \sigma^2_e]$) was calculated for each domain to quantify the proportion of the total variance attributable to between-patient differences.

The overall significance of the time effect for each domain was assessed using a likelihood ratio test (LRT) comparing the categorical time model against a null model with random intercept only (score modeled as a function of 1 + [1 | participant]). Estimated marginal means with 95% CIs were derived from model 1 for each domain at each time point. Adjusted MDs vs baseline with 95% Wald CIs were displayed as a forest plot; the linear slopes per month from model 2 were appended to the same forest plot for each domain. Individual patient trajectories were overlaid with the LMM population fit in a spaghetti plot (Figure S1 in Multimedia Appendix 1) to illustrate individual-level heterogeneity and the pattern of missing data. In addition to the domain-level analyses, item-level LMMs (score modeled as a function of time point + [1 | participant]) were fitted for all 40 individual LT-QoL items to identify specific symptoms or concerns driving the observed domain-level changes.



All analyses were performed using R (version 4.4.2; R Foundation for Statistical Computing) with the *lme4* package for LMM estimation, the *lmerTest* package for Satterthwaite df and *P* values, and the *emmeans* package for estimated marginal means and pairwise contrasts.

Results

Clinical Characteristics

Of the 66 patients who underwent LTx at our center, 15 (22.7%) were excluded: 8 (53.3%) of them declined participation, 1 (6.7%) underwent retransplantation, and 6 (40%) withdrew consent. A total of 51 eligible patients completed 203 valid QoL interviews from baseline to 6 months postoperatively. The median number of interviews per patient was 5 (IQR 2 - 6), and 80.4% (41/51) and 66.7% (34/51) of the patients completed at least 2 and 3 valid interviews, respectively (Figure 1).

Figure 1. Patient enrollment and interview completion: (A) flowchart of patient screening, eligibility assessment, and inclusion and (B) interview completion for each patient across time points. Solid lines indicate consecutive follow-up visits; dashed lines indicate gaps due to missing interviews. T0: baseline (before surgery); T1 to T6: first to sixth month after lung transplantation.

XSL•FO
RenderX

The mean age of the eligible patients was 56.4 (SD 9.3) years, and most were male (44/51, 86.3%) and did not have a history of smoking (39/51, 76.5%). Few of them self-reported current smoking, alcohol use, or major comorbidities (hypertension: 5/51, 9.8%; diabetes: 2/51, 3.9%; cerebrovascular or cardiovascular disease: 4/51, 7.8%). The most frequent pretransplant diagnosis was idiopathic pulmonary fibrosis (26/51, 51.0%), followed by chronic obstructive pulmonary disease (13/51, 25.5%) and pneumoconiosis (10/51, 19.6%). Mean BMI was 20.5 (SD 3.7) kg/m^2, indicating a generally lean cohort consistent with end-stage lung disease. Bilateral sequential LTx was the most common surgery type (27/51, 52.9%), followed by single transplantation (Table 1).

Table . Demographic and clinical characteristics of the patients (N=51).

[g]VA: veno-arterial ECMO.
[h]VAV: veno-arterial-veno ECMO.

Respiratory Symptoms

In the random-intercept LMM, the model-estimated baseline mean for the respiratory symptom domain was 1.71 points (SD 0.14; 95% CI 1.43-1.98) on the item mean scale from 0 to 4 (Figure 2). The overall time effect was significant (LRT: χ^2_6=47.8; P<.001), and the ICC was 0.40, confirming that repeated measures within patients were substantially correlated and that the mixed-effects approach was appropriate (Table S1 in Multimedia Appendix 1).

XSL•FO
RenderX

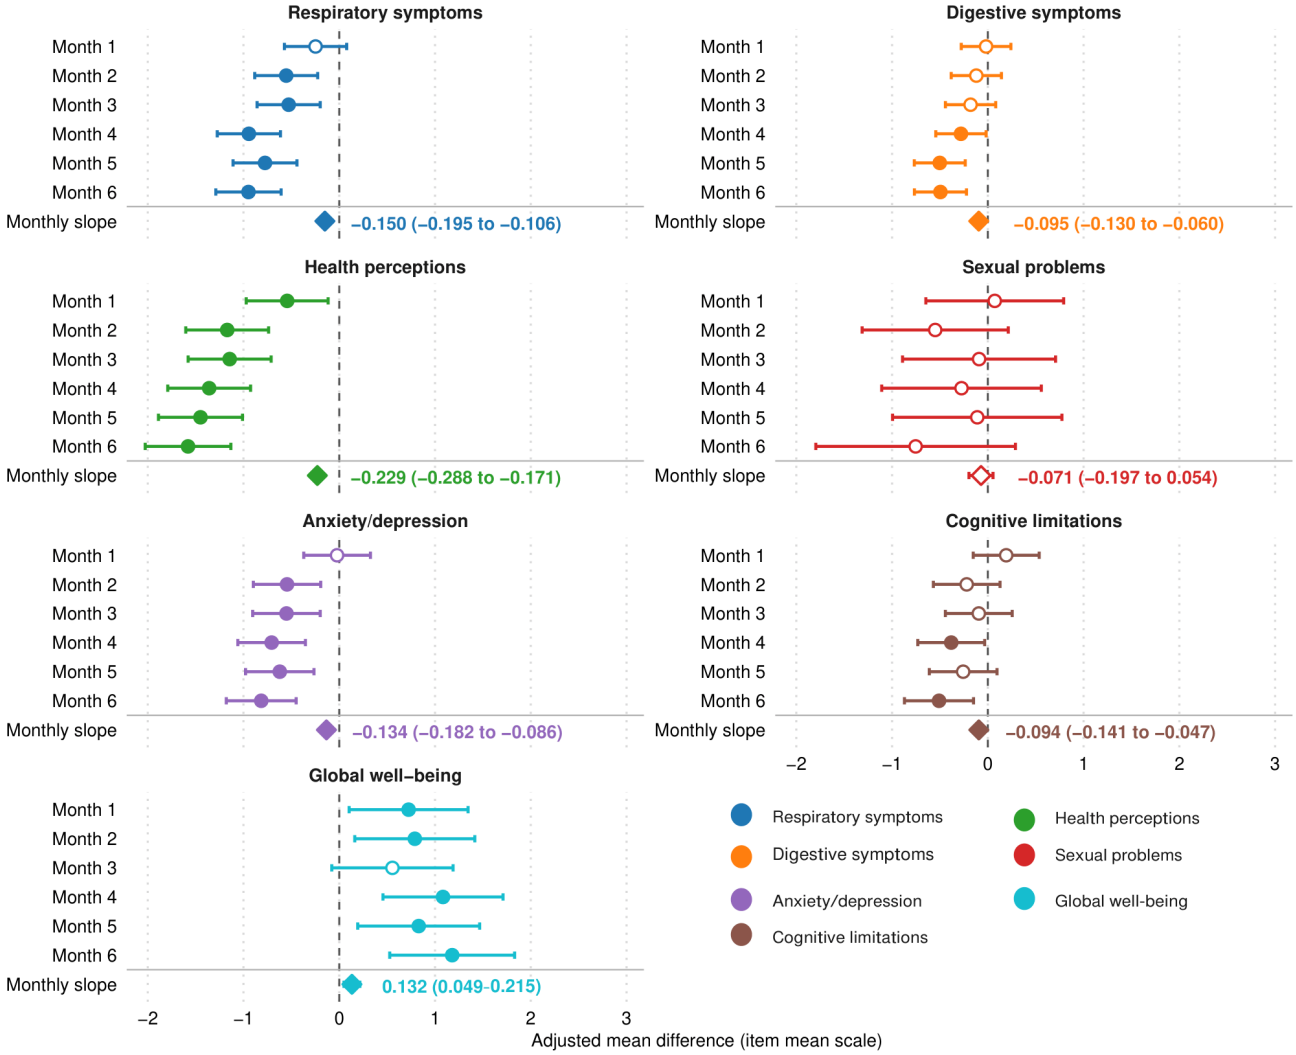

Figure 2. Linear mixed model (LMM)–estimated marginal means of quality of life domains over 6 months after lung transplantation. Random-intercept LMMs were fitted separately for each domain. Shaded bands represent 95% Wald CIs. Lower scores indicate better status in all domains except global well-being, for which higher scores represent better outcomes. T0: baseline (before surgery); T1 to T6: first to sixth month after lung transplantation.

The adjusted MD vs baseline was not significant at month 1 (MD −0.25, 95% CI −0.57 to 0.07; *P*=.13) but became significant from month 2 onward (MD −0.57, 95% CI −0.89 to −0.24; *P*=.001). The improvement continued to increase, reaching an MD of −0.95 (95% CI −1.29 to −0.61; *P*<.001) at month 6. The linear slope was −0.15 points per month (95% CI −0.20 to −0.11; *P*<.001), indicating a steady and clinically meaningful decline in respiratory symptoms over the 6-month follow-up period (Figure 3).

XSL•FO
RenderX

Figure 3. Forest plot of linear mixed model–adjusted mean differences vs baseline and linear slopes per month by quality of life domain. Circles denote time point contrasts vs baseline (model 1); diamonds denote the linear slope per month (model 2). Filled markers indicate a *P* value of .05 or less; blank markers indicate a *P* value above .05. Error bars represent 95% Wald CIs. The dashed vertical line marks the null value of 0 (no change).

At the item level (Table S2 in Multimedia Appendix 1), the most burdensome preoperative respiratory symptoms were cough with sputum (baseline β_0=2.79), sputum production (baseline β_0=2.75), wheezing (baseline β_0=2.71), and shortness of breath (baseline β_0=2.65). These items also showed the largest LMM-adjusted 6-month improvements (shortness of breath: MD −1.65 and *P*<.001; wheezing: MD −1.58 and *P*<.001; sputum production: MD −1.22 and *P*<.001; cough: MD −1.18 and *P*<.001). Chest tightness (baseline β_0=2.05) showed no early change (month 1: MD −0.40; *P*=.24) but a significant improvement at month 6 (MD −1.45; *P*<.001). Notably, chest pain showed a transient worsening at month 1 (MD 0.70; *P*=.02) before declining, consistent with the typical early postoperative course; however, this improvement did not reach statistical significance by month 6 (MD −0.52; *P*=.07).

Digestive Symptoms

The estimated baseline mean for the digestive symptom domain was 0.84 points (SD 0.11; 95% CI 0.62-1.06), substantially lower than that of the respiratory symptom domain. The overall time effect was significant (LRT: χ^2_6=28.0; *P*<.001; ICC=0.41; Table S1 in Multimedia Appendix 1).

Digestive symptoms followed a slower improvement trajectory than respiratory symptoms. No significant change was detected at months 1 to 3 (*P*>.15 in all cases; Figure 2). The adjusted MD first became significant at month 4 (MD −0.28, 95% CI −0.54 to −0.02; *P*=.03) and strengthened throughout months 5 and 6 (month 5: MD −0.50, 95% CI −0.77 to −0.24, and *P*<.001; month 6: MD −0.50, 95% CI −0.77 to −0.22, and *P*<.001). The slope was −0.10 points per month (95% CI −0.13 to −0.06; *P*<.001).

At the item level (Table S2 in Multimedia Appendix 1), the most burdensome baseline digestive symptom was loss of appetite (baseline β_0=1.66), which also showed the largest 6-month improvement (MD −1.09; *P*=.001). Fear of being far from a toilet showed both an early improvement at month 1 (MD −0.58; *P*=.005) and a sustained 6-month reduction (MD −0.77; *P*<.001). Altered taste improved significantly by month 6 (MD −0.75; *P*=.02). In contrast, stomach cramps and pain showed a transient worsening at month 1 (MD 0.45; *P*=.02) before returning to baseline levels.

XSL•FO
RenderX

Cognitive Limitations

The estimated baseline mean for the cognitive limitation domain was 0.96 points (SD 0.15; 95% CI 0.67-1.25), with a significant overall time effect (LRT: χ^2_6=22.4; *P*=.001; ICC=0.36; Table S1 in Multimedia Appendix 1). As shown in Figures 2 and 3, the trajectory of improvement was not significant at months 1 to 3 (month 1: MD 0.19 and *P*=.17; month 3: MD −0.11 and *P*=.18). A significant reduction was first observed at month 4 (MD −0.39, 95% CI −0.73 to −0.04; *P*=.003) and persisted at month 6 (MD −0.51, 95% CI −0.87 to −0.15; *P*=.006). The slope was −0.09 points per month (95% CI −0.14 to −0.05; *P*<.001). Item-level analyses showed the largest 6-month improvements in difficulty sustaining attention (MD −0.80; *P*<.001; Table S2 in Multimedia Appendix 1) and difficulty concentrating and thinking (MD −0.50; *P*=.01), followed by slowed reactions to past events (MD −0.57; *P*=.02). General forgetfulness showed only a nonsignificant numerical decline (MD −0.25; *P*=.35).

Sexual Problems

For the sexual problem domain, the LMM-estimated baseline mean was 1.17 points (SD 0.28; 95% CI 0.63-1.71). The overall time effect was not significant (LRT: χ^2_6=5.3; *P*=.55; Table S1 in Multimedia Appendix 1), and no individual postoperative time point reached statistical significance vs baseline (*P*>.15 in all cases; Figures 2 and 3). The slope was −0.07 points per month (95% CI −0.20 to 0.05; *P*=.27). The wide CIs reflected substantial missingness in this domain. At the item level, none of the 3 sexual problem items showed significant changes at any time point (*P*>.08 in all cases).

Health Perceptions

The health perception domain showed the largest and earliest improvement of all 7 domains. The LMM-estimated baseline mean was 1.99 points (SD 0.18; 95% CI 1.63-2.34), the highest baseline score of any domain, indicating that concerns about health status were the most prominent source of preoperative distress. The overall time effect was highly significant (LRT: χ^2_6=65.1; *P*<.001; ICC=0.34; Table S1 in Multimedia Appendix 1).

Crucially, a significant reduction was already clear at month 1 (MD −0.55, 95% CI −0.97 to −0.12; *P*=.01), and the improvement increased monotonically thereafter, reaching an MD of −1.58 (95% CI −2.02 to −1.14; *P*<.001) at month 6 (Figures 2 and 3). The slope was the steepest among all 7 domains: −0.23 points per month (95% CI −0.29 to −0.17; *P*<.001). At the item level (Table S2 in Multimedia Appendix 1), all 5 health perception items improved significantly by month 6, such as fear of infection (MD −1.77; *P*<.001), uncertainty about future health (MD −1.76; *P*<.001), worry about worsening health (MD −1.73; *P*<.001), worry about graft failure or rejection (MD −1.68; *P*<.001), and difficulty planning for the future (MD −0.97; *P*<.001). Notably, uncertainty about future health and worry about graft rejection were already significantly lower at month 1 (MD −0.99 with *P*<.001 and MD −0.55 with *P*=.03, respectively), whereas fear of infection improved more gradually and only reached significance in month 6 (MD −1.76; *P*<.001).

Anxiety and Depression

The estimated baseline mean for the anxiety and depression domain was 1.14 points (SD 0.15; 95% CI 0.85-1.43). The overall time effect was significant (LRT: χ^2_6=37.1; *P*<.001; ICC=0.36; Table S1 in Multimedia Appendix 1). As with respiratory symptoms, there was no detectable change at month 1 (MD −0.02; *P*=.89), but a significant improvement emerged from month 2 onward (MD −0.56, 95% CI −0.90 to −0.21; *P*=.003) and continued up to month 6 (MD −0.82, 95% CI −1.18 to −0.46; *P*<.001). The slope was −0.13 points per month (95% CI −0.18 to −0.09; *P*<.001).

Item-level analyses showed that the largest 6-month reductions were in uncontrollable worry (MD −1.27; *P*<.001), low mood (MD −1.09; *P*<.001), feeling sad (MD −0.99; *P*<.001), and irritability (MD −0.97; *P*<.001). The items reflecting more severe psychological distress, including inability to stop worrying (MD −0.64; *P*=.003), feeling guilty (MD −0.66; *P*=.001), and feeling like a burden to others (MD −0.66; *P*=.001), also improved significantly, suggesting a broad amelioration of emotional distress (Table S2 in Multimedia Appendix 1). Difficulty sleeping improved significantly by month 6 (MD −0.67; *P*=.02), although there was a nonsignificant trend toward worsening at month 1 (MD 0.51; *P*=.06). Perceived loss of interest in daily activities did not reach significance at month 6 (MD −0.41; *P*=.10).

Global Well-Being

The global well-being domain (higher scores indicate better outcomes) was the only domain with a positive trajectory. The estimated baseline mean was 1.85 points (SD 0.26; 95% CI 1.35-2.36), and the overall time effect was significant (LRT: χ^2_6=15.7; *P*=.01; ICC=0.27; Table S1 in Multimedia Appendix 1).

The adjusted MD rose to 0.71 (95% CI 0.09-1.33; *P*=.23) at month 1, indicating that patients already perceived meaningful improvement in life quality within the first month after transplantation. The improvement peaked at month 4 (MD 1.01, 95% CI 0.46-1.71; *P*<.001) and was sustained up to month 6 (MD 1.18, 95% CI 0.53-1.83; *P*<.001). The slope was 0.13 points per month (95% CI 0.05-0.22; *P*=.002). At the item level, enjoyment of life showed a borderline improvement at month 1 (MD 0.60; *P*=.08) that became highly significant by month 6 (MD 1.27; *P*<.001). Satisfaction with current QoL improved earlier and more robustly: it was already significantly higher at month 1 (MD 0.89; *P*=.02) and continued to improve up to month 6 (MD 1.11; *P*=.004), suggesting that patients' subjective life satisfaction recovered more rapidly than their ability to enjoy daily activities following LTx.

Discussion

Principal Findings

In this study, we found significant improvements in the QoL of patients undergoing LTx in the perioperative period, with the

XSL•FO
RenderX

earliest and largest improvement in health perceptions followed by respiratory symptoms and anxiety and depression. In contrast, the sexual problem domain showed no significant change over time, partly attributable to high missingness and cultural reporting barriers. These findings demonstrate that LTx meaningfully improves overall QoL for patients with end-stage lung diseases across multiple domains, with clinically important reductions in symptom burden, psychological distress, and health-related concerns.

Respiratory symptoms were the predominant preoperative concern, with an estimated baseline mean of 1.71 points (95% CI 1.43-1.98), and the overall time effect was highly significant. This finding is consistent with those of previous studies linking forced vital capacity and forced expiratory volume improvements with pulmonary function recovery after transplantation [23,24]. Unlike previous studies that primarily focused on pulmonary function [25,26], we also monitored gastrointestinal symptom changes using LMMs. The digestive symptom domain showed a slower improvement trajectory than respiratory symptoms: no significant change was detected until month 4, with the improvement strengthening up to month 6. A possible explanation for this improvement may be the resolution of hypoxia and the subsequent enhancement in overall health, which collectively contribute to the restoration of normal metabolic and digestive functions [27]. Notably, stomach cramps and pain showed a transient worsening at month 1 before returning to baseline levels, and chest pain similarly worsened early. This early symptom exacerbation pattern likely reflects the combined effects of surgical stress [28], immunosuppressive medications (eg, steroids and calcineurin inhibitors) [29], and associated gastrointestinal complications. Similar gastrointestinal symptom profiles have been reported in kidney transplant recipients, with strong associations with poorer QoL [30]. Our findings support the integration of routine gastrointestinal symptom monitoring and proactive management into posttransplant care protocols.

Postoperative cognitive impairment is a common clinical phenomenon with a reported incidence of 58.3%, influenced by factors such as operation time, intensive care unit stay, pain, and cold ischemia time [31,32]. Decreases in processing speed and executive function at 6 months may signify worse survival and higher occurrence of chronic lung allograft dysfunction [33]. In contrast, the sexual problem domain was the only domain for which the LMM detected no significant overall time effect, and no individual postoperative time point reached significance vs baseline. In traditional Chinese culture, sexual health remains a sensitive and often stigmatized topic, which may lead to underreporting or social desirability bias. We did not apply analytical adjustments for potential underreporting as the degree cannot be quantified from the available data. Therefore, this null finding should be interpreted with caution. Compared to liver or kidney transplantation, where sexual problems are more prevalent [34,35], the sexual health domain in LTx remains understudied, and future research should consider culturally sensitive approaches such as anonymous electronic surveys, gender-matched interviewers, or validated proxy measures to improve assessment accuracy in Chinese transplant populations.

The health perception domain showed the earliest and largest improvement of all 7 domains, indicating that health-related concerns were the most prominent source of preoperative distress. The gradual resolution of these concerns suggests that patients experienced progressive confidence recovery. However, the persistent concern about infections despite decreasing scores underscores the challenges of living with immunosuppressive therapy. More than 30% of patients undergoing liver transplant have been reported to experience clinically significant mental distress after surgery [36], and our findings reinforce the importance of sustained psychological support throughout recovery. For the anxiety and depression domain, the adjusted improvement followed a similar delayed pattern to that of respiratory symptoms, which involved no change at month 1 but significant improvement from month 2 onward, combined with the largest item-level reductions in uncontrollable worry, low mood, and feeling sad. These findings suggest a broad amelioration of emotional distress rather than improvement in isolated symptoms.

One notable finding is the global well-being trajectory, which was the only domain with a positive slope, and the fact that the adjusted improvement was already significant at month 1. This early peak aligns with the prior longitudinal study by TenVergert et al [37], who found significant improvement in physical mobility, pain, energy, and emotional reaction at the first postoperative month. This initial peak may represent a “honeymoon effect”—an initial euphoria from surviving major surgery and receiving a new organ combined with relief from severe preoperative symptoms. However, the LMM estimates suggest a complex pattern wherein well-being peaked at month 4 rather than at month 1, and a nonsignificant dip was observed at month 3. This dip may reflect encounter with postoperative complications such as atrial arrhythmias [38], hyperglycemia [39], acute rejection [40], and medication side effects [41]. Despite this fluctuation, well-being scores remained above preoperative levels at all postoperative time points, reflecting a dynamic trajectory of initial optimism, subsequent adaptation, and long-term net improvement. Unmet life expectations after transplantation may contribute to increased stress [42]. To mitigate the emotional fluctuations observed after month 1, psychological interventions should be tailored to the early recovery phase, potentially beginning during the transition from hospital to home [43,44].

Comparison With International Studies

The overall improvement trajectory we observed is consistent with that of the original LT-QoL validation cohort from the United States in the study by Singer et al [17], although direct numerical comparisons are limited by differences in follow-up protocols and population characteristics and our use of LMMs rather than raw score comparisons. Our findings also align with those of Ricotti et al [43], who reported significant QoL and functional improvements after LTx in a Chinese single-center study. The cultural specificities of our population, particularly regarding psychological and sexual health reporting, highlight the importance of developing culturally adapted PRO assessment strategies for diverse transplant populations.

XSL•FO
RenderX

Clinical Implications

Our findings carry several important clinical implications. First, the LMM analysis identified month 1 as a critical window characterized by transient worsening in chest pain and stomach cramps, whereas global well-being simultaneously peaked. This paradoxical pattern characterized by symptom worsening alongside perceived improvement suggests that targeted gastrointestinal symptom management and immunosuppressive protocol adjustment should be implemented during this period without assuming that patients' optimism reflects symptom resolution. Second, the delayed cognitive improvement (significant only from month 4) highlights the need for continued monitoring and rehabilitation throughout the recovery period. Long-term tracking of cognitive function changes is important for capturing early signals of impairment, allowing for timely implementation of targeted interventions such as cognitive training, rehabilitation, and support group therapy [45]. Postoperative rehabilitation, including physical therapy, aerobic exercise, and resistance training, can also help patients adapt to their new life [46]. Third, our findings demonstrate that PRO-based monitoring using disease-specific instruments and LMM analysis can capture clinically meaningful QoL changes that may not be detectable by standard clinical assessments alone. The integration of routine PRO monitoring into posttransplant care can facilitate early identification of patients requiring additional support, enable personalized care planning, and improve shared decision-making between clinicians and patients. In our clinical practice, we have established a peer support program named the LTx Patients Association, which invites well-recovered transplant recipients to provide guidance and emotional support to recent transplant recipients, encouraging social reintegration through community-based activities.

Limitations

Several limitations should be acknowledged. First, our data were derived from a relatively small cohort at a single center with follow-up limited to 6 months. Although we used LMM, which appropriately handles incomplete data under the MAR assumption, survivorship bias remains a concern in that patients who remained in follow-up may represent a healthier subset, potentially leading to overestimation of QoL improvement at later time points. Second, the reasons for missing data are multifactorial, including patient death, geographic barriers to follow-up, health deterioration preventing participation, and the urgency of transplant surgeries precluding baseline assessment for some patients. While our LMM approach provides valid inference under the MAR assumption and the ICCs (0.25 - 0.41 across domains) confirmed the appropriateness of the mixed-effects framework, unmeasured confounding related to differential attrition cannot be ruled out. Third, while the LT-QoL questionnaire has been validated for the Chinese context, certain domains, particularly sexual function, may be subject to cultural response bias, as discussed above. The high missingness in this domain severely limits statistical power. Additionally, the relatively short follow-up period may not capture long-term QoL fluctuations. Future studies should implement strategies to minimize attrition, establish multicenter cohorts, extend follow-up duration, and develop culturally tailored assessment approaches to comprehensively evaluate QoL in Chinese patients undergoing LTx.

Conclusions

In this prospective cohort study, LTx significantly improved overall QoL in patients with end-stage lung diseases over 6 months, as demonstrated by random-intercept LMM analysis across 7 QoL domains. The health perception domain showed the earliest and largest improvement, followed by respiratory symptoms, anxiety and depression, and cognitive limitations. Additionally, the first postoperative month represents a critical intervention window for gastrointestinal symptom management and psychological support. These findings support the integration of disease-specific PRO monitoring and LMM-based longitudinal analysis into posttransplant clinical care to identify critical intervention time points, personalize supportive care, and optimize long-term recovery outcomes.

Abstract

Background: Cardiac resynchronization therapy with defibrillator (CRT-D) improves survival, reduces hospitalization, and enhances quality of life in patients with heart failure and reduced ejection fraction (HFrEF). As heart failure prevalence increases in aging societies such as Japan, the associated clinical and economic burden continues to rise. Previous cost-effectiveness analyses conducted in multiple countries indicate that CRT-D may be cost-effective in selected patients with HFrEF. However, its cost-effectiveness within the Japanese health care system remains uncertain.

Objective: This study aimed to evaluate the cost-effectiveness of CRT-D in patients with HFrEF within the Japanese health care setting.

Methods: A partitioned survival model was developed with 3 health states: after treatment (follow-up), hospitalization, and death. Survival for CRT-D was estimated by reconstructing individual patient-level data from the Kaplan-Meier curve of the RAFT (Resynchronization-Defibrillation for Ambulatory Heart Failure Trial) study using the method proposed by Guyot et al followed by fitting multiple parametric models; the gamma distribution was selected for the base case analysis. Survival for optimal medical therapy (OMT), the comparator, was estimated by applying a hazard ratio from a published meta-analysis. Hospitalization rates and device longevity were derived from prior studies. Cost estimates were obtained from the JROAD-DPC (Japanese Registry Of All cardiac and vascular Disease-Diagnostic Procedure Combination) database and the Japanese medical fee schedule. Utility values were assigned according to New York Heart Association class assuming treatment-specific distributions. The analysis was conducted from the public health care payer perspective using a monthly cycle over a 20-year time horizon. Deterministic and probabilistic sensitivity analyses were performed. Additionally, scenario analyses were conducted by varying the duration of treatment effect.

Results: In the base case analysis, per capita costs were ¥12,258,410 (¥1=US $0.006 as of July 7, 2026) for CRT-D and ¥640,056.90 for OMT, resulting in an incremental cost of ¥11,618,353. CRT-D generated 7.07 quality-adjusted life years (QALYs) compared with 4.75 QALYs for OMT, yielding an incremental gain of 2.32 QALYs. The incremental cost-effectiveness ratio (ICER) was ¥5,009,880 per QALY. Scenario analyses showed that, when treatment effect waned after 7.5 years, the ICER increased to ¥5,423,235 per QALY. When the time horizon was shortened to 10 years or extended to 30 years, the ICERs were ¥8,523,072 and ¥4,386,803 per QALY, respectively. Deterministic sensitivity analysis identified CRT-D efficacy (hazard ratio), discount rate, and initial treatment cost as primary ICER drivers. Probabilistic sensitivity analysis produced a median ICER of

XSL•FO
RenderX

¥5,022,618 (IQR ¥4,448,306–¥5,760,425) per QALY, with a 95% credible interval of ¥3,804,418 to ¥7,178,795. At a willingness-to-pay value of ¥5,000,000 per QALY, CRT-D had a 49.2% probability of being cost-effective.

Conclusions: CRT-D demonstrated acceptable cost-effectiveness in patients with HFrEF in Japan. Treatment efficacy and initial cost were the primary determinants of economic value, emphasizing the importance of appropriate patient selection and strategies to reduce device costs.

cost-effectiveness analysis; cardiac resynchronization therapy with defibrillator; heart failure and reduced ejection fraction; JROAD-DPC database; Japan

Introduction

Cardiac resynchronization therapy with defibrillator (CRT-D) is an established device-based treatment for patients with heart failure (HF) and reduced ejection fraction (HFrEF) [1]. By integrating biventricular pacing with defibrillation capability, CRT-D reduces all-cause mortality, prevents sudden cardiac death, decreases hospitalization for HF, and improves functional status and quality of life in appropriately selected patients [2,3]. Population aging in high-income countries, including Japan, has accelerated the increase in HF prevalence, resulting in a growing population eligible for CRT-D implantation [4,5]. In Japan, earlier reports estimated HF prevalence at approximately 1% [6,7]; however, recent analyses using large administrative claims databases have reported substantially higher estimates of 3% to 6.5% [8]. The European Society of Cardiology estimates that HF accounts for up to 2% of total health care expenditures in high-income countries [9]. These findings indicate a rising HF burden with significant implications for health care spending and resource allocation.

Given constrained health care resources, prioritizing cost-effective therapies is essential. Cost-effectiveness studies of CRT-D conducted outside Japan have produced mixed results, and its economic value remains controversial. Existing evidence indicates that cost-effectiveness varies according to clinical characteristics, including QRS duration, left bundle branch block (LBBB) status, and ischemic vs nonischemic etiology [10-12]. CRT-D has demonstrated cost-effectiveness in patients with QRS duration of 150 ms or higher and New York Heart Association (NYHA) class II to III symptoms, whereas in patients with more advanced HF, such as NYHA class IV, cardiac resynchronization therapy with pacemaker may represent a more economically favorable option [11]. However, most evaluations have been conducted in Western health care systems, limiting generalizability to Japan because of differences in reimbursement structures and cost frameworks. In Japan, cost-effectiveness studies of CRT-D remain limited, and existing health technology assessments have primarily evaluated incremental device features such as automated optimization algorithms and reactive atrial-based antitachycardia pacing (rATP) [13,14]. Therefore, this study aimed to evaluate the cost-effectiveness of CRT-D in the Japanese health care setting using large-scale registry data to provide real-world evidence supporting clinical and policy decision-making.

Methods

Overview

The analysis was conducted from the public health care payer perspective using a monthly cycle over a 20-year time horizon, consistent with Japanese guidelines [15]. A reference value of ¥5,000,000 (¥1=US $0.006 as of July 7, 2026) per quality-adjusted life year (QALY) was used to evaluate cost-effectiveness. The incremental cost-effectiveness ratio (ICER) of CRT-D was assessed relative to optimal medical therapy (OMT).

Study Population

The modeled cohort reflected the CRT-D group of the RAFT (Resynchronization-Defibrillation for Ambulatory Heart Failure Trial) study [16]. The mean age was 66.3 (SD 9.3) years, and 84.8% of the participants were male. NYHA functional class distribution was 76.7% class II and 23.3% class III. The mean left ventricular ejection fraction was 22.5% (SD 5.4%), and mean QRS duration was 158.1 (SD 23.8) ms. Ischemic etiology accounted for 68.7% of cases, and LBBB morphology was present in 71.7%.

Model Structure and Inputs

A partitioned survival model was developed to evaluate CRT-D cost-effectiveness in patients with HFrEF, with OMT as the comparator. The model included 3 health states: after treatment (follow-up), hospitalization, and death. Hospitalization events included admissions due to cardiac arrest (CA), worsening HF, and CRT-D–related complications. The CRT-D survival curve was derived by digitizing Kaplan-Meier data from long-term RAFT follow-up [16] and reconstructing individual patient-level survival data using the method proposed by Guyot et al [17]. Parametric survival models, including exponential, Weibull, Gompertz, log-logistic, log-normal, gamma, and generalized gamma distributions, were evaluated. On the basis of the Akaike information criterion (AIC), Bayesian information criterion (BIC), and visual inspection, the gamma distribution provided the best fit and was selected. Comparative AIC and BIC results can be found in Table S1 in Multimedia Appendix 1. Survival for OMT was estimated by applying a hazard ratio (HR) for all-cause mortality from the meta-analysis by Woods et al [3] (0.54, 95% CI 0.43-0.69), assuming proportional hazards.

The primary outcome was QALYs, integrating survival and health-related quality of life. Utility values were assigned according to NYHA functional class and differed by treatment

XSL•FO
RenderX

group. Adverse outcomes were modeled as hospitalization events, including HF, CA, device-related complications, and temporary disutility associated with device replacement. The incidence of HF hospitalization was obtained from a prior study [18], which reported cumulative rates of 19.5% in the CRT-D group and 26.1% in the OMT group over a median follow-up of 40 months. These cumulative incidences were converted into monthly transition probabilities for each treatment group, assuming a constant hazard throughout the observation period. The incidence of hospitalization due to CA was estimated from indirect published evidence [19-21]. In the CRT-D group, Tseng et al [19] reported that 6.4% of all-cause deaths following cardiac implantable electronic device therapy were attributable to CA. On the basis of the annual all-cause mortality reported in the MADIT-RIT (Multicenter Automatic Defibrillator Implantation Trial–Reduce Inappropriate Therapy) trial, this proportion corresponded to an estimated CA incidence of 0.14% per year in the CRT-D group. In the OMT group, the annual incidence of CA was derived from a previously reported rate of sudden cardiac death in the conventional therapy group (4.5% per year) [21], used as a surrogate marker for arrhythmic CA requiring hospitalization. This yielded an estimated annual incidence of 6.51%. Device-related complications were modeled exclusively in the CRT-D group during follow-up, with a cumulative incidence of 14% over 48 months [22]. This value was converted into a monthly transition probability assuming a constant hazard. Among previously reported complications [23,24], superficial and systemic infections accounted for 21.7% and 26.6%, respectively, whereas lead dislodgement accounted for 51.7%. Device replacement was assumed in cases of systemic infection or lead dislodgement. Device longevity was assumed to be 111 months based on a recent large-scale observational report from a single manufacturer [25]. In the model, device replacements due to battery depletion were assumed to recur continuously without upper limits as long as the simulated cohort survived.

We included costs associated with the initial intervention; device replacement; hospitalizations (CA, HF, and device-related complications); and additional follow-up, including remote monitoring and inappropriate shocks. Costs related to procedure-related complications at initial implantation were incorporated into the initial intervention cost. Cost inputs were derived from analyses of the JROAD-DPC database (approval 20240001) and the Japanese medical fee schedule, which provides standardized reimbursement for each medical service [26]. The database, administered by the Japanese Circulation Society, contains diagnosis procedure combination and per-diem payment system data from approximately 1500 hospitals as of 2024 and covers 2012 to 2024 [27,28]. It represents one of the largest nationwide databases for cardiac and vascular diseases in Japan. For the cost analysis in this study, we extracted data on Japanese patients who underwent initial CRT-D implantation or device replacement between 2012 and 2022. Cost extraction was based on diagnostic and procedure codes. CRT-D implantation and device replacement were identified using procedure codes in the claims database. Hospitalization costs for HF and CA were assumed to be identical between groups as they reflect baseline disease management. Clinical cost differences between groups were captured by adding device-related complications to the CRT-D group. Device-related complications were classified as superficial or systemic infections using *International Classification of Diseases, 10th Revision*, diagnostic codes. The specific codes used for each definition are provided in Table S2 in Multimedia Appendix 1. Utilities were assigned according to NYHA functional class (I-IV), and cohort-level utility was calculated as a weighted average based on the distribution of NYHA classes [29]. Because treatment was assumed to modify the NYHA class distribution, different stable-state utility values were applied to each treatment group. Specifically, CRT-D was assumed to improve NYHA functional class compared with OMT. On the basis of the COMPANION (Comparison of Medical Therapy, Pacing, and Defibrillation in Heart Failure) trial [30], the proportion of patients with NYHA class improvement at 6 months was 57% in the CRT-D group and 38% in the OMT group. These improvement rates were applied to the baseline NYHA class distribution to estimate follow-up utility. The magnitude of improvement was assumed to be equivalent for patients with baseline NYHA class II and III, and the difference in improvement rates between treatment groups was assumed to persist throughout the time horizon. On the basis of these assumptions, the mean health-related utility during follow-up was 0.805 for CRT-D and 0.781 for OMT. For hospitalization events, mean utility values were 0.649 for HF hospitalization and 0.44 for CA hospitalization. Disutility values of −0.10 for complications and –0.05 for device replacement were applied [31]. All model inputs are summarized in Table 1. Costs and utilities were discounted at an annual rate of 2%, consistent with Japanese cost-effectiveness analysis guidelines [15]. All analyses were conducted using R (version 4.4.3; R Foundation for Statistical Computing).

Scenario and Sensitivity Analysis

Formal subgroup analyses were not performed because the individual patient-level clinical characteristics required to define subgroups were unavailable in the data sources. Instead, heterogeneity in treatment effects was evaluated through sensitivity analyses by varying key parameters, including the HR of CRT-D, across plausible ranges reported in the literature.

Scenario analyses examined uncertainty related to treatment effect duration and time horizon. In one scenario, the treatment effect remained constant for 7.5 years and then declined linearly up to 20 years, consistent with prior studies [12,32]. Specifically, this decline was modeled by allowing the HR to approach 1.0 and the difference in utility values between the groups to approach 0. In separate scenarios, the time horizon was set to 10 and 30 years, whereas the treatment effect remained constant and identical to the base case, which used a 20-year horizon.

To evaluate parameter-level and overall model uncertainty, both deterministic sensitivity analysis (DSA) and probabilistic sensitivity analysis (PSA) were performed. Parameter ranges and probability distributions were applied from published sources when available. For parameters lacking reported ranges or distributions, a –20% to +20% variation from base case values was assumed. The discount rate was varied between 0% and 4% in accordance with relevant guidelines [15].

Ethical Considerations

This study was reviewed and approved by the institutional review board of the Japanese Heart Rhythm Society (approved 20240001) This study used anonymized data from the JROAD-DPC registry. The requirement for individual informed consent was waived by the Institutional Review Board, and participants were provided with the opportunity to opt out in accordance with the applicable ethical guidelines.

Results

Base Case and Scenario Analysis

In the base case analysis, per capita costs were ¥12,258,410 for CRT-D and ¥640,056.90 for OMT, yielding an incremental cost of ¥11,618,353. CRT-D produced 7.07 QALYs compared with 4.75 QALYs for OMT, corresponding to an incremental gain of 2.32 QALYs. The resulting ICER was ¥5,009,880 per QALY (Table 2).

Table . Results of base case and scenario analyses (¥1=US $0.006 as of July 7, 2026).

	Total cost (¥)	Incremental cost (¥)	Total QALYs[a]	Incremental QALYs	ICER[b] (cost per QALY)
Base case analysis					
CRT-D[c]	12,258,410	11,618,353	7.07	2.32	5,009,880
OMT[d]	640,056.90	—[e]	4.75	—	—
Scenario analysis[f]					
CRT-D	12,258,410	11,597,980	7.04	2.14	5,423,235
OMT	660,429.90	—	4.9	—	—

[a]QALY: quality-adjusted life year.

[b]ICER: incremental cost-effectiveness ratio.

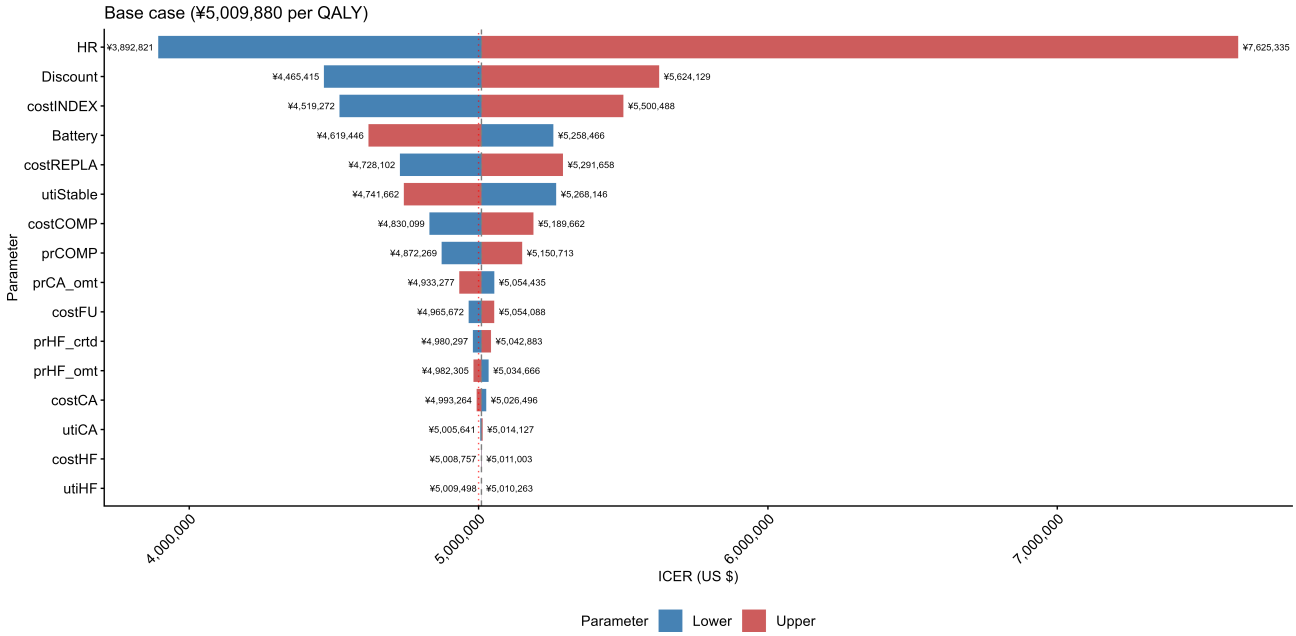
[c]CRT-D: cardiac resynchronization therapy with defibrillator.

[d]OMT: optimal medical therapy.

[e]Not applicable.

[f]The treatment effect was assumed to remain constant for 7.5 years and then decline linearly up to 20 years.

In the scenario analysis, the ICER increased to ¥5,423,235 per QALY when the treatment effect was assumed to decline after 7.5 years (Table 2). When the time horizon was shortened to 10 years, the ICER increased to ¥8,523,072 per QALY. Conversely, extending the time horizon to 30 years reduced the ICER to ¥4,386,803 per QALY.



Sensitivity Analysis

DSA identified the primary drivers of the ICER as CRT-D efficacy (HR), discount rate, and initial treatment cost (“costINDEX”; Figure 1). Variation in CRT-D efficacy produced ICERs ranging from ¥3,892,821 to ¥7,625,335 per QALY. Variation in the discount rate resulted in ICERs ranging from ¥4,465,415 to ¥5,624,129 per QALY, whereas variation in initial treatment cost yielded ICERs ranging from ¥4,519,272 to ¥5,500,488 per QALY.

PSA results are shown in Figure 2. The median ICER was ¥5,022,618 per QALY, with a range of ¥3,804,418 to ¥7,178,795 per QALY across the 2.5th and 97.5th percentiles. At a willingness-to-pay threshold of ¥5,000,000 per QALY, the probability that CRT-D was cost-effective was 49.2%.

RenderX

Figure 1. Tornado diagram of the deterministic sensitivity analysis. This diagram depicts the effect of varying individual parameters on the incremental cost-effectiveness ratio (ICER). Bar width represents the ICER range obtained when each parameter varied between its lower and upper bounds. The vertical dotted line denotes the base case ICER of ¥5,009,880 (¥1=US $0.006 as of July 7, 2026) per quality-adjusted life year (QALY). Parameters are ordered from top to bottom according to their relative influence on the ICER. costCA: cost of hospitalization for cardiac arrest; costCOMP: cost of hospitalization for complications; costFU: additional follow-up cost; costHF: cost of hospitalization for heart failure; costINDEX: initial treatment cost; costREPLA: device replacement cost; HR: hazard ratio; prCA_crtd: probability of cardiac arrest in the CRT-D group; prCA_omt: probability of cardiac arrest in the OMT group; prCOMP: probability of hospitalization for complications; prHF_crtd: probability of heart failure in the CRT-D group; prHF_omt: probability of heart failure in the OMT group; utiCA: utility of the cardiac arrest state; utiHF: utility of the heart failure state; utiStable: utility of the stable state.

XSL•FO
RenderX

Figure 2. Probabilistic sensitivity analysis scatterplot. This figure presents incremental costs vs incremental quality-adjusted life years (QALYs) across 10,000 simulations. The dotted line indicates the willingness-to-pay threshold of ¥5,000,000 per QALY (¥1=US $0.006 as of July 7, 2026). Black dots represent simulations below the reference value (cost-effective), whereas gray dots indicate simulations exceeding the threshold.

Discussion

Principal Findings

Using the Japanese JROAD-DPC database, we assessed the cost-effectiveness of CRT-D compared with OMT from a public health insurance perspective. Over a 20-year horizon, CRT-D generated an incremental cost of ¥11,618,353 and a QALY gain of 2.32, yielding an ICER of ¥5,009,880 per QALY. This estimate approximated the Japanese reference value. When a waning treatment effect was incorporated, the ICER increased to ¥5,349,656 per QALY, remaining comparable to the reference threshold. In UK settings, Mealing et al [11] reported that CRT-D was cost-effective in only 10 of 24 patient subgroups at a £30,000 per QALY threshold (£1=US $1.34 as of July 7, 2026), highlighting substantial heterogeneity. In 4 subgroups similar to our population (QRS duration of ≥150 ms and NYHA class II and III with or without LBBB), the ICER for CRT-D vs OMT ranged from £15,000 to £20,000, below the accepted UK threshold of £30,000. In a US study [12] using a reference value of US $100,000 per QALY, CRT-D was consistently the most cost-effective strategy among patients with QRS duration above 150 ms regardless of LBBB status or NYHA class. Although reference thresholds differ across the United Kingdom, United States, and Japan, our findings appear conservative in this international context. An ICER of approximately ¥5 million per QALY suggests that further gains in cost-effectiveness will likely depend on refined patient selection.

DSA identified populations in which higher economic value may be achieved. The principal ICER driver was the HR, indicating that greater treatment effects improve

XSL•FO
RenderX

cost-effectiveness. A meta-analysis by Woods et al [3] showed that, compared with OMT, the HR for CRT-D was lower in female than in male patients irrespective of QRS duration or age. The same analysis demonstrated that, when CRT-D was compared with OMT, the HR approached 1.0 among patients without LBBB or with QRS duration below 150 ms, indicating attenuation of survival benefit in these subgroups. Because survival was modeled using all-cause mortality, CRT-D is likely to be more cost-effective in patients with a lower burden of high-mortality comorbidities. This interpretation aligns with a recent patient-level meta-analysis of 8 randomized trials [33], which reported substantial survival benefit in patients with no comorbidities (adjusted HR 0.54) but diminished benefit in those with 3 or more comorbidities (adjusted HR 0.83). Accordingly, patients with a lower comorbidity burden may tend to exhibit a more favorable ICER, although this trend requires careful interpretation regarding cumulative longitudinal costs. However, a detailed analysis of specific comorbidities was not feasible in the present study, and further research is warranted to evaluate cost-effectiveness stratified by comorbidity profiles. Additionally, the crucial trials underpinning our efficacy estimates were conducted over a decade ago. Since then, contemporary OMT has advanced significantly with modern foundational therapies (ie, angiotensin receptor–neprilysin inhibitors and sodium-glucose cotransporter 2 [SGLT2] inhibitors) [34,35]. In particular, SGLT2 inhibitors are now widely used in Japan as a key component of guideline-directed medical therapy [36]. If these modern drugs substantially improve baseline outcomes, the incremental benefit of CRT-D over OMT might be attenuated in current practice, potentially increasing the ICER. Future modeling studies incorporating clinical data from the modern therapy era are warranted. Recent incremental innovations in CRT-D, including rATP and optimization algorithms, have improved efficacy but increased device costs. Several studies have shown these enhancements to be cost-effective in Japanese and other national settings [13,14,37]. Overall, the additional costs associated with these functional upgrades appear acceptable from a cost-effectiveness perspective. Another influential determinant was the initial treatment cost, driven largely by device price. The current reimbursement for CRT-D devices in Japan is between ¥3,090,000 and ¥4,750,000 depending on the model. Together with lead costs, this accounts for more than half of the initial treatment cost. Device price also affects downstream costs related to battery depletion and infection requiring replacement; therefore, reductions in device price would likely generate substantial savings. In PSA, the 95% credible interval for the ICER was ¥3,804,418 to ¥7,178,795, with a 49.2% probability of remaining below ¥5 million per QALY. These findings indicate moderate parameter uncertainty, with ICER estimates distributed within approximately –¥2.5 million to +¥2.5 million of the reference value.

Limitations

Several limitations of this study should be acknowledged. First, although the JROAD-DPC database captures a substantial proportion of acute care hospitals in Japan, it does not include all medical institutions. Furthermore, the JROAD-DPC database was not used to derive clinical event probabilities because this database possesses inherent limitations in tracking long-term, longitudinal patient outcomes across different medical institutions once patients are discharged to outpatient care. Consequently, cost inputs may be subject to selection bias, limiting generalizability to all patients with HF in Japan. Second, the 20-year time horizon required extrapolation of survival and costs beyond observed follow-up. To mitigate this limitation, survival curves were generated using parametric modeling of long-term data from the RAFT study. Although using overseas trial data (RAFT) requires caution regarding generalizability, the trial's mean age (66.3 years) is comparable to that of major Japanese CRT-D registries (66.5 or 68.4 years) [38]. Nevertheless, this population-level cost-effectiveness model does not incorporate individual risk factors. Future Japanese studies incorporating patient-level subgroup analyses are needed to refine estimates and support value-based allocation within the health care system. Finally, detailed subgroup analyses by clinical characteristics, such as QRS duration, LBBB status, or comorbidity burden, were not feasible because of data constraints. Instead, the potential influence of these factors was examined through DSA by varying HRs rather than directly estimating subgroup-specific effects.

Despite these limitations, to our knowledge, this study represents one of the first comprehensive cost-effectiveness evaluations of CRT-D in the Japanese health care setting using real-world cost data.

Conclusions

CRT-D for patients with HFrEF in Japan demonstrated cost-effectiveness within an acceptable range relative to the reference value. Sensitivity analyses identified the HR and initial treatment cost as key determinants of value. These findings emphasize the importance of identifying patient subgroups with a high expected treatment response. Specifically, future cost-effectiveness analyses stratified by comorbidity profiles will provide further valuable insights. From a policy perspective, reducing device costs may further enhance the societal value of this intervention.

Abstract

Background: Hypertension is a significant modifiable risk factor for cardiometabolic syndrome, leading to increased morbidity and premature mortality. Understanding the differences in cardiometabolic risk profiles between hypertensive and normotensive adults is essential for effective prevention strategies.

Objective: This study examined cardiometabolic risk profiles among adults in Johannesburg South, Gauteng Province, South Africa.

Methods: A cross-sectional study was conducted with 209 adults aged 25 to 65 years who were recruited from 3 Johannesburg townships in Region G. Anthropometric measures (BMI and waist circumference), blood pressure, and biochemical indexes (random glucose, total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, and triglycerides) were assessed. Statistical analyses were performed using Stata (version 19), with statistical significance set at $P<.05$.

Results: Hypertension prevalence increased significantly with BMI ($P<.001$) and waist circumference ($P=.003$). In multivariable analysis, age and elevated glucose levels were independently associated with hypertension, whereas obesity and central adiposity were not significantly associated after adjustment.

Conclusions: Hypertension was independently associated with advancing age and elevated glucose levels in this population. Although obesity and central adiposity showed significant associations in unadjusted analyses, they were not independently associated with hypertension after adjustment. These findings highlight the importance of early screening and targeted interventions to address cardiometabolic risk in underserved South African communities.

Introduction

Hypertension remains a persistent global health challenge, significantly elevating the risk of cardiovascular and other noncommunicable diseases (NCDs). These conditions often lead to long-term disability. In 2017, NCDs accounted for 67% of all-age disability-adjusted life years in sub-Saharan Africa [1]. Commonly referred to as a silent killer, hypertension typically presents no obvious symptoms, making early detection difficult [2]. Regular screening is a reliable diagnostic method; however, it remains largely inaccessible in many low- and middle-income countries, including South Africa. As a result,

XSL•FO
RenderX

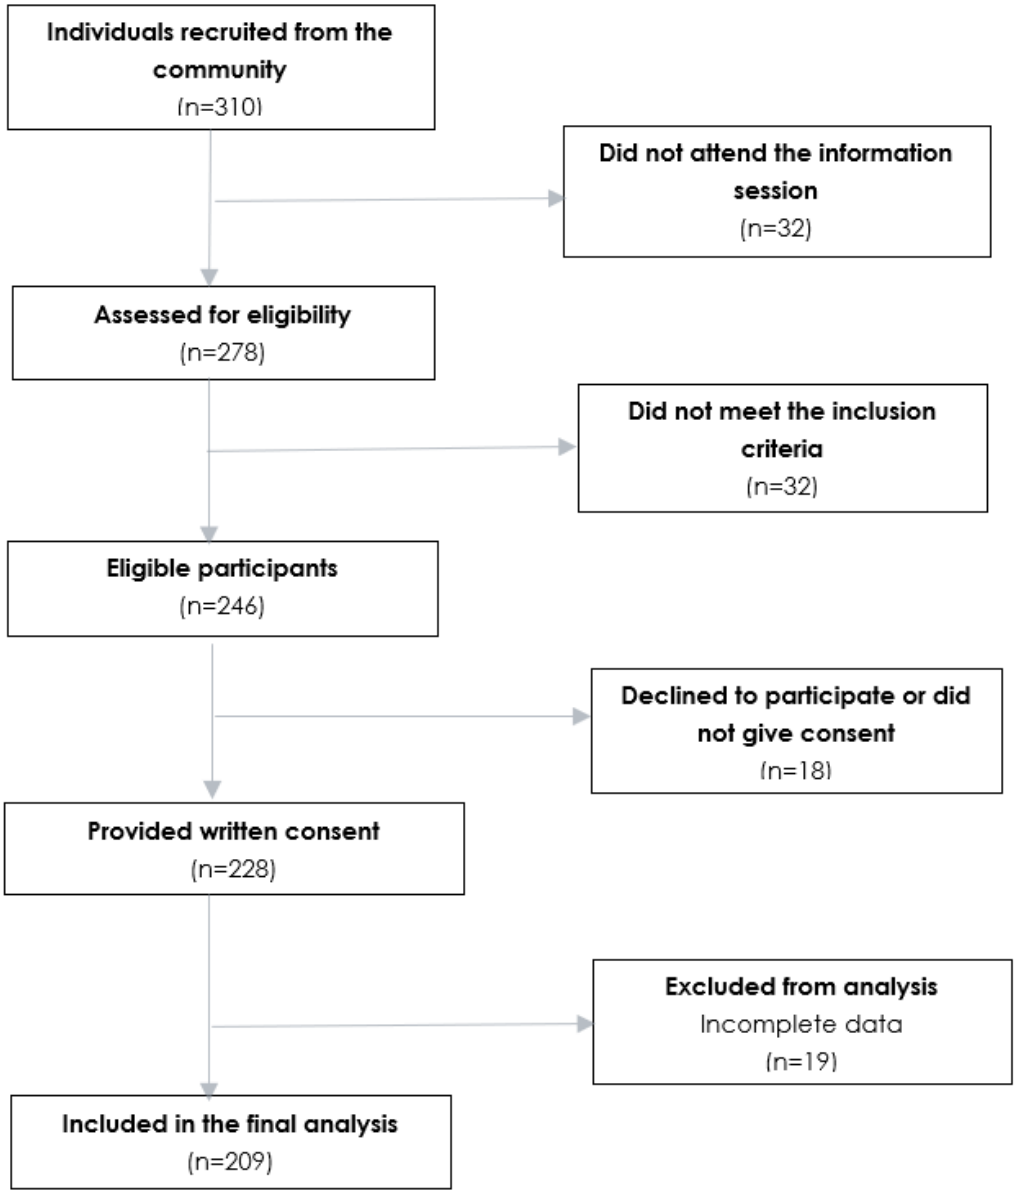
the prevalence of hypertension continues to rise, particularly in countries in the World Health Organization (WHO) African region, where it stands at 27%, notably higher than the 18% reported in the WHO American region [3].

With the rising prevalence of hypertension, research has increasingly focused on cardiometabolic risks, highlighting obesity as the most prominent predictor [4,5]. Onagbiye et al [6] identified abdominal obesity as a major contributor to cardiometabolic disease among university staff employees. Similarly, Modjadji et al [4] found that the odds of developing hypertension were high for obese truck drivers based on waist circumference (WC; adjusted odds ratio [AOR] 4.68, CI 1.92-11.34) and waist-to-height ratio (AOR 5.49, CI 1.74-17.27). Interestingly, a study among a younger population also concurred with these findings [7]. Despite consistent evidence across different populations, regions, and demographic groups, the global prevalence of overweight and obesity continues to increase.

It is important to note that a decade ago, central obesity was proven to be the key determinant of the prevalence of metabolic syndrome in sub-Saharan Africa [8]. Efforts to address this burden have encountered several challenges. For instance, a recent study in Kenya revealed a high prevalence of central obesity, with women being significantly more affected than men (58.3% compared to 35.6%) [9]. Furthermore, the 2025 WHO report highlights a continuing upward trend in global obesity rates, noting that 43% of adults aged ≥18 years are overweight and 16% are living with obesity. This growing trend is concerning, as obesity significantly increases the risk of developing type 2 diabetes mellitus, hyperlipidemia, hypertension, and other cardiovascular diseases [10]. These illnesses often coexist, increasing health risks and reducing life expectancy. Their combined effects extend beyond individuals; they have a substantial negative impact on the national economy, health care systems, and workplace productivity.

The increased cost of treating associated comorbid diseases related to obesity imposes a substantial financial burden on the South African health care system. In particular, overweight and obesity accounted for ZAR 28,734 million (ZAR 1=US $0.060 as of July 29, 2026) in expenses related to cardiovascular and endocrine diseases, with approximately 91% of this cost coming from hypertension and diabetes [11]. These figures are alarming, as access to quality health care varies widely across South Africa. Currently, 44% of all health care expenditure occurs in the private sector, serving only 16% of the South African population [12]. This means the rest of the population relies on a public health system that is underresourced and often inaccessible due to geographical, financial, or knowledge barriers [13].

Given this background, comprehensive profiling of cardiometabolic risk factors in underresourced communities is essential to inform targeted prevention and early intervention strategies. Although previous South African studies have demonstrated associations between obesity, central adiposity, and hypertension, most have focused on occupational cohorts, such as truck drivers and university staff, with limited evidence from community-dwelling adults living in underresourced urban settings. Consequently, there remains a significant gap in localized epidemiological data describing cardiometabolic risk profiles among township populations. This study addresses this gap by examining the cardiometabolic risk profiles of adults residing in selected townships in Johannesburg South. Specifically, the study aimed to compare the cardiometabolic risk profiles of hypertensive and normotensive adults and to identify independent predictors of hypertension.



Methods

Study Design and Participants

This cross-sectional study used purposive sampling to recruit male and female adults aged 25 to 65 years from selected townships in Johannesburg South. Although purposive sampling may limit representativeness and external validity, it was the most feasible approach because of the absence of reliable sampling frames in informal township settings. This approach enabled the inclusion of underrepresented community members and provided valuable baseline evidence to inform future probabilistic studies. A total of 310 individuals were recruited. Of these, 101 (32.6%) were excluded because they did not attend the information session (n=32, 10.3%), did not meet the inclusion criteria (n=32, 10.3%), declined to provide informed consent (n=18, 5.8%), or had incomplete anthropometric or biochemical data (n=19, 6.1%). The final analytic sample comprised 209 participants (n=72, 34.4% men and n=137, 65.6% women) with complete data for all study variables, including demographic characteristics, blood pressure, anthropometric measurements, and biochemical indexes. Missing data were handled using listwise deletion; therefore, no imputation methods were applied. Analyses were restricted to complete cases to maintain the consistency and reliability of statistical comparisons. Participant recruitment, eligibility assessment, enrollment, exclusion, and inclusion in the final analysis are summarized in Figure 1.

XSL•FO
RenderX

Figure 1. Flow diagram of participant recruitment, eligibility assessment, enrollment, exclusion, and inclusion in the final analysis.

Between 2023 and 2025, participants were recruited from community churches, households, and social gatherings in selected townships within Region G of the city of Johannesburg using a purposive sampling approach. Region G is the second most populated administrative region in the municipality and experiences considerable socioeconomic deprivation [14]. Eligible participants were permanent residents of the 3 selected townships and were aged 25 to 65 years.

The city of Johannesburg covers approximately 1645 km^2 in Gauteng Province. The central and northern suburbs are predominantly occupied by middle- and upper-income populations, whereas the southern suburbs and the far northern fringes are characterized by greater socioeconomic disadvantage. Approximately 20% of the city of Johannesburg population lives in informal settlements with limited access to basic municipal services, while a further 40% resides in inadequate housing with insufficient municipal support [15].

Ethical Considerations

This study forms part of a PhD project approved by the Faculty Committee for Research Ethics–Science (FCRE-SCI), Tshwane University of Technology (FCRE-SCI 2023/05/016 [SCI; FCPS 02]). The study was conducted in accordance with the ethical principles of the Declaration of Helsinki and its subsequent amendments. Written informed consent was obtained from all participants prior to enrollment. Participants with elevated blood pressure, abnormal blood glucose levels, or other clinically significant findings identified during the screening were informed of their results and verbally advised to visit their nearest primary health care facility for further clinical evaluation and management.

Instrumentation

Anthropometric Measurements

Anthropometric measurements were taken after participants completed the questionnaires, with assistance from research assistants or the principal investigator. Body mass was recorded to the nearest 0.1 kg, using a calibrated BFW 300 Platform Scale (Adam Equipment Co Ltd), and body stature to the nearest 0.1 cm, using the portable Seca 213 stadiometer (CE 0123) according to the validated protocols of the International Society for the Advancement of Kinanthropometry [16]. BMI was categorized according to the American College of Sports Medicine cut points [17] as follows: BMI<18.5 kg/m^2=underweight, BMI 18.5-24.9 kg/m^2=normal, BMI 25.0-29.9 kg/m^2=overweight, and BMI≥30.0 kg/m^2=obese.

WC measurements were recorded to the nearest 0.1 cm using a nonstretchable standard Lufkin tape measure manufactured by Cooper Tools of Apex. The WC risk measurements were categorized according to low risk (WC<80 cm in women and <94 cm in men) and high risk (WC≥88 cm in women and ≥94 cm in men) [18].

Biochemical Measurements

Blood pressure was measured with the arm supported at the heart level (European Society of Hypertension) with a sphygmomanometer (Omron) using the Riva-Rocci or Korotkoff method on the left arm [19]. An appropriately sized blood pressure cuff was used, and participants were instructed to refrain from smoking cigarettes and from ingesting caffeine for 30 minutes prior to measurements. Measurements were taken thrice with a 5-minute resting period between each measurement [20]. The average of the measurements was used for data analysis.

The blood pressure cutoff points used for analysis were assessed according to guidelines of the American College of Cardiology and American Heart Association, where normal blood pressure is defined as <120 mm Hg systolic and <80 mm Hg diastolic, elevated blood pressure as 120 to 129 mm Hg systolic and <80 mm Hg diastolic, stage 1 hypertension as 130 to 139 mm Hg systolic or 80 to 89 mm Hg diastolic, and stage 2 hypertension as ≥140 mm Hg systolic or ≥90 mm Hg diastolic [19]. Participants who were on hypertensive medication with a known diagnosis were considered hypertensive. Participants who presented with hypertension at baseline and who were not on medication were referred to the clinic.

A peripheral blood sample was collected to determine random glucose levels, total cholesterol, high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and triglycerides. The values were recorded in millimoles per liter according to the manufacturer's CardioChek Plus analyzer user guide v1.12 or later. Random glucose levels <7.8 mmol/L were classified as low risk and ≥7.8 mmol/L as high risk. Random glucose was a practical measure in township settings where fasting requirements and laboratory access for hemoglobin A_{1c} (HbA_{1c}) testing were not feasible, whereas less precise, random glucose testing would have allowed immediate, point-of-care screening and referral, thereby ensuring participation from underresourced communities. Cholesterol norms were classified as total cholesterol<5 mmol/L=normal, LDL-C<3 mmol/L=normal, HDL-C<1.04-mmol/L=low, and HDL-C≥1.2 mmol/L=optimal. Triglyceride concentrations were classified as normal (<1.7 mmol/L) and high risk (≥1.7 mmol/L) [18]. Persons taking antiglycemic medication were also classified as diabetic.

Statistical Analysis

Data were cleaned, coded, and analyzed using Stata SE (version 19; StataCorp). The distribution of continuous variables was assessed using the Shapiro-Wilk test, histograms, and Q-Q plots to evaluate normality and guide the selection of appropriate descriptive statistics. As the continuous variables were not normally distributed, they are presented as medians with IQR. Categorical variables are presented as frequencies and percentages. The prevalence of cardiometabolic risk factors and hypertension was summarized using proportions.

A multivariable logistic regression (LR) model was used to identify independent predictors of hypertension. Prior to model fitting, the assumptions of LR were evaluated. The outcome variable was binary (hypertensive vs normotensive), observations were independent, multicollinearity was assessed using variance inflation factors, and model fit was evaluated using the Hosmer-Lemeshow goodness-of-fit test. Variance inflation factor values ranged from 1.11 to 1.93, indicating no evidence of problematic multicollinearity among the predictors included in the model. Statistical significance was set at P<.05.

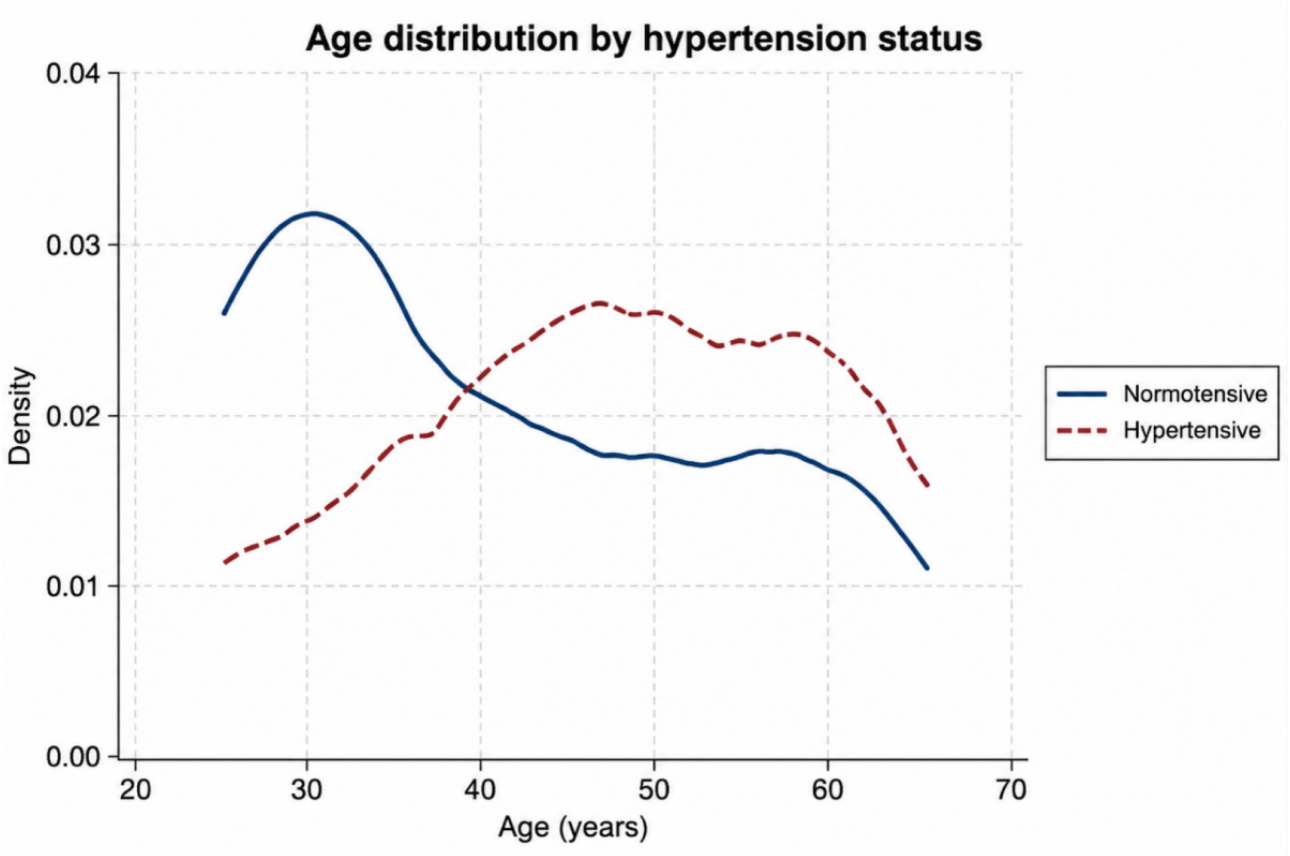
Results

Descriptive Statistics

The baseline characteristics of the 209 study participants are summarized in Table 1. The median age was 45 (IQR 32-57) years. Additional anthropometric and clinical characteristics included a median BMI of 27.6 (IQR 15.8-52.7) kg/m^2 and a median systolic blood pressure (SBP) of 122 (IQR 65-181) mm Hg.

XSL•FO
RenderX

Table 1. Demographic and anthropometric characteristics (N=209).



Variables	Median (IQR)
Age (years)	45 (32-57)
BMI (kg/m^2)	27.6 (24.1-33)
Waist circumference (cm)	94 (82-106)
Systolic blood pressure (mm Hg)	122 (112-134)
Diastolic blood pressure (mm Hg)	80 (71-89)
Glucose (mmol/L)	5.8 (5.2-7)
Total cholesterol (mmol/L)	3.76 (3.18-4.46)
HDL[a] cholesterol (mmol/L)	1.11 (0.91-1.37)
LDL[b] cholesterol (mmol/L)	1.97 (1.11-2.48)
Triglycerides (mmol/L)	1.22 (0.8-1.76)

[a]HDL: high-density lipoprotein.

[b]LDL: low-density lipoprotein.

Figure 2 presents the age distribution of participants according to hypertension status. The normotensive group, represented by the blue curve, peaked in the late 20s to early 30s and gradually declined with increasing age. In contrast, the hypertensive group (red curve) showed increasing density with advancing age, peaking in the late 50s to early 60s. The 2 distributions intersected at approximately 45 to 50 years, suggesting a shift in the age range at which hypertension became more prevalent than normotension. These findings support the well-established association between advancing age and increased hypertension prevalence.

Figure 2. Density plot showing the age distribution of normotensive and hypertensive participants. The blue curve represents normotensive participants, and the red curve represents hypertensive participants.

RenderX

Association Between Obesity, Central Obesity, and Hypertension Status

Table 2 presents the association between BMI, WC, and hypertension status, which was analyzed using chi-square tests. A statistically significant association was observed between BMI category and hypertension (*P*<.001). The prevalence of hypertension increased progressively with higher BMI, rising from 30.4% (17/56) among individuals with normal BMI to 64.6% (53/82) among those classified as obese. Similarly, WC showed a significant association with hypertension (*P*=.003), with 53.4% (79/148) of participants with high WC being hypertensive, compared to 31.1% (19/61) of those with normal WC.

Table 2. Association between obesity, central obesity, and hypertension status among study participants (N=209).

Variable and category	Normotensive, n (%)	Hypertensive, n (%)	*P* value[a]
BMI			<.001
Underweight	4 (50)	4 (50)	
Normal weight	39 (69.6)	17 (30.4)	
Overweight	39 (61.9)	24 (38.1)	
Obese	29 (35.4)	53 (64.6)	
Waist circumference			.003
Normal	42 (68.9)	19 (31.1)	
High	69 (46.6)	79 (53.4)	

[a]*P* values were calculated using Pearson chi-square test.

Lipid Profiles

The association between several lipid categories and the presence of hypertension is presented in Table 3. Chi-square test results for these variables indicate no statistically significant association with hypertension. The *P* values for HDL cholesterol (*P*=.65), LDL cholesterol (*P*=.70), and triglycerides (*P*=.25) are well above the conventional significance level of .05. This means that, in this dataset, the distribution of hypertension across the categories for these lipid variables is not different from what would be expected by chance.

Table 3. Comparison of lipid profile categories between normotensive and hypertensive participants (N=209).

Variable and category	Normotensive (n=111), n (%)	Hypertensive (n=98), n (%)	Chi-square (*df*)	*P* value[a]
HDL[b] cholesterol			0.2 (1)	.65
Normal	43 (51.2)	41 (48.8)		
High risk	68 (54.4)	57 (45.6)		
LDL[c] cholesterol			0.1 (1)	.70
Normal	99 (52.7)	89 (47.3)		
High risk	12 (57.1)	9 (42.9)		
Triglycerides			1.3 (1)	.25
Normal	87 (55.4)	70 (44.6)		
High risk	24 (46.2)	28 (53.8)		
Total cholesterol			3.3 (1)	.07
Normal	102 (55.4)	82 (44.6)		
High risk	9 (36)	16 (64)		

[a]*P* values were calculated using Pearson chi-square test.

[b]HDL: high-density lipoprotein.

[c]LDL: low-density lipoprotein.

Interestingly, the results for total cholesterol show a borderline association with hypertension. While the *P* value of .07 is slightly above the .05 significance threshold, the association was not statistically significant. The table shows that a lower percentage of participants in the high-risk total cholesterol category (9/25, 36%) had no hypertension, and a higher rate (16/25, 64%) had hypertension, compared with participants in the normal total cholesterol category. This suggests that having a higher total cholesterol level might be associated with an increased likelihood of hypertension, but the finding is not statistically significant at the 5% level.

XSL•FO
RenderX

Predictors of Hypertension

A multivariable LR model was fitted to identify predictors of hypertension status. The model was statistically significant (LR: χ^2_{11}=76.3; *P*<.001), indicating that the predictors collectively explained variation in hypertension. The LR model demonstrated adequate fit to the data based on the Hosmer-Lemeshow goodness-of-fit test (χ^2_8=7.2; *P*=.52).

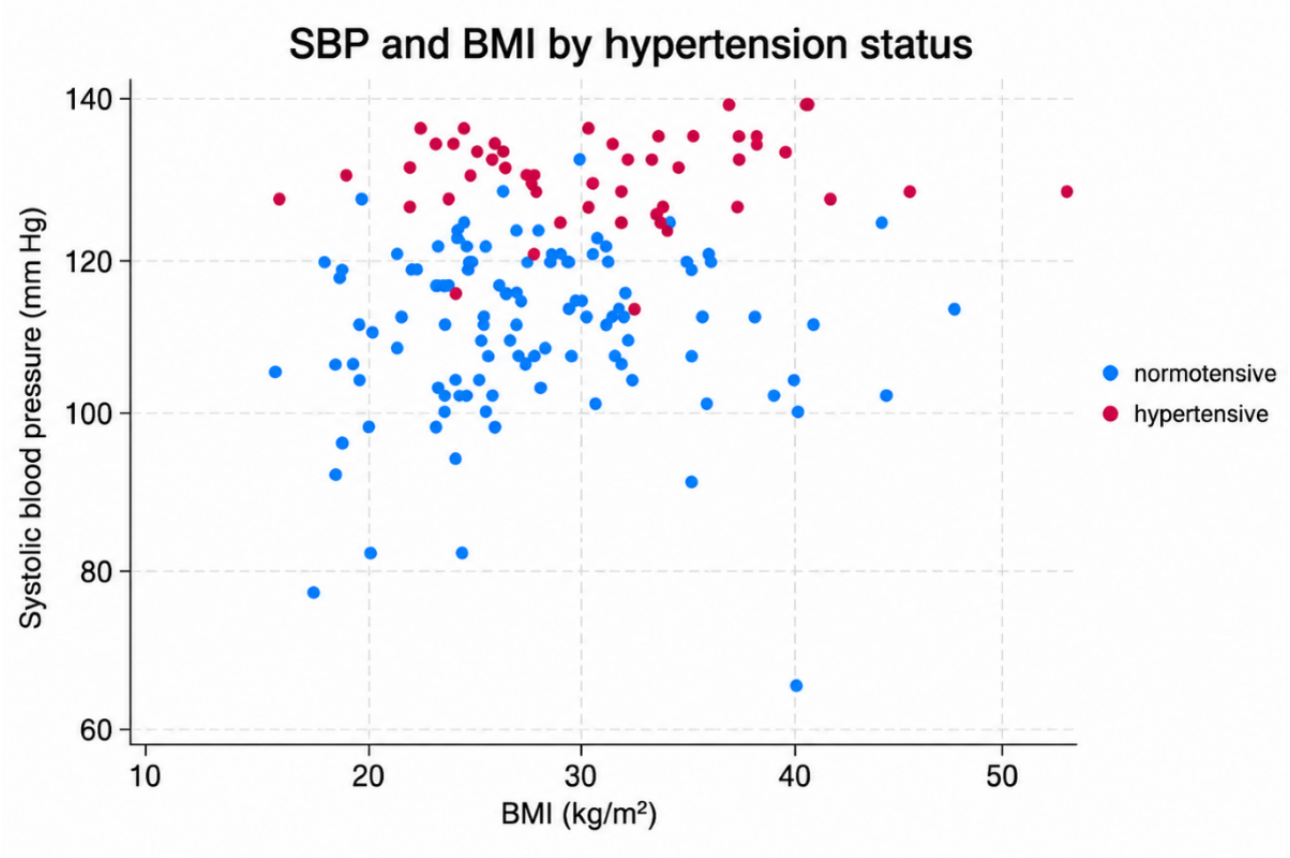
As shown in Table 4, age and elevated glucose levels were independently associated with hypertension. Increasing age was positively associated with hypertension (β=0.07, 95% CI 0.041-0.099; *P*<.001). Elevated glucose levels were also independently associated with hypertension (β=2.277, 95% CI 0.684-3.871; *P*<.005). Other variables, including gender, BMI category, WC, and lipid levels, were not significantly associated with hypertension after adjustment. The crude associations observed for BMI and WC in the bivariate analyses may reflect their correlation with advancing age.

Table 4. Multivariable logistic regression (LR) analysis of independent predictors of hypertension.

Variable	β (95% CI)	*P* value
Individual-level factors		
Age (years)	0.07 (0.041 to 0.099)	<.001
Sex (female vs male)	0.155 (−0.677 to 0.987)	.71
Metabolic factors		
BMI category		
Normal weight	−1.51 (−3.207 to 0.186)	.08
Overweight	−1.238 (−3.031 to 0.556)	.18
Obese	−0.058 (−1.874 to 1.757)	.95
Waist circumference (high vs normal)	0.124 (−0.966 to 1.214)	.82
HDL[b] cholesterol (high vs normal)	−0.219 (−0.986 to 0.549)	.58
LDL[c] cholesterol (high vs normal)	−1.043 (−2.286 to 0.200)	.10
Triglycerides (high vs normal)	−0.178 (−0.984 to 0.628)	.67
Total cholesterol (high vs normal)	0.806 (−0.518 to 2.130)	.23
Glucose category (high vs normal)	2.277 (0.684 to 3.871)	.005

[b]HDL: high-density lipoprotein.

[c]LDL: low-density lipoprotein.



Statistical significance was set at *P*<.05. Model fit: likelihood ratio χ^2_{11}=76.3.

Association Between SBP, BMI, and Hypertension

Figure 3 illustrates the relationship between SBP and BMI according to hypertension status. Hypertensive participants consistently exhibited higher SBP values than normotensive participants across the BMI spectrum. Although higher BMI values were observed in both groups, substantial overlap was evident, suggesting that BMI alone did not clearly distinguish hypertension status in this population.

XSL•FO
RenderX

Figure 3. Scatter plot showing the relationship between systolic blood pressure (SBP) and BMI among normotensive and hypertensive participants. Blue points represent normotensive participants, and red points represent hypertensive participants.

Discussion

Principal Findings

This study compared cardiometabolic risks between hypertensive and normotensive adults in selected townships of Johannesburg. The primary finding of this study was that older age and elevated glucose levels were the strongest independent predictors of hypertension in the adjusted models. Our analysis showed that increasing age and elevated glucose levels were both independently associated with hypertension. These findings align with established evidence linking advancing age to vascular stiffening and other physiological changes that contribute to elevated blood pressure [21,22].

Although obesity and central adiposity showed significant associations with hypertension in crude analyses, these associations were attenuated primarily in adjusted models. This suggests that the relationship between obesity and hypertension in this population is primarily mediated by age, which plays a dominant role. Consistent with longitudinal evidence, the risk of developing hypertension increases steadily with advancing age [23]. At the same time, cohort studies consistently demonstrate that elevated BMI and WC are strongly linked to hypertension risk across all stages of life, underscoring the critical role of excess adiposity in disease development [23,24].

Notably, life stage–specific research has shown that high baseline BMI is the strongest predictor of hypertension in early adulthood, whereas high WC exerts the greatest impact during childhood [25]. The high prevalence of obesity among hypertensive individuals in our study (53/82, 64.6%) is clinically significant and mirrors global trends [26-28]. While other studies emphasize obesity as a key independent risk factor [29-31], our findings highlight the need to account for the strong independent effect of age when designing targeted interventions for this community.

From a public health perspective, these results suggest that interventions should focus on 2 key areas: addressing excess body fat across the lifespan and tailoring strategies to the specific risk profiles of different age groups. For younger populations, prevention efforts should prioritize weight management, physical activity, and healthy dietary habits to help prevent the onset of hypertension. In contrast, for older adults, interventions should focus on regular blood pressure screening, management of existing health conditions, and lifestyle modifications that are practical and achievable in later life. Community-based programs that combine age-sensitive approaches with obesity prevention strategies could have the greatest impact.

In contrast to other studies that reported dyslipidemia as a prevalent comorbidity [32-34], we did not find statistically significant independent associations between lipid markers (HDL, LDL, and triglycerides) and hypertension. However, the *P* value for total cholesterol was close to the conventional significance threshold (P=.07), suggesting a potential trend warranting further investigation. Although these lipid parameters did not reach statistical significance, their prevalence in the population remains clinically relevant and should be considered in risk reduction efforts.

XSL•FO
RenderX

Evidence from larger cross-sectional studies has consistently demonstrated a strong relationship between hypertension and dyslipidemia. For example, a study conducted in Poland reported a significant association between hypertension and abnormal cholesterol levels (P<.001), with hypertensive individuals showing a 3-fold increase in the odds of having abnormal cholesterol levels [35]. Similar trends have been observed in sub-Saharan Africa, where dyslipidemia frequently coexists with hypertension and contributes to elevated cardiometabolic risk [33,36]. In light of these findings, the absence of statistically significant associations in our study may be due to sample size limitations, population-specific characteristics, or unmeasured confounding factors, such as diet, physical activity, and socioeconomic status.

The South African context magnifies the importance of these findings. Research from other local populations has demonstrated strong correlations between BMI, WC, and SBP [6,37], mirroring the current study's outcomes. International evidence further highlights the growing burden of obesity, particularly among middle-aged adults and rural populations [9,28,30]. Together, these results emphasize the urgency of community-level interventions that combine regular health screenings, obesity management, and culturally tailored health education.

Overall, the findings suggest a clustering of cardiometabolic risk factors, with obesity and glucose dysregulation playing central roles in hypertension pathogenesis. The substantial proportion of undiagnosed or uncontrolled hypertension observed in Johannesburg South underscores the need for early detection, integrated screening, and multifactorial interventions.

Limitations

Several limitations must be acknowledged. First, the cross-sectional design precludes the determination of causal relationships. The observed relationships should be interpreted as correlations rather than causal pathways. Longitudinal studies are necessary to establish temporal and causal links between age, glucose dysregulation, obesity, and hypertension.

Second, although purposive sampling limits representativeness and external validity, it was considered the most feasible approach because of the absence of reliable sampling frames in township settings. This method ensured the inclusion of underrepresented community members, providing valuable baseline evidence to inform future probabilistic studies.

Third, the final sample of 209 participants may have limited statistical power to detect modest associations, particularly for lipid-related variables and within the multivariable LR model. Consequently, some nonsignificant findings may reflect insufficient statistical power rather than the absence of a true association. Larger studies are needed to confirm these findings and improve the precision of the estimates. Furthermore, excluding participants with incomplete data or those who did not return for screening may have introduced selection bias, potentially limiting the representativeness of the final analytic sample. In addition, the underrepresentation of men, which is common in South African epidemiological research, may limit the generalizability of the findings.

Additionally, glycemic status was assessed using random blood glucose measurements rather than fasting plasma glucose or HbA_{1c}. Although random glucose testing was the most feasible approach in this community-based setting, it is less precise than standard diagnostic measures and may have resulted in misclassification of glycemic status.

Finally, the study did not include socioeconomic and behavioral factors, such as dietary intake, physical activity, and stress, which may have influenced the observed associations.

Recommendations

Future research should use longitudinal designs with larger, more diverse samples to strengthen causal inference and generalizability. Incorporating dietary, lifestyle, and socioeconomic data will provide a more comprehensive understanding of modifiable risk factors. Moreover, the use of sensitive lipid biomarkers is essential to elucidate their role in hypertension. Evaluating community-based screening and health education programs could further inform effective prevention strategies.

Conclusions

Hypertension was independently associated with advancing age and elevated glucose levels in this population. Although obesity and central adiposity showed significant associations in unadjusted analyses, they were not independently associated with hypertension after adjustment. While lipid markers were not statistically significant predictors, their prevalence remains clinically relevant and warrants continued monitoring. These findings highlight the importance of early screening and multifactorial interventions to address cardiometabolic risk in underserved South African communities.

Abstract

Background: Dance is a complex mode of physical activity (PA) behavior and an art form, and one's participation in dance may occur across discrete contexts throughout the lifespan. To further advance the study of lifetime participation in dance behavior, reliable questionnaires are needed.

Objective: This study aimed to develop and test the reliability of a self-report, online questionnaire for surveilling lifetime participation in professionally led dance classes among adults.

Methods: Community-dwelling adults (N=373) completed the Lifetime Dance Exposure Questionnaire for Professional Training (LDEQ-T) at baseline (T1), and 150 adults repeated the LDEQ-T after an 8-week delay (T2). Test-retest reliability for self-reported dance training frequency, duration, and PA intensity was analyzed for the LDEQ-T between T1 and T2. Reliability for the LDEQ-T item on total years of professional dance training was assessed using intraclass correlation coefficients (ICCs; 2-way, random effects); linearly weighted kappa ($_w$) was used for ordinal variables on dance class duration, intensity, and frequency; an unweighted kappa ( ) statistic was used to test the reliability of 3 dance training exposure groups (no or low, homogenous, or variable lifetime exposure to professional dance training). The significance level was set a priori with α=.05.

Results: Adults reported having no or low (n=92), homogenous (n=196), or variable (n=85) lifetime exposures to professional dance classes at T1. Among adults who self-reported homogenous exposures to dance training throughout the lifespan, years of dance training were found to be reliable across all age periods (ICC range 0.83-0.94); as were weeks/month, months/year, and hours/week of dance training ($_w$ range 0.35-0.61); but not any measure of PA intensity. Among adults who self-reported variable exposures to dance training, years of dance training across all age periods (ICC=0.70-0.96); classes/week, weeks/month, months/year, and hours/week ($_w$ range 0.32-0.56); and some estimates of PA intensity ($_w$ range 0.30-0.41) were found to be sufficiently reliable.

Conclusions: The LDEQ-T appears to be a reliable instrument for quantifying lifetime participation in professional dance training among adults with self-reported low, homogenous, or variable exposures to professional dance classes throughout the lifespan. Among adults, researchers may surveil lifetime exposure to dance training in early childhood, childhood, adolescence, young adulthood, and middle or older adulthood using the LDEQ-T.

Introduction

Dancing is positively associated with physiological, psychological, cognitive, and functional health outcomes across the lifespan [1-6]. Participation in dance refers to any of a wide range of unique or codified physical activity (PA) behaviors (eg, walking, running, sitting, standing, and jumping) performed with artistic or aesthetic intent [7]. It is widely known that PA dose—the product of the frequency, duration, and intensity of an exposure to a given mode of PA—is associated with health outcomes [8]. To that end, engaging in dance behavior, when compared to specific non-dance PA behaviors, has been reported to confer especial health benefits such as lower risk for cardiovascular disease mortality [9] and improve flexibility and balance [10]. However, additional research is needed to further extend available measures that are specifically designed to

XSL•FO
RenderX

surveil lifetime participation in dance behavior from a lifespan development perspective.

Some existing long-term PA recall surveys on lifetime PA participation include items on dance and provide general estimates of the total number of years spent engaged in dance [11,12], and a subset of these instruments provides self-reported estimates on the PA intensity of dance exposures throughout the lifespan [11]. Each of these instruments can be used to obtain global estimates of the total number of years spent participating in dance across solo, professional, and social contexts. However, studies show that the PA intensity of dance may depend, in part, on the conditions under which dancing is performed or upon participant-level factors. For example, a study on the PA intensity of modern dance across class, rehearsal, and performance contexts reported dance intensities that ranged from 2.9 metabolic equivalents (METs) to 7.1 METs depending upon the context in which the dance behavior was performed [13] Another study conducted in young to older adults reported the mean intensity of solo, free-form dancing with and without music ranged from 5.6 METs to 7.5 METs and that PA intensity during dance was inversely associated with age and BMI [14]. Given that the PA intensity of dance may vary when performed across different contexts, in addition to its inverse relationship with age, the need for self-report instruments that are expressly designed for quantifying context-specific exposures to dance across the lifespan is clear. Relatedly, studies show that lifetime participation in professionally led dance classes may be interrupted for variable periods of time across the lifespan due to injury [15], for example, or due to other barriers such as insufficient resources available to pay for dance classes [16]. Moreover, some research also indicates that early developmental exposures to professionally led dance classes may be negatively associated with psychological health outcomes during adulthood in some individuals [17]. Together, these studies point toward the need for context-specific measures of lifetime dance participation that allow researchers to specifically account for exposures to professionally led dance classes, while also accounting for potential variability in professional dance training exposures across the lifespan due to factors such as barriers to access.

Though some available measures of lifetime participation in PA provide the means for estimating years of dance participation generally (ie, undifferentiated exposures to dance across solo, professional, and social contexts), studies that aim to specifically quantify exposures to professionally led dance classes at different periods across the lifespan require the development of additional measures. Dance behavior, as a term, is inclusive of dance across any context (eg, solo dancing, dancing in rehearsal and performance, or dancing socially). Professionally led dance classes refer specifically to exposures to dance that are facilitated by a professional. With specific data on exposures to dance in professionally led class environments across the lifespan, researchers can better understand how the context in which dance behavior occurs relates to markers of health. Further, more granular data on professionally led dance classes with regard to chronological age and the timing of dance exposures across the lifespan may extend future analyses on the benefits of dance for health from a developmental perspective [18]. The design of a flexible instrument for quantifying exposures to professionally led dance classes across developmental periods would thus facilitate future research on dance and health from a lifespan development perspective and augment measures of lifetime participation in PA. Therefore, the purpose of this study was to develop and determine the reliability of a new PA questionnaire, the Lifetime Dance Exposure Questionnaire for Professional Training (LDEQ-T), specifically designed to surveil exposures to professionally led dance classes throughout the lifespan among adults.

Methods

Participants

Adults aged 18 years and older were recruited to participate in this research study. Prospective participants were recruited via flyers, social media (ie, Facebook [Meta] and Twitter), email, and word of mouth. Flyers were posted in the Pioneer Valley of Massachusetts and via social media. Within the Pioneer Valley, flyers were posted in dance studios, senior centers, at local community events, and within local businesses that were not directly associated with dance (eg, coffee shops or martial arts training venues). The link to the questionnaire was included in emails that the lab sent as part of a quarterly newsletter. Research team members shared information about the study informally throughout their personal networks and in social settings (ie, word of mouth).

Procedures

Participants were asked to complete a brief sociodemographic questionnaire online via REDCap (Research Electronic Data Capture; Vanderbilt University) [19]. Participants were then asked to complete the novel LDEQ-T. After 8 weeks, participants received an email invitation via REDCap to complete the LDEQ-T for a second time. Participants received reminder emails to complete the LDEQ-T for 6 weeks or until they completed the questionnaire. Prior studies that have evaluated the reliability of self-report questionnaires for measuring lifetime exposures to PA have delayed readministering the instrument for intervals of 1 - 8 weeks [12,20,21], with some studies extending the delay period for up to 8 months [11].

Sample Size Considerations

In considering the final study sample size, it was determined that at least thirty adults [22] should complete the LDEQ-T at the second time point.

Materials

Sociodemographic Questionnaire

Self-reported age in years and biological sex were collected using a brief online questionnaire.

LDEQ-T

Development

The LDEQ-T is an original questionnaire designed by an expert (AKM) in dance, dance education, and movement science to

XSL•FO
RenderX

specifically quantify self-reported participation in professionally led dance classes throughout the lifespan.

Conceptual Framework

As stated previously, PA dose is defined as the product of the intensity, duration, and frequency of a given PA exposure [8]. It follows that the LDEQ-T includes items on the PA intensity, duration, and frequency of professionally led dance classes taken throughout life.

Item Generation and Draft Questionnaire

The questionnaire assesses total years of dance training, the duration, frequency, and intensity of dance exposures, and it categorizes respondents into 1 of 3 dance exposure groups based upon total dance training volume and regularity. The original questionnaire had a total of 24 items; however, the number of items differs for respondents based upon branching logic [23]. Respondents categorized as having low exposure complete a single-item questionnaire; respondents categorized as having homogenous exposure complete a 13-item questionnaire; respondents categorized as having variable exposure complete a 24-item questionnaire. Each exposure group is described further below.

Exposure Groups

Among those who report that they have completed ≥40 professionally led dance classes, the LDEQ-T accounts for potential variability in dance participation throughout the lifespan by asking respondents to identify whether there were any major discontinuities during their participation in professionally led dance classes throughout life. Individuals who self-report that they have completed <40 professionally led dance classes conclude the questionnaire once they have completed the first questionnaire item.

Low Exposure

A single item on the questionnaire (ie, "Have you participated in 40 or more professionally led dance classes in your life? For reference, participating in 40 dance classes is approximately equal to taking a dance class once a week, every week, for about 10 months.") was used to identify individuals with low exposure to professional dance training throughout life. The response format is a radio button [23] with options of "YES" and "NO" only. Respondents who self-report that they have completed <40 professionally led dance classes throughout life are categorized as individuals with low exposure to professionally led dance classes. The <40 class cut point was selected as a meaningful threshold that would represent having completed <1 year of dance training (ie, less than one class per week in a given year, assuming that annual curricula in a dance studio for children and adolescents may typically extend across a training period of ~10 months).

Homogenous Exposure

A single item on the questionnaire (ie, "Thinking only of the years you participated in dance classes on a regular basis, describe the usual amount of time that you spent taking dance classes year-to-year. Taking dance classes on a regular basis means participating in dance classes for 90 minutes or more per week, each week. While taking dance classes on a regular basis, the amount of time I spent taking dance classes year-to-year was.") was used to identify individuals whose exposure to professional dance training throughout life was consistent within and across dance training periods. The response format was a radio button with options of "about the SAME each year" and "much MORE on some years and much LESS on other years" only. Respondents who self-report engaging in dance classes consistently throughout life are categorized as individuals with homogenous exposure to professionally led dance classes.

Variable Exposure

Individuals who self-report discontinuities in dance class engagement throughout life (ie, individuals who reported taking dance classes "much MORE on some years and much LESS on other years") are categorized as individuals with variable exposures to professionally led dance classes.

Total Years

The LDEQ-T asks respondents to identify each year in which they participated in dance classes that were led by a teacher from early childhood (age <2 years) to older adulthood (age >85 years). Using checkboxes [23], respondents are asked to select the checkbox next to each year that they engaged in professionally led dance classes. Individuals in the "Homogenous Exposure" group complete the total years item one time; those in the "Variable Exposure" group complete the total years item twice—once for the years in which they engaged in "MORE" dance classes than other years and once for the years in which they engaged "LESS" in taking dance classes. Questions on total years of participation were based upon the Lifetime Physical Activity Questionnaire [11], which asks respondents to select the year they began and stopped participating in each given mode of PA.

Duration, Frequency, and Intensity

Finally, the questionnaire asks respondents to self-report the duration and PA intensity of the professionally led classes they attended. The format for these questions used drop-down menus and absolute open-ended quantifiers [23]. Individuals in the "Homogenous Exposure" group complete each item on the duration, intensity, and frequency one time; those in the "Variable Exposure" group complete each item on duration, intensity, and frequency twice—once for the years in which they engaged in "MORE" dance classes than other years and once for the years in which they engaged "LESS" in taking dance classes. Questions on duration, PA intensity, and frequency were based upon the Modifiable Activity Questionnaire and Godin-Shephard Leisure-Time PA questionnaire [24-26]. Questions on the duration and frequency of taking professionally led dance classes were fashioned after the Modifiable Activity Questionnaire, which asks respondents to report the number of times per month and the average number of minutes spent each time one engages in a given mode of PA. Questions on the perceived PA intensity of professionally led dance classes were fashioned after the Godin-Shephard Leisure-Time PA questionnaire, which asks respondents to report the total number of 15-minute bouts per week that they engaged in exercise at self-reported strenuous, moderate, and mild or light levels of effort. Examples of PA modes provided in the LDEQ-T for each level of effort were kept largely

XSL•FO
RenderX

consistent with those included in the original Godin-Shepard Leisure-Time PA questionnaire, with the inclusion of dance-related behaviors. LDEQ-T items on duration, intensity, and frequency appear below:

- Duration: hours per week spent taking dance classes (drop-down menu).
- Frequency: class sessions per week (absolute open-ended quantifier; min: 1; max: 40), weeks per month (drop-down menu), and months per year (drop-down menu).
- Intensity: (1) Minutes per class spent dancing at a strenuous effort level (absolute open-ended quantifier; min: 1; max: 240); (2) Minutes per class spent dancing at a moderate effort level (absolute open-ended quantifier; min: 1; max: 240); (3) Minutes per class spent dancing at a mild or light effort level (absolute open-ended quantifier; min: 1; max: 240); (4) Times per week spent dancing in class for about 15 minutes at a strenuous effort level (absolute open-ended quantifier; min: 1; max: 160); (5) Times per week spent dancing in class for about 15 minutes at a moderate effort level (absolute open-ended quantifier; min: 1; max: 160); and (6) Times per week spent dancing in class for about 15 minutes at a mild or light effort level (absolute open-ended quantifier; min: 1; max: 160).

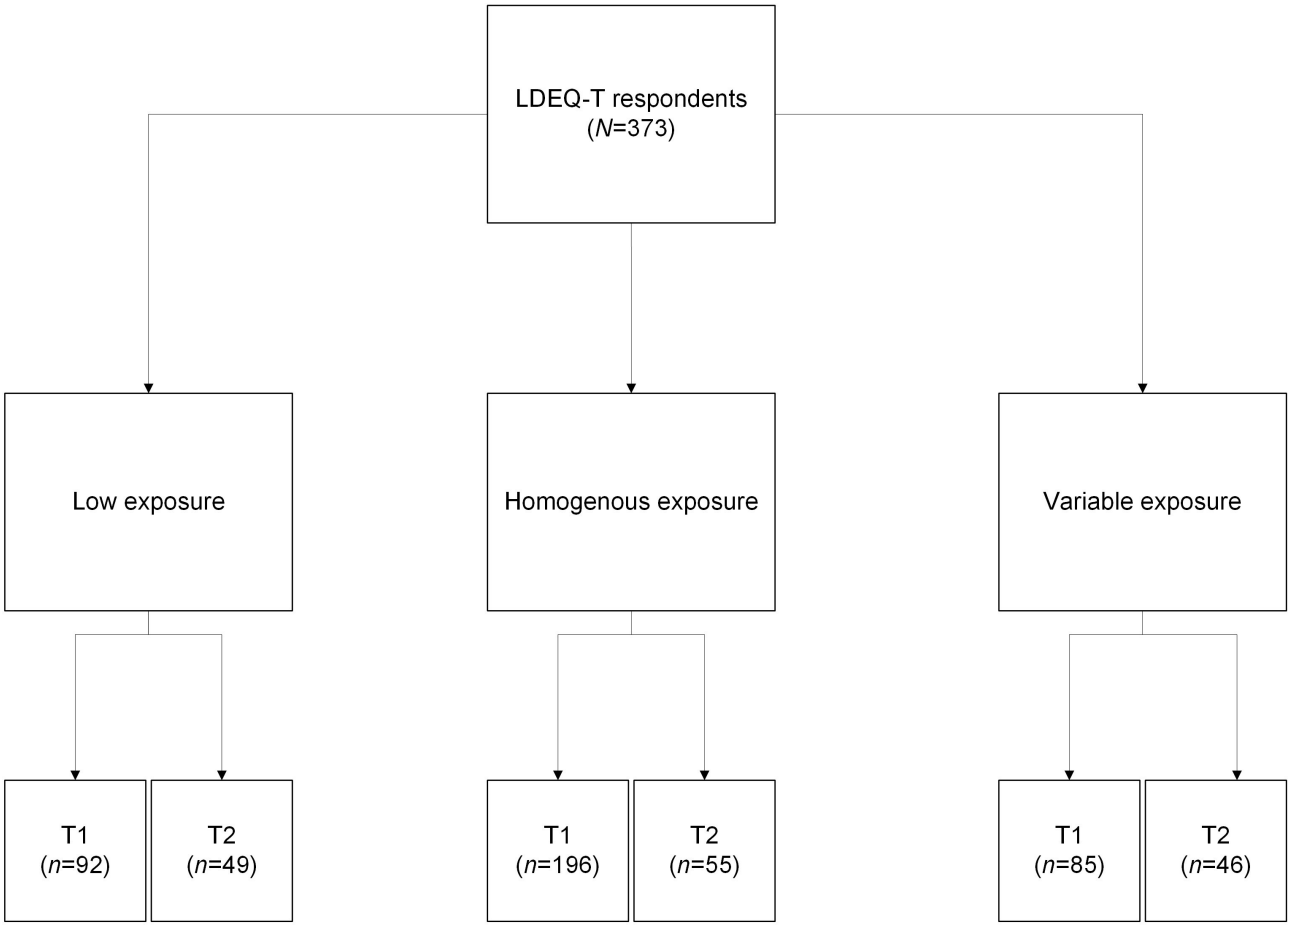
Statistical Analyses

Data were analyzed in MATLAB R2024a (The MathWorks, Inc). Descriptive statistics are reported as mean (SD), median (IQR), and frequencies (percentages). LDEQ-T test-retest reliability was evaluated using data collected at time point 1 (week 0) and time point 2 (week 8+). To do this, the item-level reliability of the LDEQ-T was evaluated across time points using intraclass correlation coefficients (ICCs) and Cohen kappa coefficients. ICCs (2-way, random effects) were used to evaluate whether LDEQ-T–derived estimates were sufficiently reliable (ICC≥0.70) for total years of dance training and years of training by age group (ie, early childhood, childhood, adolescence, young adulthood, and middle-age to older adulthood). Categories of low, moderate, and high exposure were respectively developed for the self-reported frequency (classes/wk, wk/mo, and mo/y) of taking professionally led dance classes and the duration (h/wk) of classes using tertiles. Similarly, tertiles were used to bin self-reported minutes spent engaged in each PA intensity while in class into categories of low, moderate, and high exposure. Finally, tertiles were used to bin the self-reported number of 15-minute bouts spent dancing in each PA intensity into categories of low, moderate, and high exposure. Reliability for each respective categorical measure was then determined using linearly weighted kappa coefficients ($_w$) to account for the ordinal scale of the data, and unweighted kappa coefficients ( ) were reported otherwise [27,28].

To produce a final version of the LDEQ-T, any item that was found to have insufficient reliability was removed from the instrument following the item-level reliability analyses. The final version of the LDEQ-T can be scored simply by calculating the sum of the total years spent taking dance classes over any age period, and by applying the tertile-based cut points to any items on class duration, frequency, and intensity to categorize respondents into low, moderate, and high exposure groups for each respective item. The questionnaire may also be scored with the LDEQ-T companion app [29], which was developed by the researcher (AKM) using MATLAB and is available to be downloaded. The significance level in all models was set a priori with α=.05.

Ethical Considerations

The study was approved by the Institutional Review Board at the University of Massachusetts Amherst (IRB #2495), and all participants provided written informed consent. Data were collected between February 2022 and August 2023, data were deidentified, and the study was conducted entirely online.



Results

Overview

A total of 373 adults (Figure 1) completed the LDEQ-T at timepoint one (T1). Of the overall sample, 365 adults reported their age (range 18 - 84 y) at T1; 81.9% (n=299) were young adults (aged 18 - 39 years; median 27, IQR 23-30) and 18.1% (n=66) were middle age to older adults (aged 40 - 84 y; median 49, IQR 43-57). A total of 150 adults repeated the questionnaire at time point 2 (T2). LDEQ-T test-retest reliability between T1 and T2 was sufficient for the self-reported lifetime exposure categories of low exposure, homogenous exposure, and variable exposure [(SE)=0.53 (0.06), 95% CI 0.42-0.64; *P*<.001]. Figure 2A shows self-reported dance training across the lifespan, by biological sex, using LDEQ-T responses collected at T1. The range of self-reported years of participation in professionally led dance classes ranged from 0 to 68 total years at T1.

XSL•FO
RenderX

Figure 1. Responses to the Lifetime Dance Exposure Questionnaire for Professional Training note: Figure 1 shows the total number of Lifetime Dance Exposure Questionnaire for Professional Training responses collected at baseline (timepoint 1; T1) and after an 8+ week delay (timepoint 2; T2) among adults who self-reported having low exposure to professionally led dance classes throughout life, in addition to those who reported homogenous or variable exposures to dance training year-to-year. LDEQ-T: Lifetime Dance Exposure Questionnaire for Professional Training.

Figure 2. Participation in professional dance classes across the lifespan by sex (A) and by dance exposure pattern (B) among adults aged 18 to 84 years as reported using the Lifetime Dance Exposure Questionnaire (LDEQ-T). Note: Figure 2A shows the relative percentage of adults who self-reported participating in professionally led dance classes across the lifespan for female and male LDEQ-T respondents. Figure 2B shows the relative percentage of adults who self-reported participating in professionally led dance classes across the lifespan by exposure pattern (ie, homogenous or variable exposures to dance).

XSL•FO
RenderX

Low Exposure to Dance Training

A total of 92 adults (mean age 32, SD 12.8 y; biological sex: female 52.2%, 48/92, male 47.8%, 44/92) self-reported engaging in <40 professionally led dance classes throughout life, and of these, a total of 49 adults completed the LDEQ-T at T2. The percent agreement between T1 and T2 for those who self-reported low exposure to dance training was 73.5%—among adults who reported low exposure to dance training at T1, the range of self-reported total years of dance training at T2 was 0 to 16 years.

Homogenous Exposure to Dance Training

A total of 196 adults (mean age 30, SD 10.7 y; biological sex: female 60.7%, 119/196, male 38.8%, 76/196, not reported 0.5%, 1/196) indicated that they experienced homogenous exposures to professionally led dance classes throughout life when completing the LDEQ-T at T1, and of these n=55 adults completed the LDEQ-T at T2. Figure 2B shows self-reported exposures to professionally led dance classes across the lifespan for adults who reported homogenous exposures to dance training at T1.

Self-reported years of dance training were found to be sufficiently reliable (ICC range 0.83-0.94) for those who self-reported experiencing homogenous exposures to professionally led dance classes across the lifespan (Table 1). As Table 2 shows, the frequency and duration of self-reported professional dance classes were also found to be reliable when assessed in terms of weeks/month, months/year, and hours/week ($_w$ range 0.35-0.61). Remaining items on frequency, duration, and intensity had low kappa coefficients and were excluded from the final version of the LDEQ-T due to insufficient reliability (P>.05). These items included average class sessions per week ($_w$=0.23); average minutes of dance at strenuous ($_w$=0.18), moderate ($_w$=0.19), and mild or light levels of perceived exertion ($_w$=0.17) per class; and average times per week spent dancing for about 15 minutes in class at strenuous ($_w$=0.21), moderate ($_w$=0.10), and mild or light ($_w$=0.05) levels of perceived exertion.

Table . Lifetime Dance Exposure Questionnaire for Professional Training reliability (homogenous exposure): years of training by age group. Note: Table 1 shows the mean (SD), and intraclass correlation coefficients for years of dance training for five age groups across timepoint 1 (T1) and timepoint 2 (T2) among adults who reported having homogenous exposures to professionally led dance classes throughout life.

Years of training	T1, mean (SD)	T2, mean (SD)	ICC[a] (95% CI)

Variable Exposure to Dance Training

A total of 85 participants completed the LDEQ-T at T1 and indicated having variable exposure to dance training throughout life (mean age 30, SD 13.4 y; biological sex: female 68.2%, 58/85, male 30.6%, 26/85, not reported 1.2%, 1/85), and of these, a total of 46 adults completed the LDEQ-T at T2. Figure 2B shows self-reported dance training across the lifespan for adults who reported variable exposure to dance training at T1. Self-reported years of dance training were found to be sufficiently reliable (ICC range 0.70-0.96) for those who reported experiencing variable exposures to dance training across the lifespan (Table 3).

Table . Lifetime Dance Exposure Questionnaire for Professional Training reliability (variable dance exposure): Years of training by age group. Note: Table 3 shows the mean (SD), and intraclass correlation coefficients (ICC) for years of dance training for five age groups across timepoint 1 (T1) and timepoint 2 (T2) among adults who reported having variable exposure to professionally led dance classes throughout life.

Years of training	T1, mean (SD)	T2, mean (SD)	ICC[a] (95% CI)
Total lifetime training (n=46)	13.6 (13.1)	11.6 (10.4)	0.93 (0.89-0.96)

Training during middle and older adulthood (age >40 years; n=18)	1.2 (4.4)	0.5 (1.8)	0.70 (0.56-0.84)

[a]ICC: intraclass correlation coefficients.

High Exposure Years

As shown in Table 4, the frequency and duration of self-reported professional dance classes were also found to be reliable when assessed in terms of classes/week, weeks/month, months/year, and hours/week ($_w$ range 0.38-0.56).

XSL•FO

All but 2 items pertaining to dance intensity were reliable, summarized in Table 5 ($_w$: 0.33-0.42). Items with low kappa coefficients and insufficient reliability (*P*>.05) were average class minutes spent dancing at mild or light levels of perceived exertion ($_w$=0.17) and average times per week spent dancing for about 15 minutes in class at strenuous levels of perceived exertion ($_w$=0.23), which were excluded from the finalized LDEQ-T.

Table . Lifetime Dance Exposure Questionnaire for Professional Training reliability (variable dance exposure): Time spent engaged in dance class at mild to strenuous physical activity intensities—tertiles during high exposure years. Note: Table 5 summarizes the percentage of participants within low, moderate, and high tertiles for items on dance intensity (minutes and number of 15-minute bouts of dancing per week at different levels of perceived exertion) during their high dance exposure years at baseline (T1) and after an 8+ week delay (T2). Italic values represent corresponding tertiles for each respective item on intensity.

Low Exposure Years

As shown in Table 6, the frequency and duration of self-reported professional dance classes were also found to be reliable when assessed in terms of classes/week, weeks/month, months/year, and hours/week ($_w$ range 0.32-0.43) during self-reported less active dance training years.

Table . Lifetime Dance Exposure Questionnaire for Professional Training reliability (variable dance exposure): Dance class frequency and duration tertiles during low exposure years. Note: Table 6 summarizes the percentage of participants within low, moderate, and high exposure tertiles for items on dance exposure frequency (weeks/months; months/year) and duration (hours/week) during their low dance exposure years at baseline (T1) and after an 8+ week delay (T2). Italic values represent corresponding tertiles for each respective item on frequency and duration.

Measures	Low	Moderate	High	$_w$	SE (95% CI)	*P* value
Classes per week (N=46)	*1*	*2*	*3*	0.33	0.15 (0.06-0.62)	.021

Two items on perceived dance intensity were sufficiently reliable for less active dance training years, as summarized in Table 7 ($_w$ range 0.30-0.31). Remaining items with low kappa coefficients and insufficient reliability (*P*>.05) were excluded from the final LDEQ-T, which were average class minutes spent dancing at strenuous levels of perceived exertion ($_w$=0.30) and average times per week spent dancing for about 15 minutes in class at strenuous ($_w$=0.23), moderate ($_w$=0.24), and mild or light ($_w$=0.21) levels of perceived exertion.

Table . Lifetime Dance Exposure Questionnaire for Professional Training reliability (variable dance exposure): Minutes spent engaged in dance class at mild or light and moderate physical activity intensities—tertiles during low exposure years. Note: Table 7 summarizes the percentage of participants within low, moderate, and high tertiles for items on dance intensity (minutes of dancing per week at different levels of perceived exertion) during their low dance exposure years at baseline (T1) and after an 8+ week delay (T2). Italic values represent corresponding tertiles for each respective item on intensity.

LDEQ-T Refinement and Companion App

Questionnaire Refinement

Items with insufficient reliability were removed from the original 24-item version of LDEQ-T. The final LDEQ-T (18 items) can be downloaded as a *.pdf and as a REDCap "Data Dictionary" [29]. The total number of items for each exposure group in the final version of the questionnaire was 1, 6, and 18 for those in the low, homogenous, and variable exposure groups, respectively. Field notes show that the questionnaire may be completed in 1 - 15 minutes.

XSL•FO
RenderX

LDEQ-T Companion App

The LDEQ-T app (KinetiWave) allows users to select a spreadsheet with LDEQ-T responses, as exported from REDCap, and it returns a summary of the total number of years spent engaged in professional dance training, as well as a summary of the years spent engaged in dance classes across each age group from early childhood to middle and older adulthood. In addition, the LDEQ-T companion app applies the empirically derived, tertile-based cutoff points to all LDEQ-T items on the self-reported duration, frequency, and perceived intensity of professionally led dance classes. An example summary report can be downloaded with the LDEQ-T app [29].

Discussion

Overview

This study aimed to determine the reliability of a new questionnaire, the LDEQ-T, which was specifically designed to surveil lifetime exposures to professionally led dance classes among adults. Analyses of the LDEQ-T revealed that it is a reliable questionnaire for assessing lifetime participation in professionally led dance classes among adults aged 18 to 84 years. When the LDEQ-T was used to assess dance training among adults who self-reported experiencing homogenous exposures to professionally led dance classes throughout life, self-reports on the frequency and duration of dance classes, but not the PA intensity of classes, were found to be reliable. Among adults who self-reported experiencing variable exposure to professionally led dance classes across life, self-reports on the frequency, duration, and the PA intensity of dance classes were respectively found to be reliable for LDEQ-T items depending upon the overall level of self-reported dance training activity each year. Overall, results show the LDEQ-T is a reliable instrument for assessing lifetime participation in professionally led dance classes among adults with a range of prior exposures to dance training.

Principal Results

In a sample of adults aged 18 to 84 years, the LDEQ-T provided reliable estimates of the total number of years in which respondents engaged in professionally led dance classes across the lifespan. Among a cohort of adults with prior exposures to dance training, LDEQ-T reliability estimates were observed to be good to very good (ICC>0.89) for self-reported total years of experience in professionally led dance classes. Reliability estimates for the LDEQ-T were also observed to be sufficient when years of dance training were analyzed by dance exposure by age groups, early childhood, adolescence, young adulthood, middle or older adulthood (ICC>0.70). Study results showed that the LDEQ-T can be used as a reliable measure of the total number of years in which adults have engaged in professionally led dance classes, in addition to providing a measure of age-specific exposures to dance training across the lifespan. Prior studies that have evaluated the reliability of lifetime PA questionnaires report ICCs in the range 0.67 - 0.89 [11,12]. Thus, the reliability of the LDEQ-T is comparatively strong, and future studies may use the LDEQ-T to obtain self-reports of the total number of years one has engaged in professionally led dance classes across the lifespan, as well as assess exposure to professionally led dance classes by developmental age groups.

Reliability for LDEQ-T items about the PA intensity of dance classes was found to be sufficient among adults who self-reported experiencing variable exposure to dance training throughout life. Specifically, during years that adults reported as being more active dance training years, reliability was found to be sufficiently high for items on self-reported time spent at strenuous and moderate ($_w$: 0.33-0.41) levels of perceived effort and on self-reported weekly bouts of activity performed at moderate and mild or light ($_w$: 0.36-0.42) levels of perceived effort. Similarly, for the years adults reported they were less engaged in dance training, reliability was found to be sufficient [30] for items on self-reported minutes spent at moderate and mild or light levels of perceived effort ($_w$: 0.30-0.31). For adults who reported experiencing homogenous exposures to dance training throughout life, no items on the perceived intensity of dance classes were found to be sufficiently reliable. Average years of dance training experience were qualitatively higher among adults with variable exposures to dance training (13.6 y) versus those with homogenous exposures to dance training (7.3 y). It is possible that those who participated in dance over a greater number of years were more consistently able to recall the perceived PA intensity of professionally led dance classes; however, additional research is needed to understand how lifetime PA exposure patterns may potentially affect long-term PA intensity recall.

The results of this study suggest that, among adults with variable exposures to dance training throughout life, the LDEQ-T can be used to recall and assess the self-reported perceived PA intensity of dance classes during both more active and less active dance training years. Among adults with homogenous exposures to dance training, results also show the LDEQ-T can be used to recall and assess the self-reported frequency and duration of dance classes taken throughout life. The LDEQ-T questionnaire can be obtained, along with a copy of the questionnaire items, response scale characteristics, and REDCap “Data Dictionary” as part of the LDEQ-T app download [29]. The LDEQ-T app includes a calculator for LDEQ-T responses; the app applies the tertile cut points, as presented in our study results, and returns summary statistics on professionally led dance class exposure for respondents. Work from our group showed that total years of exposure to professionally led dance classes, as measured by the LDEQ-T, were related to movement qualities associated with free-form dance in a study that used wearable devices to quantify motor behavior quality among adults aged 18 to 83 years with a range of 0 to 56 years of professional dance training [31].

Limitations and Delimitations

A limitation of the study is that no concurrent measure of lifetime exposure to professionally led dance training was used to validate the LDEQ-T. This is because, to our knowledge, this is the first study to develop a method for surveilling exposure to professionally led dance classes throughout life. While the lack of a concurrent measure of PA may be a limitation that is typical of most studies that have developed long-term PA recall questionnaires [21,32], studies have also been previously

XSL•FO
RenderX

conducted that concurrently integrated the use of wearable devices in the development of long-term PA recall instruments [33]. Importantly, a major difference between this study and prior studies that have used wearable devices to validate long-term PA recall instruments is that the LDEQ-T accounts for dance training in childhood, while prior studies that have used wearable devices to validate their questionnaire were focused only on PA in adulthood. Future studies on dance that seek to further develop surveys for long-term PA recall should consider including wearable sensors as part of the questionnaire design process to further advance PA recall-based methods [32,33]. Given that no other measure exists for expressly assessing exposures to professionally led dance classes across the lifespan, all reports on years of dance training experience that were represented in this study sample were obtained from the LDEQ-T. A delimitation of the study is that children and adolescents were not included in the sample. The study sample included young to older adults, and the item-level reliability of the LDEQ-T questionnaire was found to be sufficient across age groups. Nevertheless, it is important to note that the study sample was comprised mostly of adults aged 18 to 39 years (~82%), and adults aged 40 to 84 years comprised the remaining ~18 % of the sample. Future studies are required to determine if the LDEQ-T can be used among non-adult respondents; additional research on the LDEQ-T among older adults, especially >75 years, may be needed. Finally, the LDEQ-T does not include any open-ended questions on self-reported dance style; therefore, researchers may need to additionally allow respondents to provide qualitative feedback in order to further document dance heritage or style when characterizing lifetime dance exposure.

Strengths

A strength of the study is that a sample of young to older adults, aged 18 to 84 years, both with and without prior dance training, were recruited to complete the LDEQ-T. The LDEQ-T provides a novel measure of dance training that allows researchers to account for variable exposures to dance training throughout the lifespan. Furthermore, the LDEQ-T offers a context-specific measure of dance training that focuses on exposure to dance in professionally led classes. In view of the promising findings presented in this study, we recommend that researchers consider using the LDEQ-T, and its companion calculator app [29], to assess exposures to professionally led dance classes across the lifespan in future studies of dance and health among adults with or without prior dance training. Finally, we present the item-level reliability for the LDEQ-T questionnaire, which enables researchers to select and use any of the LDEQ-T items that are most relevant to the purposes of their research.

Conclusions

The LDEQ-T appears to be a reliable self-report instrument for assessing the frequency and duration of lifetime participation in professionally led dance classes among adults aged 18 to 84 years, with a range of 0 to 68 years of dance training. Adults who have experienced variable exposure to professional dance training throughout life may additionally use the LDEQ-T to reliably report the perceived intensity of dance classes. Future studies on lifetime exposures to dance training among adults may use the LDEQ-T to surveil dance exposures from a lifespan development perspective.

Acknowledgments

The authors wish to thank the study participants who volunteered their time, and the research team members from Laboratory for the Scientific Study of Dance (LAB:SYNC) for their diverse support. The authors also wish to thank the specialists in dance and physical activity who provided feedback on the initial draft of the Lifetime Dance Exposure Questionnaire for Professional Training. Abstract

Background: With population aging and the growing burden of chronic diseases, the number of patients with cardiovascular disease (CVD) in China continues to rise. Nursing robots have been recognized as one potential approach to help alleviate nursing workload. However, patient-centered functional needs with respect to such robots among patients with CVD remain insufficiently explored in China.

Objective: On the basis of the Kano model, this study aimed to analyze attitudes toward and demand priorities regarding nursing robot functions among patients with CVD. The findings may provide evidence to support function optimization and wider clinical application of nursing robots in China.

Methods: A cross-sectional study was conducted at Wuhan Asia Heart Hospital from July 2024 to June 2025. Convenience sampling was used to enroll 156 patients with CVD. Data were collected using a self-designed questionnaire, including demographic characteristics and a 15-item Kano scale for nursing robot functions. Data were analyzed using descriptive statistics, Kano classification, better-worse coefficients, and a 4-quadrant diagram.

Results: Among 15 functional items, accompanying care, consulting education, information management, and monitoring and warning were classified as must-be attributes; activity management, rehabilitation physiotherapy, drug management, security management, and logistics transfer were one-dimensional attributes; infection management, first aid skills, and nutritional care were attractive attributes; and sampling operation, personal hygiene management, and excretory care were indifferent attributes.

Conclusions: Our study reveals that patients with CVD generally exhibited high acceptance of nursing robots, but there were significant differences in functional requirements. When introducing nursing robots into clinical settings, priority should be given to essential attributes such as monitoring and warning, as well as educational consultation, along with expected attributes such as medication management. At the same time, attractive attributes such as infection management can be developed as value-added features. For nondifferentiated attributes such as personal hygiene management, selective configurations can be implemented based on clinical needs to enhance the clinical applicability and patient acceptance of nursing robots.

Introduction

Worldwide, cardiovascular disease (CVD) has emerged as one of the primary risk factors adversely affecting public health [1]. According to a global statistical report by the American Heart Association, by 2021, there were over 19.91 million deaths attributed to CVD worldwide [2]. Over the past few decades, both the incidence and mortality rates of CVD in China have exhibited a significant upward trend. The number of patients with CVD in China alone amounts to 330 million [3]. Given the substantial population in China with risk factors for CVD, the fact that its incidence and mortality rates continue to rise poses significant challenges to the Chinese health care system [4].

Parallel to the growing CVD burden is the intensifying challenge of population aging and a shortage of professional nursing resources. Older adults account for a large proportion of patients with CVD and rely heavily on long-term, specialized care, yet the nursing workforce in China is underresourced and

XSL•FO
RenderX

overloaded, especially in cardiovascular departments, where nurses undertake repetitive, high-intensity tasks such as vital sign monitoring, medication guidance, and rehabilitation support [5-7]. In this context, nursing robots have emerged as a promising solution to alleviate workload, improve care efficiency, and supplement human resources in cardiovascular settings [8-11].

As a key component of intelligent health care, nursing robots have shown strong potential in supporting routine care and improving clinical delivery [12]. Current applications span health monitoring [13], daily living assistance [14,15], social companionship [16], and improvement of cognitive function [17]. Despite these advances, most research and functional designs focus on general older adult or rehabilitation populations, with limited consideration of the unique clinical needs of patients with CVD. Patients with CVD typically experience long disease courses, frequent exacerbations, polypharmacy, cardiac function–stratified rehabilitation, and elevated infection risk, creating distinct requirements for real-time monitoring, precise medication support, personalized rehabilitation guidance, and infection control [18]. Failure to address these specific needs may limit clinical translation and sustainable adoption of nursing robots in cardiovascular settings.

In recent years, research attention has shifted from technical development of robots to user needs and acceptance, with studies investigating perspectives of nursing managers, frontline nurses, and medical students [19-21]. As direct recipients of robot-assisted care, patients' views are critical for functional design and clinical adoption, yet their needs remain understudied.

The Kano model is a framework useful for categorizing user needs and ranking functional priorities and has been applied in some health care studies [18]. It can help classify needs into must-be, one-dimensional, attractive, and indifferent attributes. Previous studies have used the Kano model in medication management [22], pulmonary rehabilitation [23], psychological care [24], and nurses' needs for nursing robots [25]. However, few studies have used the Kano model to quantitatively explore the functional needs of patients with CVD regarding nursing robots.

Accordingly, this cross-sectional study used the Kano model to investigate the functional needs and priorities of patients with CVD regarding nursing robots. The findings may help bridge gaps between patient needs and robot function design and support the clinical translation of intelligent nursing technologies in cardiovascular care.

Methods

Study Design

A cross-sectional design was used to investigate functional needs regarding nursing robots among patients with CVD at a single time point.

Research Setting

This study was conducted at Wuhan Asia Heart Hospital, the only tertiary specialized hospital in central China dedicated to the diagnosis and treatment of CVD. The hospital operates multiple departments, including cardiovascular medicine, cardiac surgery, and cardiovascular intensive care unit, with an annual patient volume of 128,000 for CVD. The patient population encompasses various conditions, such as atherosclerotic CVD, hypertensive CVD, and valvular heart disease. The distribution of patients is balanced in terms of age, educational background, disease duration, and severity, ensuring a strong representative sample that reflects the general needs of patients with CVD in central China.

Participants

Convenience sampling was used to select patients with CVD who visited Wuhan Asia Heart Hospital from July 2024 to June 2025 as the primary study participants.

Inclusion criteria were (1) adults aged 18 years and older regardless of gender, (2) patients with a precise diagnosis of CVD (any type), and (3) voluntary participation in the study.

Exclusion criteria were (1) failure to provide valid informed consent or incomplete questionnaires, (2) individuals with significant cognitive impairment (a Mini-Mental State Examination score of <27), (3) those with decreased vision or hearing impairments making it impossible to read text or engage in conversation, (4) participants with critical acute conditions or those with end-stage disease, and (5) individuals who participated in a similar nursing robot needs survey within the previous 3 months.

Sample Size Calculation

The minimum required sample size for the questionnaire was calculated using the following formula:

$$N=Z2\times p(1-p)2d2$$

A 95% CI (Z=1.96) and a 7.5% margin of error were applied. The minimum required sample size was 171. Considering an expected 10% invalid rate, 190 questionnaires were distributed.

Research Tools

The survey tool comprised an online questionnaire designed with 2 sections. The first section was a general information survey that included 9 questions related to the participants' gender, marital status, age, educational level, type of CVD, duration of illness, previous experience with nursing robots, receipt of robot services, and methods of interaction with robots. The second part featured the Kano survey scale, which addressed functional needs regarding nursing robots. On the basis of a preliminary literature analysis, we identified and analyzed tasks in nursing that could potentially be replaced by robots, classifying them into 15 demand items [26,27] using card sorting methods (Table 1). In our developed Kano demand scale, each of the 15 included items was designed to assess participants' attitudes and preferences regarding specific functional areas of artificial intelligence (AI) nursing robots through both positive and negative questions. For instance, one question asked the following: "How do you feel if the nursing robot has/does not have a medication management function?" Each question encompassed 5 evaluation dimensions: "like it," "must-be," "neutral," "accept it," and "dislike." Consequently, participants' evaluations of a single item could yield 25 possible results (5

XSL•FO
RenderX

× 5), with each result corresponding to a specific attribute category (Table 2).

Table . Classification of functional areas of application of nursing robots.

Category	Application scenario
Drug management	• Intravenous dispensing • Drug distribution • Medication reminder
Monitoring and warning	• Physiological indicator measurement and early warning • Ward patrol • Vital sign monitoring
Logistics transfer	• Transfer of patients • Transfer of goods
Consulting education	• Medical information query • Drug guidance • Disease-related knowledge guidance • Prevention of misinformation and education
Security management	• Prevention of falls and other accidental injuries • Disaster prevention
Nutritional care	• Diet and nutrition guidance • Feeding meals
Activity management	• Postural transition • Bed-chair transfer • Auxiliary walking
Excretory care	• Assistance with toileting
Personal hygiene management	• Organization and changing of bed linens • Showering assistance • Grooming (including brushing teeth, washing face, and shaving) • Dressing and undressing
Accompanying care	• Interpersonal interaction • Accompaniment for checkups • Cognitive training
Infection management	• Ward cleaning, disinfection, and sterilization • Wound disinfection and dressing
Rehabilitation physiotherapy	• Rehabilitation knowledge guidance • Development and adjustment of the rehabilitation plan • Assessment of rehabilitation effect
First aid skills	• Assisted CPR[a] • Oxygen and sputum absorption
Information management	• Personal electronic medical information storage and record
Sampling operation	• Venous blood sampling • Collecting nasal or pharyngeal swabs

[a]CPR: cardiopulmonary resuscitation.

XSL•FO
RenderX

Table . Kano evaluation table.

Positively worded items: how would you feel if the nursing robot had X function?	Negatively worded items: how would you feel if the nursing robot did not have X function?				
	Like it	Must be	Neutral	Accept it	Dislike
Like it	Q	A[a]	A	A	O
Must be	R	I	I	I	M
Neutral	R	I	I	I	M
Accept it	R	I	I	I	M
Dislike	R	R	R	R	Q

[a] Definition of categories in the Kano model. A = One-dimensional quality; M = Must-be quality; I = Indifferent quality; O = Attractive quality. One-dimensional quality means user satisfaction increases linearly with the fulfillment of requirements. Must-be quality is the basic requirement; dissatisfaction occurs if unfulfilled, while satisfaction cannot be greatly improved even if fulfilled. Attractive quality brings great satisfaction when realized and causes no dissatisfaction when absent. Indifferent quality has no influence on user experience. Reverse quality leads to lower satisfaction with higher implementation. Questionable quality represents contradictory and invalid responses.

Reliability and Validity Test

Following the completion of the questionnaire design, we invited 5 experts—3 specializing in CVD nursing and 2 specializing in AI and communication technology—to evaluate our designed Kano demand scale. They assessed the relevance of the questions using Likert scales. The item-level content validity index for the Kano demand questionnaire ranged from 0.71 to 1.0, whereas the scale-level content validity index was 0.8. We assessed the effectiveness of the questionnaire using the Cronbach α coefficient, which was found to be 0.929. Additionally, internal consistency was evaluated through the retest coefficient, which yielded a value of 0.871. These results indicate that the effectiveness and reliability of the questionnaire were acceptable.

Data Collection and Analysis

Participants were enrolled at Wuhan Asia Heart Hospital from July 2024 to June 2025. First, after completing the questionnaire design, the researchers created a survey using an online platform called Wenjuanxing (“Questionnaire Star”). Subsequently, the study objectives, content, risks, and benefits were explained to the participants, who voluntarily signed an electronic informed consent form. Finally, patients were guided to complete the questionnaire via mobile phones or tablets, with a completion time of 15 to 25 minutes. During this process, only the definitions of questionnaire items were explained, and no intervention was made on the participants’ choices. After the submission of the questionnaires, data collection began. During this phase, questionnaires exhibiting incomplete responses or evident logical contradictions were identified as invalid and excluded from subsequent analytical procedures.

SPSS (version 26.0; IBM Corp) was then used for data analysis. General data were described using descriptive statistics (numbers and percentage distributions). To comprehensively and accurately delineate the functional requirements regarding nursing robots among patients with CVD, 3 analytical approaches were used: the Kano model classification, the better-worse coefficient analysis for prioritization, and the construction of a Kano demand quadrant diagram.

First, cross-tabulation was performed on the positive and negative responses to each function in the questionnaire, categorized into 4 types (must attributes [M], one-dimensional attributes [O], attractive attributes [A], and indifferent attributes [I]). The frequency and proportion of each function being classified as different attributes were statistically analyzed, with the attribute type with the highest proportion serving as the final attribute classification for that function.

Second, we used the better-worse coefficient analysis method [23] to prioritize questionnaire items, thereby clarifying the impact level of specific functional domains on survey participants. This analytical method consists of “better” coefficients and “worse” coefficients, where the absolute values of the coefficients (ranging from 0 to 1) reflect satisfaction or dissatisfaction with the provision of services. Specifically, the closer the “better” value is to 1, the more satisfied patients are when the target attribute is provided. Conversely, the closer the absolute value of the “worse” coefficient is to 1, the higher the dissatisfaction level when the target attribute is not provided. The calculation formula for the coefficients is as follows:

$$\text{Better coefficient}=A+OA+O+M+I,\ \text{Worse coefficient}=O+MA+O+M+I$$

Finally, a 4-quadrant diagram was constructed with the “better” coefficient as the vertical axis and the absolute value of the “worse” coefficient as the horizontal axis. Specifically, “O” attributes located in the first quadrant (upper right region) exhibit both the “better” coefficient and the absolute value of the “worse” coefficient exceeding the mean, representing desirable needs that warrant greater attention and should be prioritized. “A” attributes with high “better” coefficients and low absolute values of the “worse” coefficient are situated in the second quadrant (upper left region), indicating desirable needs. “M” attributes in the fourth quadrant (lower right region) exhibit lower “better” coefficients and higher absolute values of the “worse” coefficient, representing essential attributes. “I” attributes in the third quadrant (lower left region) exhibit both lower “better” coefficients and lower absolute values of the “worse” coefficient, indicating nondifferentiated needs. These

XSL•FO
RenderX

needs are not significant to patients and may be omitted or do not require improvement [28].

Ethical Considerations

The ethics committee of Wuhan University of Science and Technology (2024-096-02) approved this study, which adheres to the ethical standards outlined in the Declaration of Helsinki. Participation in this survey was voluntary and anonymous, and the participants provided informed consent. Participants could refuse or withdraw at any time, and the information collected was used solely for academic research purposes and not for commercial gain. All data were exclusively collected for this study, encrypted using a dual-password system (with passwords kept separately by 2 researchers), and stored on a hospital-specific research data server. The server undergoes regular security audits and backups. Data leakage, tampering, or use for other purposes are strictly prohibited. Upon completion of the survey, the data were archived in the hospital's research data platform for a period of 5 years, after which they will be uniformly destroyed in accordance with regulations.

Results

Basic Information of Survey Participants and Their Understanding of Nursing Robots

From July 2024 to June 2025, this study distributed 190 questionnaires, of which 6 (3.2%) were not completed due to privacy concerns. Of these 190 questionnaires, after excluding 28 (14.7%) that were invalid, a total of 156 (82.1%) valid questionnaires were collected. Although the final sample was slightly below the calculated target, post hoc evaluation indicated that the sample size was adequate for Kano classification and coefficient analysis, which rely on proportion comparisons rather than mean estimation.

The survey primarily focused on the Wuhan area of Hubei Province. The demographic characteristics of the study participants are summarized in Table 3. A total of 75.6% (118/156) of the participants were male, 45.5% (71/156) were aged over 60 years, 52.6% (82/156) had a bachelor's degree or higher, and 59% (92/156) had a disease duration of less than 10 years. Among the participants, 48.1% (75/156) had experience using nursing robots, 68.6% (107/156) had received nursing robot services, and 45.5% (71/156) preferred interactive methods such as images and videos.

Demand Attribute Classification Analysis

Through the Kano model, we analyzed the requirements regarding nursing robots for patients with CVD across 15 functional areas. As shown in Table 4, based on the final survey results, we identified 3 items as "M" attributes: monitoring and warning, consulting education, and information management. Drug management and rehabilitation physiotherapy were categorized as "O" attributes. "A" attributes included 5 items: security management, logistics transfer, nutritional care, infection management, and first aid skills. The presence of these functional areas would make the nursing robots more acceptable to patients. The remaining 5 items were categorized as "I" attributes, which are not important to patients. These were excretory care, personal hygiene management, accompanying care, activity management, and sampling operation.

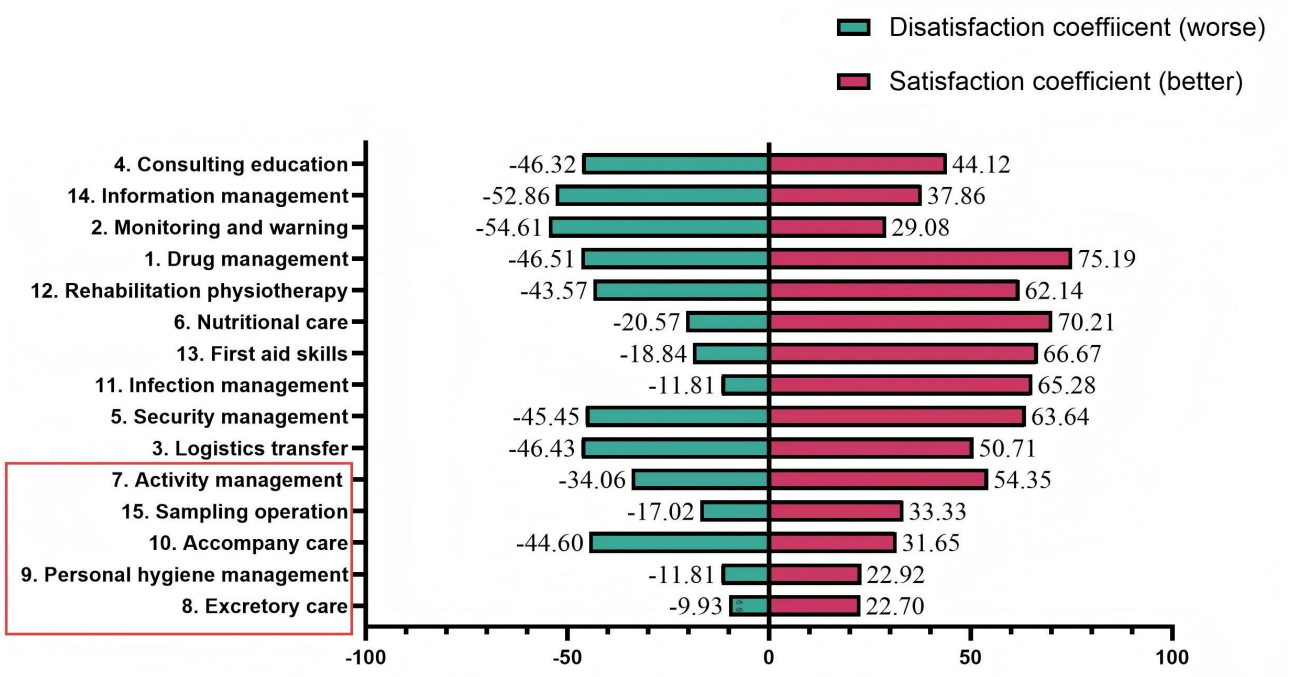
[a]Percentages are presented without subgroup n within cells. Each cell reflects joint results from two-dimensional Kano evaluation, and separate subgroup counts may cause misinterpretation. The overall sample size is reported in the main text.



[b] Definition of categories in the Kano model. A = One-dimensional quality; M = Must-be quality; I = Indifferent quality; O = Attractive quality; One-dimensional quality means user satisfaction increases linearly with the fulfillment of requirements. Must-be quality is the basic requirement; dissatisfaction occurs if unfulfilled, while satisfaction cannot be greatly improved even if fulfilled. Attractive quality brings great satisfaction when realized and causes no dissatisfaction when absent. Indifferent quality has no influence on user experience. ontradictory and invalid responses.

Better-Worse Coefficient Analysis

To better visualize the functional differences across domains, we also created a comparative bar chart of “better” and “worse” coefficients for the functional requirements of patients with CVD regarding nursing robots. In Figure 1, among the top 10 functional areas, drug management, rehabilitation physiotherapy, nutritional care, first aid skills, infection management, security management, and logistics transfer had relatively high satisfaction index values ranging from 0.5 to 0.8. This indicates that, when the nursing robot possesses these functions, it will achieve high levels of satisfaction and acceptance. The other 3 functions (consulting education, information management, and monitoring and warning), although they had lower satisfaction index values, exhibited a high absolute dissatisfaction index value. This suggests that, if these requirements are not met, users will be highly dissatisfied regardless of how well other functions are performed, leading to a lack of increased favorability toward the product.

XSL•FO
RenderX

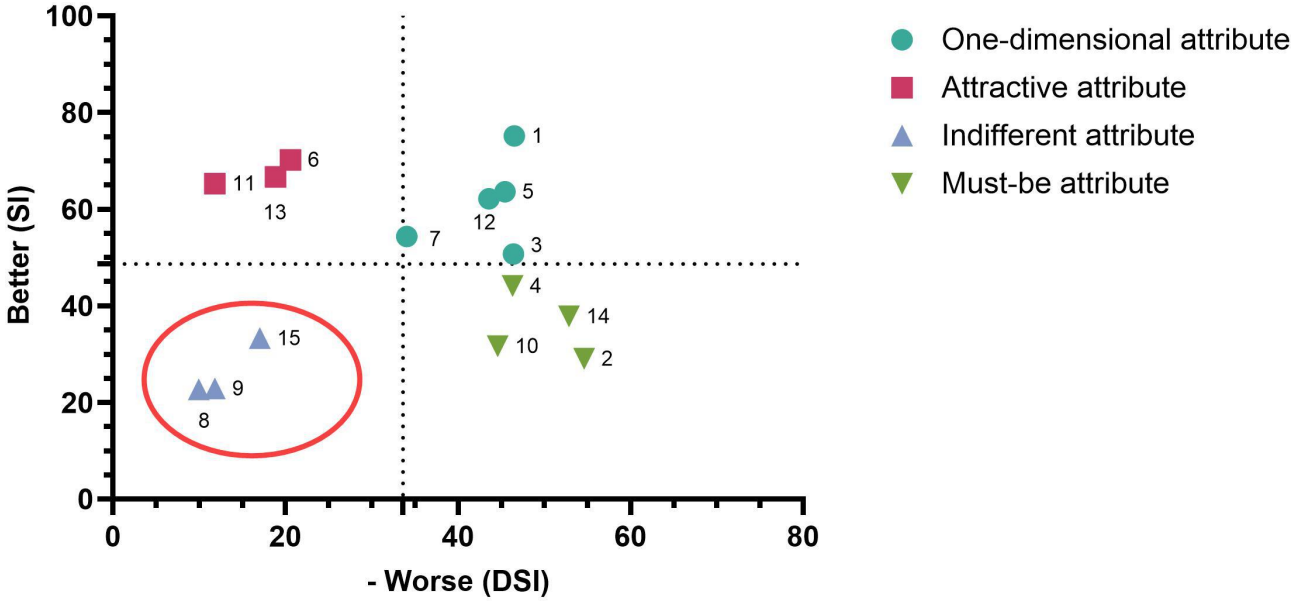


Figure 1. Satisfaction index and dissatisfaction index of functional requirements regarding nursing robots of patients with cardiovascular disease.

Kano Demand Quadrant Diagram

We plotted a Kano demand quadrant diagram (Figure 2) using the better-worse coefficients. The results indicated that 4 items were categorized within the must-be attribute quadrant: monitoring and warning, consulting education, accompanying care, and information management. Five items were classified in the one-dimensional attribute quadrant: drug management, security management, logistics transfer, activity management, and rehabilitation physiotherapy. The attractive attribute quadrant included 3 items: nutritional care, infection management, and first aid skills. The remaining 3 items were placed in the indifferent attribute quadrant: excretory care, personal hygiene management, and sampling operation. Compared to the straightforward classification of needs presented in Figure 1, Figure 2 offers a more nuanced prioritization of each functional area, resulting in more precise outcomes. The findings illustrated in Figure 2 further corroborate that the functional areas of sampling operation, excretory care, and personal hygiene management are of relatively low priority.

Discussion

Acceptance and Interaction Preference Characteristics Regarding Nursing Robots Among Patients With CVD

In this study, 68.6% (107/156) of participants with CVD had received nursing robot–assisted care, and 48.1% (75/156) reported prior exposure to the technology. This high familiarity likely stems from the 2-year clinical deployment of the Noah nursing robot in the study hospital's cardiology ward, which allowed patients to gradually build trust in this care model. This preexposure may have positively biased participants' attitudes toward nursing robots and, in turn, their perceptions of functional needs and Kano classification results. Our findings should therefore be generalized with caution to settings without routine nursing robot use and further validated in larger, multicenter cohorts across different hospital tiers and regions.

For interaction preferences, 45.5% (71/156) of patients preferred visual or video-based interaction, 30.1% (47/156) favored text input, and only 18.6% (29/156) chose voice recognition. This pattern is closely tied to the 45.5% (71/156) of older adult patients in our cohort: visual and video formats deliver medication guidance and rehabilitation instructions more intuitively for older adults, whereas many patients also voiced concerns about the accuracy of voice recognition in busy wards and associated privacy risks, leading to a preference for traceable, visual interaction.

Consistent with previous work [29], voice interaction still has clear potential for efficient human-machine communication. Our findings suggest that nursing robot design should prioritize multimodal interaction, with targeted optimization of voice recognition for older adult patients' dialects plus accessible interaction record functions to strengthen privacy and security for users.

Structural Analysis of the Functional Needs of Patients With CVD Regarding Nursing Robots Based on the Kano Model

Using the Kano model, we categorized 15 core nursing robot functions into 4 attributes: must be (M), one-dimensional (O), attractive (A), and indifferent (I). This classification clarifies the clinical positioning and optimization priorities of each function, providing evidence-based guidance for the design and clinical deployment of nursing robots for CVD care.

"M" attributes included monitoring and early warning, information management, and consultation and education, all of which align with the core needs of long-term monitoring and self-management for patients with CVD. Notably, the monitoring and early warning function had an absolute "worse" coefficient of 54.6, meaning that more than half of the patients would report reduced satisfaction if this function were absent. This is consistent with the chronic, fluctuating nature of CVD, where real-time monitoring and timely warning are critical to prevent adverse events [30]. These core basic functions should be prioritized in robot design as they form the foundation of clinical acceptance and align with the shift toward proactive, precision smart nursing.

Medication management and rehabilitation physiotherapy were classified as "O" attributes, with "better" coefficients over 60 for both, showing that optimizing these functions directly improves patient satisfaction. Patients with CVD typically take an average of 3.2 concurrent medications, with complex regimens carrying a high risk of dosing errors and nonadherence [31], explaining the strong demand for integrated medication reminders, dose verification, and supply alerts. For rehabilitation, patients preferred personalized plans stratified by New York Heart Association cardiac function class over standardized programs, reflecting the need for personalized, rather than one-size-fits-all, smart nursing support.

Infection management, nutritional care, and first aid skills were identified as "A" attributes. While not mandatory for patients, these functions drive significant improvements in satisfaction. The infection management function had a "better" coefficient of 65.3, which aligns with the higher infection risk in immunocompromised patients with CVD [32]. Personalized nutrition plans tailored to lipid and glucose levels also fit the model of precision nutritional support, making these functions useful value-added features for high-acuity settings such as cardiovascular intensive care units.

Personal hygiene management, excretion care, and sampling operations were classified as "I" attributes, with minimal patient demand for robot delivery of these services. This low demand is likely driven by 2 key factors: privacy concerns regarding highly personal care tasks and patient preference for functions that directly improve self-care safely rather than high-risk, specialized operations. This preference for robot involvement in noninvasive, nontechnical care aligns with findings of previous studies [17,33,34]. Routine large-scale deployment of invasive functions such as blood sampling is therefore not recommended; these may only be selectively used in specific settings such as isolation wards. Optimizing privacy protection features will also be key to addressing patient trust concerns around these functions.

Overall, the clinical deployment of nursing robots for CVD care should be guided by patient needs following a hierarchical optimization framework: prioritizing essential must-be functions, optimizing one-dimensional functions to improve care quality, adding attractive functions as value-added features, and limiting indifferent functions to scenario-specific use. This framework aligns robot design and technical development with clinical needs, supporting the practical advancement of smart nursing.

Implications for Clinical Practice and Future Research

Our findings have direct implications for the clinical deployment of nursing robots in Wuhan and beyond, as well as for the advancement of patient-centered intelligent cardiovascular nursing. Locally, the hierarchical priority structure we identified can be used to refine existing nursing robot programs in Wuhan hospitals, with prioritized ward deployment of high-demand functions such as monitoring and early warning, medication management, and nutritional support to align services with patient needs.

For routine nursing practice, integrating robots into high-demand processes such as medication monitoring can standardize care,

XSL•FO
RenderX

reduce human error, and improve continuity of care. Rather than large-scale changes to existing nursing workflows, we recommend a phased approach: piloting high-priority functions, evaluating safety and acceptability, and then gradually expanding successful modules.

These findings also highlight key directions for future research. Larger multicenter studies are needed to validate the generalizability of these demand patterns, whereas subgroup analyses can clarify heterogeneous needs across patient groups. Longitudinal studies evaluating the safety, usability, and clinical outcomes of robot-assisted care will also be critical to support evidence-based translation into practice.

Ultimately, this study addresses a key gap between nursing robot technical development and real-world clinical needs by centering patient perspectives in function design. The proposed hierarchical framework supports a shift from generalized robot deployment to precision, patient-centered intelligent care, which has the potential to reduce nursing workload, improve care standardization, and enhance patient safety and satisfaction in cardiovascular care.

Limitations

This study has several limitations. First, the sample was limited to 1 hospital in Wuhan using convenience sampling, which may reduce generalizability. Second, subgroup analyses by age, educational level, or disease severity were not performed, although age stratification was explored and showed limited between-group differences in this cohort. Third, this was a cross-sectional self-reported survey, which may be subject to response bias. Future studies should use larger, multicenter samples; perform stratified analyses; and include longitudinal follow-up to strengthen the evidence base.

Summary

The presence of robots and the advent of more advanced robotics technologies have led to an increase in studies assessing user acceptance of robots and needs analyses in the past 2 years. Wichmann et al [35] showed that perceived usefulness, attitude, and trust significantly and positively predict willingness to use AI and use behaviors in short- and long-term treatment. In our view, clarifying the needs of patients can effectively improve users' acceptance of AI and may become a shortcut to achieving intelligent medical care in China. Our study explores the differences in prioritizing needs regarding nursing robots from the perspective of patients with CVD. This paper suggests that researchers should emphasize understanding the patient experience, which is crucial for advancing various fields, including counseling, education, companion care, and more. We hope that our research can help nursing robot developers design targeted functional services for patients with CVD, promoting the continuous development and application of nursing robotics as well as innovation and progress in the medical field.

Acknowledgments

First, the authors would like to thank the nurses and head nurses at Wuhan Asia Heart Hospital for their support in this study. Second, they sincerely thank the editors, statisticians, and anonymous reviewers for their insightful comments, which greatly improved the paper. The authors declare the use of generative artificial intelligence (GenAI) in the research and writing process. According to the Generative Artificial Intelligence Delegation Taxonomy (2025), the following tasks were delegated to GenAI tools under full human supervision: preparation of press releases and outreach materials. The GenAI tool used was Doubao (ByteDance). Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes. In addition, the authors used Doubao to generate the table of contents image for this paper.

Funding

The authors declared no financial support was received for this work.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: There is a worldwide movement toward competency-based medical education to equip dental students with essential competencies required to meet health care needs. In Syria, dental faculties currently lack a formal competency-based curriculum for endodontics at the undergraduate level. Moreover, the quality of root canal treatment performed by general dentists is frequently described as inadequate or substandard.

Objective: This study aimed to develop a national consensus on the required competencies for undergraduate endodontics in Syria in order to establish a foundation for a standardized national curriculum, which can guide educators in adopting best practices in both dental education and clinical endodontics.

Methods: This study was conducted at Syrian Virtual University between April and June 2025. A modified Delphi technique was used to determine endodontic competencies. Initially, a group of 5 Syrian endodontic consultants identified preliminary competencies. In the first round, 53 experts evaluated these competencies by using a 5-point Likert scale. Based on these results, a second round was conducted with 38 experts. Competencies with a weighted average above 4.20 were considered essential. Data analysis was performed using IBM SPSS package 27, and survey reliability was measured by Cronbach α.

Results: Following the final Delphi round, a set of 31 competencies was established, comprising 9 knowledge, 13 skills, and 9 attitudes competencies. Cronbach α was more than 0.9 in the first and second round. The standard deviation across all questionnaires was low (≤0.85). The standard error was also minimal (≤0.12).

Conclusions: This study identified a set of core endodontic competencies for the undergraduate level in Syria. These competencies are intended to support students in acquiring the required knowledge, skills, and attitudes, and assisting policymakers in implementing competency-based medical education within Syria and similar contexts.

Introduction

General dentists frequently serve as the primary providers of endodontic treatment for patients requiring such care [1,2]. However, cross-sectional studies often report the quality of root canal treatment as inadequate or below standard [3-7]. This may be attributed to the complexity of root canal procedures or the graduation of practitioners with limited experience [8,9].

The Commission of Dental Accreditation, the Association of Dental Education in Europe, and the European Society of Endodontology (ESE) have all recommended adopting competency-based medical education (CBME) within a comprehensive clinical care environment [8,10,11].

According to the International CBME collaborators, CBME is "an outcome-based approach to the design, implementation, assessment, and evaluation of medical education programs using an organized framework of competencies" [12]. The goal of CBME is to produce graduates who can effectively incorporate knowledge, skills, and attitudes and apply them clinically to deliver the best patient care [13]. CBME emphasizes outcomes and practice-based learning while considering societal and patient needs by tailoring competency frameworks accordingly [14]. As a result, several countries have adopted CBME into undergraduate medical education [15,16] although its application remains in early stages [16].

In Syria, medical education follows a traditional, time-based approach that emphasizes teacher-centered learning, hospital-based training, and opportunistic learning methods [17]. To our knowledge, there is no existing literature detailing the design and implementation of curricula in Syrian medical schools. Typically, curriculum development and review are undertaken by a small group of academic members without formal consensus from all faculty members before final approval by the faculty and university councils [18].

Competency-based education is a fundamental part of the academic curriculum, as it measures and verifies the attainment of the intended program learning outcomes [19]. Therefore, the initial step in implementing a CBME is to identify the required competencies [20]. This method offers medical students focused and well-structured training in endodontics, ensuring they acquire the necessary knowledge, skills, and attitudes to provide effective patient care. Within this framework, this study aims to establish a national consensus on the core competencies required for undergraduate endodontics curricula in Syria.

CBME considers competencies as the key outcomes that should guide curriculum development at every stage, including implementation, assessment, and evaluation [21-23]. To embrace CBME and adequately prepare medical students for clinical practice, educators usually rely on an organized national or international competency framework that describes the abilities physicians need to meet patients' and societal demands [24].

The Delphi technique, a widely used consensus method for identifying health professional competencies, has been applied independently [25] or alongside focus groups [26] and consultation meetings [27]. In this study, a competency framework for undergraduate endodontics was developed using a combination of the Delphi technique and consultation meetings to identify essential competencies. Therefore, this study aims to develop a national consensus on essential undergraduate endodontic competencies in Syria by using a modified Delphi method.

Methods

Overview

This exploratory qualitative study was undertaken at the Syrian Virtual University from April to June 2025. The modified Delphi technique was used to reach a consensus on the competencies for the undergraduate endodontics curriculum.

The consultation group included 5 Syrian members holding a PhD in endodontics and working in academic roles at various universities. Additionally, experts were either Syrians or held equivalent qualifications, possessed at least a specialist certificate (Syrian board) in endodontics, and they were currently actively involved in clinical, academic, and/or administrative practice inside or outside Syria.

The principal researcher (MS) developed a preliminary list of endodontic competencies based on a literature review [28-30]. Individuals' consultation meetings were then held via telephone or social media platforms, lasting at least 15 minutes each, and conducted at least twice with each consultant. These meetings reviewed the initial list of competencies, allowing for modifications and additions. The consultation meetings produced a final list of 54 competencies divided into 19 knowledge, 21 skills, and 14 attitude items. A structured questionnaire was developed using Google Forms, consisting of six sections: (1) an introductory letter explaining the study's objectives, confidentiality assurance, participation instructions, and consent acknowledgement; (2) demographic data, including name, age, gender, nationality, workplace, years of experience, academic qualifications, and practice type; (3,4,5) the initial lists of knowledge, skills, and attitudes competencies in the third, fourth, and fifth sections, respectively; and (6) a free-text section for respondents to suggest additional competencies (Multimedia Appendix 1).

The Delphi methodology was conducted in 2 rounds to identify the essential endodontic competencies for undergraduate dental students in Syrian dental schools. The principal researcher MS invited 98 endodontists who met the expert panel criteria to participate, with 73 accepting the invitation. To ensure a national consensus, these experts represented dental schools from both public and private universities across Syria. Participants rated each competency on a 5-point Likert scale reflecting its importance: 1 (not important at all), 2 (not important), 3 (unsure), 4 (important), and 5 (very important). Consensus was defined as over 80% agreement or a mean score above 4.20 [25,31].

Strict deadlines were set to maintain study momentum while allowing participant flexibility with accountability to ensure a smooth and efficient progression through its phases [32]. The first Delphi round lasted 3 weeks, starting on May 2, 2025, with reminders sent to nonrespondents on the 5th, 10th, and 15th. Competencies scoring above 4.20 in the first round, along with

XSL•FO
RenderX

those suggested through free-text comments, were included in the second round. The second round had a 2-week deadline, with reminders on days 5 and 10 for those who had not responded.

Data analysis was performed using the SPSS package (version 27; IBM Corp). The survey's reliability was assessed using Cronbach α, and descriptive statistics, including the mean, standard deviation, and standard error, were calculated.

Ethical Considerations

Ethical approval was obtained from the research committee of the Syrian Virtual University (455/0, dated April 27, 2025). Informed consent was obtained from all participating consultants and experts before the study.

Results

The characteristics of the participants in both the first and second Delphi rounds are shown in Table 1. Following the consultation meetings, a preliminary list of 54 competencies was established, comprising 19 (35.2%) knowledge competencies, 21 (38.8%) skills competencies, and 14 (26%) attitudes competencies (Multimedia Appendix 1). In the first Delphi round, 53 out of the 73 participants completed the survey, yielding a response rate of 72.6%.

Table 1. Characteristics of the respondents in the two Delphi rounds.

Characteristics	Round 1, n (%)	Round 2, n (%)
Sample		
Participants	73 (100)	73 (100)
Respondents	53 (72.6)	38 (52)
Gender		
Male	40 (75.5)	27 (71)
Female	13 (24.5)	11 (29)
Qualifications		
PhD	38 (71.7)	27 (71)
Master	13 (24.5)	9 (23.7)
Other	2 (3.8)	2 (5.3)
Years of experience		
≤ 5 y	6 (11.3)	2 (5.3)
6-10 y	13 (24.5)	9 (23.7)
11-15 y	10 (18.8)	7 (18.4)
16-20 y	7 (13.2)	9 (23.7)
21-25 y	10 (18.9)	4 (10.5)
25 y	7 (13.2)	7 (18.4)
Type of work		
Academic only	14 (26.4)	14 (36.8)
Clinical only	11 (20.7)	9 (23.7)
Academic & clinical	22 (41.5)	10 (26.3)
Academic, clinical, & administrative	6 (11.3)	5 (13.2)

In the first Delphi round, 34 competencies were approved, consisting of 10 knowledge, 15 skills, and 9 attitudes. Additionally, participants suggested 4 new competencies, 1 knowledge, and 3 attitudes, bringing the total to 38 for the second round (Multimedia Appendix 2). These newly suggested competencies were evaluated by participants using the same criteria as in the first round. In the second Delphi round, 38 out of 73 experts completed the survey, resulting in a 52% response rate. Table 1 presents the characteristics of the second-round participants. Of the 38 competencies, 31 (81.5%) received mean ratings above 4.20. These were distributed across the domains as follows: 9 (29%) knowledge, 13 (42%) skills, and 9 (29%) attitude (Table 2). In this round, competencies were ranked based on experts' weighted responses.

Table 2. Final competencies in endodontics for the undergraduate level.

Competency	Mean	SE	SD
Knowledge			
Diagnostic investigations, 2D and 3D radiography	4.68	.083	.518
Dental materials, biomaterials, and adjunct therapies applied to the management of endodontics	4.53	.080	.499
Oral and dental diseases related to endodontics	4.42	.079	.494
Basic sciences and their relationship to endodontics	4.39	.078	.489
Pharmacology and therapeutics as applied to the management of dental patients	4.39	.094	.587
Principles of general medicine and surgery applied to the management of dental patients (including endodontics)	4.24	.093	.582
Principles of optical magnification	4.24	.107	.666
Principles of management of immature teeth	4.21	.098	.614
Treatment options for a postendodontic problem	4.21	.111	.694
Skill			
Management of endodontic emergencies	4.58	.079	.494
Reliable and appropriate isolation	4.53	.080	.499
Use various intraoral anesthesia techniques and pain control	4.50	.080	.500
Establishing a reliable root canal irrigation protocol	4.50	.088	.550
Diagnose and differentiate odontogenic pain or lesions	4.47	.080	.499
Reaching a diagnosis and identifying possible differential diagnoses, including their etiology	4.42	.125	.782
Performing high-quality endodontic treatments on extracted or simulated (Acrylic Blocks) teeth of various types	4.42	.114	.712
Perform high-quality clinical endodontic treatment using conventional methods for easy or moderately difficult teeth (according to the American Association of Endodontics classification)	4.42	.087	.544
Develop a treatment plan and communicate this to the patient	4.39	.101	.630
Restoration of endodontically treated teeth, including root canal posts	4.37	.100	.625
Conducting a comprehensive clinical examination of a patient presenting with an endodontic-related problem	4.34	.123	.770
Assess the case difficulty and request a consultation or refer the patient	4.34	.123	.770
Conducting a detailed general and dental history	4.24	.107	.666
Attitudes			
Respect patient privacy and confidentiality	4.66	.076	.474
Self-efficacy	4.42	.087	.544
Time and priority management	4.42	.087	.544
Commitment to lifelong learning	4.37	.100	.625
Compliance with local regulations regarding infection control, radiation protection, record keeping, and documentation	4.37	.100	.625
Handling medical waste	4.37	.093	.581
Communicate verbally and in writing with dental and medical colleagues	4.34	.112	.699
Communicate effectively with the patient or their family	4.34	.099	.619
Informed consent	4.34	.099	.619

Based on the results of the second Delphi round, the final list of competencies for the undergraduate endodontics curriculum was finalized (Table 2).

The standard deviation for all questionnaire items was low, not exceeding 0.85, and the standard error was also minimal, remaining below 0.12. These values indicate a close alignment between experts' individual ratings and the overall mean. Additionally, Cronbach α exceeded 0.9 for both the first and second rounds, demonstrating a high reliability level of internal consistency reliability (Table 3).

XSL•FO
RenderX

Table 3. Cronbach α results in both Delphi rounds.

Domain of competency	Total	Attitude	Skill	Knowledge
First round	0.901	0.783	0.828	0.863
Second round	0.909	0.832	0.845	0.749

Discussion

Principal Findings

The findings of this study support a national consensus among experts regarding the core competencies required in endodontics at the undergraduate level in Syria. A set of 31 competencies was established, comprising 9 knowledge, 13 skills, and 9 attitudes.

There is no universally accepted definition of endodontic competency for the new general dentist [33]. Moreover, there are currently no national or international guidelines for undergraduate endodontic education specifying the essential materials and equipment that students should be competent in using [34]. This study was conducted to address that gap.

Developing a national or international framework for undergraduate endodontic education can help educators reach consensus and implement best practices in education and endodontics [29]. Clearly defining the required materials and equipment is crucial for standardized practical training [34]. The primary goal of undergraduate endodontic education is to produce competent clinicians who understand the basic science of endodontics and recognize limitations, ensuring safe general dental practice. Clinical training should also emphasize the appropriate use of treatment consent and case difficulty assessment [29], which were listed in the core competencies in this study.

While CBME shows promise, implementation faces real challenges: resistance to change, budget constraints, and difficulty assessing competencies like attitudes. To succeed, institutions should involve stakeholders in redesign efforts, pursue external funding, and employ diverse assessment methods—including observation and simulation—to evaluate competency development more comprehensively [35].

According to a systematic review, questionnaires are the most widely used tool for identifying required competencies in medical education worldwide [24]. This aligns with the approach taken in this study.

The Delphi technique is among the most widely used techniques for defining competencies in medical education, offering many advantages over other decision-making methods. It stimulates a sense of responsibility and supports acceptance of consensus outcomes, minimizing bias from dominant individuals. This enhances the reliability and validity of the required core competencies [15,25]. A modified Delphi method incorporating consultation meetings with endodontic consultants was preferred for its accuracy and efficiency in identifying initial competencies and selecting experts. These meetings were conducted individually to prevent the influence of more senior or dominant consultants on others' opinions. The survey's results validated the consultation group, as all 27 excluded competencies were rated within the "important" range, except 3, which were in the "unsure" range. Notably, none of the 4 competencies proposed by participants in the first round were approved in the second round.

The diverse backgrounds of the participants contributed to a well-rounded and unbiased consensus on core endodontics competencies tailored to the needs of a Syrian society. Despite this diversity, the low standard deviation across both questionnaires indicates a strong agreement and minimal variation in opinions. The small standard error demonstrates that the mean ratings of the experts' opinions closely matched the approved means (Table 2). Finally, Cronbach α results confirm the internal consistency and reliability of the survey in both rounds (Table 3).

Medical literature suggests a sample size of approximately 20 individuals for this type of study [36], though larger sample sizes tend to yield more accurate results [37]. In this study, the sample size was sufficiently large, with at least 38 participants, whereas most similar studies typically involve 15-30 participants [38].

While multi-round studies with large samples often struggle with declining response rates—potentially undermining consensus credibility—our study achieves more than 70% response rate (38 of 53 participants), which meets or exceeds the standard benchmark many researchers consider essential for robust consensus findings [39,40].

The use of an electronic questionnaire via Google Forms was chosen to save time, effort, and cost. Nair et al [41] suggested strategies to improve survey response rates, including sending reminders at specific time intervals, an approach that was successfully implemented in this study, resulting in significant increases in responses after each reminder. Two rounds were adopted because no new competencies were added in the second round, and less than 9% of competencies were excluded. Jünger et al [42] stated in his methodological study that most Delphi-based research is satisfied with 2 rounds, which aligns with the procedure followed in this study. The threshold for accepting a competency as essential (must know) was set at a mean score above 4.20. Jünger et al [42] explained that the researcher determines this cutoff based on the nature and objectives of the research. This approach is consistent with similar studies identifying core competencies within specific medical specialties [18,32,40].

Twenty competencies, representing 37% of those proposed by the researcher and consultants, were excluded after the first round—a notably large proportion. This is because the primary references used to develop these competencies, especially as reported by Baaij et al [28] from the ESE, do not differentiate between the basic competencies required in undergraduate versus postgraduate endodontics, as the vast majority of

XSL•FO
RenderX

European countries do not recognize endodontics as a separate, independent specialty, but instead, they consider it as part of a general dentist's responsibilities [43,44]. Furthermore, these competencies were intended as recommendations for undergraduate endodontics curricula rather than essential competencies that students should master before graduation.

The [28] framework established 3 competency levels: be competent, have knowledge, and be familiar with. This study mirrors most ”be competent“ items, with 2 notable exceptions: managing uncertainty and maintaining pulp vitality were rated as “important“ by our expert panel. This distinction reflects expert opinion that these advanced competencies fall outside the general dentistry scope and are more appropriately reserved for endodontic specialists.

It is worth noting that 85% of the excluded competencies were still rated within the “important” category. These can be interpreted as important competencies for the student, and ”it is good to know,“ but they are not essential to master them at the undergraduate level.

By the end of the second round, 7 competencies were further excluded, including all 4 additional competencies suggested by participants. The remaining 3 competencies were close to the inclusion threshold for core competencies (Table 2).

Despite extensive research on identifying competencies in endodontics, no prior studies have directly addressed this topic comprehensively [29]. However, several institutions involved in medical and dental education such as the American Association of Endodontics, Association of Canadian Faculties of Dentistry, Canadian Medical Education Directives for Specialists, Commission of Dental Accreditation of Canada, ESE, General Dental Council, and the Saudi Commission for Health Specialties have provided guidelines for designing undergraduate or residency-level endodontic curricula.

The ESE recommended essential undergraduate endodontic competencies [28]. While this study identifies competencies that align closely with ESE's recommendations, the division of competency domains and the method of determining the competencies differ significantly. The ESE did not use a questionnaire nor distinguish between undergraduate and postgraduate endodontics, reflecting the absence of endodontic specialization in most European countries.

The study has some limitations that should be considered. Involving additional stakeholders such as students, patients, and health care or education administrators, through interviews rather than questionnaires, could enrich the findings but would also broaden the study's scope and complicate data analysis. So it would be preferable to build upon the results of this study, which relied on the endodontists’ opinions, with further studies targeting the views of other stakeholders to determine their needs and perspectives based on these findings.

Additionally, assigning numerical values 1-5 to responses may not capture the nuances of expert input; for example, a professor with more than 30 years of experience carries the same weight as a recent graduate. Nevertheless, including a range of perspectives across generations is important to ensure balanced and unbiased results. The high degree of harmony in opinions among the experts’ panel indicates an implicit agreement on the core competencies that a graduate should possess as a graduation requirement.

Conclusion

This study identifies the essential endodontics competencies for undergraduate education in Syria by using a modified Delphi method. Further studies involving a broader range of stakeholders should be considered to confirm the results. Additionally, developing an international framework for undergraduate endodontics competencies through collaboration with researchers worldwide would be beneficial. The final list of the identified competencies provides a framework for developing a formal competency-based endodontics curriculum for the undergraduate stage, which can assist students in achieving the required standards and advancing the adoption of CBME in Syria and other similar settings.

A similar study must be conducted to identify the core competencies required for the postgraduate stage in endodontics in Syria. This would clearly differentiate between undergraduate and postgraduate endodontic requirements.

This study employs a modified Delphi method to identify essential endodontics competencies for undergraduate dental education in Syria. The resulting competency framework has been established as a foundation for developing a competency-based endodontics curriculum that supports students in meeting established standards and advancing CBME adoption across Syria and comparable contexts.

To strengthen these findings, broader stakeholder engagement is needed to validate the competency list. It is recommended that the research scope be expanded by including diverse stakeholders to confirm and refine results. Additionally, an international competency framework should be established through collaborative efforts with global researchers to ensure consistency and align best practices across regions.

Implementation of this framework should incorporate continuous assessment strategies, including clinical observation; multi-source feedback from patients, peers, and students; and learner self-assessment to monitor competency development and identify areas for improvement. These varied assessment methods enable timely intervention and support the transition toward CBME in Syria and similar settings.

Finally, a parallel study should be conducted to identify core competencies for postgraduate endodontics training in Syria. This research would create clear differentiation between undergraduate and graduate-level requirements, establishing a coherent progression pathway for dental professionals and ensuring comprehensive competency development across all training stages.

Abstract

Background: Observation of COVID-19 rebound after nirmatrelvir plus ritonavir (NPR) has driven important questions surrounding one of the only direct-acting antiviral treatments for COVID-19.

Objective: The objective of this study was to examine the epidemiology of COVID-19 rebound among COVID-19–positive outpatients in the United States who independently decided whether or not to take NPR.

Methods: This prospective, decentralized observational cohort study was conducted from August 2022 through December 2023 and included frequent proctored COVID-19 rapid antigen tests and self-report symptom surveys for 15 days. The primary outcome was the incidence of viral and symptom rebound. Secondary outcomes included time to initial viral and symptom clearance, rebound probability among patients who cleared by day 15, and symptom frequency.

Results: Of 917 consenting participants, 669 (73%) were eligible for inclusion in the analysis (n=443, 66% in the NPR group; n=226, 34% in the control group). The mean age was 46.1 (SD 12.9) years, 62.6% (n=419) of participants were female, and 49.2% (n=329) had at least one preexisting condition. Overall, 15-day cumulative incidence was higher in the NPR group than the control group for both viral (70/443, 15.8% vs 12/226, 5.3%) and symptom (73/443, 16.5% vs 19/226, 8.4%) rebound. Time to initial viral and symptom clearance was similar between groups, and among those who experienced clearance by day 15, the probability of viral rebound (NPR: 19.1%, 95% CI 15.1%-24.0% vs control: 7%, 95% CI 4.0%-12.6%; *P*<.001) and symptom rebound (NPR: 47.7%, 95% CI 36.1%-60.8% vs control: 16.9%, 95% CI 10.9%-25.7%; *P*<.001) was higher in the NPR group than the control group.

Conclusions: This study demonstrates that while COVID-19 rebound occurs in both NPR-treated and untreated outpatients, the incidence is higher in the NPR group.

KEYWORDS

COVID-19; COVID-19 rebound; nirmatrelvir plus ritonavir; symptom rebound; viral rebound

Introduction

In the United States, more than 1 million deaths and approximately 7 million hospitalizations reflect the toll of SARS-CoV-2 [1]. After initial emergency use authorization in December 2021 [2], nirmatrelvir plus ritonavir (NPR; Paxlovid) became the first fully approved oral antiviral treatment by the US Food and Drug Administration in May 2023 [3]. US COVID-19 treatment guidelines align on a strong recommendation for a 5-day course of NPR in outpatients at high risk of progression to severe COVID-19 [4-6].

The guidance in favor of NPR is largely based on studies showing significant protective effects against hospitalization and death for high-risk outpatients, with little evidence of serious side effects, across changing COVID-19 variants and baseline population risk levels [4-7]. Despite this, it has been estimated that less than a quarter of eligible patients use NPR, potentially missing opportunities to further reduce serious illness and death

XSL•FO
RenderX

rates [8-10]. Hesitation in NPR prescription may be associated with anecdotal reports and poor knowledge about COVID-19 rebound [8,11].

COVID-19 rebound is the resurgence in viral load and/or COVID-19 symptoms after initial recovery. This phenomenon first gained attention as a secondary finding in early studies testing NPR effectiveness against severe disease outcomes, although it also occurs in untreated individuals [12,13]. In direct response to the need for further investigation, we opened a prospective observational cohort in 2022 (COVID-19 Rebound Study) to evaluate the epidemiology of viral and symptom rebound differences in NPR treatment and control individuals based on high-frequency testing and symptom surveys [14]. Preliminary results found higher than previously reported COVID-19 viral and symptom rebound in both NPR and control groups [14]. While the amount of research on rebound is increasing, evidence supporting a potential association with NPR treatment is still relatively weak, relying on retrospective chart reviews or secondary analyses [15].

This paper describes the final results of the COVID-19 Rebound Study, expanding upon our previously published preliminary analysis [14], with a larger sample size and extended enrollment period to evaluate the epidemiology of COVID-19 rebound in participants who were clinically eligible for NPR and who did or did not decide to take NPR.

Methods

Study Design and Recruitment

This decentralized, prospective observational study was completed via collaboration between the Scripps Research Translational Institute (SRTI) and eMed, which implemented the National Institutes of Health Home Test to Treat Program, a 24/7 virtual health platform that provides proctor-guided at-home testing with public health reporting through a digital Clinical Laboratory Improvement Amendments (CLIA)–waived laboratory. Eligibility criteria included a positive rapid antigen test for COVID-19 within 48 hours prior to study enrollment, residing within the United States, speaking English, and aged at least 18 years. eMed users who tested positive were offered NPR at the discretion of an eMed provider. NPR was the only COVID-19 oral antiviral therapy offered through the eMed platform. There were two study recruitment cohorts: (1) from August 2022 through December 2023, eligible eMed users that tested positive for COVID-19 through an eMed telehealth appointment were invited via follow-up email, text, and/or phone call; and (2) from August 2023 through December 2023, social media campaigns and SRTI blog posts invited people who self-tested positive to consider participation. Participation required a virtual meeting with an eMed provider to confirm a positive COVID-19 rapid antigen test and for further eligibility screening.

Study Procedures

Interested individuals were sent to a landing page with more information on the study, an eligibility screener survey, and e-consent forms. Upon providing consent, participants reported baseline information (self-reported demographic characteristics, preexisting conditions, and vaccination history) and completed a symptom survey prior to requesting a study kit. Study kits were shipped overnight and included detailed instructions for the 15-day acute study phase and eMed live-proctor–enabled COVID-19 test-to-treat rapid antigen test kits (containing Abbott BinaxNOW Home tests). Participants who enrolled after August 2023 (cohort 2) were additionally sent 2 at-home blood collection devices with biohazard shipping materials. Cohort 2 was instructed to return blood samples and testing swabs to SRTI for serological analyses and viral genome sequencing. Results from blood sampling and sequencing are forthcoming in a future report.

Participants were asked to complete a survey (capturing symptoms and NPR use) and a proctored eMed COVID-19 rapid antigen test on days 2, 5, 7, 9, 11, 13, and 15 from enrollment (acute study phase). To complete a rapid antigen COVID-19 test, participants were instructed to scan a QR code on their test box to initiate a telehealth proctored visit where they were guided through the testing procedure and test results validated. If a participant tested positive during the visit and had not already received care either in person or through a telemedicine visit, they were offered an optional eMed telemedicine visit that could provide a prescription for a 5-day course of NPR (provided under the brand name Paxlovid). Postacute COVID-19 symptom surveys were sent to all participants at 1-, 3-, and 6-months after enrollment, with results forthcoming. Participants received up to 3 notification reminders per task using their preferred mode of communication (email, text, and phone) unless they chose to withdraw early. Research Electronic Data Capture (REDCap) tools were used for survey and notification administration [16,17]. Participants were offered an incentive of electronic gift cards totaling up to US $200, which were issued over the study period according to completion of required tasks.

Outcomes

The primary outcomes were cumulative incidence of viral and symptom rebound in NPR and control groups within 15 days of enrollment. *Viral rebound* was defined as a positive rapid antigen test after previously testing negative. *Symptom rebound* was defined as reporting at least one symptom on a survey after reporting zero symptoms on a previous survey. Secondary outcomes included time from enrollment to initial negative rapid antigen test and to symptom resolution (viral and symptom clearance, respectively), and rebound probability among patients with clearance by day 15. Exploratory outcomes included comparing characteristics of rebound and nonrebound groups and symptom frequency during the acute study phase. Reported symptoms were aggregated into binary categories of systemic, respiratory, gastrointestinal, neurological, and other symptoms.

Statistical Analyses

Treatment Groups

Participants who reported their independent decision to take at least one NPR dose were classified as the NPR group, and remaining participants were classified as the control group. Participants were excluded if they did not complete the baseline survey or at least 2 follow-up surveys, or if they had missing

XSL•FO
RenderX

data precluding ascertainment of rebound. Participants reporting no symptoms at baseline (n=5) were excluded from symptom rebound analyses.

Main Analyses

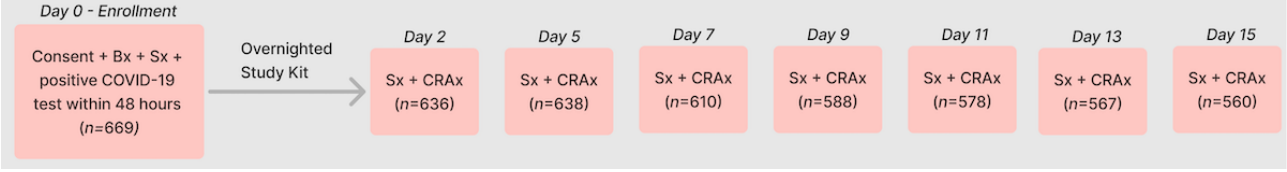
Cumulative incidence was calculated as the number of rebound events across the 15-day acute study phase divided by the number of eligible participants. Kaplan-Meier survival curves were generated and stratified by NPR and control groups to compare timing of rebound since study enrollment, of viral and symptom clearance (time from positive test or symptoms to first negative test or no symptoms), and of rebound probability among patients who cleared by day 15 (time from negative test or no symptoms to subsequent positive test or symptoms). In each time-to-event analysis, participants were censored at the time of missing more than 2 consecutive surveys or rapid antigen tests or after day 15 if they did not have an event. The 95% CIs were calculated using the Greenwood exponential formula.

Secondary Analyses

Due to potential differences between participants recruited via the eMed platform and social media, we conducted sensitivity analyses comparing baseline characteristics and outcomes between recruitment cohorts. We additionally conducted 5 secondary analyses. First, we compared baseline participant characteristics, rebound incidence, and symptom frequency between the 2 cohorts (ie, recruited before or after August 2023). Second, we assessed sensitivity of cumulative incidence estimates to different censoring (restricted to those with no missing data or those with at least 3 surveys before missing any data), time (11- vs 15-day estimates), and amount of NPR use (none, 1 - 4 days, or 5 days) criteria. Participant characteristics and frequency of symptom surveys were additionally compared between groups defined by the amount of NPR use reported. Third, we adjusted rebound incidence comparisons for baseline characteristics using Cox proportional hazards regression models. Separate models were run separately for viral and symptom rebound and included covariates for age, number of vaccines, sex, race, and preexisting conditions. As compared with the main participant characteristic table groupings, additional data cleaning was performed to collapse small cell counts, including grouping of cardiovascular conditions (heart disease, heart failure, and high blood pressure), grouping of lung conditions (asthma, chronic bronchitis, chronic obstructive pulmonary disease, emphysema, and other lung conditions), removing the single intersex participant, and combining race categories with fewer than 3 participants into the other category. Fourth, we examined congruence between symptom and test positivity by counting the number of person-days (ie, unique participant surveys) where symptoms and tests were both positive, negative, or opposite of each other. This was done for all acute phase days and for the subset of person-days where a participant was testing positive in an episode of viral test positivity. Fifth, we compared baseline characteristics of participants who were and were not eligible for inclusion in analyses.

Analyses were done with Python (version 3.8; Python Software Foundation). Between-group statistical comparisons of baseline characteristics and symptoms were performed using the TableOne package with 2-sided chi-square tests for categorical variables and *t* tests for continuous variables, alpha level .05 [18]. The Benjamini-Hochberg procedure to control for false discovery rate was applied across multiple tests. Time-to-event analyses were performed using the lifelines package [19]. We followed STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) reporting guidelines [20] (Multimedia Appendix 1).

Ethical Considerations



The study was approved by the Scripps Institutional Review Board (22 - 7978). All participants provided electronic informed consent. SRTI performed safety oversight.

Results

Study Population

Of 917 consented participants, 669 (73%) were eligible for inclusion in analyses (Figure 1); of these, 443 (66.2%) reported taking at least one dose of NPR (NPR group) and 226 (33.8%) did not (control group). Within the NPR group (n=443), 197 (44.5%) reported taking all 5 days of their NPR prescription. The average age was 46.1 (SD 12.9) years, and 62.6% (419/669) of participants were female. The most common preexisting condition was high blood pressure (132/669, 19.7%), and half of participants (340/669, 50.8%) did not report any preexisting conditions. While sex was similar between groups, there were differences in age (56/67, 83.6% of those older than 65 years opting to take NPR compared with 189/258, 73.3% of those aged 45-65 years and 198/344, 57.6% of those aged 18-44 years), race (351/491, 71.5% of White participants opting to take NPR compared with 85/168, 50.3% of non-White participants), and the presence of preexisting conditions (Table 1). The proportion of participants in the NPR group was higher in the first cohort (181/251, 72.1%) than the second cohort (262/418, 62.7%; Table S1 in Multimedia Appendix 1).

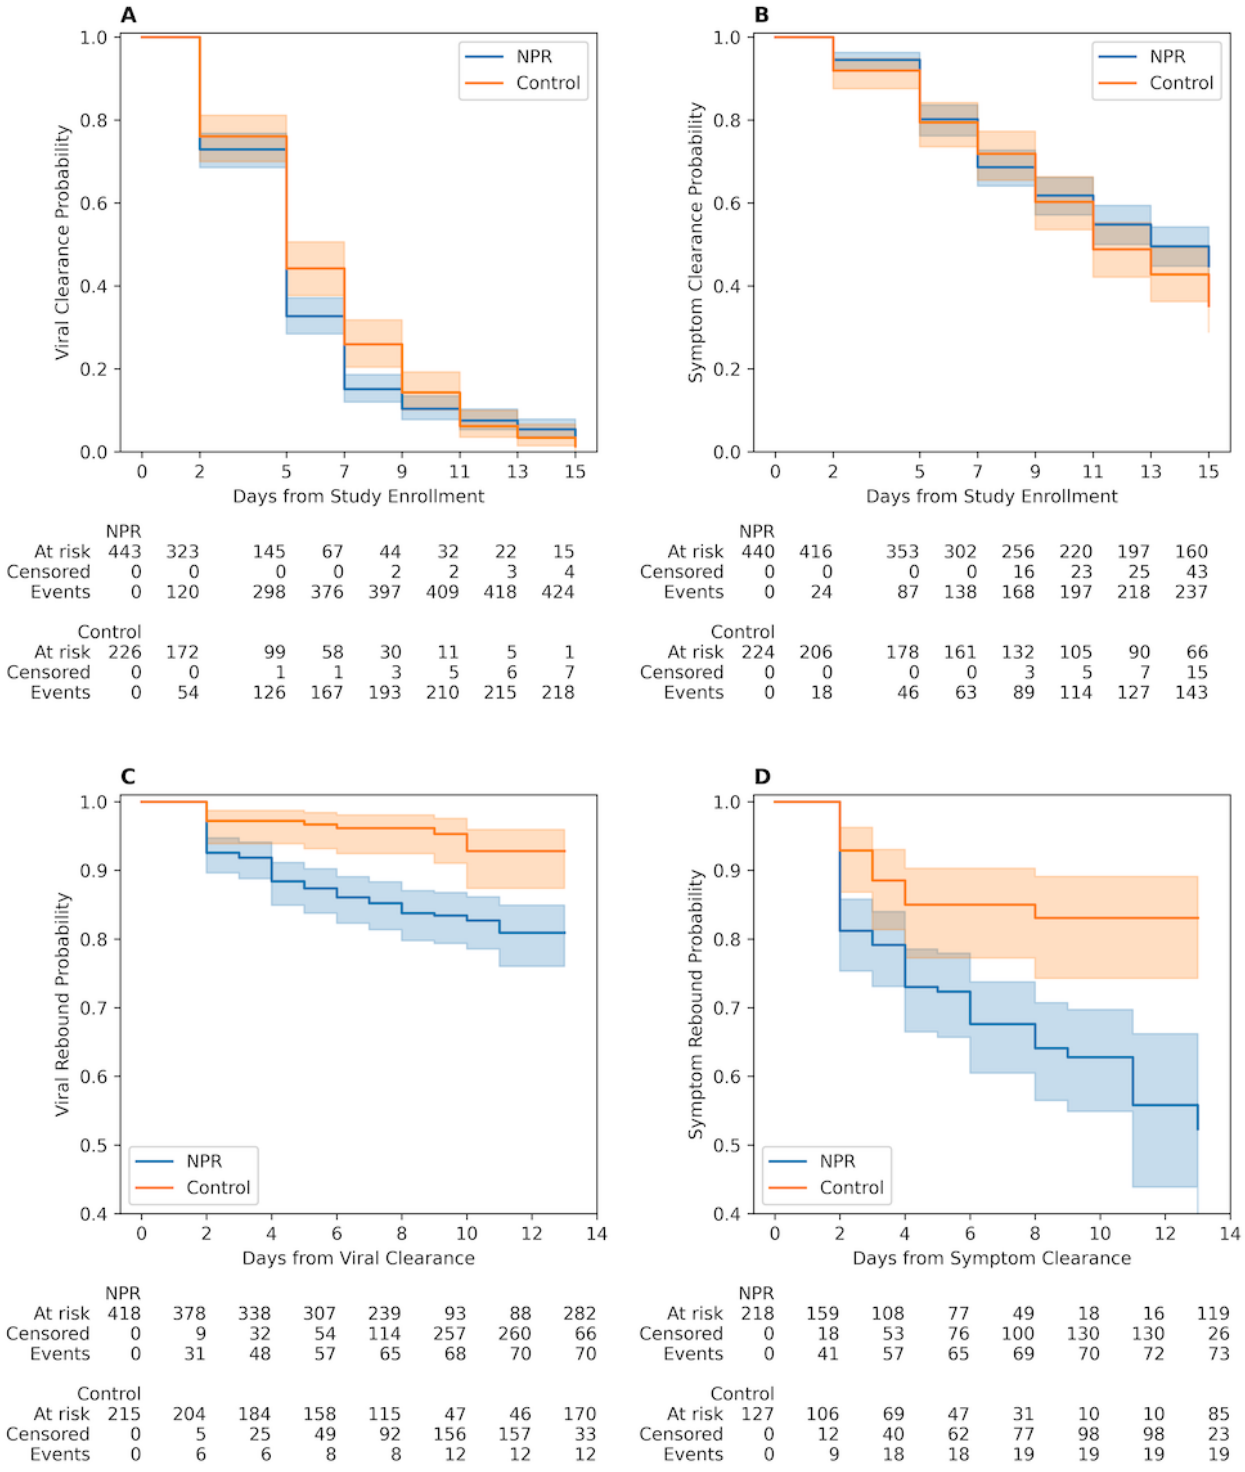
[b]NPR: nirmatrelvir plus ritonavir.

Primary Outcome: Rebound Incidence

The 15-day cumulative viral rebound incidence was 12.3% (82/669) overall (NPR: 70/443, 15.8% and control: 12/226, 5.3%). The 15-day cumulative symptom rebound incidence was 13.8% (92/664) overall (NPR: 73/443, 16.5% and control: 19/226, 8.4%). Kaplan-Meier curves showed significantly increased probability of viral test rebound by day 15 of 16.2% (95% CI 13.1% - 20.1%) for the NPR group and 5.6% (95% CI 3.2% - 9.6%) for the control group (Figure 2; log-rank P<.001). Probability of symptom rebound by day 15 was 17.2% (95% CI 13.9% - 21.1%) and 8.8% (95% CI 5.7% - 13.4%) for NPR and control groups, respectively (Figure 2; log-rank P=.004). Secondary analyses examining incidence across different eligibility and timing criteria (Table S2 in Multimedia Appendix 1), whether a partial (1 - 4 days) or full (5 days) prescription of NPR was taken (Table S3 in Multimedia Appendix 1), and adjusted for baseline demographic and clinical characteristics using Cox proportional hazards regression (Tables S4 and S5 in Multimedia Appendix 1) did not change conclusions.

Figure 2. Kaplan-Meier curves between nirmatrelvir plus ritonavir (NPR) and control groups for overall rebound risk from baseline. Curves present the probability of events for our primary outcome measure of overall (A) viral and (B) symptom rebound risk since study enrollment.

Secondary Outcomes



Initial Viral and Symptom Clearance

Time from enrollment to initial viral clearance was similar in the NPR and control groups (Figure 3; log-rank P=.11). Among the 669 participants, 642 (96%) who experienced viral clearance, the mean time to clearance was 5.4 (SD 2.9) days (NPR: mean 5.2, SD 2.8 days and control: mean 5.9, SD 3.1 days; Figure S1 in Multimedia Appendix 1). A total of 16 (2.4%) participants (NPR: 15/16, 93.7% and control: 1/16, 6.3%) never tested negative throughout the 15-day acute study phase. Another 11 (1.6%) participants (NPR: 4/11, 36.4% and control: 7/11, 63.6%) had unknown clearance timing due to too many sequentially missing tests.

Time to initial symptom clearance tended to take longer than viral clearance but was also similar between the NPR and control groups (Figure 3; log-rank P=.06). Of the 664 participants who reported at least one symptom at baseline, 380 (57.2%) reported symptom clearance in a mean of 8.1 (SD 3.8) days (NPR: mean 7.9, SD 3.7 days and control: mean 8.5, SD 4.0 days; Figure S1 in Multimedia Appendix 1). There were 226 (34%) participants (NPR: 160/226, 70.8% and control: 66/226, 29.2%) who did not report symptom clearance by day 15. An additional 58 (8.7%) participants (NPR: 43/58, 74.1% and control: 15/58, 25.9%) had too many sequentially missing symptom surveys to determine clearance timing.

XSL•FO
RenderX

Figure 3. Kaplan-Meier curves between nirmatrelvir plus ritonavir (NPR) and control groups for clearance and clearance-dependent rebound risk. Curves present the probability of events for our secondary outcomes of initial clearance of (A) virus test positivity or (B) resolution of symptoms and (C and D) risk of rebound following initial clearance or resolution.

Rebound Following Initial Clearance

The primary outcome was rebound incidence among all participants under evaluation, regardless of whether they experienced initial viral or symptom clearance. Therefore, the previous evaluation provided an estimate of risk for a patient group that did not yet know if they would clear the virus or symptoms in time to become “eligible” to experience a rebound event within the 15-day acute phase. Thus, we also explored the critical question of rebound probability among patients who cleared by day 15.

Among the 633 participants who experienced initial viral clearance before day 15, the risk of viral rebound by day 15 was 19.1% (95% CI 15.1% - 24.0%) for the NPR group compared with 7.2% (95% CI 4.0% - 12.6%) for the control group (Figure

XSL•FO
RenderX

3; log-rank *P*<.001). The mean number of days from initial viral clearance to rebound positive test was 4.3 (SD 2.7) overall (NPR: mean 4.1, SD 2.5 days and control: 5.2, SD 3.5 days; Figure S2 in Multimedia Appendix 1). Almost one-third (139/418, 30%) of viral rebound cases in the NPR group lasted 2 days or less, while 17.1% (71/418), 11.4% (48/418), and 2.9% (12/418) lasted 2 to 4, 4 to 6, and 6 to 8 days, respectively (Figure S3 in Multimedia Appendix 1). A total of 38.6% (27/70) NPR and 3.6% (4/110) control group viral rebound cases did not reclear prior to the end of the acute phase follow-up or when they were censored for missing tests.

Among the 345 participants who experienced initial symptom clearance before day 15, the risk of symptom rebound by day 15 was 47.7% (95% CI 36.1% - 60.8%) for the NPR compared with 16.9% (95% CI 10.9% - 25.7%) for the control group (Figure 3; log-rank *P*<.001). The mean number of days from initial symptom resolution to rebound was 3.5 (SD 2.3) overall (NPR: mean 3.6, SD 2.5 days and control: mean 3.0, SD 1.4 days; Figure S2 in Multimedia Appendix 1). The duration of rebound symptoms is presented in Figure S3 in Multimedia Appendix 1, with 54.8% (40/73) of NPR and 47.4% (9/19) of control group symptom rebound cases not resolved by day 15 or when they were censored.

Exploratory Analyses

Characteristics of the Rebound and Nonrebound Groups

Table 2 compares characteristics of participants that did and did not experience each type of rebound. Of the 669 participants, there were 26 (3.9%) who experienced both viral and symptom rebound.

[b]COPD: chronic obstructive pulmonary disease.

Symptom Frequencies

Respiratory symptoms were the most commonly reported symptoms overall, with a mean number of 4.8 (SD 2.4) surveys in the NPR group and 4.5 (SD 2.4) surveys in the control group (P=.13; Table 1). The viral rebound group tended to report slightly more surveys with symptoms than those without viral rebound, with respiratory symptoms being the only statistically significant difference (P=.005; Table 2).

Discussion

Principal Findings

This COVID-19 Rebound Study found that participants who independently decided to take at least one dose of NPR had triple the 15-day cumulative incidence of viral test rebound and double the cumulative incidence of symptom rebound than the control group. These findings persisted in our secondary analysis after adjusting for baseline characteristics that may confound the association between NPR and COVID-19 rebound. Furthermore, when restricting the analysis to participants who achieved initial clearance before day 15, NPR use was significantly associated with a higher probability of both viral rebound (19.1% vs 7.2%; P<.001) and symptom rebound (47.7% vs 16.9%; P<.001) at study completion.

The estimates in our study are comparable to other studies, which have reported cumulative incidence of viral rebound in NPR treatment populations from 4% to 27%, and symptom rebound from 0.8% to 32% [21-23]. Studies with lower estimates tended to be secondary analyses of randomized controlled trials or retrospective analyses of electronic medical record data, which may only capture more severe cases [12,22-26]. Studies with higher estimates tended to use more sensitive measures of viral load, and in some cases, they did not require full resolution of symptoms for participants to be eligible for symptom rebound [21,27]. A strength of our study is that it was designed with rebound as the primary outcome and used frequent telehealth, proctor-verified home testing, and symptom surveys. Furthermore, in contrast to most other studies, we did not exclude participants who took partial doses of NPR, which was more common than taking the full 5-day prescription (n=226, 33.7% none, n=246, 36.7% partial, and n=197, 29.4% full), allowing for more accurate real-world estimates of rebound.

We found minimal overall differences in time to initial viral or symptom clearance between the NPR and control groups, suggesting that further investigation was needed into the discordance between how NPR reduces the potency of the virus to ultimately reduce the progression to severe COVID-19, as found in previous studies, and the identified increased rates of rebound or persistent virus. Time to initial symptom clearance was longer than viral clearance, consistent with another prospective study [21]. The tendency for symptoms to remain after testing negative was further seen in examinations of consistency between positive tests and symptoms across the 15-day acute phase follow-up (Table S6 in Multimedia Appendix 1). Of note, we captured self-reported presence or absence of symptoms, whereas symptom severity might yield additional insights.

An additional finding from our study is that at 5 days after enrollment (corresponding to up to 7 days after first turning positive), more than one-third (244/669, 36.5%) of participants remained positive on rapid antigen tests (Figure 3). Although Centers for Disease Control and Prevention guidance has largely recommended ending isolation after 5 days, our findings suggest that individuals may remain infectious for longer and should therefore remain cautious.

Numerous mechanisms have been hypothesized for why rebound occurs. The constant push and pull between virus and immunity drives “predator-prey dynamics,” where the virus’ presence triggers the activation of immune defenses, and virus clearance signals these immune defenses to shift toward a recovery mode [28]. If the shift is too early, the relaxed defenses can allow remaining virus to rapidly re-expand. Regarding NPR and increased rebound risk, it is possible that early treatment initiation pharmaceutically drives down virus growth while abrogating the need to raise a robust immunological defense. Thus, upon removal of NPR, remaining virus could replicate at a rate that outpaces immune defenses, leading to a virus rebound until defenses catch up. Consistent with many COVID-19 symptoms in an era of widespread immunity that represent activating immune defenses (ie, fever and congestion), rebound symptoms generally reflect mounting immune defenses. If immunity must increase to clear residual virus after completion of NPR treatment, many individuals would be expected to experience symptoms; this would lead to a more common symptom rebound phenomenon and a less common full virus rebound, which aligns with our results [29-31].

The COVID-19 Rebound Study was not designed to investigate the efficacy of NPR. Prior studies clearly demonstrate the impact of NPR on reducing COVID-19–related hospitalizations and severe outcomes [3-7,15]. On the basis of our rebound-related findings, our recommendation to clinical health care providers prescribing NPR is to inform patients of the higher likelihood of viral and symptom rebound, that there is insufficient evidence regarding the severity of these symptoms, and that the evidence supporting reduction in hospitalizations and progression to severe COVID-19 is strong.

This was a nonrandomized study that may be limited by selection bias, recall bias, and an unbalanced sample size. While NPR was the primary COVID-19 oral antiviral therapeutic, we did not systematically capture use of emerging alternative antiviral therapies in the control group, which may influence rebound estimates. Our definition of symptom rebound (≥1 symptom after resolution) is sensitive but may have lacked specificity, potentially overestimating clinically meaningful rebound events. Another limitation is that we required enrollment within 48-hours of a positive rapid antigen test; however, participants may have had symptoms and disease for longer durations prior to self-testing and/or asymptomatic participants may have tested at an unknown time point after infection, thereby leading to underestimates on time to viral or

XSL•FO
RenderX

symptom clearance. Timing estimates were also impacted by the length of the study as not all participants experienced clearance by day 15. The relatively large numbers of participants in both groups helps to mitigate, though not necessarily eliminate, the impact of these potential biases as they pertain to relative differences between groups. The social media recruitment arm was opened partway through the study primarily to increase the number of participants who were not intending to take NPR, as those recruited through the eMed platform may have been drawn to the test-to-treat virtual care paradigm. The analysis excluded 27% (248/917) of consented participants due to missing data that precluded capture of potential rebound. Excluded participants tended to be less vaccinated, NPR users, and non-White (Table S7 in Multimedia Appendix 1). There was also nonresponse or dropout during the study, whereby 67.6% (452/669) of the analysis sample completed all acute study phase surveys.

Conclusions

In summary, this prospective observational study of COVID-19–positive outpatients showed that NPR treatment decision was associated with a substantially increased risk of both viral and symptom COVID-19 rebound. No difference was found in the overall time to initial clearance of viral test positivity or symptoms between the NPR and control groups, although the NPR group was older and had more preexisting conditions at baseline. With this important caveat for interpretation of our findings, there is a clear-cut need for more durable antiviral therapies or regimens and for improved knowledge regarding optimal patient selection.

Acknowledgments

The authors thank Katie Quartuccio for planning and preparing participant materials for biosample collection and return, and Yuray Rodriquez for leading the kitting and logistics associated with this research.

Funding

Data Availability

Data from the COVID-19 Rebound Study carry a risk of reidentification and therefore cannot be shared in accordance with the approved institutional review board protocol. Questions regarding access to the dataset should be directed to the corresponding authors.

Authors' Contributions

GQ, DCC, EGS, JP, ER, LR, KGA, EJT, JAP, and MJM contributed to the conception and design of the study. JKK and KK performed the data analysis. JKK, MJM, and JAP interpreted the data and drafted the manuscript. DCC, JP, ER, KGA, and EJT provided substantial revisions. All authors reviewed and approved the final draft.

Conflicts of Interest

MJM is chief scientific officer of eMed, a home test-to-treat company. He is the owner of BioHealth Engineering, a consulting firm providing advisory and consulting services to numerous diagnostics and life science companies. All other authors declare no other conflicts of interest.

Multimedia Appendix 1

The figures show time to initial viral and symptom clearance, time from clearance to rebound, and duration of rebound. The tables show differences between the two outreach cohorts, sensitivity analyses of 15-day COVID-19 cumulative incidence estimates, Cox proportional hazard regressions for symptom rebound, congruence of viral and symptom reports, and characteristics of participants included vs excluded from analyses.

Abstract

Background: Accurate clinical coding is critical in the casemix system to ensure proper resource allocation, health care policy planning, and data reliability. Inaccurate coding can result in significant financial losses to the hospital. To date, the implications of inaccurate coding in casemix implementations in Malaysia have rarely been explored.

Objective: This study aimed to evaluate the accuracy of clinical coding and identify factors associated with accurate coding practices in a major teaching hospital in Malaysia.

Methods: A cross-sectional study was conducted using 445 inpatient discharge records from Hospital Canselor Tuanku Muhriz from January 2023 to December 2023. Stratified random sampling was applied across 4 departments. Coding accuracy was determined by comparing electronic medical record entries to a gold-standard set by trained coders and specialists. Descriptive and bivariate analyses were performed accordingly.

Results: This study found that the overall clinical coding accuracy was 76.4% (340/445). Documentation completeness (P<.001) and coding turnaround time (P=.02) were significantly associated with coding accuracy. Other variables such as patients' sex, patient age, department, and coder experience were not significantly associated. Clinical coding accuracy in this setting was suboptimal.

Conclusions: Continuous training and regular audits are recommended to improve coding quality and ensure reliable casemix data for policy and funding decisions.

KEYWORDS

clinical coding; casemix; diagnosis-related group; ICD-10; coding errors; coding accuracy

Introduction

Clinical coding serves as the backbone of the casemix system, translating detailed patient diagnoses and procedures into standardized alphanumeric codes, such as those defined by the *International Classification of Diseases* and related classifications [1,2]. These codes are crucial for enabling workload analysis, hospital performance benchmarking, resource allocation, reimbursement processes, epidemiological research, and national health planning [2,3]. In Malaysia, the casemix system, specifically the Malaysian Diagnosis-Related Group (My-DRG), was first introduced at a major university hospital under the Ministry of Higher Education, aiming to improve efficiency and accountability in health care service delivery [4].

Despite the well-established role of casemix systems internationally, Malaysia's nationwide implementation continues to face challenges, including shortages of trained coding professionals, inadequate infrastructure, and limited political and institutional commitment. One of the critical barriers to broader adoption is persistent concern over coding accuracy. Coding errors can lead to significant negative consequences such as financial discrepancies, misallocation of health care resources, flawed health policy decisions, and compromised data quality for research and planning [5,6]. Accurate clinical coding is especially vital in teaching hospitals, where patient caseloads are typically complex and involve multidisciplinary management.

The process of clinical coding is inherently intricate, involving the translation of complex diagnostic and procedural data into

XSL•FO
RenderX

standardized codes while ensuring fidelity to clinical records. This process depends heavily on accurate and comprehensive documentation by health care providers, coders' competence, and institutional systems supporting coding practices [7]. Studies have consistently demonstrated that coding errors arise from various sources, including incomplete or ambiguous medical documentation, coder experience and training gaps, and systemic factors such as departmental practices or weak organizational culture regarding data quality [7-9].

Several patient-related factors may influence coding accuracy. Older patients, for instance, often present with complex medical conditions and multiple comorbidities, making precise coding more difficult [10,11]. Similarly, longer hospital stays may indicate complex cases requiring multifaceted care, which can increase the potential for coding errors, although findings in the literature on this relationship remain mixed [12,13]. Departmental factors also play a role; surgical departments typically exhibit higher coding accuracy due to standardized procedural documentation, whereas medical and obstetric units face greater challenges due to diagnostic complexity and unplanned interventions [7,13].

Documentation quality is a critical determinant. Poorly written records, nonstandard abbreviations, or incomplete discharge summaries have all been linked to higher coding error rates [4,8]. Electronic medical records (EMRs), while intended to enhance documentation, can sometimes contribute to inaccuracies due to poor usability or reliance on default entries and copying-and-pasting practices [14,15]. Coder-related characteristics, including age, educational level, experience, and ongoing training, have also been shown to influence accuracy. Coders with higher qualifications and those who receive regular training tend to perform better [16-18]. In contrast, high workloads and time pressure are consistently associated with decreased accuracy [9,19].

Although international literature highlights these factors, research within the Malaysian context, particularly in teaching hospitals, is limited. Available studies suggest that coding accuracy levels in Malaysia vary widely, with error rates ranging from 25% to nearly 50% in different settings [6,7]. This variability underscores the need for localized investigations to identify modifiable factors that can enhance coding practices and data quality.

Therefore, this study aimed to determine the level of clinical coding accuracy and explore the patient, coder, documentation, and systemic factors associated with coding accuracy among discharged inpatients in a Malaysian teaching hospital. The findings will provide critical evidence to inform interventions aimed at improving coding practices, supporting effective casemix implementation, and strengthening the health system's capacity for data-driven decision-making.

Methods

Overview

A cross-sectional study was conducted at Hospital Canselor Tuanku Muhriz (HCTM), a university hospital in Malaysia. It was formerly known as Universiti Kebangsaan Malaysia Medical Centre. It serves as a referral center for patients from Klang Valley and is also the first hospital in Malaysia that implemented a casemix system. HCTM requires coders to conduct active and ongoing diagnosis and procedure coding exercises.

This was a cross-sectional comparative study using secondary data obtained from inpatient discharge lists between January 2023 and December 2023. The aim was to assess the accuracy of clinical coding for the principal diagnoses. All patient information for the episode of admission was stored in the EMR system in the hospital database. In addition, the casemix unit at the International Centre for Casemix and Clinical Coding (ITCC) HCTM performed the diagnosis and procedure codings by extracting data from the EMR system. The database was accessed from June 1, 2024, to July 31, 2024. The authors had no access to information that could identify individual patients during or after data collection. Stratified random sampling was applied to obtain patients from 4 groups of departments: medicine, surgery, orthopedics, and obstetrics and gynecology. Subsequently, systematic random sampling was used via a computer system to select patient records from each department to ensure equivalent representativeness. The required sample size was calculated using the formula for finite populations, targeting a 95% confidence level and 5% margin of error. An estimated population of 31,103 discharges in 2023 yielded a required sample size of 384. A 20% buffer for incomplete data was added, yielding a final target of 445 records.

This study included secondary information from the discharge summaries in the EMR system, casemix-coded patient data, and coder demographic profiles. A comparison was made between the coders' codes and the codes reassigned by a trained medical officer and casemix experts. The gold-standard codes were determined through a structured review process conducted by a trained medical officer with casemix coding experience and verified by certified casemix experts at HCTM. Each sampled record was independently reviewed against the discharge summary in the EMR, and the reassigned code was agreed upon through consensus between the medical officer and the casemix expert. In cases of disagreement, a third senior casemix expert served as the final arbiter to ensure a consistent and predefined adjudication process. To minimize assessment bias, the trained medical officer and casemix experts who reassigned the principal diagnosis codes were blinded to the original coder-assigned codes at the time of review. The original codes were only compared after the gold-standard codes had been independently assigned, ensuring that the reassignment process was not influenced by knowledge of the coders' prior decisions. In this study, the dependent variable was coding accuracy, defined as whether the principal diagnosis was coded correctly by the casemix coder, identical to the codes assigned by the trained medical officer or casemix experts. The data were categorized into 2 groups: accurate or inaccurate. This study deliberately focused on the accuracy of the principal diagnosis code only rather than secondary diagnoses or procedure codes. This decision was based on the fact that the principal diagnosis is the primary driver of My-DRG casemix grouping and hospital reimbursement in the Malaysian casemix system, making it the most consequential code for financial and policy outcomes. It

XSL•FO
RenderX

is important to note that this study evaluated the accuracy of the *International Classification of Diseases, Tenth Revision*, principal diagnosis coding specifically rather than the resulting My-DRG group assignment itself. My-DRG grouping accuracy depends on the joint accuracy of multiple coded elements (principal diagnosis, secondary diagnoses, procedures, age, and length of stay) and was beyond the scope of this study. Furthermore, restricting the analysis to the principal diagnosis allowed for a focused and interpretable measure of coding performance, consistent with several prior studies in similar health care settings [7].

Four components of independent variables were included: (1) patient-related factors such as age, sex, and length of stay; (2) clinical departments; (3) documentation factor; and (4) coder-related factors, namely, length of service, educational level, and time taken to assign a clinical code. The length of stay in hospital was defined as the number of days that the patient stayed in the hospital and was further divided into inliers and outliers. The discharge summary was reviewed for completeness of diagnosis. Documentation was considered complete if an actual primary diagnosis was recorded. Specifically, a discharge summary was considered complete if it contained an explicitly stated primary (principal) diagnosis written in full clinical terminology without reliance on abbreviations, symbols, or ambiguous shorthand. Summaries that contained only nonspecific descriptors (eg, “unwell,” “fever,” or “query diagnosis”), left the primary diagnosis field blank, or contained illegible entries were classified as incomplete. This operational definition was consistently applied by the reviewing medical officer across all sampled records.

For coder-related factors, the length of service was divided into less than 10 years and greater than or equal to 10 years. This threshold was used as it is consistent with the minimum reckonable service period for confirmed or pensionable status and optional retirement eligibility under Malaysia’s Pensions Act 1980 (Act 227), section 12 [20]. Educational level was categorized as having a degree or not, and the time taken for the coding officer to complete coding was calculated from the date of discharge until the date when the coding data were finalized. This period was divided into 2 categories: 3 days and below and 4 days and above. These cutoff points are consistent with the international discharged, not final coded benchmark used in health information management departments, where 3 days after discharge is the standard threshold for flagging a record as overdue for coding completion [21].

Descriptive analysis was conducted to present the background and study variables. Bivariate analyses were performed to understand the association between independent variables and the dependent variable. All associations were considered statistically significant if the *P* value was below .05. All data were recorded in Microsoft Excel and analyzed using SPSS (version 29; IBM Corp). Bivariate analysis using the Pearson chi-square test was performed to examine whether the coding accuracy status (accurate vs inaccurate) differed significantly across subgroups of each patient and coder characteristic. This approach was adopted to identify which specific variables were statistically associated with coding inaccuracy, thereby allowing for the prioritization of variables for targeted quality improvement interventions. In addition to the test of association, the coding accuracy rate for each variable category was calculated as the proportion of accurately coded records out of the total records in that category to provide a more interpretable measure of coding performance at the variable level. All 445 sampled records had complete data for discharge summary completeness status and coder-related variables. No records required exclusion due to missing data.

Ethical Considerations

This study received ethics approval from the Medical Research and Ethics Committee of Universiti Kebangsaan Malaysia, with approval reference number JEP-2024-289. All patient data were anonymized to ensure participant confidentiality, and no individual participants could be identified during or after data collection. Informed consent was not required as the study used deidentified retrospective administrative data.

Results

Of 445 inpatient records, this study found that 340 (76.4%) were coded correctly, whereas 105 (23.6%) were coded incorrectly. Of the 445 records included, 174 (39.1%) were of male patients, and 271 (60.9%) were of female patients. Regarding patient age range, the highest frequency was 30 to 39 years at 21.1% (n=94), followed by 60 to 69 years at 18.2% (n=81). The lowest frequency was in the ranges of 0 to 9 years and 10 to 19 years at 4.7% (n=21) each.

It was also found that 76.6% (341/445) of the inpatient records were categorized as inliers and 23.4% (104/445) were categorized as outliers. Among the 445 samples, the largest number corresponded to the medical department (n=123, 27.6%), followed by the obstetrics and gynecology department (n=110, 24.7%) and both the surgery and orthopedics departments (n=106, 23.8% each). Regarding the documentation of discharge summaries, 88.1% (392/445) of the records were complete, and 11.9% (53/445) were incomplete. Coders without a degree coded 28.1% (125/445) of the records, and those with a degree coded 71.9% (320/445). The number of records coded by coders with less or more than 10 years of service was almost equal. In terms of coding turnaround time, 72.1% (321/445) of the records were coded within 3 days or less, and 27.9% (124/445) were coded in 4 days or more. The descriptive analysis of patient sociodemographic and clinical characteristics and coder profiles is shown in Table 1.

Time taken for coding (d)	
≤3	321 (72.1)
≥4	124 (27.9)

A total of 4 casemix coders were responsible for the 445 coded records included in this study. On average, each of them coded 100 to 110 cases. This uneven distribution reflects the actual workload allocation within the casemix unit at HCTM during the study period.

To determine which patient and coder characteristics were associated with coding accuracy, bivariate analyses were conducted alongside the calculation of accuracy rates per variable category. This dual approach allowed for identification of both the magnitude of coding accuracy for each subgroup and whether observed differences were statistically significant.

Table 2 shows the coding accuracy rate for each variable. Overall, 76.4% (340/445) of the records were coded accurately for the main diagnosis. At the variable level, coding accuracy varied across patient and coder characteristics. For sex, the accuracy rate was 79.9% (139/174) for male patients and 74.2% (201/271) for female patients, with no statistically significant association ($\chi^2(1)=1.9$; $P=.17$). Across age groups, accuracy ranged from 61.9% (13/21) in the group of 10 to 19 years to 84% (42/50) in the group of 40 to 49 years, although this variation was not statistically significant ($\chi^2(8)=8.8$; $P=.36$). For length of stay, accuracy was comparable between inliers (259/341, 76%) and outliers (81/104, 77.9%), with no significant difference ($\chi^2(1)=0.2$; $P=.69$).

Male	139 (40.9)	35 (33.3)		
Female	201 (59.1)	70 (66.7)		
Age (y)			8.8 (8)	.36
0 - 9	15 (4.4)	6 (5.7)		
10 - 19	13 (3.8)	8 (7.6)		
20 - 29	39 (11.5)	11 (10.5)		
30 - 39	63 (18.5)	31 (29.5)		
40 - 49	42 (12.4)	8 (7.6)		
50 - 59	28 (8.2)	10 (9.5)		
60 - 69	66 (19.4)	15 (14.3)		
70 - 79	47 (13.8)	12 (11.4)		
≥80	25 (7.4)	6 (5.7)		
Length of stay			0.2 (1)	.69
Inliers	259 (76.2)	82 (78.1)		
Outliers	81 (23.8)	23 (21.9)		
Department			3.6 (3)	.31
Medical	98 (28.8)	25 (23.8)		
Surgical	85 (25)	21 (20)		
Orthopedic	79 (23.2)	27 (25.7)		
Obstetrics and gynecology	78 (22.9)	32 (30.5)		
Discharge summary			42.4 (1)	<.001
Complete	319 (93.8)	73 (69.5)		
Not complete	21 (6.2)	32 (30.5)		
Coders' educational level			0.1 (1)	.71
No degree	94 (27.6)	31 (29.5)		
Degree and above	246 (72.4)	74 (70.5)		
Coders' length of service (y)			1.5 (1)	.23
<10	168 (49.4)	59 (56.2)		
>10	172 (50.6)	46 (43.8)		
Time taken for coding (d)			5.9 (1)	.02
≤3	255 (75)	66 (62.9)		
≥4	85 (25)	39 (37.1)		

Regarding clinical department, the highest coding accuracy was observed in the surgical (85/106, 80.2%) and medical (98/123, 79.7%) departments, whereas obstetrics and gynecology recorded the lowest accuracy rate at 70.9% (78/110), followed by orthopedics at 74.5% (79/106). However, these differences were not statistically significant ($\chi^2(3)=3.6$; $P=.31$).

The completeness of discharge summaries showed the most striking difference in accuracy rates. Records with complete discharge summaries had an accuracy rate of 81.4% (319/392) compared to only 40.4% (21/52) for those with incomplete summaries, a difference that was highly statistically significant ($\chi^2(1)=42.4$; $P<.001$). For coder-related factors, accuracy rates were similar between coders without a degree (94/125, 75.2%) and those with a degree or a higher educational level (246/320, 76.9%), with no significant association ($\chi^2(1)=0.1$; $P=.71$). Similarly, coders with less than 10 years of service had an accuracy rate of 74.0% (168/227) compared to 78.9% (172/218) for those with 10 or more years, which was not statistically significant ($\chi^2(1)=1.5$; $P=.23$). Finally, records coded within 3

XSL•FO
RenderX

days of discharge had a higher accuracy rate of 79.4% (255/321) compared to 68.5% (85/124) for those coded after 4 or more days, a difference that was statistically significant ($\chi^2(1)=5.9$; $P=.02$).

Overall, demographic and departmental factors did not significantly influence coding accuracy, whereas documentation completeness and timely coding emerged as key contributors. These findings highlight the importance of structured documentation practices and effective coder workflow management.

Discussion

Principal Findings

This study aimed to assess the accuracy of clinical coding for principal diagnoses at a major Malaysian teaching hospital. The findings revealed an overall coding accuracy rate of 76.4% (340/445). These results are consistent with those of prior literature but highlight room for improvement. For example, Olagundoye et al [22] reported a slightly higher accuracy rate of 78.7% at Lagos State University Teaching Hospital. Worldwide, clinical coding accuracy varies substantially, with a systematic review by Burns et al [23] identifying a median accuracy rate of 83.2%, ranging from as low as 50.5% to as high as 97.8%. Our findings fall within this range but remain below the optimal threshold for high-performing health systems.

Interestingly, our error rate was lower than the 49.8% reported by Zafirah et al [7] and comparable to the 25.2% observed by Saizan et al [6]. This difference may be attributed to methodological differences: while our study focused solely on the principal diagnosis, many others have evaluated multiple diagnoses and procedural codes, which are inherently more complex and prone to error. Such methodological clarity is a strength of our study, allowing for a focused and interpretable measure of accuracy that reflects core hospital performance in coding.

One of the most significant findings was the strong association between the completeness of discharge summaries and coding accuracy. In our sample, 88.1% (392/445) of the records were complete, substantially higher than the 7% completeness rate reported by Zafirah et al [7]. This likely stems from our focus on the principal diagnosis, whereas previous studies have assessed full diagnostic and procedural completeness. Nevertheless, our statistical analysis confirmed that complete documentation significantly improves coding accuracy ($P<.001$). These results align with those of Taiwo Adeleke et al [24], who reported that incomplete or poor-quality documentation was a leading contributor to coding inaccuracy in Nigerian hospitals. Moreover, Foster et al [5] emphasize that continuous auditing and feedback, combined with electronic discharge summary systems, can meaningfully enhance both documentation and coding standards. Active clinician engagement in the documentation process, as advocated by Nouraei et al [25], is also vital as the absence of clear diagnostic notes can critically impair the coder's ability to assign appropriate codes.

Another notable finding was the statistically significant association between coding timeliness and accuracy. Records coded within 3 days of discharge were significantly more accurate than those coded after 4 or more days (75% vs 25%; $P=.02$). This supports the view that shorter coding turnaround times may reflect more efficient workflows or more straightforward cases. However, longer durations could also indicate increased care and attention to complex cases. Studies have found that coders who took additional time often achieved better accuracy, particularly for complex cases [26,27]. This raises the possibility that longer turnaround time may, in part, reflect greater case complexity rather than inefficient workflow alone, a distinction this study could not disentangle as case-level complexity (eg, number of comorbidities, diagnostic ambiguity, and length and diversity of documentation) was not independently measured. Coding complexity has been recognized elsewhere as a substantive, measurable construct that affects coder workload and throughput independent of coder efficiency [26,27], and future studies should consider incorporating a complexity measure (eg, number of secondary diagnoses, comorbidity index, or casemix index) to formally test whether case complexity confounds the turnaround time–accuracy relationship. Conversely, studies have also reported that prolonged delays might signal coder fatigue, systemic inefficiencies, or excessive workloads, factors that could compromise coding quality [28,29]. These findings suggest that turnaround time is a multifaceted indicator that could be used by hospital administrators to identify bottlenecks and improve workflow efficiency.

While the analysis of department-specific trends showed that obstetrics and gynecology had the highest rate of coding errors followed by orthopedics, internal medicine, and surgery, these differences were not statistically significant. Nevertheless, this trend aligns with findings by Zafirah et al [7] indicating that certain specialties may be more vulnerable to documentation and coding errors. This calls for department-specific interventions such as targeted coder training or closer clinician-coder collaboration, particularly in departments with complex case profiles.

Interestingly, coder-related factors such as educational attainment and years of experience did not significantly affect coding accuracy in this study. While this contrasts with literature suggesting that formal qualifications and experience enhance coder performance, our findings may be due to the small number of coders (n=4) and the relatively uniform training they receive at the ITCC. Future studies with larger and more diverse coder samples could provide more definitive insights into these relationships.

This study has several strengths. It is one of the few Malaysian investigations to focus specifically on principal diagnosis coding, providing a clear and interpretable metric of performance. It also combines administrative data with manually validated recoding, enhancing data reliability. Moreover, the statistically significant findings on discharge summary completeness and coding timeliness offer actionable insights for quality improvement.

However, some limitations must be acknowledged. This study was conducted at a single teaching hospital, limiting generalizability to other health care settings, including private

XSL•FO
RenderX

or nonacademic hospitals. Teaching hospitals such as HCTM typically have access to specialist input; structured coder training programs; and more complex, tertiary-level case mixes than nonteaching public hospitals. Nevertheless, teaching hospitals may also differ from private hospitals in EMR infrastructure, documentation culture, and staffing ratios of coders to caseload. The coding accuracy patterns observed in this study, particularly the influence of documentation completeness and turnaround time, may therefore not directly generalize to district or state public hospitals or private health care settings, and multisite studies are recommended to confirm these findings across different hospital types.

Additionally, the small number of coders limited our ability to explore demographic factors robustly. With only 4 coders contributing to the 445 coded records, coder-level variables (such as educational level and years of service) were effectively compared across just 4 clusters rather than 445 independent units, substantially limiting statistical power to detect true coder-level effects. Nonsignificant associations for these variables should therefore be interpreted with caution rather than as confirmed null findings. This study also did not engage clinicians directly to understand root causes of documentation lapses, which could have enriched the analysis. Additionally, a formal interrater reliability assessment between the trained medical officer and casemix experts was not conducted, which is acknowledged as a limitation of this study. Future studies should incorporate a structured reliability assessment such as the Cohen κ to strengthen the validity of the gold-standard coding process.

It is acknowledged that the use of separate bivariate chi-square tests to examine associations between individual variables and coding accuracy status has limitations as this approach does not account for confounding between variables. In particular, potential confounders such as comorbidity burden, admission type (elective vs emergency), discharge disposition, and overall casemix severity were not captured in this dataset and could not be adjusted for. As this was a preliminary descriptive study designed to characterize bivariate associations rather than isolate independent predictors, these factors represent important variables for inclusion in future multivariable analyses. Future studies should consider using multivariable logistic regression, with coding accuracy status as the dependent variable and coder-related factors, including educational level, years of service, time taken for coding, and department, as independent variables. Such an approach would yield adjusted estimates and provide more robust evidence on the independent predictors of coding inaccuracy. In this analysis, chi-square tests were used to examine bivariate associations between coding accuracy and the variables of interest, rather than to identify independent predictors. The findings were intended to describe patterns of association and inform variables that may warrant further investigation in future multivariable analyses.

The analysis was limited to bivariate associations as an exploratory first step. A multivariable logistic regression model was not developed as this study aimed to describe preliminary associations rather than establish causal or predictive relationships. The small number of coders (n=4) further precluded robust multivariable modeling, and future studies with larger coder samples are encouraged to build on these findings. A multivariable logistic regression model was therefore not pursued at this stage as the primary aim was to describe the pattern of associations across variables rather than determine independent predictors. Future studies with larger and more diverse samples are recommended to perform logistic regression analysis to confirm these preliminary findings and identify independent predictors of coding inaccuracy.

Additionally, a sensitivity analysis restricting the sample to records with complete discharge summaries was not performed in this preliminary study. Given that documentation completeness was the strongest predictor of accuracy, future work should also examine whether other associations (eg, turnaround time and years of service) persist when analysis is restricted to records with complete documentation to rule out confounding by documentation completeness itself.

Despite these limitations, the findings have important implications for policymakers and hospital administrators. Improving the completeness and clarity of discharge summaries through training, digital templates, and clinical documentation improvement initiatives can directly enhance coding accuracy. In turn, more accurate coding enables better casemix classification, fairer hospital reimbursements, and more reliable health service planning. The significant relationship between coding timeliness and accuracy also suggests the need for balanced workload distribution and process optimization to reduce coding delays without compromising quality.

Hospitals should implement a structured, recurring coding audit program, for example, auditing 3.5% to 5% of monthly coded records on a weekly cycle, consistent with established health information management auditing practice, rather than relying on ad hoc or annual reviews [30]. Coder feedback should be delivered promptly after each audit cycle, with individualized scorecards highlighting recurring error patterns (eg, specific diagnosis categories or documentation gaps). A formal, structured clinician query process following established frameworks such as the American Health Information Management Association and Association of Clinical Documentation Integrity Specialists *Guidelines for Achieving a Compliant Query Practice* should be adopted to standardize how coders seek clarification from clinicians when discharge documentation is ambiguous or incomplete [30]. Standardized discharge summary templates with mandatory fields for principal diagnosis and key clinical indicators should also be piloted to reduce documentation-related coding errors, the single strongest predictor of inaccuracy identified in this study.

As health systems move toward performance-based financing and data-driven policy, coding accuracy becomes not merely a technical concern but also a strategic priority. In this context, this study's findings offer a timely reminder that investments in documentation quality, coder support, and integrated clinical workflows are essential to realizing the full value of casemix systems in Malaysia and beyond.

Conclusions

The results of this study showed that clinical coding accuracy was 76.4% (340/445), lower than the key performance index

XSL•FO
RenderX

set by the Ministry of Health of Malaysia, which is 90%. The findings underscore the importance of complete documentation and timely coding in enhancing the accuracy of clinical coding in casemix systems. Hospitals should invest in ongoing coder training and implement systematic audits to ensure high-quality data, which is critical for planning, financing, and evaluating health care services.

Acknowledgments

The authors are grateful to all officers at the Health Informatics Centre, Hospital Canselor Tuanku Muhriz, Universiti Kebangsaan Malaysia. They confirm that generative AI tools were used solely for English-language editing of this manuscript. No AI was used for data generation, analysis, or scientific interpretation.

Funding

The authors declared no financial support was received for this work.

Authors' Contributions

AA and WMWM wrote the manuscript. WMWM, HJ, and NMDH conducted all statistical analyses. ANA provided supervision throughout the study and the writing of the manuscript. All authors reviewed the final manuscript.

Abstract

Background: Acquiring external funding for academic research is a crucial element of researcher performance assessment. However, funding opportunities are often concentrated among a limited number of researchers, reinforcing existing structural inequalities. Under these conditions, it is important to clarify how individual researchers can improve their ability to secure external funding through their own actions and thereby build sustainable academic careers. In addition, fair faculty evaluation requires recognizing disciplinary differences in funding acquisition without assuming a normative research environment.

Objective: This study aimed to examine whether research-related behaviors at different career stages contribute to variations in funding acquisition capability across research fields.

Methods: We used funding data from Grant-in-Aid for Scientific Research, Japan's largest competitive research funding program, and classified 1152 professors according to their lifetime patterns of research funding acquisition. We also collected data on individual research-related behavioral characteristics, including supervisor prestige, authorship position, publication quality, collaborative research structure, and funding acquisition strategies, from publication records and administrative data, constructing a dataset of 804 researchers. By integrating these datasets, we conducted univariate and multivariate regression analyses to examine the factors associated with research funding acquisition.

Results: Field-specific differences were observed in the upper range of funding levels and individual behaviors. High-funding recipients were found only in the field of basic and internal medicine. Univariate logistic regression analyses showed that early-career publication success (basic medicine: odds ratio [OR] 1.48, 95% CI 1.22 - 1.79; internal medicine: OR 1.34, 95% CI 1.06 - 1.69; and surgery: OR 1.70, 95% CI 1.28 - 2.27) and midcareer senior authorship were significantly associated with funding acquisition (basic medicine: OR 5.99, 95% CI 2.63 - 13.65; internal medicine: OR 3.17, 95% CI 1.16 - 8.70; and surgery: OR 9.79, 95% CI 3.26 - 29.43). In addition, supporting specific collaborators (surgery: OR 2.09, 95% CI 1.10 - 3.97) and the quality of publications during the first 12 years of a researcher's career were major determinants of success (surgery: OR 2.22, 95% CI 1.18 - 4.17). In multiple linear regression analyses with total funding as the outcome, the adjusted R^2 values were 0.576 for surgery, 0.890 for social medicine, and 0.738 for dentistry, indicating that the models accounted for many behavioral factors associated with funding acquisition. However, the model fit suggests that additional relevant factors may influence funding acquisition in basic medicine, internal medicine, and nursing.

Conclusions: This study identified individual behaviors that influence Grant-in-Aid for Scientific Research funding acquisition across research fields. While organizational and academic structures have a significant impact, personal initiative during researchers' transition from peripheral to core roles becomes important, emphasizing strong relationship-building skills and outstanding publication records. As effective actions and their timing vary by field, individuals must consider their field characteristics and implement appropriate measures at suitable times.

KEYWORDS

researcher performance; funding acquisition; Grant-in-Aid for Scientific Research (KAKENHI); research-related behaviors; collaborative research; research agenda reconfiguration

Introduction

The increasing emphasis on quantifiable outcomes has normalized metric-driven evaluation in faculty career progression. Publishing productivity and acquisition of external funding are crucial elements in researcher performance assessment [1]. External funding not only enhances a university's reputation as an external evaluator of researchers' competence but also holds significant importance for university management under financial constraints [2].

XSL•FO
RenderX

The pronounced Matthew effect, whereby success in securing research funding leads to further success, should be taken into account when evaluating researchers' performance [3-5]. Since the 2000s, there has been a significant disparity in research funding acquisition, with a Gini coefficient exceeding 0.6, indicating that a disproportionate share of funding is concentrated among a small number of elite researchers [6]. Although total US health research funding has doubled, National Institutes of Health (NIH) Research Project Grants have become increasingly concentrated, with approximately 10% of funding going to a small number of elite researchers (the top 1%) [7]. A researcher's affiliated institution, past awards, and outstanding publication records create a "halo effect" that influences evaluators' judgments and, ultimately, determines the success or failure of research grant applications [8]. Previous studies have identified factors influencing funding acquisition, including the principal investigator's (PI) gender [9], age, academic rank [10], publication quality, international visibility [11], experience in collaborative research [12], and research interdisciplinarity [13]. These factors amplify and entrench initial, minor disparities throughout the course of a researcher's career. In other words, before researchers are able to lead original research grounded in their own experience, the success of their careers is strongly shaped by structural factors beyond their control.

Research on the "science of science" emphasizes that scientific success is structurally linked to embeddedness in elite academic networks rather than individual excellence [14,15]. The identified characteristics of outstanding researchers have led to policies aimed at fostering excellence, such as enhancing international mobility, promoting team science, and encouraging interdisciplinary collaboration. However, when considering the cumulative advantages, the factors regarded as determinants of scientific success can be understood as reflecting a researcher's position within organizational and academic structures—specifically, holding senior positions at prestigious universities. Consequently, research performance assessment based on currently available quantitative indicators may have limited value in assessing sustained and incremental academic contributions.

In parallel with growing recognition of persistent structural inequalities in academia, recent studies have increasingly examined the strategies through which researchers sustain their careers under such conditions. According to a study that analyzed the career development process at each stage in detail, researchers strategically exercised agency by adopting and constructing their own professional roles to secure the resources necessary to maximize their achievements as their careers progress [16]. In this context, investigating how the strategies adopted at different career stages contribute to the long-term sustainability of individual funding acquisition could provide insights for sustaining individual careers as well as maintaining the vitality of the research ecosystem [17].

Previous studies on academic success assumed a normative research environment and did not account for field-specific research practices. There is a well-known disparity between the humanities and natural sciences in publication and citation counts. In the medical field, the number of researchers exceeding a given threshold for the *h*-index varies by specialty [18], and the success rate of obtaining research grants as one's career progresses, particularly the transition from NIH-mentored career development (K) grants to independent investigator-initiated (R) grants, differs by specialty [19]. Disregard for field-specific contexts hinders fair evaluation within medical schools that encompass basic, clinical, and translational research. An accurate understanding of the differences in funding acquisition across fields is essential for valid researcher performance assessment.

Accordingly, this study investigated whether research-related behaviors at different career stages contribute to variations in funding acquisition capability across research fields.

Methods

Overview

In Japan, the Grant-in-Aid for Scientific Research (GIA) provides fundamental financial support for academic research in all fields. GIA offers a range of programs, including basic programs classified by the amount awarded, innovation programs that address new challenges, and specially promoted research programs that support outstanding original research and pioneer new areas of study. Funding allocation is based on evaluations of researchers' past achievements and the originality, scientific significance, feasibility, and soundness of proposed research projects. Therefore, a track record of securing GIA grants directly demonstrates a researcher's capabilities and future potential. For this reason, the amount of GIA funding received by each national university is a key indicator in university evaluations and is also a major metric for faculty recruitment and promotion.

Data Source

Researchers in the medical field were extracted from the GIA database [20]. Given that GIA is effectively the only source of public funding scheme in Japan that supports investigator-initiated (bottom-up) research and that a track record of securing such grants is highly valued in recent faculty recruitment, it is reasonable to assume that this database covers nearly all researchers actively engaged in medical research at Japan's national universities, with the exception of those in the early stages of their careers or those whose primary duties are clinical work.

As many GIA-funded projects span 3 to 4 years, extracting researchers who initiated new projects in a given fiscal year enables us to identify approximately one-third of the population of scholars continuously engaged in GIA-funded research. Annual fluctuations in the amount and distribution of GIA grants reported by the funding agency are minimal; therefore, this sampling method yields a sample that is representative of the population.

In the GIA database, research institutions and implementation periods can be used as search terms to obtain information such as project titles, program categories, grant amounts, and researcher names. Information on the year of degree acquisition was obtained from the CiNii Research database [21] and used as an alternative indicator of researcher age, as exact ages were not publicly available. Each researcher's productivity and

XSL•FO
RenderX

publication quality were calculated from publication histories using data from the SciVal database, which is licensed by the University of Tsukuba, with the Scopus IDs as the search key [22].

Ethical Considerations

This study did not require ethical approval because it did not involve data collection from human or animal subjects. Researchers' names and their grant statuses are publicly available. The GIA database, which is managed by the Ministry of Education, Culture, Sports, Science, and Technology in Japan, was created to ensure transparency in public research funding allocations and allow users to search for current research information in Japan. Researchers' publication statuses are available under the commercial license. The analysis plan was not registered because this study was a secondary analysis of data extracted from databases.

Samples

We focused on medical school professors to understand how various activities at different career stages influence the success of research proposals over time. We identified 1526 professors as participants from national university medical schools who had secured new GIA projects in 2024 (Table 1). To understand the career stages of these professors at the time they received GIA grants, we analyzed the years in which they obtained their doctoral degrees. This allowed us to identify the doctoral graduation years and institutions of 1157 professors (Table 1). We then used the number of years since degree completion to examine when and through which programs these professors received project grants, thereby identifying patterns in GIA acquisition across career stages.

Table . Researcher population and their characteristics.

Population	N	Female, n (%)	Field, n (%)					
			Basic medicine	Clinical medicine (internal medicine)	Clinical medicine (surgery)	Social medicine	Nursing	Dentistry
Initial sample (N_0)	1526	187 (12.25)	424 (27.79)	283 (18.48)	446 (29.23)	105 (6.88)	152 (9.96)	116 (7.60)
Degree matched (N_1)	1152	87 (7.55)	369 (32.03)	229 (19.88)	338 (29.34)	62 (5.38)	59 (5.12)	95 (8.25)
Publication record retrieved (N_2)	804	68 (8.46)	240 (29.85)	162 (20.14)	247 (30.72)	48 (5.97)	54 (6.71)	53 (6.59)

We further linked the data for the 1157 professors to behavioral indicators derived from their publication records. As SciVal provides publication data only from 1996 onward, the analysis was restricted to researchers who obtained their doctoral degrees in or after 1996 to capture publication activities from the early stages of their careers. Using SciVal, we successfully identified publication histories for 804 professors. For the calculation of behavioral indicators, we included all publication types rather than restricting the analysis to research articles alone. This approach was intended to capture diverse forms of scholarly contribution and account for the increasing diversity of publication practices accompanying the expansion of interdisciplinary research. Subsequent analyses were therefore conducted using this subset (Table 1).

Metrics

The metrics used in this study are as follows (Multimedia Appendix 1). For researcher competitiveness, we calculated the total grant amount secured as a PI (total funding) and the total grant amount secured as a PI during the 12 years following the completion of a doctoral degree (funding_0–12y). The latter was included as a lagged variable to mitigate endogeneity.

Individual attributes include the number of years since obtaining a doctoral degree (career length), gender (gender), and the rank of the university where each researcher obtained their doctoral degree (university rank [graduated]) and the university with which they are currently affiliated (university rank [currently affiliated]).

To evaluate the quality of research output and leadership throughout a researcher's career, we calculated several metrics based on publication data: the total number of publications (total publication counts); the proportion of publications in which the researcher was listed as the first, second, or senior author (% lead-authored publications); and the average Source Normalized Impact per Paper (SNIP) of lead-authored publications (average SNIP). Journal SNIP scores were used as a proxy for research quality rather than paper-level metrics because they demonstrate that a paper meets the journal's publication standards. These metrics indicate the researcher's overall scholarly strength.

Furthermore, to clarify research activities and achievements during the initial career stage, we quantified the mentor's competitiveness (mentor level). On the basis of the organizational structure of GIA projects, we defined a participant's mentor as the PI who first appointed the participant as a co-investigator in a GIA project. Mentor level was quantified using the largest GIA awarded to that mentor. Additionally, we calculated the number of first-authored publications produced within the first 5 years after degree completion (#first-authored_0–5y) and the total SNIP of those publications (SNIP_0–5y).

XSL•FO
RenderX

To identify participants' strengths as collaborators and leaders within research networks, we calculated the following two metrics: (1) the ratio of total to unique PIs across projects involving the participant as a project member, reflecting the extent to which a researcher is repeatedly recruited by the same PI, capturing the researcher's value and reliability as a research collaborator and their access to established research environments (elite reliance); and (2) the ratio of total to unique collaborators across projects secured by the participant as a PI, reflecting the extent to which a researcher repeatedly recruits the same collaborators across their own projects, capturing the ability to build and sustain collaborative research networks (selective mobilization ability). These 2 indicators were conceived based on the findings suggesting that early-career researchers enhance their competitiveness by gaining experience in large-scale projects led by established researchers, while established researchers improve their research outcomes by connecting projects involving diverse participants under a broad conceptual framework [23,24].

Regarding researchers' funding acquisition strategies, we calculated the number of research projects secured as a PI (# projects); the number of research projects secured as a PI in large-scale research programs (Grant-in-Aid for Specially Promoted Research, Grants-in-Aid for Scientific Research (S), and (A)) (# large-scale projects); and the proportion of research grants acquired as a PI in the category of Challenging Exploratory Research (which, following institutional reforms, includes Grant-in-Aid for Exploratory Research, Challenging Exploratory Research, and Challenging Research [Pioneering] or [Exploratory]) (% challenging research). In this context, engagement in large-scale research programs was interpreted as indicating commitment to a core research agenda, whereas participation in challenging exploratory research was interpreted as indicating engagement with complementary research agendas.

Finally, to examine research performance across different career stages, we divided academic careers into 3 periods according to years since degree completion: early career (0 - 12 y), midcareer (13 - 24 y), and late career (≥25 y). For each stage, we calculated the average SNIP of publications in which the researcher served as the first, second, or senior author. Indicator names were defined according to author position and career stage. For example, SNIP_first_0–12y denotes the average SNIP of first-authored publications during the early career stage, whereas SNIP_second_13–24y and SNIP_senior_25+y denote the corresponding indicators for second-authored publications during the midcareer stage and senior-authored publications during the late career stage, respectively.

Statistical Analysis

Agglomerative hierarchical clustering was performed using XLSTAT statistical software (Addinsoft) to group the participants. Univariate logistic regression and multiple linear regression analyses were conducted using XLSTAT to estimate the impact of factors such as career length, university ranking, professional networks, productivity, output quality, leadership in academic writing, and grant acquisition strategies on GIA acquisition.

Results

Researcher Types Based on Funding Acquisition Status and Distribution by Field

Table 2 presents the descriptive statistics of the variables used in the analysis. For agglomerative hierarchical clustering, we calculated the total GIA funding acquired throughout each researcher's career as a PI and funding acquired during the first 12 years. Researchers (N=1152) were grouped based on total funding (indicator: total funding), early career funding (indicator: funding_0–12y), and career duration (indicator: career length). Six phenotype clusters were identified (Table 3). On the basis of the total funding and acquisition patterns (Multimedia Appendix 2), the groups were classified as follows: group 1, established type; group 2, emerging type; group 3, catching-up trajectory type; group 4, plateaued type; group 5, moderate-level stable type; and group 6, low-slope stable type.

[b]These variables were quantified based on The Times Higher Education World University Rankings 2023.

[c]Not applicable.

[d]SNIP: Source Normalized Impact per Paper.

[e]These variables were quantified based on the size of the Grant-in-Aid for Scientific Research projects secured by the mentor, with smaller values indicating greater competitiveness. The categories are coded as 1=Grant-in-Aid for Scientific Research on Innovative Areas, 2=the Grant-in-Aid for Specially Promoted Research, 3=Grant-in-Aid for Scientific Research (S), 4=Grant-in-Aid for Scientific Research (A), and 5=Grant-in-Aid for Scientific Research (B) or smaller.

[f]The ratio of the total number of principal investigator (PI)–participant collaborations to the number of distinct PIs across all projects in which the participant served as a project member. Larger values indicate higher level of reliance.

[g]The ratio of the total number of collaborator participations to the number of distinct collaborators across projects secured by the participant as a PI. The closer the value is to 1, the greater the team's diversity; conversely, higher values indicate stronger ability to mobilize specific collaborators.

Table . Grant acquisition status as a principal investigator by phenotype clusters.

Metrics	All	Phenotype clusters

The distribution of personal attributes and research fields by phenotype cluster is summarized in Table 4. No differences were observed between clusters in gender, but a significant difference was found in the distribution of university rank (Fisher exact test, P<.05). Notably, participants in groups 1, 2, and 3, characterized by high funding acquisition capabilities, appeared regardless of the university ranks (graduated); within group 1, a total of 4 participants had graduated from top-tier universities, 3 had graduated from midtier universities, and 4 had graduated from lower-tier universities (Table 4).

[a]The characteristics and median total funding amounts for each group are as follows: group 1, established type, US $11.62 million; group 2, emerging type, US $9.80 million; group 3, catching-up trajectory type, US $7.45 million; group 4, plateaued type, US $4.72 million; group 5, moderate-level stable type, US $1.00 million; and group 6, low-slope stable type, US $0.20 million.

[b]Groups 1 and 2 were combined because of sparse cell counts. *P* values were calculated using Fisher exact test with Monte Carlo simulation (5000 simulations).

[c]These variables were quantified based on The Times Higher Education World University Rankings 2023.

Research fields were categorized into 6 areas: basic medicine, clinical medicine (internal medicine), clinical medicine (surgery), social medicine, nursing, and dentistry (Table 4). Basic medicine and clinical medicine (both internal medicine and surgery) accounted for the largest proportion of participants because the analysis focused on professors affiliated with medical schools and excluded researchers from independent nursing or dental schools. Public health studies are less developed in Japan than in some other countries and do not constitute an independent faculty member. The distribution of researchers securing high funding varied by field (Fisher exact test, $P<.01$). Group 1 participants were only observed in basic medicine and internal medicine (Table 4). In surgery and dentistry, group 3 received the highest total funding, whereas in social medicine, group 2 ranked highest (Table 4). None of the nursing researchers secured high levels of research funding, defined as group 4 or higher, with a median total grant amount of US $4.72 (IQR US $3.83 - US $4.82) million (JP ¥1 [US $0.0067]). These results suggest field-specific differences in the upper funding level ranges.

To examine differences in behavioral characteristics by field, we compiled indicator values (n=804; Table 5). Significant differences were found across fields for all indicators, revealing distinct research practices between fields (ANOVA, $P<.05$). Basic medicine and internal medicine were characterized by high-quality outcomes early in careers (SNIP_0–5y: basic

XSL•FO
RenderX

medicine, mean 1.86, SE 0.11; and internal medicine: mean 1.86, SE 0.12) and throughout their careers (average SNIP: basic medicine: mean 0.94, SE 0.03; internal medicine: mean 0.89, SE 0.03), while basic medicine secured more large-scale research grants (# large-scale projects: mean 0.28, SE 0.05). Internal medicine, surgery, and social medicine demonstrated high productivity (total publication counts: internal medicine, mean 197.58, SE 11.11; surgery, mean 189.33, SE 8.88; social medicine, mean 199.40, SE 22.70). Social medicine was characterized by high initial productivity (# first-authored_0–5y: mean 5.19, SE 1.12), high collaborator diversity—indicated by low values for the following metrics (elite reliance: mean 1.34, SE 0.05; selective mobilization capacity: mean 1.15, SE 0.08)—and frequent implementation of large-scale projects (# large-scale projects: mean 0.25, SE 0.09). The use of complementary research programs was more common among nurses (% challenging research: mean 0.26, SE 0.08). In dentistry, the same researchers frequently collaborated on multiple projects (as indicated by high values for elite reliance: mean 1.72, SE 0.09 and selective mobilization capacity: mean 1.49, SE 0.09).

Table . Behavioral characteristics by fields (N_2=804).

Associations Between Behavioral Characteristics and Funding Acquisition Capabilities by Field

We examine the association between behavioral characteristics and funding acquisition using univariate logistic regression analyses conducted separately for each field (Table 6). Researchers in group 6 were used as the reference group, and all other types were pooled into a single comparison group (Table 6). Several common patterns emerged regarding the factors associated with substantial funding acquisition.

[e]<.01.

[f]SNIP: Source Normalized Impact per Paper.

[g]No results were produced by XLSTAT software for this group.

For the majority of participants (basic medicine, internal medicine, and surgery), becoming a high-funding recipient required early success. Specifically, higher SNIP_0–5y values were positively associated with becoming a high-funding recipient in basic medicine (odds ratio [OR] 1.48, 95% CI 1.22 - 1.79), internal medicine (OR 1.34, 95% CI 1.06 - 1.69), and surgery (OR 1.70, 95% CI 1.28 - 2.27). Likewise, researchers whose mentors had higher competitiveness scores were more likely to become high-funding recipients, as indicated by the inverse association with the mentor-level score (basic medicine: OR 0.49, 95% CI 0.36 - 0.66; internal medicine: OR 0.67, 95% CI 0.46 - 0.96; surgery: OR 0.38, 95% CI 0.22 - 0.68). Sustained high-quality leadership outputs were also significant (average SNIP: basic medicine, OR 5.99, 95% CI 2.63 - 13.65; internal medicine, OR 3.17, 95% CI 1.16 - 8.70; surgery, OR 9.79, 95% CI 3.26 - 29.43; Table 6). This was further supported by the results of our analysis that explored factors characterizing high-funding recipients without distinguishing fields (Multimedia Appendices 3 and 4).

For surgery, in addition to these factors, supporting specific collaborators (surgery: elite reliance: OR 2.09, 95% CI 1.10 - 3.97) and the quality of publications during the first 12 years of a researcher's career were major determinants of success (surgery: SNIP_first_0–12y, OR 1.56, 95% CI 1.04 - 2.35; SNIP_second_0–12y: OR 2.22, 95% CI 1.18 - 4.17; Table 6).

As funding acquisition data were characterized by small amounts for most researchers and large outliers for a limited number of researchers, some estimates showed wide CIs. Therefore, these associations should be regarded as exploratory. Nevertheless, positive associations (Multimedia Appendix 5) with high funding were observed for elite reliance in the field of social medicine (OR 9.09, 95% CI 1.32 - 62.57), early-career senior-author impact (SNIP_senior_0 - 12y: OR 11.66, 95% CI 1.75 - 77.73), and engagement in challenging research (% challenging research: OR 12.67, 95% CI 1.13 - 142.10; Table 6). In dentistry, selective mobilization capacity (OR 5.98, 95% CI 1.42 - 25.21) and late-career second-author impact (SNIP_second_25+y: OR 4.80, 95% CI 1.07 - 21.55) were also positively associated with high funding (Table 6).

To assess the robustness of funding acquisition patterns, we conducted multiple linear regressions using personal attributes and behavioral characteristics. As total funding raised (indicator: total funding) was inherently related to the total number of funded projects (indicator: # projects), the latter variable was excluded from the regression analyses to avoid structural redundancy. Consistent with this relationship, the 2 variables were strongly correlated (r=0.847; Multimedia Appendix 6).

To mitigate concerns regarding reverse causality and the influence of unmeasured variables, we first constructed models using theoretically relevant covariates for each career stage and assessed multicollinearity prior to model selection (Table 7). Model 1 included variables related to personal attributes and

XSL•FO
RenderX

early-career activities. In model 2, we additionally included early-career funding acquisition to account for the cumulative effects of prior funding success. Following the inclusion of this variable, the coefficient for graduate university rank changed direction but remained close to zero and statistically nonsignificant (from −0.02±0.04 to 0.02±0.03; not significant; Table 7), suggesting minimal independent association with subsequent funding acquisition. As the influence of graduate university rank appeared to be limited and largely accounted for by early-career funding success, this variable was not retained in subsequent models.

Model 3 further incorporated variables reflecting research activity across the entire career (indicators: % lead-authored publications and average SNIP). Following the inclusion of these variables, the coefficient for mentor level reversed direction while remaining statistically significant—it changed from −0.24±0.03 to 0.12±0.03 ($P<.001$). The coefficient for early success became significant for the number of papers (indicator: # first-authored_0–5y, −0.02±0.03 to −0.21±0.03; $P<.001$), whereas the coefficient for impact lost statistical significance (indicator: SNIP_0–5y: 0.17±0.03 to −0.03±0.03; $P>.05$). This suggests that part of the influence of early-career variables may be mediated through subsequent career experiences. To reflect the temporal structure of career development and clarify how associations change across career stages, we decided to retain the early-career variables in the model. In model 3, variables related to collaborative research relationships and acquisition strategies were excluded (indicators: elite reliance, selective mobilization capacity, # large-scale projects, and % challenging research; Table 7) because their univariate associations demonstrated wide CIs and appeared to be strongly influenced by extreme outliers (Table 6).

Finally, model 4 replaced the career-wide research quality variable used in model 3 (indicator: average SNIP) with research quality variables stratified by career stage and author position within 12-year career intervals (Table 7). As model 1 already captured early-career activity patterns as a first-author during the first 5 years (indicator: # first-authored_0–5y and SNIP_0–5y), additional variables representing first-author activity across the first 12 career years were not included in model 4 to avoid redundancy among temporally overlapping indicators. Furthermore, first-author activity indicators from the midcareer stage onward were excluded because their univariate associations were not statistically significant (Table 6). Therefore, only variables representing second-author and senior-author activity from the midcareer stage onward were added.

After confirming acceptable variance inflation factor values across alternative model specifications (Table 7), model 4 was selected as the final modeling framework because it allowed stage-specific research activity indicators to be evaluated while minimizing redundancy among temporally overlapping variables. Field-specific regression models were subsequently constructed based on this framework (Table 8). The model fit, evaluated with adjusted R^2 values, was high for social medicine and dentistry with low Akaike information criterion (AIC) values, suggesting that funding acquisition in these fields can be explained and predicted with considerable accuracy (model 4: adjusted R^2=0.890; model 6: adjusted R^2=0.738; Table 8). In surgery, an adjusted R^2 of 0.576 indicated a reasonably good predictive performance, although a high AIC suggested limited justification for retaining variables with nonsignificant coefficients. Conversely, the results for nurses showed limited explanatory power, suggesting that key determinants in this field might not have been fully captured (model 5: F test not significant; adjusted R^2=0.047; Table 8). For basic medicine and internal medicine, relatively low adjusted R^2 values and high AIC values suggested that additional factors outside this analysis may influence funding acquisition (model 1: adjusted R^2=0.288; model 2: adjusted R^2=0.318; Table 8).

Discussion

Principal Findings

Funding disparities across academic fields have been analyzed through publication-linked funding information, showing both the breadth and concentration of funding distribution within medical subfields [25,26]. However, because these are research evaluations rather than assessments of individual achievements, they do not sufficiently analyze the differences in researchers' abilities to secure funding. The analysis demonstrated that the maximum funding secured by individual researchers varies by field.

One possible explanation for the limited number of high-funding recipients in nursing is the study design itself. While the initial data extraction yielded a sample believed to reflect the structure of the population, subsequent procedures—specifically the inclusion criteria of being affiliated with a national university medical school and having obtained a doctoral degree since 1996—excluded researchers from private universities with well-established nursing programs, as well as many experienced nursing researchers whose scholarship is grounded primarily in extensive clinical practice (from 9.96% to 5.12%; Table 1). On the other hand, observations from researchers affiliated with Japanese medical schools suggest that highly funded nursing researchers are often leaders who have created and are driving emerging subfields such as patient-participatory nursing and nursing digital transformation. Consequently, the research population may be smaller in these new subfields. This may partly explain the limited number of recipients of very large-scale research funding in nursing.

The scarcity of high-funding recipients in surgery and dentistry (Table 4) may reflect the historical origins of these practice-oriented professions and their field cultures that traditionally value technical crafts. Clinically oriented publications receive fewer citations than those focused on basic science, making funding acquisition more difficult [27]. While low citation counts may reflect a narrow readership due to high specialization, there is evidence that lower-prestige publications may hinder the diffusion of cross-disciplinary ideas [28]. US NIH data indicate that selecting themes favored by a broader scientific community (ie, more fundamental or mechanistic themes) can influence funding decisions regardless of the quality of future outcomes [29]. In Japan's GIA large-scale projects, the broader range of reviewers' specialties compared with small-scale projects may be one reason fewer high-funding recipients are found in surgery and dentistry. Greater clinical demands, driven by the growing importance of revenue-generating activities for university hospitals following the 2004 partial privatization reform of national universities, may also contribute [30].

This study showed the impact of individual efforts, such as demonstrating leadership to produce high-quality outcomes at each career stage (Table 6). The importance of second authorship, previously underexamined, indicates the degree of centralization of the research ecosystem in each field [31]. The finding that early success in surgery accounted for nearly the entire outcome (Table 8) suggests a strong influence of institutional and academic structures. However, the reversal of the coefficients for mentor level and early success after controlling for career-long achievements suggests that the apparent effects of these early-career factors may be partly attributable to their association with subsequent research performance (Table 7). Funding success therefore appears to reflect not only early-career advantages but also achievements accumulated throughout a research career.

Promoting complementary research while supporting specific collaborators in social medicine or maintaining a subleadership position while mobilizing specific researchers as supporters in dentistry (Table 6) can be regarded as evidence that researchers are taking proactive measures in these fields. The field-specific research design of this study, by excluding typical leaders who tend to attract an excessive concentration of funding in these fields, may have highlighted the importance of the actions of individuals with relatively less influence. Examining the moderate funding recipients and diverse research behaviors may be more informative than focusing solely on top recipients.

This study provides new insights into individual agency within the process through which researchers transition from peripheral to central roles. As effective individual actions and timing for securing funding vary by field, it is necessary to concentrate efforts at the most advantageous time (Table 6).

Limitations

The limitations of this study are as follows. First, it does not cover all professors conducting research with GIA grants, as the analysis is restricted to researchers who obtained their doctoral degrees after 1996 and whose publication records can be traced from the early stages of their careers. Consequently, researchers in the oldest age group and those without doctoral degrees are excluded. However, this restriction is consistent with the purpose of the study. As Japan's research funding system shifted toward a competitive funding model in 2004, focusing on researchers whose careers developed under this system provides an appropriate basis for examining its effects. Accordingly, the findings should be interpreted as reflecting trends within the post-2004, globally standardized research environment. The experiences of older researchers and those without doctoral degrees remain important topics for future

XSL•FO
RenderX

research. In particular, historical comparisons could provide valuable insights into how research was nurtured within Japan's pre-2004 research ecosystem.

Second, SciVal is a commercial database with limited journal coverage, and reliance on this source alone may underestimate researchers' publication output. The extent of this underestimation may vary across fields. On the basis of our previous analysis of researcher career outcomes, SciVal data appear to reasonably capture researcher performance in fields with globally shared research interests, such as basic and clinical medicine [32]. In contrast, the limitations are more pronounced in fields where findings are frequently disseminated in local languages. Further discipline-specific investigations are needed. Furthermore, this analysis included all forms of research output to capture diverse scholarly contributions, including conceptual synthesis in review articles. While our preliminary analyses suggest that review articles are not strongly associated with grant acquisition, recent advances in AI and laboratory automation suggest the need to reevaluate scholarly contributions beyond traditional academic publications.

The third limitation concerns the indicators used in this study. While this study demonstrated that second authorship can serve as a stepping stone to a core role, the path to senior author excellence remains unclear. Future research should develop new metrics that capture the diverse contributions of middle authors to understand the determinants of core and peripheral roles [33,34]. Moreover, it could not account for aspirations to lead large-scale research projects, which may be partially reflected in their rates of submitting large-scale grant applications. Future analyses should incorporate variations in application behavior to better capture such ambitions. In addition, funding acquisition may also be influenced by finer behavioral differences, such as promotional language in proposals. Addressing these factors will require new behavioral measures beyond existing research evaluation metrics.

Finally, potential confounding between early-career variables and total-career indices should be considered when interpreting the results. Early-career variables were retained in the models because the attenuation of their effects after adjustment for total-career factors was itself a finding of interest. As a result, some confounding may remain, and the estimated coefficients should be interpreted with caution. Furthermore, residual confounding due to unmeasured factors cannot be excluded, limiting causal interpretation of the observed associations.

Conclusions

This study identifies individual research-related behaviors that influence GIA funding acquisition across research fields. The results highlight that while organizational and academic structures have a significant impact, personal initiative during researchers' transition from peripheral to core roles becomes important, emphasizing strong relationship-building skills. In other words, both participants and coordinators in collaborative research, commitment to reshaping research agendas, and excellent publication records as the lead author are crucial factors that affect funding acquisition. Effective actions and timing vary by field, reflecting the maturity of each field's ecosystem. These survey results indicate the actions and timing that enable individual researchers to maximize funding acquisition and expand their research, providing a foundation for more effective institutional support strategies.

Acknowledgments

The authors thank Naoko Manabe, Natsuho Ishikawa, and Himika Tamura for assistance with data acquisition. During the preparation of this paper, we used generative AI to improve its readability. Furthermore, the text was edited by a professional English proofreader. The authors thank Editage [35] for English language editing.

Funding

This study was supported by grants from the Japan Society for the Promotion of Science (JSPS KAKENHI grant 23K02545), Sumitomo Electric Group, and Inamori Research Grants to AH.

Data Availability

The datasets generated or analyzed during this study are not publicly available because they contain publication data obtained from commercial databases but are available from the corresponding author on reasonable request.

Authors' Contributions

AH contributed to conceptualization, data curation, investigation, visualization, and original draft preparation. ST contributed to conceptualization, resources, writing, reviewing, and editing.

Abstract

Background: During a public health emergency, emergency department (ED) clinicians can improve care delivery if they identify and adopt innovations that are safe and effective. However, little is known about the factors that impact ED clinicians' decision-making around using or discontinuing innovations when evidence-based information is limited.

Objective: The goal of this study was to understand the processes and factors that led ED clinicians to discontinue (deimplement) the use of COVID-19 care innovations.

Methods: This is a qualitative study using semistructured focus groups with ED clinicians from 8 hospitals across the United States. Hospitals were purposively sampled and recruited to capture a diversity of perspectives based on location, facility type (academic or community hospital), rurality (urban or rural), and safety-net status. In this study, 17 physicians, 7 advanced practice providers, 18 nurses, and 7 respiratory therapists participated. We utilized both inductive and deductive techniques to perform content and thematic analysis of transcripts.

Results: Clinicians shared that their own experiences (eg, direct observation of patient outcomes), contextual factors, and emerging research evidence contributed heavily to decisions about deimplementing innovations during the COVID-19 pandemic. Processes related to discontinuing innovations depended on leadership guidance and collaboration among colleagues. However, in some cases, there were no official processes to discontinue innovations, and innovations were passively deimplemented.

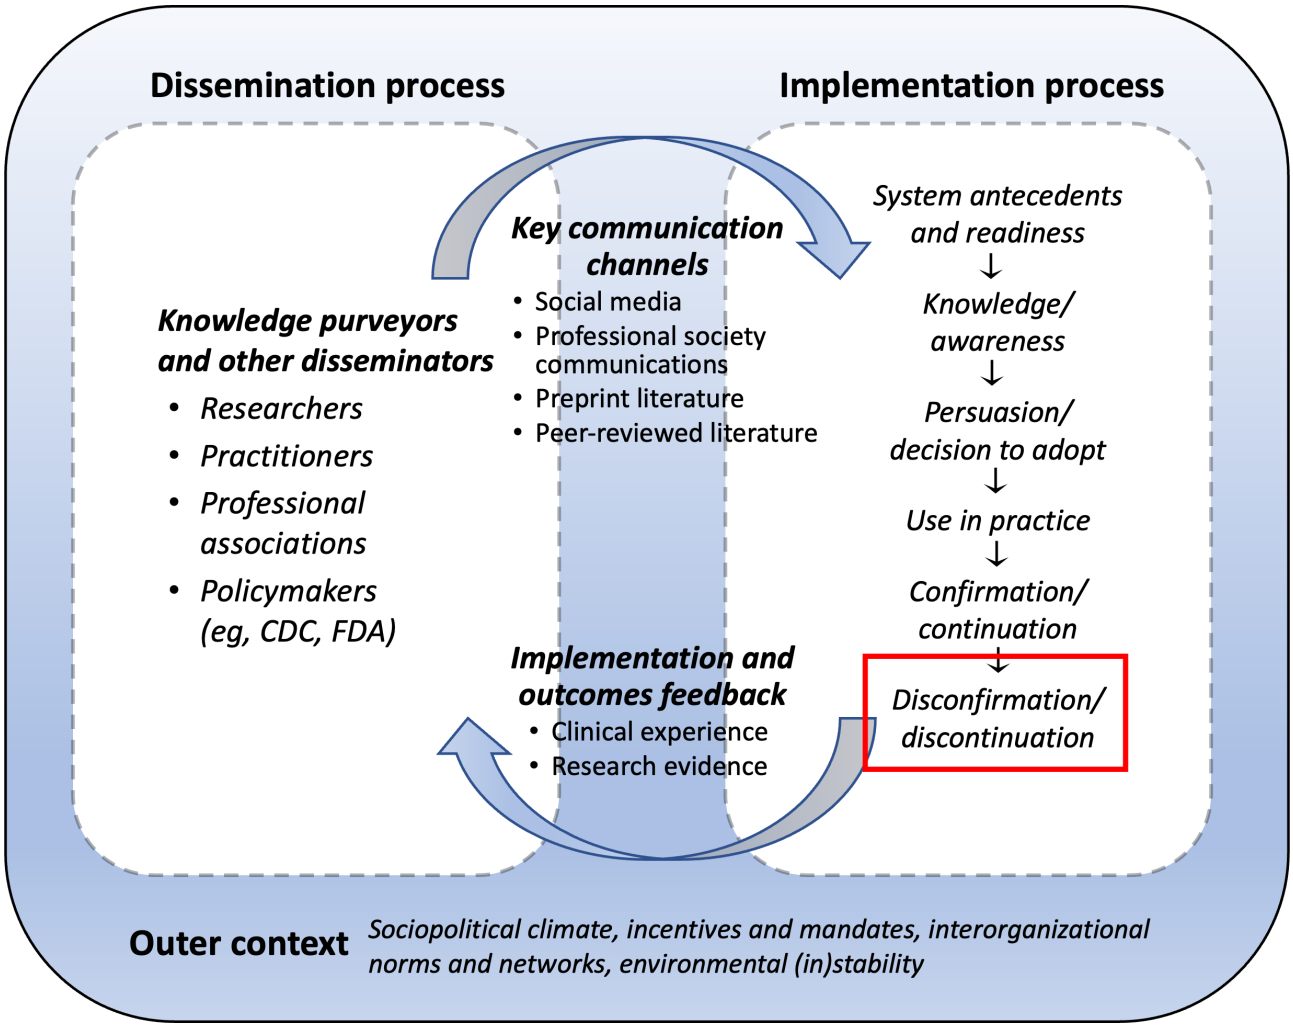
Conclusions: Decision-making regarding the discontinuation of innovation in ED settings during the COVID-19 pandemic differed from routine conditions due to the lack of information and the rapid evolution of evidence within a short period of time. The level of evidence required to implement and deimplement innovations was significantly lower. Our findings indicate that factors influencing deimplementation during a public health emergency were highly localized and were treated similarly to pilot tests of new innovations. Future work is necessary to develop mechanisms for implementing promising innovations during evolving public health emergencies and monitoring their effectiveness and safety after implementation, enabling evidence-based decisions about whether to continue implementation or proceed with deimplementation.

(Interact J Med Res 2026;15:e82088) doi:10.2196/82088

KEYWORDS

deimplementation; COVID-19 pandemic; innovation; emergency department; decision-making

Introduction



During the COVID-19 pandemic, emergency department (ED) clinicians influenced patient health outcomes by rapidly identifying and implementing care innovations to manage and treat patients with COVID-19. We define care innovations as "new or improved health policies, systems, products and technologies, and services and delivery methods that improve people's health." [1] Examples of care innovations used in EDs during COVID-19 included utilizing prone positioning [2], high-flow oxygen [3], telemedicine [4,5], and intubation boxes [6], as well as reusing personal protective equipment (PPE) [7].

Amid the public health emergency, ED clinicians learned about innovations (dissemination process) and decided whether and

XSL•FO
RenderX

how to implement them (implementation process; see Figure 1). Many innovations were also adopted throughout the hospital in response to COVID-19, but a large number were first implemented in the ED. As new evidence emerged, there were changes in innovation adoption and use: some innovations were sustained, while others were discontinued. In response to emerging anecdotal and peer-reviewed evidence during the pandemic, clinicians discontinued practices that proved unnecessary, ineffective, or even dangerous. This process is called deimplementation. Deimplementation, or deadoption, is the process by which practices deemed harmful, ineffective, or no longer necessary are discontinued within an organization [8-10].

Figure 1. Diffusion framework for COVID-19-related emergency department innovations [11]. CDC: Centers for Disease Control and Prevention; FDA: US Food and Drug Administration.

While the implementation of care innovations has been and continues to be well studied in the ED setting [12,13], less attention has been paid to deimplementation. Deimplementation differs from implementation in many important ways. A recent review noted that psychological factors and biases are more relevant to deimplementation than implementation, as many deimplementation activities involve stakeholders actively changing their behaviors [14,15]. Consequently, different behavioral change techniques are used in implementation and deimplementation studies, making the case that deimplementation should be studied as a separate process from implementation [16]. Compared to implementation, deimplementation seems to be hindered more greatly by local (ie, departmental) priorities and biases among leaders and practitioners within health systems, in addition to the traditional outside factors impacting implementation, such as social and economic barriers [14], likely due to the relative autonomy providers have in providing health services. Additionally, a narrative review of recent studies of embedded pragmatic clinical trials found that factors outside of effectiveness can determine deimplementation, such as perceived benefits, costs, and alignment with other policies or priorities [17]. However, information regarding factors that impact clinician decision-making around the deimplementation of innovations is limited [18], and even less is known about factors influencing deimplementation during a public health emergency, such as the COVID-19 pandemic. Further study of important processes and determinants for successful deimplementation is critical [19].

Attempts to formalize deimplementation in the context of implementation have linked both using 4 types of change for deimplementation: partial reduction, complete reversal, substitution with related replacement, and substitution with unrelated replacement of existing practices [20]. Unlike many

XSL•FO
RenderX

previous deimplementation studies, these changes are usually related to deimplementing care processes rather than reducing the use of low-value treatments, such as improper medication delivery. In the context of the COVID-19 pandemic, this provides an opportunity to update and enhance preexisting deimplementation literature to focus on cases where the deimplementation involves the entire intervention, not just the degree or dose [21]. The synthesis model proposed by Niven et al [22] for the process of deadoption better aligns with deimplementation decision-making in the ED: identifying and prioritizing low-value practices is a key component of the model.

This study is part of a larger examination of the dissemination and implementation of care innovations during COVID-19. We utilized an adapted form of the Greenhalgh et al [11] framework for the diffusion of innovations in health services to systematically assess both implementation and deimplementation activities. In this paper, we examined factors relating to the deimplementation of innovations and the resulting deimplementation processes in the ED during the COVID-19 pandemic. The goal of this study was to understand how ED clinicians decided to discontinue using COVID-19 care innovations by identifying processes and factors that influenced decision-making.

Methods

Study Design and Setting

We conducted virtual pilot interviews and focus groups with ED clinicians to understand their experiences with practices related to the deimplementation of COVID-19 care innovations. The discussion guide was informed by a framework adapted from Greenhalgh et al [11] and modified after piloting with 1 physician, 1 nurse, and 1 nurse practitioner. After the initial pilot interviews, no changes were made to the content discussed or focus group guides. Thus, findings from the 3 pilot interviews were included in our overall analysis.

To meet our study objective, we conducted 13 subsequent focus group discussions with clinicians from 8 hospital-based EDs across the United States in 2022 and 2023. Because we believed that responses would differ by provider type and that professional hierarchy power dynamics could impact participant responses and comfort levels, we organized separate groups for ED prescribers (ie, physicians [medical doctors; MDs] and advanced practice providers [APPs]) and for other ED clinicians (ie, registered nurses [RNs] and respiratory therapists [RTs]) at each hospital to facilitate deeper conversations and limit concerns about nonparticipation [23].

Focus Group Recruitment

We used maximum diversity sampling to recruit personnel in hospital–based EDs to participate in focus groups [24]. Hospitals were diverse by US Census Bureau region (4 regions) [25], academic hospital status (binary), rurality (binary), and safety net status (binary), including one at the epicenter of the pandemic (New York City). A site-specific champion was recruited by email and assisted with recruitment and scheduling.

Participant Recruitment and Data Collection

Focus group participants were recruited by email. Participants were eligible if they had experience providing care in a participating hospital's ED during the COVID-19 pandemic. Forty-nine clinicians from 8 hospitals participated in the focus groups.

Focus groups lasted approximately 60 to 90 minutes and included at least 1 moderator and 1 notetaker. Three researchers (SF, CB, and CC) with both clinical and focus group experiences led the discussions, while other researchers (SH and NQ) took notes. Before each focus group, the moderator introduced themselves and provided a brief description of the research project. Focus group discussion topics included gaining information about COVID-19 treatment and sources of information, facilitators and barriers to adopting innovations, processes for confirming and sustaining promising innovations, processes for discontinuing innovations that were not promising, and how contextual factors impacted innovation implementation and deimplementation. Textbox 1 displays focus group questions specifically related to deimplementation, as discussed in this paper (for the full interview protocol, see Huilgol et al [26]). We continued conducting focus groups until thematic saturation was determined [27]. Study leaders assessed thematic saturation in team discussions after each focus group based on insights shared during the discussions.

Textbox 1. Sample focus group questions.

Deimplementing innovations

Sample questions:

- Tell me about a time you tried something and immediately said, I'm not doing that again? What was that like? What made you decide not to try it again?
- Here are some examples of things you might have stopped using: intubation boxes, reusing PPE, plasma, nasal steroids. Were any of these things you were doing and then stopped? Tell us about it. What made you make that decision?
- Can you give an example of one innovation you or your institution adopted and later rejected? Please describe how the decision was made to reject it. [Reject is defined as to stop using after having tried it.]
    - How did you personally decide whether to reject it?
    - How did your department or ED decide whether to reject it?
    - How did the institution as a whole decide to reject it?

XSL•FO
RenderX

Ethical Considerations

This work was approved by the RAND Human Subjects Protection Committee (project 2021-N0714). Participants provided verbal consent at the start of the focus group and were compensated with a US $150 gift card for their time and participation. After receiving participant consent, focus groups were audio-recorded and transcribed for analysis. Participants' privacy and confidentiality were protected by securely storing focus group transcripts and recordings, limiting access to authorized researchers, and de-identifying data prior to analysis to ensure no personal information was linked to participant responses.

Data Analysis

We used both deductive and inductive analysis techniques to thematically code the focus group data [28]. We started by creating a preliminary codebook defined by topics included in the focus group discussion guide. We then used inductive processes to identify broader patterns and themes from the coded data. After the first focus group was completed, 2 researchers with expertise in health services and qualitative methodology (SH and NQ) independently reviewed a single transcript and applied codes to assess the quality of the codebook and the frequency of codes, representing approximately 10% of all coded data. The 2 coders performed an interrater reliability test and calculated a κ score of 0.72, indicating good agreement [29]. The codebook was updated and finalized based on this coding. As new themes and insights emerged during focus group discussions, the authors updated and added new codes to the codebook. Additions to the codebook were shared via regular weekly meetings among the project team [30].

The remaining transcripts were then divided in half and each coded by a single author. The same 2 authors met regularly to review coding and address any questions that emerged to ensure consistent code application. After coding was completed, the authors discussed coded excerpts holistically to identify general themes and subthemes that differed across groups. To ensure accuracy, one author reviewed a transcript coded by the other author at the beginning and end of the coding process.

The results are categorized by the first 2 phases of deadoption from the framework proposed by Niven: (1) identifying and prioritizing low-value clinical practices and (2) facilitating the deimplementation process. These 2 phases complemented the Greenhalgh framework guiding our analysis as they further explicate specific issues related to deimplementation [11]. All qualitative analyses were conducted in Dedoose [31]. We followed the COREQ (Consolidated Criteria for Reporting Qualitative Research) (Checklist 1) as a framework for data reporting [32]. Results about the implementation of innovations and information uptake in EDs have been published in detail elsewhere (see Huilgol et al [26] and Qureshi et al [33]).

Results

Hospital and Participant Characteristics

In addition to 3 pilot interviews, we conducted 13 semistructured focus group discussions. In total, 49 clinicians from 8 hospitals participated: 24 *prescribers* (17 ED physicians and 7 APPs) in a total of 7 focus groups, ranging from 3 to 6 participants per site focus group, and 25 *other clinicians* (18 RNs and 7 RTs) in a total of 6 focus groups, ranging from 3 to 6 participants per site focus group (Table 1). Fourteen additional clinicians were invited to participate in focus groups but declined, bringing our total response rate to 78%.

Table . Hospital and participant characteristics.

Hospital ID	Region	Focus group type				Total
		Physicians (MDs[a])	APPs[b]	RNs[c]	RTs[d]	
Hospital 1	Midwest	6	0	5	0	11
Hospital 2	West	4	0	2	1	7
Hospital 3 (including 1 APP pilot)	West	3	1	5	2	11
Hospital 4	Northeast	2	1	1	4	8
Hospital 5	South	1	2	4	0	7
Hospital 6	South	0	3	0	0	3
Hospital 7 (pilot)	West	0	0	1	0	1
Hospital 8 (pilot)	West	1	0	0	0	1

Of the participating EDs, 4 EDs were in the West (3 Pacific and 1 Mountain), 2 were in the South (1 South Atlantic and 1 East South Central), 1 ED was in the Midwest (West North Central), and 1 ED was in the Northeast (Middle Atlantic). Some hospitals

XSL•FO
RenderX

had 2 focus groups within their EDs, while others only had one. Overall, clinicians averaged 11.2 (SD 7.5) years of experience in their profession as ED clinicians (mean 9.4, SD 7.9 for physicians; mean 11, SD 4.3 for APPs; mean 12, SD 8.1 for RNs; and mean 14, SD 7.5 for RTs; Table 2). In addition, 67% (33/49) identified as female, 71% (35/49) identified as White, and 6% (3/49) identified as Hispanic.

During focus groups, we asked participants about examples of innovations they or their institutions adopted and later rejected. We asked them to describe how the decision was made to reject the use of the innovation at the *individual*, *departmental*, and *institutional* levels. Textbox 2 lists examples of discontinued COVID-19 care innovations mentioned by participants in focus groups, such as intubation boxes, plasma, PPE reuse protocols, and nasal steroids.

Table . Participant demographic characteristics.

Respondent type	Number of respondents	Average years of experience, mean (SD)
APP[a]	7	11 (4.3)
Female	5	11.8 (5.0)
Male	2	9 (1.4)
ED[b] physician	17	9.4 (7.9)
Female	6	6.8 (5.7)
Male	11	10.8 (8.8)
Nurse	18	12 (8.1)
Female	16	11.4 (7.1)
Male	2	16.5 (17.7)
Respiratory therapist	7	14 (7.5)
Female	6	12.8 (7.5)
Male	1	21 (N/A)[c]
Grand total	49	11.2 (7.5)

[a]APP: advanced practice provider.

[b]ED: emergency department.

Textbox 2. Examples of discontinued COVID-19 care innovations.

- Intubation boxes/shields
- Early intubation
- Plasma
- Deep cleaning COVID-19 patient rooms
- Varieties of COVID-19 tests
- V60 (ventilator type)
- PPE reuse protocols
- Nasal steroids and fluids

We present findings related to innovation deimplementation in Table 3, with subsections on factors and processes related to deimplementation. Tables 3 and 4 highlight quotations that are representative of the major themes. We then identified the factors related to the deimplementation of COVID-19 care innovations that participants shared during focus groups.

Table . Identifying and prioritizing innovations for deimplementation: themes and illustrative quotations.

Themes	Illustrative quotation
Poor patient outcomes	*By the time we were regularly dealing with severely ill patients, it was evident from the experience—largely out of other [ED[a] group] sites but also somewhat early in the publications—that early intubation actually turned out to be a really bad idea due to bad outcomes. So, we were actually I think early adopters of not [doing] early intubation in relation to our tertiary care receiving facilities.* -MD[b], West
Little to no evidence of change	*I think it was a little bit of kind of seeing your patients with the plasma, it never really seemed to change anything. And there was also a lot of data coming out that was showing plasma, a) doesn't really seem to work and even there've been a couple of studies that were showing harm with plasma…I think we kind of just were like, eh, it doesn't really seem to be doing much and the patients it maybe gets some gains or it's very minimal and so let's just stop wasting our time with it.* -MD, Midwest
Burdensome	*I honestly don't recall there being a discussion, like, oh, these [intubation boxes] are so cumbersome to use, we're just not going to use them anymore. I don't, I think we all probably just got comfortable with our PPE[c] and I think we were pretty lucky. So maybe there are things that happened that I'm not aware of but it seems like we all did a really good job with PPE.* -MD, Midwest
Compliance	*I feel like we just realized nobody is using [telemedicine]. And that's kind of how you know that you kind of stop that process. So I think that's one, is just realizing that nobody is using that equipment or following those processes anymore. In the ED if it works people will usually stick with it or create a workaround as needed. But telemedicine is really, really hard for us to do….* -RN[d], West
Patient volume	*I think a lot of [discontinuing innovations] was if we were going to surge or not. So, they would have contingency plans, based on national predictions if things were going to surge or not. So they would be like, okay, we're having lower volumes now, so we're going to start discontinuing this. But in two weeks if it starts going back up, this is the order in which we're going to start things back.* -MD, South
Availability	*Yeah, the only thing I stopped doing was double using the N95. Because now it's available, so I don't have to. And another thing we did was to...you know, they provided more supplies which was good, so you don't have to reuse the N95. And you don't have to reuse the surgical mask which is good. And it makes everyone feel more comfortable.* -APP[e], South
Leadership	*I think one of our doctors has an ER throughput committee, and so that was brought up in that throughput committee. And he discussed it with infection prevention. And then was able through leadership to make that decision. Like, we [stopped deep cleaning rooms] before but it wasn't official and then people were questioning it. So that's when the committee got involved.* -RN, Midwest
New information	*…In the case of intubation boxes, it was a pain to use and then I think there was just like an abstract where they had done an airflow study and they showed how airflow happened and that it actually directed more viral particles back onto the [person performing the procedure] or something like that. And so then that was just the excuse that everyone needed to let us be like 'Oh, thank God,' and we got rid of that thing.* -MD, West

Table . Processes related to the deimplementation of innovations: themes and illustrative quotations.

Themes	Illustrative quotation
Leadership guidance	*I remember that we were really counting on the guidance that we were getting from our leadership in terms of what the next, you know, what the next steps were, and then obviously they were using government resources and what not to pass that guidance on to us.* - APP[a], Northeast
Collaboration among colleagues	*And so it all came down to…just [saying], "I think we should hold off" or "hey, I think we should talk to the ICU and see what they think about this because they're the ones who are gonna be managing it later down the road." And then ultimately that dialogue facilitated our own institutional changing in practice and how we approached intubation…it also evolved with the amount of information that we knew about COVID later on, saying that early intubation will not necessarily save someone's life.* -MD[b], West
No process/passive	*So I think that's one, is just realizing that nobody is using that equipment or following those processes anymore. Some other things, like we were doing the antibodies for a while, those kind of treatment plans that you don't really ever stop doing but you just realize that you don't have a patient population that fits that requirement anymore. So I can't think of a lot of things that we purposely stop. Things just kind of tend to run their course.* -RN[c], West

[a]APP: advanced practice provider.

[b]MD: medical doctor.

[c]RN: registered nurse.

Factors Contributing to Identifying and Prioritizing Innovations for Deimplementation

Clinician Experiences

During focus groups, multiple clinicians noted that the experience of observing poor patient outcomes was a common reason for discontinuing COVID-19 care innovations. For example, participants frequently mentioned early intubation as a deimplemented innovation: early in the pandemic, it was common practice to immediately intubate many patients affected by COVID-19 when they arrived at the ED as this practice was thought to be clinically beneficial. Several focus group participants shared that they stopped early intubation after their direct observation of poor outcomes. As one clinician elaborated:

> *Yeah, so we did try early intubation; we were very aggressive about it. And then I think after we realized that early intubation wasn't necessarily for temporary outcomes in patients who are on the ventilator for a long time and they get complications, learning from our ICU colleagues, and the challenges of the intubation itself are…in post-intubation. it was even harder to deal with, then we scaled it back….* [MD, West]

Witnessing poor outcomes made clinicians reconsider whether it was useful to intervene early with intubation. One participant talked about how the "initial panic" of COVID-19 caused clinicians to initiate intubation early in care processes. The results of this intervention were not always beneficial for the patient. Another clinician highlighted how tracking outcomes and data were important in deciding whether to discontinue an innovation. Relatedly, if a care innovation showed little to no evidence of change in patient outcomes, it was stopped. For example, a participant mentioned that giving patients plasma—an innovation hoped to provide antibodies to sick patients from recovered patients—was an innovation that "never seemed to change anything," with minimal gains. One ED clinician stated that giving plasma never seemed to make a difference for patients:

> *…there was also a lot of data coming out that was showing plasma doesn't really seem to work and even there've been a couple of studies that were showing harm with plasma…I think we kind of just were like, eh, it doesn't really seem to be doing much and the patients it maybe gets some gains or it's very minimal and so let's just stop wasting our time with it.* [MD, Midwest]

Additionally, intubation boxes were frequently brought up as a discontinued innovation because clinicians highlighted that they were cumbersome to use. As new evidence-based information became available, clinicians stopped using them.

Contextual Factors and Research Evidence

Participants reported that once they realized nobody was using the equipment or following procedures for certain innovations, those innovations were eventually discontinued. As one clinician stated, "the innovation[s] just ran [their] course." For example, one clinician reported that telemedicine was an innovation that was never officially discontinued but was eventually stopped due to lack of use. One participant shared that decision-making around discontinuing innovations was based on whether there was a predicted surge or high patient volume. With lower patient volumes, clinicians would discontinue certain innovations, particularly those affecting triage or physical management. Conversely, if they were predicting a high patient volume or a surge, they would restart certain innovations (eg, implementing a surge schedule with overnight coverage).

Relatedly, the availability of the innovation mattered as well. One prominent example was related to reusing PPE. Once there

XSL•FO
RenderX

were adequate supplies of N95 masks available, participants shared that they stopped reusing the PPE:

> *Yeah, the only thing I stopped doing was double using the N95. Because now it's available, so I don't have to. And another thing we did was to...you know, they provided more supplies which was good, so you don't have to reuse the N95. And you don't have to reuse the surgical mask which is good. And it makes everyone feel more comfortable.* [APP, South]

Leadership also played a significant role in identifying and prioritizing discontinued innovations. Across focus groups, participants mentioned that directions regarding innovation deimplementation came from leadership guidance or hospital-wide committees. Oftentimes, official guidance from leadership teams or committees legitimized deimplementation decisions:

> *I think one of our doctors has an ER throughput committee, and so that was brought up in that throughput committee. And he discussed it with infection prevention. And then was able through leadership to make that decision. Like, we [stopped deep cleaning rooms] before but it wasn't official and then people were questioning it. So that's when the committee got involved.* [RN, Midwest]

Finally, as research evidence on different care processes and new innovations emerged, such as high-flow oxygen, clinicians realized that they were able to disregard early intubation and its associated risks and replace it with other modalities. A clinician noted that utilizing other innovations led to the deimplementation of early intubation:

> *…as time went by, we started to use high flow [oxygen], we started other modalities and were able to avoid [early] intubation.* [RT, Northeast]

Early intubation quickly ceased to be viewed as a standard of care and was described as a discontinued innovation by multiple focus groups.

Processes Related to the Deimplementation of Innovations

Leadership Guidance

The process of deimplementing innovations occasionally included some sort of leadership or committee. The decisions were made and applied hospital-wide, usually in tandem with Centers for Disease Control and Prevention guidance or other government resources. As one participant shared, "We had a couple APPs who started using [ivermectin] in the beginning. And then once we got some leadership direction, it stopped. But we had a couple that did." Another clinician underscored the importance of leadership for guidance during the process of discontinuing innovations:

> *I remember that we were really counting on the guidance that we were getting from our leadership in terms of what the next steps were…* [APP, Northeast]

Collaboration Among Colleagues

Collaboration between hospitalists and colleagues was another commonly discussed topic during focus groups when asked about deimplementation. For example, one clinician stated:

> *[with] every COVID patient, we were really thinking out loud. We were just kind of having open conversations about disposition for each of them, just because it wasn't standardized. It wasn't like a kidney stone that we kind of knew the process. I think every patient was truly thought out loud and it was really kind of a team-based decision.* [APP, South]

Additionally, during early intubation, clinicians shared how they would discuss the process with other clinicians in the intensive care unit and determined what worked best for the patient. A clinician described how the approach of early intubation evolved and was eventually discontinued—the process involved multiple factors, such as discussing with colleagues in the intensive care unit, sharing information, and examining outcomes:

> *And so it all came down to…just [saying]… "Hey, I think we should talk to the ICU and see what they think about this because they're the ones who are going to be managing it later down the road." And then ultimately that dialogue facilitated our own institutional changing in practice…it also evolved with the amount of information that we knew about COVID later on, saying that early intubation will not necessarily save someone's life.* [MD, West]

No Process/Passive Deimplementation

Sometimes, however, there was no process to officially deimplement innovations; it was passive. One participant shared that they stopped using monoclonal antibodies because the patient population for it had declined. The clinician stated,

> *So I think that's one, is just realizing that nobody is using that equipment or following those processes anymore…Some other things, like we were doing the antibodies for a while, those kind of treatment plans that you don't really ever stop doing but you just realize that you don't have a patient population that fits that requirement anymore. So I can't think of a lot of things that we purposely stop.* [RN, West]

In these cases, it seems that enough people simply stop doing something, without any central decision or authority, to the point that it is no longer used.

Discussion

Principal Findings

While there have been calls to identify and reduce low-value care before [18,33,34] and during [35] the COVID-19 pandemic, this study adds to what is known about innovation deimplementation during the pandemic by characterizing the factors and processes that led ED clinicians to decide to discontinue using COVID-19 care innovations. Overall, clinicians highlighted that patient outcomes, collaboration and discussion with ED colleagues, supply availability, and protocols

XSL•FO
RenderX

from leadership as factors that contributed heavily to decisions about sustaining or deimplementing innovations in EDs during the COVID-19 pandemic.

Prior studies show that, in routine conditions, enablers of effective low-value care deimplementation include leadership commitment, provider engagement, provider training, performance feedback to providers, and shared decision-making with patients [18,35]. Under usual conditions, deimplementation involves strong external support, provider engagement, and training and education to impact knowledge and behavior; therefore, it is typically a slow process [36]. Fundamental to its goals, the deimplementation of health services involves engaging with and changing the behavior of health care providers. A recent systematic review of determinants of deimplementation found that health care provider knowledge, expectations, attitudes, and behaviors are key determinants of deimplementation [37]. In addition, a central concern of health care providers is the trust that the deimplementation effort is necessary and will not harm patients currently receiving a low-value treatment, while also improving patient health in the long term. This requires building support and buy-in for deimplementation from front-line staff [38]. Clinicians need both motivation and support to properly facilitate deimplementation. Our findings confirm the importance of leadership, collaboration, and discussion with ED colleagues for the deimplementation of newly adopted innovations.

However, the speeds and processes for innovation deimplementation differ significantly during a public health emergency compared to more stable time periods in terms of scientific discoveries related to health. For example, hydroxychloroquine was once thought to be potentially helpful before evidence ultimately discouraged its use. Bradley et al [39] examined hydroxychloroquine deimplementation and found that the proportion of hospitalized patients receiving hydroxychloroquine in 2020 decreased drastically over the span of a few months (55.2% in March and April, 4.8% in May and June, and 0.8% in July and August). The authors hypothesize that this was because hydroxychloroquine was not deeply entrenched in hospital practice; the deimplementation of long-standing innovations may be more challenging due to the sunk cost fallacy and loss aversion [40]. Clinicians may have been more amenable to rapid deimplementation due to awareness of their own limited knowledge, along with the limited evidence-based information and the rapidly changing information during the pandemic, the latter of which was a factor related to innovation deimplementation that we identified during focus groups.

Although there are some conceptual frameworks and criteria for innovation and intervention deimplementation, they may not adequately describe the factors affecting deimplementation during rapidly evolving situations, such as the COVID-19 pandemic [22]. Much of the deimplementation literature focuses on stopping long-standing low-value care, whereas during the pandemic, many discontinued practices were short-term and context-dependent as new evidence emerged [9,10,18,33]. The pace and timing of discontinuing innovations in ED settings during COVID-19 was a major distinguishing factor. The 3 criteria posed by McKay et al [9] to identify if interventions are appropriate for deimplementation (ie, interventions that are "not effective or harmful," "not the most effective or efficient to provide," and "that are no longer necessary") also may fall short in describing conditions during the COVID-19 pandemic because decisions about innovations had to be made in the absence of evidence-based information about innovation efficacy, harm, and efficiency.

Overall, innovation deimplementation in ED settings during the COVID-19 pandemic was different from typical deimplementations due to a lack of information as well as the rapid evolution of information in response to emerging and dynamic environments. Clinicians tended to discontinue the innovation if leadership support, evidence-based information, funding, or resource availability were limited. We also found differences between innovations that were actively stopped due to poor outcomes and new evidence emerging, such as early intubation and intubation boxes, and those that were stopped due to passive processes or a lack of necessity. Prior deimplementation models and frameworks do not account for circumstances where deimplementation is unintentional. Passive deimplementation of innovations may require additional clinician autonomy and greater flexibility, whereas active deimplementation involves highly formalized and structured pathways. Active deimplementation is more difficult compared to passive deimplementation because passive deimplementation occurs without follow-up and drastic changes to practice.

These findings have implications for public health emergency situations. Our focus groups suggest that institutions will be most able to quickly adopt and deimplement innovations informed by local conditions, such as leadership, patient volume, replacement, new information, compliance, and availability, as described above. While prior research identified several other factors that are linked to deimplementation, such as fear of medical malpractice, revenue, competitive advantage, and liability [18], those factors were less relevant in the high-pressure fast-paced environment at the beginning of the pandemic. Our findings also show that factors around deimplementation during a public health emergency were highly localized and akin to a pilot-testing approach—innovations were often hospital-specific and performed at a local scale. Using limited knowledge, clinicians were willing to try and adopt innovations rapidly within their organizations, and the level of evidence needed to implement the innovations was much lower. However, when new evidence-based information became available, clinicians also had to be willing to deimplement those tested innovations quickly. Future public health emergencies will require rapid evaluation and will likely be driven by a narrower group of factors than during normal times.

At the same time, as seen through the Greenhalgh framework, overarching factors that are important for implementation and deimplementation in normal times are still needed during public health emergencies, such as stakeholder engagement, leadership buy-in, and organizational readiness [11,36]. In the future, we should prepare for and embrace the adoption of innovations with limited data, with the willingness to easily deimplement as those data appear and with the knowledge that the deimplementation of innovations used for shorter periods of time may be easier [38,40,41].

XSL•FO
RenderX

Limitations

Because our focus groups were conducted 2 to 3 years after March 2020, recall bias may have influenced ED participants' self-reported experiences. Additionally, despite recruiting from a diverse set of EDs, our sample is not nationally representative, and we do not have information on those who declined to participate in the focus groups. We also do not believe our results are generalizable, but they have been influential in informing the development of a nationwide survey that will be administered to ED physicians and nurses about implementation and deimplementation during the COVID-19 pandemic. Some of the focus groups were coded by only 1 coder, but the interrater reliability of dually coded transcripts was high [42]. Finally, at the time of writing this article, many COVID-19 care innovations implemented and deimplemented in the early stages of the pandemic now have more evidence to support their benefit or lack thereof.

Conclusion

ED clinicians are critical to the response to disease outbreaks, such as the COVID-19 pandemic. During uncertain times, clinicians must rapidly implement new protocols and practices and assess these changes in real time under uncertain and potentially dangerous conditions. Stopping unhelpful or harmful practices appropriately is equally important. This study is unique because it examined sustainability and deimplementation during a time of uncertainty and identified unique factors and processes that affect the decision to deimplement innovations, such as poor outcomes, patient volume, availability, and leadership support, when trying to choose the best approach to treating an acute and serious disease.

Acknowledgments

The authors would like to acknowledge and thank the participating emergency department clinicians who offered their time and insights to the study. Generative artificial intelligence was not used in manuscript preparation.

Abstract

Background: Waning immunity and recurring COVID-19 waves point to the importance of sustained booster vaccination strategies. With repeated boosters needed to sustain population-level immunity, evaluating public preferences for COVID-19 booster vaccination is important for informing future vaccination strategies, as changing perceptions of urgency, threat, and motivation may alter willingness to receive vaccine boosters compared with initial uptake.

Objective: This study aimed to explore the public's stated preferences and implicit willingness to pay for COVID-19 vaccine boosters in Singapore and to identify the sociodemographic factors and health-risk acceptance profiles associated with these outcomes.

Methods: A discrete choice experiment survey was conducted among the general population in Singapore, recruited from an online panel in June 2022. Discrete choice experiment scenarios presented hypothetical scenarios varying by booster characteristics, including effectiveness, protection duration, and cost, and risks of COVID-19 infection, hospitalization, and death. A 2-stage discrete choice design was used: participants first selected between 2 hypothetical scenarios and then reported real-life booster acceptance of their chosen option. A mixed logit model was used for analyses. We also estimated implicit willingness to pay for vaccine boosters, as well as assessed the associations of sociodemographic factors and health-risk profiles with booster acceptance or hesitancy.

Results: A total of 1567 participants were included in the analysis. Overall, respondents preferred boosters that offered a longer duration of protection, particularly under higher risks of COVID-19 infection and death. Respondents were willing to pay S$1.43 for every percentage-point increase in booster effectiveness, S$4.95 (S$1=US $0.77 as of July 10, 2026) per additional month of protection, and an additional S$55.23 for a vaccine booster under the hypothetical worst-case scenario of COVID-19. Younger adults, women, individuals of non-Chinese ethnicity, those without children, people with higher socioeconomic status, individuals who had received 2 or fewer COVID-19 vaccine doses, and those with chronic conditions or on chronic disease medication were more likely to receive a booster. On the other hand, older adults, individuals with lower education or socioeconomic status, those with prior COVID-19 infection, and those exhibiting higher health-risk acceptance were less likely to accept booster vaccination.

Conclusions: Our findings demonstrate how vaccine attributes, sociodemographic factors, and health-risk attitudes influence booster acceptance. These insights can guide policymakers in tailoring strategies and communication efforts that address population needs and behavioral drivers to improve booster uptake, address hesitancy, and support sustainable long-term immunization coverage, contributing to adaptive vaccination planning in the ongoing management of COVID-19.

KEYWORDS

population preferences; booster vaccination; social determinants; vaccine acceptance; vaccine hesitancy

Introduction

Over 3 years into the COVID-19 pandemic, the World Health Organization declared the end of the Public Health Emergency of International Concern on May 5, 2023 [1]. As the pandemic transitioned into an endemic phase, many countries resumed prepandemic norms. However, the shift to endemicity does not imply that SARS-CoV-2 has become less transmissible or less virulent. Historical experiences with past influenza pandemics have shown that periodic outbreaks can occur during the endemic phase, influenced by factors such as the emergence of new viral variants, changes in population immunity, vaccine

XSL•FO
RenderX

coverage, and the implementation of public health and social measures [2].

Epidemiological studies show that COVID-19 exhibits a cyclical pattern of waves during its endemic phase [2,3]. Furthermore, according to surveillance data on SARS-CoV-2 activity globally monitored by the Global Influenza Surveillance and Response System, there have been periodic peaks observed over the past few years [4]. In May 2025, several Asian regions, including Hong Kong, Thailand, Singapore, and China, reported a resurgence of COVID-19 cases [4-6]. Health authorities attributed this surge to the emergence of a highly transmissible COVID-19 variant, increased social interactions during festivities, and waning population immunity [6,7]. These developments underscore the ongoing threat posed by SARS-CoV-2 and highlight the need for sustained immunological protection.

Protective immunity through vaccination remains critical in the fight against COVID-19. However, evidence shows that vaccine-induced immunity wanes over time, potentially leading to increased susceptibility to infection and severe outcomes [8,9]. This has reinforced the importance of routine COVID-19 booster vaccinations to maintain sufficient population-level immunity and mitigate severe outcomes, particularly among vulnerable groups. Therefore, it is imperative to better understand the public's attitudes toward COVID-19 vaccine boosters.

COVID-19 vaccines have demonstrated varying levels of effectiveness and durability against infection, hospitalization, and death [10]. Understanding the trade-offs associated with COVID-19 vaccine boosters—such as the balance between vaccine effectiveness, durability, risks associated with COVID-19, and booster out-of-pocket costs—is critical for informing adaptive and effective vaccination strategies. These insights can guide public health decisions on optimal booster intervals, target populations, and allocation of health care resources, while also accounting for opportunity cost and public acceptability. In this study, we assessed these trade-offs using a discrete choice experiment (DCE), which is a preference elicitation technique commonly used to determine the relative importance of different factors influencing people's choices when choosing between alternatives. Several DCE studies have explored public preferences for COVID-19 vaccinations [11], but there is a lack of studies focusing on booster vaccination decisions [12,13]. Public acceptance of boosters may shift from initial vaccination uptake as perceived urgency and threat decline, pandemic fatigue sets in, and trust in vaccine safety evolves [14]. Reassessing public preferences during the transition from pandemic response to endemic management is important for anticipating future booster uptake under changing conditions. Such evidence is crucial for informing public health policies, optimizing booster schedules, and tailoring communication strategies to sustain population-level immunity.

This study aimed to explore the public's stated preferences and implicit willingness to pay (WTP) for COVID-19 vaccine boosters in Singapore and to identify the sociodemographic factors and health-risk acceptance profiles associated with these outcomes. The results will enable differentiated outreach and health-risk communication based on various profiles of vaccine booster acceptance. They will also allow policymakers, community leaders, and researchers to identify key target groups and roll out targeted measures and interventions to increase vaccine booster uptake.

Methods

Study Participants

The study was a cross-sectional online survey administered through the Singapore Population Health Studies Online Panel, approved by the National University of Singapore Institutional Review Board (NUS-IRB; reference number: H-18 - 011). This panel served as an online research platform that facilitated public health research on a diverse range of topics through monthly surveys related to public health. When the survey was conducted, the panel comprised 2058 active participants who were demographically representative of the general population of Singapore.

Setting

Singapore is a city-state nation located in Southeast Asia with a population of over 5.7 million. Following the first COVID-19 case detected in January 2020, Singapore increased social distancing measures, with an eventual 2-month national partial lockdown (termed a circuit breaker) in April 2020 [15]. The COVID-19 vaccines were first introduced in Singapore in December 2020 [16]. Subsequently, a COVID-19 vaccine booster program was introduced in Singapore in September 2021 for older adults, residents of aged care facilities, and individuals with weakened immune systems, which was then gradually expanded to all other age groups [17]. In January 2022, it was announced that all individuals aged 18 and older would need to receive a vaccine booster no later than 270 days after their primary vaccination series to maintain their fully vaccinated status [18]. The survey was administered in June 2022, during the period when this policy was still in force.

As the pandemic situation stabilized, Singapore announced the easing of COVID-19 measures and the transition to an endemic phase of COVID-19 in February 2023 [19]. The nation has since been living with the endemic new normal; however, routine COVID-19 vaccination was still regarded as an important key preventive measure against severe COVID-19 illness and hospitalization [19,20].

Survey Structure

The survey was designed with 2 main parts. The first part presented participants with two sets of DCEs, each with seven choice tasks, to elicit (1) the public's level of acceptance of and WTP for COVID-19 vaccine boosters and (2) the nonpharmaceutical intervention measures they would be inclined to trade off if they did not want to receive and/or pay for the vaccine boosters. This manuscript focuses on the discussion of the first DCE, as the second DCE is of a different study design, with the results published elsewhere [21].

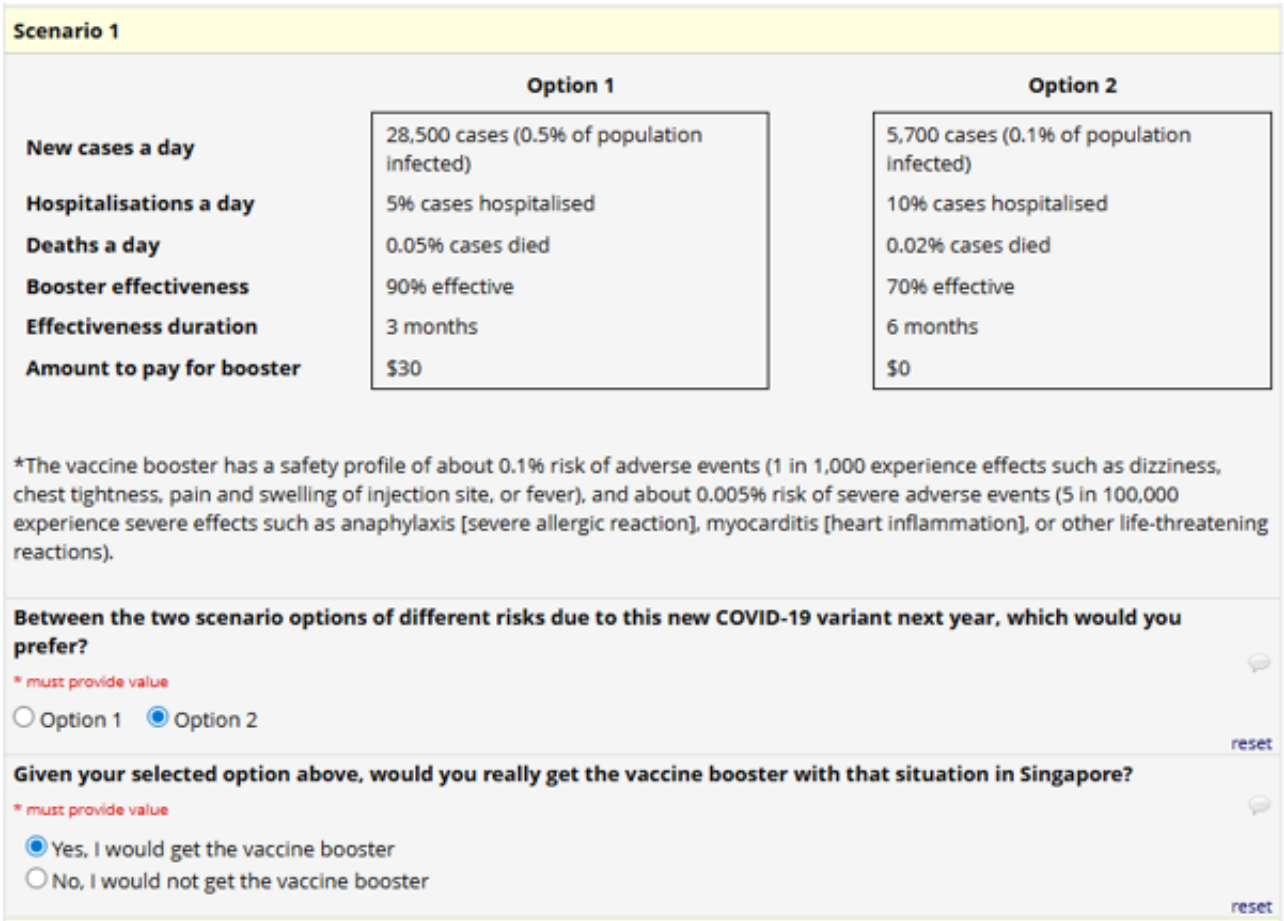
The second part of the survey consisted of 41 questions that collected sociodemographic information and assessed the level of risk acceptance and tolerance in the health domain using the

XSL•FO
RenderX

Health Risk Attitude Scale (HRAS-13). The HRAS-13 is a psychometric instrument measuring risk attitudes in the health domain [22], which has demonstrated strong reliability and has been used in various population surveys and WTP studies [23,24].

DCE Design

Selection of Attributes and Levels



The DCE scenarios presented a combination of different levels of the various factors of interest, focusing on vaccine booster characteristics against different risks of COVID-19 in Singapore, with the following attributes tested: (1) new cases a day: personal risk of COVID-19 infection, (2) hospitalizations a day: personal risk of hospitalization due to COVID-19, (3) deaths a day: personal risk of death from COVID-19, (4) booster effectiveness: effectiveness of the booster shot against the dominant strain, (5) effectiveness duration: duration of the booster shot maintained its level of efficacy, and (6) amount to pay for booster: the out-of-pocket booster cost.

The selection of attributes corresponding to the risks of COVID-19 was based on commonly reported statistics in news articles and press releases by the health authorities (ie, daily numbers of new COVID-19 cases, hospitalizations, and deaths), with which the respondents would be familiar [25]. The levels for the COVID-19 risk attributes were determined based on reasonable event rates relative to Singapore's population size, supplemented by informal consultations with researchers familiar with the local epidemiological context. The attribute levels for vaccine booster's effectiveness and effectiveness duration were selected based on what was similarly presented in the literature [26,27].

Experimental Design

The DCE questions were designed using Sawtooth Software Inc's Lighthouse Studio (version 9.8) [28]. The DCE used an unlabeled choice-based conjoint design with a "dual-response none" approach. Participants were presented with a choice task consisting of 2 scenarios for them to choose in the first stage, followed by a second-stage question regarding a "no-choice option." In the second stage, participants were asked whether they would get themselves vaccinated with a booster shot in real life given the COVID-19 situation illustrated in the option they selected in the first stage. Vaccine booster acceptance and hesitancy were defined based on participants' responses to the second-stage question of the DCE tasks. Participants who answered "Yes, I would get the vaccine booster" were classified as demonstrating booster acceptance, while those who answered "No, I would not get the vaccine booster" were classified as demonstrating booster hesitancy. An example of a DCE choice task is presented in Figure 1.

Figure 1. Sample of discrete choice experiment choice task.

A simulation exercise was conducted to examine the coverage matrix of the design and test the required sample size. A preliminary power analysis was conducted for the 2 DCEs. A rule of thumb has been proposed for determining the minimum

XSL•FO
RenderX

sample size for aggregate-level full-profile choice-based conjoint modeling: n ≥500 *c*/*ta*, where n is the number of respondents, *t* is the number of choice tasks, *a* is the number of alternatives per task (not including the none alternative), and *c* is the largest number of levels for any attribute [29,30]. By this formula, the required number of respondents was 167. We tested the DCE designs using the Test Design function within the software. The projected standard errors for each attribute level of both DCEs were all less than 0.05.

The DCE survey underwent 2 rounds of user acceptability testing to obtain feedback on suitability, ease of understanding and phrasing, and survey length. The survey and the DCEs were refined before being rolled out to the full panel.

Each participant was randomly assigned to one of the 20 DCE questionnaire sets. Each questionnaire set had 6 unique choice tasks, totaling 120 unique choice tasks, and an additional dominant choice task for a logic check. As this was an online self-administered survey and the DCE questions can be relatively complicated compared with typical survey questions, we took a precautionary step to ensure the quality of responses by applying a dominance test, whereby one of the two choice alternatives was clearly superior. The dominance task helped to identify participants who did not understand the DCE questions or responded randomly without meaningful processing of the choice tasks. Participants who failed the dominance test were excluded from the analysis.

Statistical Analysis

The DCE data were analyzed using a mixed logit model [31] in the following 3 steps.

Overall Preferences for COVID-19 Vaccine Boosters and WTP

First, a mixed logit model was used to understand participants' overall level of acceptance of and WTP for vaccine boosters, as well as their preferences for COVID-19 vaccine boosters based on booster effectiveness and effectiveness duration. The mixed logit model considers preference heterogeneity for the attributes of the alternatives while accounting for random preference heterogeneity at the individual level.

The random utility U_{ij} of individual *i*, for attribute *j*, where x_{ij} is a vector of observed variables describing the attributes of the alternatives $_{ij}$ and is the idiosyncratic error term assumed to follow a type 1 extreme value distribution, was specified as

(1)Uij=βi×xij+ ij

where the term is

(2)βi=β+ηi

The η_i term follows a multivariate normal distribution representing the random preference heterogeneity, which includes all unobserved factors that affect individuals' preferences. The model assumes a linear combination of each utility component, including additional variables for (1) "none option," which captures the participants' responses in the second stage of each choice task and (2) left-and-right bias, which accounts for the tendency of participants to select only options presented on the left or the right [32].

The COVID-19 risk attributes were treated as discrete variables in the model. The price and characteristics of the vaccine booster were treated as continuous variables in the model based on the tabulation pattern of the levels of each attribute and the percentage of selections, which demonstrated a linear trend. Model selection was based on the Bayesian information criterion, comparing the model using continuous values with the model using discrete values for the 3 attributes of price, effectiveness, and protection duration of the vaccine booster, one variable at a time. The model with the minimum Bayesian information criterion value was selected.

The WTP was estimated as the ratio of the utility parameter for each attribute to the cost attribute, which was the out-of-pocket payment for a vaccine booster under the hypothetical context of this study. These estimates represent the marginal WTP for a change in a specific attribute level. For example, a WTP estimate for vaccine effectiveness reflects the additional amount respondents were willing to pay for an increase in effectiveness relative to the reference level. The WTP was presented in Singapore dollars (S$) denomination.

(3)WTP=−βjβbooster price

Preferences for COVID-19 Vaccine Boosters When Facing Higher Risks of COVID-19

Second, the mixed logit model included 2-way interactions between the characteristics of the vaccine booster and the risks associated with COVID-19 to examine how preferences for the vaccine booster's characteristics varied with the risks of COVID-19 infection, hospitalization, and death. The 2 attributes, booster effectiveness and booster effectiveness duration, were interacted with the highest levels of the risks of COVID-19 attributes (ie, 57,000 new cases [1% of the population infected], 10% cases hospitalized, and 0.1% of cases died per day, respectively). The preference weight coefficients of the interaction terms indicated the changes in preference weights as the levels of booster effectiveness and booster effectiveness duration increased under each scenario of COVID-19 situation.

Demographic Factors Associated With COVID-19 Vaccine Booster Acceptance or Hesitancy and Characteristics of Vaccine Booster

Third, the mixed logit model was used to assess the impact of demographic factors on the level of acceptance of and WTP for vaccine boosters, and on preferences for vaccine boosters based on their characteristics. Hence, the β_i term in Equation (1) was specified as

(4)βi=β+γzi+ηi

where is the demographic variables of individual *i* that influence the mean of each attribute coefficient, and γ is the matrix of parameters measuring differential preferences by demographic variables. The impact of demographic factors on each attribute was considered one at a time. Only the terms with *P* values <.10 were kept in the final model. In the final model, positive coefficients indicate lower utility for booster acceptance and, therefore, greater hesitancy to accept the booster relative to the reference group, while negative coefficients indicate

XSL•FO
RenderX

higher utility for booster acceptance and, therefore, greater willingness to accept the booster relative to the reference group.

Demographic factors that were considered included gender, ethnicity, age group, marital status, education level, employment status, housing type, family with children, family with children younger than 5 years, COVID-19 vaccination status, personal history of COVID-19 infection, having chronic diseases and taking medications for chronic diseases, and HRAS-13 score measuring health-related risk attitudes. Age was classified into 3 categories: younger than 40 years, 40 to 60 years, and older than 60 years. Ethnicity was classified into 2 categories: Chinese and non-Chinese (Malay, Indian, or others). Marital status was classified into 2 categories: married and not married (single, divorced, or widowed). Participants with a secondary school education or below were considered to have lower education, while participants with postsecondary school or tertiary education levels were considered to have higher education. Employment status was classified into 2 categories: full-time and part-time or not working. Information on housing type was used as a proxy for socioeconomic status (SES) [33], which was classified into 3 categories: 1- to 3-room public housing (low SES), 4- to 5-room public housing (middle SES), and private housing (high SES).

The HRAS-13 score was derived from a set of 13 questions, with participants rating their attitudes toward health risks on a 7-point Likert scale. The score was calculated by summing the 13 questions (some were reverse scored), and a higher score is indicative of having a higher level of risk acceptance in the health-related domain. The HRAS-13 score was modeled as a continuous variable.

For the analysis of booster acceptance or hesitancy, the base reference population consisted of those who were male, of Chinese ethnicity, aged 40 to 60 years, married with children but had no children under the age of 5 years, full-time workers, of middle SES, with a lower education level, had no previous COVID-19 infection, had received at least 3 shots of COVID-19 vaccine, had no chronic diseases, and had an HRAS-13 score of 0.

The level of statistical significance was set at $P<.05$. All statistical analyses were carried out using R software (version 4.2.2) [34].

Ethical Considerations

Singapore Population Health Studies Online Panel members had previously provided informed consent as part of a master ethical approval to participate in the panel (NUS-IRB reference number: H-18 - 011). The members received notification by email and/or SMS text messages about this survey on June 20, 2022, to access the survey via the provided link and were given 10 days to complete the survey on the REDCap platform. At the start of the online survey, participants were presented with a participant information sheet. Participation in the survey was voluntary and anonymous, and participants only proceeded to the survey questions after acknowledging that they had read and received a copy of the participant information sheet. Ethical approval and a waiver of documented informed consent were obtained for this study from the National University of Singapore Institutional Review Board (reference number: NUS-IRB-2020 - 82). To ensure anonymity, no personal identifiers were linked to the survey responses. Participants were reimbursed S$15 (S$1=US $0.77 as of July 10, 2026) upon survey completion.

Results

Participant Characteristics

A total of 1651 survey responses were received from the 2058 active participants on the online research platform, corresponding to a response rate of 80.2%. Of the 1651 survey respondents, 84 were excluded; 83 respondents failed the dominance test, and 1 respondent indicated an age less than 18 years old. Among the 1567 included respondents (Table 1), the majority were female (n=914, 58.3%), of Chinese ethnicity (n=1337, 85.3%), married (n=999, 63.8%), had no chronic disease (n=1238, 79%), had attained postsecondary or tertiary education (n=1211, 77.3%), lived in 4- to 5-room public housing (n=1005, 64.1%), had children (n=917, 58.5%), and worked full-time (n=877, 56.0%). Most of them reported that they had received at least 3 doses of COVID-19 vaccine (n=1443, 92.1%) and had not contracted COVID-19 (n=940, 60%). Slightly less than half of the included respondents (n=700, 44.7%) were aged 40 to 60 years. The HRAS-13 score had a mean of 41.89 (SD 7.90); a higher score indicates higher health-risk acceptance.

Table 2 shows the appearance and selection frequencies for the different levels of the attributes used in the DCE. In about one-fifth of the choice tasks, respondents chose not to accept the vaccine booster given their options made in the first stage of the choice task.

XSL•FO

None option (unwilling to take vaccine booster)	9402	2045 (21.8)

Overall Preferences for COVID-19 Vaccine Boosters and WTP

Table 3 summarizes the utility, or preference weight, from the mixed logit model. There was no evidence of left-and-right bias in choice selection (left=0.02, 95% CI –0.05 to 0.09; P=.48). Overall, the level of acceptance of the vaccine booster was high (coefficient for the none option=–6.58, 95% CI –6.91 to –6.24; P<.001), with a predicted uptake probability of 99.9% (95% CI 99.8% to 99.9%; P<.001). However, the random preference heterogeneity at the individual level for vaccine booster acceptance or hesitancy was large (SD for the none option=5.63, 95% CI 5.24 to 6.02; P<.001), indicating heterogeneous preferences among the respondents with respect to their decisions regarding accepting the vaccine booster in the real-world decision-making contexts.

XSL•FO
RenderX

The pattern of the estimated utilities for the attribute levels of risks of COVID-19 and vaccine booster characteristics was consistent with the expected utility theory [35]. Higher disutilities were exhibited for higher levels of risks of COVID-19, with increasing numbers of daily new cases, hospitalizations, and deaths. There were stronger preferences for a vaccine booster that offered stronger protection against COVID-19 in terms of its effectiveness and the duration of protection from COVID-19 variants. The relative utility increased with booster effectiveness (coefficient=0.05, 95% CI 0.04 to 0.05; *P*<.001) and booster effectiveness duration (coefficient=0.16, 95% CI 0.14 to 0.18; *P*<.001).

The WTP was generated using the coefficient of booster price as the base. The average WTP value for every percentage-point increase in booster effectiveness was S$1.43, and S$4.95 for every month increase in the duration of booster effectiveness. Respondents were willing to pay an additional S$55.23 for a vaccine booster under the hypothetical worst-case scenario of COVID-19 as presented in the DCE.

Table . Mixed logit model regression results.

Variable	Coefficient (95% CI)	*P* value	WTP[a]
Left	0.02 (−0.04 to 0.09)	.48	—[b]
None option	−6.58 (−6.91 to −6.24)	<.001	—
57,000 new cases	−0.60 (−0.69 to −0.51)	<.001	−18.59
28,500 new cases	−0.30 (−0.39 to −0.21)	<.001	−9.32
10% of cases hospitalized	−0.53 (−0.62 to −0.43)	<.001	−16.20
5% of cases hospitalized	−0.26 (−0.35 to −0.17)	<.001	−7.96
0.10% of cases died	−0.66 (−0.76 to −0.57)	<.001	−20.45
0.05% of cases died	−0.26 (−0.35 to −0.18)	<.001	−8.15
Booster effectiveness	0.05 (0.04 to 0.05)	<.001	1.43
Booster effectiveness duration	0.16 (0.14 to 0.18)	<.001	4.95

Preferences for COVID-19 Vaccine Booster When Facing Higher Risks of COVID-19

Results shown in Table 4 indicate that under the scenarios with the highest numbers of daily new cases and daily deaths, individuals' utility for booster effectiveness duration further increased (coefficient=0.06, *P*<.005, respectively). However, people became more price sensitive in the scenario with the highest number of daily deaths (coefficient=−0.01, 95% CI −0.01 to −0.00; *P*=.04).

Demographic Factors Associated With COVID-19 Vaccine Booster Acceptance or Hesitancy and Characteristics of Vaccine Booster

Of the 1567 included respondents, 1469 provided complete demographic information and were included in this analysis. Ninety-eight respondents were excluded due to “Prefer not to say” responses. Demographic factors associated with vaccine booster acceptance were female, non-Chinese ethnicity, aged younger than 40 years, having no children, high SES (defined as living in private housing), having received 2 shots of COVID-19 vaccine or less, having a chronic disease, and on chronic disease medication. On the other hand, vaccine booster hesitancy was noticed among those aged older than 60 years, with a lower education level, low SES (defined as living in 1- to 3-room public housing), who had previously contracted COVID-19, and with higher health-risk acceptance (see Figure 2). However, there were no strong associations observed between demographics and characteristics of vaccine booster. Results are provided in Multimedia Appendix 1.

Discussion

Principal Results

This study examined the associations between sociodemographic characteristics, individual health-risk profiles, and public preferences for COVID-19 vaccine boosters, including out-of-pocket cost, among the Singapore population using a DCE. Overall, our study showed that booster preferences varied across sociodemographic and health-risk subgroups. Individuals with lower educational attainment (coefficient=2.22, 95% CI 1.83-2.63), older adults (coefficient=0.59, 95% CI 0.34-0.85), and those living in smaller public housing types (coefficient=0.34, 95% CI 0.01-0.69) showed lower acceptance of vaccine boosters, underscoring persistent socioeconomic gradients in booster uptake. Health-risk profiles also played an important role; we found that individuals with higher health-risk acceptance were less likely to accept booster vaccination (coefficient=2.37, 95% CI 1.77-2.97). These findings provide important insights into the key drivers of booster vaccination decisions and highlight critical subgroups that may require tailored communication and policy interventions to sustain booster uptake.

Comparisons With Prior Work

Respondents were willing to pay more to gain the benefit, that is, an additional S$4.95 for every month increase in the duration of vaccine booster effectiveness. These findings imply that the risks of COVID-19 may influence people's WTP for vaccines. Respondents were willing to pay a much higher amount (ie, an additional S$55.23) for vaccine boosters to avoid the hypothetical worst-case scenario of COVID-19. The estimated average WTP value for every unit percent increase in booster effectiveness was S$1.43, which was much lower than that reported in the Australian study for COVID-19 vaccine (ie, Aus $23.92) [36]. This finding was not unexpected, as people are less willing to pay for the vaccine out of pocket considering the recurring costs of repeated vaccine boosters required. Additionally, Singapore has provided and continues to provide the COVID-19 vaccines and the booster doses free of charge.

In the multivariable analysis, we found that the health-risk profile and several sociodemographic characteristics, including age, gender, ethnicity, education level, SES, having children, chronic conditions, COVID-19 vaccination status, and previous history of COVID-19 infection, were associated with vaccine booster acceptance or hesitancy. Our findings identified that individuals with higher health-risk acceptance were less likely to accept a vaccine booster and preferred a vaccine booster with lower effectiveness. Moreover, our findings of greater booster acceptance among those who did not complete their primary vaccination series, had a chronic disease, and were taking medication for a chronic disease also provide evidence that individuals with higher risks of COVID-19 infection had a higher utility for vaccine boosters.

We found that individuals who reported that they had contracted COVID-19 were more hesitant to accept the vaccine booster. A study showed that natural immunity provides a comparable

XSL•FO
RenderX

level of protection against new COVID-19 infection as vaccine-induced immunity [37]. Those with a previous history of COVID-19 infection might feel confident in the protection by infection-induced immunity and/or not be too concerned about the effects of an infection. As such, they might deem an additional booster dose as redundant [38]. Interestingly, we found that individuals with no children were more likely to accept boosters, suggesting that individuals with and without young dependents may perceive the risks and benefits of vaccine boosters differently for adults and children. As of April 2023, the Singapore Ministry of Health reported that more than two-thirds of children aged 5 to 11 years had not completed the vaccine doses required for minimum protection against COVID-19 [39]. Despite having confidence and trust in the COVID-19 vaccine for adults, parents, who are often the decision makers of child vaccination, may have concerns about the safety of the COVID-19 vaccine for their children and may reject booster doses for themselves when they are hesitant to vaccinate their children [40,41].

Our findings corroborate previous literature showing greater booster hesitancy among those with lower educational attainment [41-43] and greater booster acceptance among those with high SES groups [42,44] and those with a chronic disease [45]. On the other hand, we found some contrary results compared to previous studies. Our findings identified that there was greater booster acceptance among females, while the opposite was previously found in a meta-analysis [42]. A previous study conducted in Singapore found no gender differences in COVID-19 vaccine hesitancy [46]. However, greater vaccine acceptance was observed among females in a population-based study conducted in Hong Kong [47].

Although most studies have reported lower COVID-19 booster hesitancy among older adults [41,42,48], this study found that booster hesitancy was higher among older adults, whereas younger individuals exhibited greater acceptance of COVID-19 booster doses in the multivariable-adjusted model. Our findings are consistent with a recent systematic review and a study from Malaysia that found higher levels of booster hesitancy among older adults, suggesting that age-related differences in booster acceptance may vary across populations and contexts [43,49]. Furthermore, recent national data from Singapore indicated that, as of June 2024, booster vaccination rates among older adults aged 60 years and older remained low, lending further support to our findings [50]. Greater effort should be put forth on educational campaigns and in targeting public health messaging to individuals of older age, lower educational attainment, and lower SES to improve vaccine booster uptake among these subpopulations. This study also found that individuals of non-Chinese ethnicity were more likely to accept vaccine boosters, suggesting that the efforts made by the government and Muslim religious authorities to reduce vaccination barriers among minority groups have been effective in addressing earlier hesitancy [46].

The predicted booster uptake probability observed in this study was high, nearly 100%. Respondents may have been influenced by the prevailing policy environment, specifically the booster vaccination recommendations and the requirement to maintain fully vaccinated status, both of which were introduced in early 2022 and remained in effect at the time of data collection. This may partly reflect the broader policy environment, as well as social desirability bias in responses, whereby respondents reported choices that aligned with perceived public health expectations rather than reflecting their actual future behavior. It may also be attributable to the characteristics of the study sample, which was highly vaccinated: 92% of respondents self-reported having received three or more vaccine doses at the time of the survey. This suggests that respondents were already predisposed toward vaccine acceptance, and the near-universal predicted uptake may therefore reflect a pre-existing provaccination orientation and prior vaccination behavior, rather than the effects of the DCE attributes alone.

As with all DCE studies, our estimates reflect stated rather than revealed preferences. A positive attitude toward a vaccine booster does not necessarily always translate to actual uptake in reality [45]. The near-universal predicted uptake observed in this study contrasts sharply with actual booster uptake in Singapore, where about half among seniors aged 60 years and older had received an additional booster dose by November 2023 [51], and fewer than 20% of the local population had received a COVID-19 booster dose within the preceding year by May 2024 [52]. This discrepancy may also reflect the influential role of policy mandates and perceived disease risk in shaping vaccination behavior. During the initial booster rollout, uptake was high, with approximately 84.5% of eligible individuals having received a first booster dose by January 2022 [53], likely reflecting the combined effects of vaccination-differentiated measures and heightened concern about COVID-19. When these measures were withdrawn and the perceived threat of COVID-19 declined, uptake of subsequent annual boosters fell markedly.

On the other hand, the discrepancy between stated preferences and actual booster uptake may partly reflect factors beyond vaccine attributes and sociodemographic characteristics. Previous studies have highlighted the influence of psychological determinants, including safety, vaccine confidence or side effects, and trust, which may affect whether favorable intentions ultimately translate into vaccination behavior [54,55].

Limitations

This study has several limitations. First, as this was a cross-sectional study, it captured a snapshot of public sentiment at a single point in time and could not account for potential changes in attitudes over time. As most countries have now transitioned to the endemic phase of COVID-19, public attitudes toward vaccine boosters are likely to evolve. Given that the study was conducted before the formal transition to the endemic phase, the findings may not be fully generalizable to the current endemic context. However, this timing allowed the study to capture public preferences during a critical phase when booster policy was being adapted from pandemic response to longer-term management under evolving risk perceptions and policy signals. Future research employing longitudinal designs would be valuable for monitoring shifts in public perceptions and acceptance of boosters in response to changing epidemiological conditions or policy cycles.

XSL•FO
RenderX

One other limitation is that DCEs may be subject to hypothetical bias. Nevertheless, we sought to reduce hypothetical bias by emphasizing the application to real-life choices. Future studies can assess the concordance between stated and revealed preferences within individuals [56], and expand on cheap-talk scripts to further reduce hypothetical bias [57]. Another limitation is that the worst-case scenarios included in the DCE (57,000 daily new cases, 10% of cases hospitalized, and 0.10% of cases died) exceeded the reported daily case burden observed in Singapore and may have been perceived as less realistic by some respondents. However, these levels were designed to represent a severe outbreak scenario and to capture preferences across a broad range of epidemiological conditions. Nevertheless, respondents who failed the dominant choice task were excluded from the analysis, providing some reassurance that participants remained engaged with and were able to meaningfully evaluate the hypothetical scenarios.

Finally, although the participant pool was demographically representative of the Singaporean population, the study was limited to those who were able to read and understand English. About 20% of the resident population aged 15 years and older are illiterate in English, with over half of them being older adults aged 55 years and older [58]. Future research could include other languages to capture individuals not included in the current study and improve the generalizability of the findings. This could be especially important to further inform comprehensive policy decision-making aimed at more targeted public health messaging. Despite these limitations, the study offers valuable insights into the determinants of booster acceptance and provides evidence to inform vaccination planning as COVID-19 management continues to evolve.

Conclusions

Vaccine boosters are a vital tool to maintain societal resilience against COVID-19. Our findings demonstrated that individuals generally preferred boosters offering longer-lasting protection, particularly in the context of heightened COVID-19 risks of infection and death. These findings underscore the dynamic nature of public attitudes, which may shift in response to evolving policy measures, vaccination recommendations, and epidemiological trends. In addition, this study identified the factors associated with booster acceptance and hesitancy, providing valuable insights that can shape targeted public health strategies and messaging to promote the uptake of vaccine boosters. These findings may extend beyond COVID-19, offering guidance for the development of vaccination policies for future pandemics and epidemics. The estimates of the WTP values in this study may also guide pricing decisions for COVID-19 vaccination in the long term. As preferences for preventive health interventions are highly context dependent, the results should be interpreted in the context of the period in which the study was conducted and may not fully represent the current setting or true endemic-phase perceptions.

Acknowledgments

We would like to thank Shumian Yeo and the rest of the Singapore Population Health Studies Online Panel team for supporting the setup, testing, and execution of the survey in this study. We would also like to thank Jason Chin Huat Yap, Qian Yang, Xian Yi Ng, and Jacinta I-Pei Chen for their input and assistance with the user acceptability testing. We would also like to thank Hwee Lin Wee for her advice on this study.

Abstract

Background: In recent years, German long-term care (LTC) insurance has experienced an unprecedented increase in the number of beneficiaries. This raises the question of the role of health care in preventing or delaying the need for LTC. At present, related findings are limited. Addressing this research gap could promote longevity and improve quality of life while reducing the financial strain on the social security system.

Objective: This study aimed to investigate the associations between the utilization of health care services and first-time LTC need.

Methods: This retrospective cohort study examined nationwide linked claims data from the German statutory health and LTC insurance fund, AOK. The dataset included all individuals aged ≥60 years. Using multiple logistic regression, we investigated the association between health care utilization during the 5-year exposure period from 2016 to 2020 and the occurrence of first-time LTC need during the first quarter of 2021. Physician care, pharmaceutical care, physiotherapy, and medical aids were analyzed while adjusting for age, sex, regional variables, and comorbidities. Metrically scaled variables were categorized using the Fisher-Jenks algorithm to explore possible nonlinearities. Individuals who needed LTC prior to 2021 were excluded.

Results: The study population comprised 5.3 million individuals. A total of 54.3% (n=2.9 million) were women, and the mean age was 71.3 (SD 8.16) years. Receiving more than 2 of the 5 recommended screenings and vaccinations examined, compared with receiving none, was associated with a strong reduction in the odds of first-time LTC need (odds ratio [OR] 0.62, 95% CI 0.60 - 0.64; *P*<.001). Odds of first-time LTC need were also significantly lower with high numbers of specialist groups and low numbers of specialist days (more than 7 specialist groups consulted and fewer than 48 billing days) compared with no specialist utilization (any specialist utilization: OR 0.82, 95% CI 0.79 - 0.85; *P*<.001; more than 7 instead of fewer than 5 specialist groups: OR 0.94, 95% CI 0.92 - 0.96; *P*<.001). Likewise, a physiotherapy prescription in between 5 and 10 quarters of the 5-year period instead of none was related to lower odds of first-time LTC need (OR 0.81, 95% CI 0.79 - 0.83; *P*<.001). Generalist care, hospitalizations, polypharmacy, and potentially inadequate medication were concomitant with first-time LTC need. Among the disease management programs and medical aids examined, there were both positive and negative relationships with first-time LTC need.

Conclusions: Utilization of recommended screenings, vaccinations, specialist physician care, and physiotherapy is substantially and significantly associated with the nonoccurrence of first-time LTC need in the older German population. Our study provides a foundation for future research on orienting health care toward preventing functional decline.

Introduction

The growing number of people in need of long-term care (LTC) in aging societies is accompanied by significant challenges for health care systems worldwide. As populations age, the prevalence of chronic diseases, functional impairments, and frailty increases, leading to a steadily rising demand for continuous support and health care services [1]. In Germany, the number of people in need of LTC doubled between 2015 and 2023 to reach 5.7 million. The 2.2% quarterly increase during this period was significantly higher than that projected based on demographic trends [2]. For the purposes of this study, the need for LTC is defined as a condition in which an individual requires significant assistance with activities of daily living and, as a result, successfully applies for benefits under Germany's statutory LTC insurance scheme [3].

The increasing number of people in need of LTC can be partly attributed to catch-up effects in LTC assessments following the COVID-19 pandemic. Additionally, the so-called "sandwich effect" is under discussion: a simultaneous rise in care-dependent baby boomers and their very old parents. This phenomenon is driven by higher life expectancy and improved survival of individuals with severe illnesses or injuries who require LTC services [4]. This trend is observed not only in Germany but also across industrialized countries worldwide, especially those where population aging is already well advanced, as a recent UN World Social Report states [5]. Although not all older individuals require formal care or support, the overall societal demand for LTC services is rising significantly. In Germany, it is projected that the number of people in need of LTC will rise from 6.0% in 2021 to 9.1% in 2055 [6,7].

Given this trend, the promotion of health and prevention in older age is becoming increasingly important. The goal is to maintain functional health—and thus autonomy and quality of life—for as long as possible, ultimately preventing or delaying the onset of LTC need. Prevention in this context encompasses a wide range of strategies, including health promotion, early detection, and rehabilitative measures. Existing research has largely focused on behavioral preventive approaches aimed at improving physical or cognitive performance among older populations [8]. In contrast, there has been relatively little investigation into structural or health care–related determinants of LTC need [9].

To our knowledge, the role of health care utilization in the years leading up to the onset of LTC need remains an unexplored area, apart from 2 observational studies from Japan, which reported that hyperpolypharmacy, defined as 10 or more medications per month, and prescription of drugs with sedative or anticholinergic properties were associated with an elevated risk of first-time LTC need [10,11]. An ecological Japanese study found that decentralized local prevention services, such as functional training, health education, and support for social activities, significantly reduced the population risk of moderate functional dependency [12]. These findings are specific to the Japanese context and either focus solely on medication or use data at the regional level. The lack of German studies analyzing the association of intersectoral health care utilization with LTC need warrants further individual-level investigation.

This study addresses this research gap by aiming to investigate the associations between the utilization of health care services and first-time LTC need. We analyzed this relationship in individuals aged ≥60 years using linked German statutory health insurance (SHI) and statutory LTC insurance claims data.

Methods

Data and Study Design

This retrospective cohort study used anonymized claims data of individuals insured with Germany's largest SHI and statutory LTC insurance fund, AOK, from 2016 to 2021. In 2024, AOK provided health insurance to one-third of the German population, and 42% of all those in need of LTC were insured with AOK [13]. To qualify as in need of LTC, individuals first must formally apply for LTC benefits. The subsequent LTC need assessment considers both mental and physical limitations to independent living. If 1 of 5 care levels is awarded after the assessment, the person becomes eligible for LTC benefits [3].

During the 5-year exposure period from January 1, 2016, to December 31, 2020, individual health care utilization in terms of outpatient and inpatient physician care, pharmaceutical care, physiotherapy, and medical aids was assessed. Subsequently, individuals were followed for one quarter, from January 1, 2021, to March 31, 2021. In this follow-up period, we determined whether a first-time LTC need was documented. First-time LTC need was dated to the retroactive commencement of services, which often aligns with the application date. To be considered for the study population, individuals had to be aged at least 60 years at the start of the follow-up period. Any individuals with conflicting information regarding date of birth, sex, date of first-time LTC need, or date of death were identified, or whose zip code could not be mapped to regional variables were excluded. LTC need or death before the follow-up period also led to exclusion. We further required continuous insurance coverage and residence in Germany throughout the entire observation period. All individuals meeting the inclusion criteria were included in the study.

Exposure Variables

Physician Care

Variables relating to physician care were defined in terms of care provided by general practitioners (GPs), specialists, inpatient care, screenings and vaccinations, and disease management programs (DMPs). The extent of care provided by GPs was quantified based on the number of days on which a service provided by a GP was documented during the exposure period. Similarly, the extent of specialist care was defined by the number of days with specialist services documented. Additionally, the number of different specialist groups consulted was included as a measure of the broadness of specialist care. Except for urologists, gynecologists, and medical services related to laboratory medicine, all specialist groups were considered for both specialist care variables. Urologists and gynecologists were excluded because, as a relevant part of their

XSL•FO
RenderX

services only applies to either sex and the importance of the 2 specialties with respect to LTC need prevention could differ, including them could introduce bias. To quantify the utilization of inpatient care, we determined the frequency of hospitalizations.

The screenings and vaccinations considered were cancer screenings (colon cancer screening through colonoscopy or stool tests, skin cancer screening, and prostate cancer or cervical cancer screening), a general health check-up, and the influenza vaccination. The extent of their utilization was operationalized as the number of screenings and vaccinations that were utilized according to the SHI reimbursement interval (Multimedia Appendix 1). Breast cancer screening was not considered because, until 2024, it was only reimbursed for women aged <70 years. Neither was the pneumococcal vaccination considered, as a single vaccination is recommended for the population aged ≥60 years. If a person had already been vaccinated against pneumococcal diseases before the exposure period, we would have been unable to correctly identify the vaccination.

Regarding structured disease management, we determined whether individuals participated in the established German asthma, chronic obstructive pulmonary disease (COPD), congenital heart disease, and type I or type II diabetes DMPs at any time during the exposure period. German DMPs address all patients with the respective disease rather than focusing on high-risk individuals [14] and promote evidence-based therapy and clinical pathways [15].

Pharmaceutical Care

In terms of drug treatment, both polypharmacy and prescription of potentially inappropriate medications (PIMs) that can cause adverse drug events in the older population were included. Polypharmacy was defined as the prescription of 9 or more different drug substances within the same quarter [16]. The definition of PIM was based on whether at least one of the substances from a list of potentially inadequate substances specific to the German context, including analgesics, anti-inflammatory drugs, antiarrhythmic drugs, antibiotics, anticholinergic drugs, antidepressants, antihypertensive agents, neuroleptic drugs, and sedatives, was prescribed [17]. To assess the extent of polypharmacy and PIM, the number of quarters during the exposure period in which an individual's medication met the defined criteria was computed.

Physiotherapy

To assess how often physiotherapy was utilized, the number of quarters with a physiotherapy prescription during the exposure period was counted.

Medical Aids

All medical aids that can be reimbursed by SHI in Germany are listed in the catalog of medical aids by the National Association of Statutory Health Insurance Funds [18]. This catalog includes 38 medical aid groups, such as insoles, walking aids, or hearing aids, that were summarized into 6 categories: disease-specific aids, aids supporting self-dependence, orthopedic aids, walking aids, hearing aids, and wheelchairs, including mobility scooters. For each category, we determined whether at least one medical aid from that category was prescribed. The assignment of medical aid groups to the 6 categories is provided in Multimedia Appendix 2.

Covariates

Comorbidities were included based on the conditions contained in the Elixhauser comorbidity index [19], typical geriatric conditions as defined by Lübke and Meinck [20], and additional diagnosis-based definitions of arthrosis, asthma, chronic obstructive pulmonary disease, and congenital heart disease developed by the AOK Research Institute [21]. The presence of these conditions was determined based on the year before the exposure period. In this way, we ensured that diagnoses were not affected by utilization behavior during the exposure period. Both inpatient and outpatient diagnoses were considered. Outpatient diagnoses were validated by requiring them to be documented as assured ("gesichert" according to the *International Statistical Classification of Diseases and Related Health Problems, 10th revision, German Modification*) in at least two quarters. Multimedia Appendix 3 includes a complete list of the conditions included.

As sociodemographic variables, age, sex, and regional variables were included. We determined the county settlement structure type with the 4 possible outcomes: metropolitan, urban, rural with agglomeration tendency, and rural as defined by the German Federal Institute for Research on Building, Urban Affairs and Spatial Development [22]. The German Index of Socioeconomic Deprivation developed at the Robert Koch Institute measures the level of socioeconomic deprivation based on administrative data on education, employment, and income [23]. It was included at zip code level and ranges from 0 (lowest deprivation) to 1 (highest deprivation).

Statistical Analysis

Logistic regression was used to assess the association between the variables of interest and first-time LTC need. The outcome data reflect the date when LTC insurance benefits were first claimed, rather than the point of time when a person would have been first eligible, but may not yet have applied for LTC need. Therefore, and given the 3-month follow-up, logistic regression analysis was chosen over using time-to-event methods. First, a crude single exposure model was estimated by univariate regression of first-time LTC need separately on each of the variables of interest. We then controlled for the named comorbidities and sociodemographic variables in an adjusted single exposure model. Finally, all variables of interest were integrated into a single adjusted multiple exposure model, in which covariates were also controlled for.

Owing to the considerable number of variables of interest, whose association with LTC need was tested for significance, we used *P*-values adjusted for multiple testing using a max-*t* test. This test controls the probability of falsely rejecting at least one of the hypotheses in question [24]. All metric variables of interest were categorized into a null category indicating no utilization of the respective service, and 3 categories of low, medium, and high utilization by classification according to the Fisher-Jenks algorithm [25]. Rather than assuming a linear relationship, this

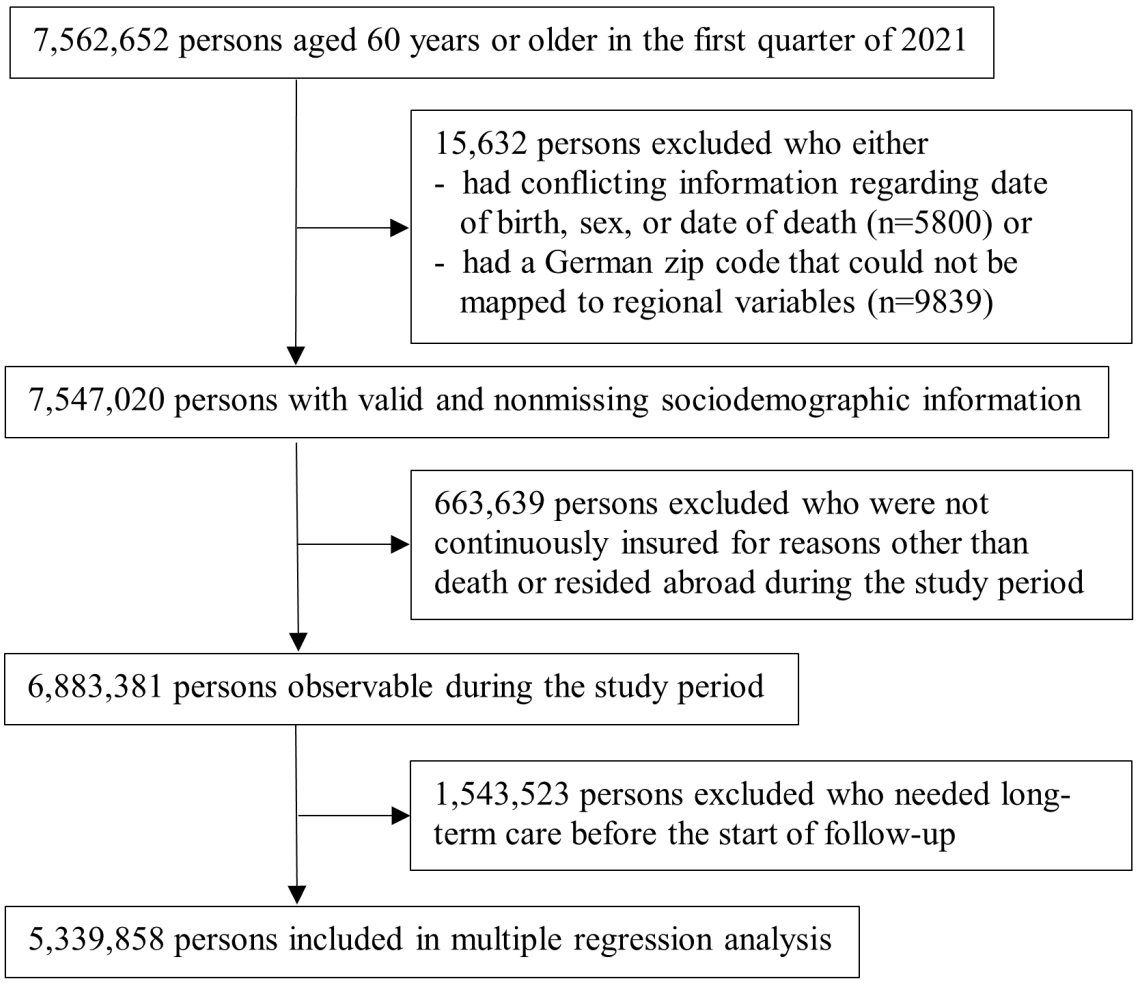
XSL•FO
RenderX

flexible approach enabled picking up possible nonlinear and nonmonotonic associations. To be able to estimate the association of the number of specialist billing days and specialist groups simultaneously despite their linear dependence if categorized, we introduced a binary variable displaying whether specialist care was utilized at all and combined the null category and the low utilization category of each of the billing days and specialist groups variable into a single reference category. Data preparation and statistical analysis were conducted using Oracle 19c Enterprise Edition (Oracle Corporation) and R 4.4.2 (R Foundation for Statistical Computing). Statistical significance was evaluated at a 2-sided significance level α of .05.

Sensitivity Analysis

To assess whether results were driven by effects specific to the observation period and the short duration of follow-up, we first defined 3 alternative observation periods that started on April 1, 2016, July 1, 2016, and October 1, 2016, each also consisting of a 5-year exposure period and one-quarter follow-up period, and second, in another alternative specification, we extended the follow-up period to 1 year. Third, to address the potential for reverse causality, we excluded the last year from the exposure period. For this analysis, we rescaled the utilization category thresholds of each of the exposure variables to reflect the shorter exposure period (Multimedia Appendix 4).

Ethical Considerations



All analyses described were conducted with the approval of the responsible ethics committee of Charité–Universitätsmedizin Berlin (EA4/147/23), in accordance with national law and the current version of the Declaration of Helsinki. We report our findings in accordance with the STROBE (Strengthening of the Reporting of Observational Studies in Epidemiology) guidelines.

Results

Description of the Study Population

Figure 1 shows the flowchart of study population selection. At the start of the follow-up, 7,562,652 persons aged ≥60 years were insured with AOK. After application of the selection criteria, the final study population comprised 5,339,858 insured persons. Descriptive statistics for the study population are presented in Table 1. The average age was 71.3 (SD 8.16) years, and 54.3% (n=2,899,228) were women. There were no missing values. During the one-quarter follow-up, 91,160 (1.7%) individuals became in need of LTC. See Multimedia Appendices 3-7 for flowcharts and full descriptive statistics, including the sensitivity analysis study populations.

[c]DMP: disease management program.

Physician Care

Regarding outpatient physician care, a low number of GP visits was related to a significant increase in the odds of first-time LTC need (OR 1.38, 95% CI 1.29 - 1.48; *P*<.001) relative to none. Odds for first-time LTC need rose further in medium (OR 1.59, 95% CI 1.48 - 1.71; *P*<.001) and high levels of utilization (OR 1.65, 95% CI 1.53 - 1.77; *P*<.001). With a low number of specialist groups and billing days, utilization of specialist care entailed a reduction of odds versus no utilization (OR 0.82, 95% CI 0.79 - 0.85; *P*<.001). Compared to this low utilization level,

XSL•FO
RenderX

odds reduced further in medium (OR 0.95, 95% CI 0.93 - 0.96; *P*<.001) and high (OR 0.94, 95% CI 0.92 - 0.96; *P*<.001) numbers of specialist groups but increased in medium (OR 1.06, 95% CI 1.04 - 1.08; *P*<.001) and high (OR 1.70, 95% CI 1.48 - 1.95; *P*<.001) numbers of specialist days. Hospitalizations were strongly and significantly associated with a higher risk of first-time LTC need. More than 6 hospitalizations within the 5-year exposure period were related to a more than 3-fold increase in the odds of first-time LTC need (OR 3.07, 95% CI 2.97 - 3.17; *P*<.001) relative to none.

A high utilization of screenings and vaccinations was related to a reduction in the odds of first-time LTC need (OR 0.62, 95% CI 0.60 - 0.64; *P*<.001). Although less strong in magnitude, low (OR 0.90, 95% CI 0.88 - 0.92; *P*<.001) and medium (OR 0.62, 95% CI 0.60 - 0.64; *P*<.001) utilization of screenings and vaccinations were also significantly negatively associated with first-time LTC need. Of the 4 DMPs, only the congenital heart disease DMP exhibited a significant protective relationship with first-time LTC need (OR 0.93, 95% CI 0.91 - 0.96; *P*<.001). COPD DMP participation predicted an increased risk of first-time LTC need (OR 1.19, 95% CI 1.14 - 1.23; *P*<.001).

Pharmaceutical Care

Both prescription of PIM and polypharmacy were accompanied by higher odds of first-time LTC need. The relationship is stronger in magnitude for high levels of polypharmacy (OR 1.68, 95% CI 1.62 - 1.74; *P*<.001) than for high levels of PIM (OR 1.14, 95% CI 1.11 - 1.17; *P*<.001).

Physiotherapy

Relative to nonuse, a low (OR 0.85, 95% CI 0.84 - 0.86; *P*<.001) or medium (OR 0.81, 95% CI 0.79 - 0.83; *P*<.001) utilization of physiotherapy correlated negatively with first-time LTC need. With a high utilization level, the association did not remain statistically significant (*P*>.99).

Medical Aids

Orthopedic aids had a significant negative association with first-time LTC need (OR 0.94, 95% CI 0.93 - 0.96; *P*<.001). Walking aids (OR 1.62, 95% CI 1.59 - 1.64; *P*<.001), wheelchairs including mobility scooters (OR 1.43, 95% CI 1.38 - 1.49; *P*<.001), aids supporting self-dependence (OR 1.31, 95% CI 1.29 - 1.33; *P*<.001), and disease-specific aids (OR 1.14, 95% CI 1.12 - 1.16; *P*<.001) were related to an increased risk of first-time LTC need.

Sensitivity Analysis

As shown in Multimedia Appendix 8, the 3 alternative observation periods yielded similar results compared to the main analysis. Multimedia Appendix 9 presents the results obtained when extending the follow-up period to 1 year. While most associations exhibited no notable difference to the main analysis, the relationship between LTC need and the number of hospitalizations became weaker, and the negative associations of the DMPs for asthma (OR 0.95, 95% CI 0.92 - 0.98; *P*=.008) and diabetes (OR 0.95, 95% CI 0.93 - 0.96; *P*<.001) with LTC need became significant. Omitting the final year of the exposure period, as displayed in Multimedia Appendix 10, produced analogous estimates but for the number of hospitalizations. As when extending the follow-up duration to 1 year, hospitalizations displayed lower estimates for all utilization categories. Relative to the main analysis, the OR of more than 6 hospitalizations (OR 1.80, 95% CI 1.74 - 1.86; *P*<.001) was almost halved.

Discussion

Principal Findings

We have shown that a wide range of measures of health care utilization display significant and strong associations with the risk of first-time LTC need. To the best of our knowledge, our study is the first to analyze the interplay of the frequency of physician visits, DMP enrollment, physiotherapy utilization, prescription of medical aids, screenings and vaccinations, and inadequate medication supply with first-time LTC need simultaneously. In the population aged ≥60 years, utilization of specialist care, physiotherapy, and screenings and vaccinations display the strongest relationship with nonoccurrence of first-time LTC need. At the same time, frequent utilization of GP care, hospitalizations, polypharmacy, and prescription of walking aids showed a significant association with first-time LTC need. As this study relied on a 5-year exposure period to evaluate health care utilization, the relationship between health care use in a 5-year period and LTC need can only be assessed in and does only apply to individuals who neither need LTC nor die within 5 years. This approach provides a longer-term perspective on the health care trajectory of a person, which may be more meaningful for prevention than a single event.

Comparison With Prior Work

Apart from the 2 studies, which corroborated that inadequate medication supply is related to an increase in future LTC risk [10,11], further evidence on the relationship of health care utilization with first-time LTC need is missing. LTC need being a sociolegal concept in Germany that differs substantially from that in other countries [3,26], prior research has focused on related outcomes, such as frailty, functional measures, morbidity, or mortality [8,27,28]. Although these outcomes must be distinguished both from each other and first-time LTC need, they are interrelated [29-32] and evidence on how they correlate with health care utilization can promote our understanding of the link between health care utilization and first-time LTC need.

Frequency of Physician Contact

We evaluated 3 variables that are closely related to the frequency of physician contact: GP billing days, specialist physician billing days, and hospital admissions. Compared to no contact, both GP billing days and hospital admissions were related to an increased risk of first-time LTC need. While utilization of specialist care with a low number of billing days and specialist groups showed a preventive association, all 3 variables have in common that compared to a low level of utilization, a higher level of physician contact was related to an increase in the risk of first-time LTC need. On the one hand, frequent physician contact may entail constant assessment of health risks and subsequent counseling and thereby exerting a preventive effect on LTC need risk [33,34]. On the other hand, there is a wealth of literature on how physical frailty is associated with a higher utilization of health care in terms of outpatient care, inpatient

XSL•FO
RenderX

care, home care, and nursing home admission [35-40]. Moreover, individuals with an adverse status in terms of living alone, social relations, and social support, referred to as socially frail, are reported to have a lower number of physician visits and lower likelihood of hospitalization, hinting at lower ability to access health care services including LTC [41]. Despite our efforts to control for comorbidities, both physical and social frailty likely act as confounders, correlating both with first-time LTC need risk and health care utilization.

In sensitivity analyses that excluded the last year from the exposure period or extended follow-up to 1 year, we also observed a markedly weaker association between hospitalizations and LTC need. This is consistent with the fact that hospitalizations frequently occur shortly before first-time LTC need [42]. If there is a time lag between the end of the exposure period and the date of first-time LTC need, hospitalizations shortly before first-time LTC need will not be reflected in the exposure variable. This underscores how the strong relationship between hospitalizations and LTC need in the main analysis reflects morbidity levels. In summary, while the frequency of physician contact is a valuable identifier of persons at risk of first-time LTC need, it cannot be assumed to be detrimental to independent living based on our analysis.

Condition-Specific Health Care Utilization

Apart from the frequency of physician contact, we also evaluated how extensive specialist outpatient care utilization was by including the number of specialist groups consulted. At a constant number of specialist billing days, an increase in specialist groups consulted was connected to a decreased risk of first-time LTC need. Similarly, another claims data–based study from Germany reported that, adjusted for GP care utilization, LTC beneficiaries are less likely to visit physicians from different specialist groups than older people without LTC need [43]. We cannot rule out that part of the promising association we estimated pertains to barriers to accessibility of specialist care. These might be more pronounced for individuals at higher risk of first-time LTC need. Still, hypothesizing that even with few patient-physician contacts, each specialist group can give specific preventive recommendations and guidance, it is plausible that a wider variety of specialist groups consulted, holding the number of billing days fixed, exerts a preventive effect. On the other hand, having visited a given specialist more frequently may reflect higher morbidity levels more so than an improved capacity to provide preventive guidance.

Of the 4 DMPs evaluated, we found a preventive relationship consistent across main and sensitivity analyses regarding only the congenital heart disease DMP, while the COPD DMP even showed a detrimental association. As we can only account for disease presence and not severity, selection effects might bias our estimates if DMP participants differ from nonparticipants in this regard. DMPs have not yet been evaluated in terms of their association with first-time LTC need, nor have there been DMP evaluations using randomized control trials in Germany [44].

While we found physiotherapy utilization to be predictive of nonoccurrence of first-time LTC need, when receiving prescriptions in up to 10 quarters within 5 years, we saw no such association for higher levels of utilization. There is prior evidence that physiotherapy can support the use of medical aids [45], prevent institutionalization after hospitalization [46], and, in the case of a Spanish study, reduce mortality through improvement in quality of life, alleviation of musculoskeletal disorders, a referral function in the health care system, and fall prevention [47]. While there is currently no evidence on the relationship between physiotherapy utilization and first-time LTC need, 2 articles report that frail persons receive physiotherapy more often than nonfrail ones [36,38].

Furthermore, our medical aids analysis showed that only orthopedic devices had a negative relationship with first-time LTC need. All other categories except for hearing aids had a positive association that was most pronounced in walking aids. A meta-analysis suggested that insoles, which make up for the largest share of prescriptions within the orthopedic devices group, were beneficial for balance improvement and fall prevention [48], supporting our finding of a preventive potential. Although walking aids are intended to prevent falls, walking aid users face a high risk of falls and injuries that might be reduced by improvements in devices and better instructions on device usage [45,49]. Likely, both difficulties in accounting for confounders such as gait quality and potential for improvement in walking aid use contribute to the strong positive association with first-time LTC need we observe.

Screenings and Vaccinations

The cancer screenings, general health check, and influenza vaccination summarized in a single variable displayed a strong relationship with nonoccurrence of first-time LTC need. There is tentative evidence supporting the health benefits of these services in the population aged ≥60 years, yet the association we find remains high against this backdrop.

Despite the potential of cancer screening to reduce all-cause mortality by 1% to 3% in Germany [50], screening cessation may be recommended for prostate cancer, cervical cancer, and colorectal cancer. With increasing age and decreasing life expectancy, potential harms in screening may outweigh potential benefits, necessitating an individualized screening decision [51-53]. On the one hand, this calls into question whether cancer screenings can have a substantial preventive effect in terms of LTC need. On the other hand, it raises the question of whether part of the observed effect reflects screening cessation recommendations being put into practice. General health checks and health risk assessments have been shown to increase uptake of other preventive services, but an effect on mortality cannot be substantiated despite positive impact on chronic diseases treatment and patient-reported outcomes [34,54-56]. The influenza vaccination provides the most concrete reference for a potential delaying effect on first-time LTC need. Not only is it crucial to influenza prevention, especially so in older adults [57], but it is also related to a decreased risk of dementia [58,59], the third most-named diagnosis for first-time LTC need in Germany in 2021 [60].

Other than effects of screenings and vaccinations themselves, preventive health behavior could contribute to the strength of the observed association. It has been shown that the uptake of preventive services is higher in individuals with

XSL•FO
RenderX

health-promoting behavior [61,62]. As we have no information on crucial behavioral aspects such as physical activity, nutrition, and alcohol and tobacco use, they likely bias the observed relationship toward prevention. Bearing that in mind, our study provides first hints for a possible delaying effect of screenings and vaccinations on first-time LTC need that further studies should investigate in more detail on a broader base of data.

Inadequate Medication Supply

Our finding that inadequate medication supply is positively related to first-time LTC need and polypharmacy, more so than PIM, is in line with prior cross-sectional [63] and longitudinal studies [10,11] from Japan. Kuroda et al [10] evaluated polypharmacy and PIM using drug prescriptions from a 2-year exposure period and reported associations of similar magnitude. Inadequate medication supply has been shown to be associated with falls, dementia, functional and cognitive decline, and sarcopenia [28,64,65], all of which are plausible causes of first-time LTC need. This suggests that correction of inadequate medication supply can be a leverage point to LTC need prevention.

Strengths and Limitations

This retrospective cohort study adheres to certain conditions necessary to justify causal statements about the observed associations. Outcome was evaluated after exposure, and thus, reverse causality through effects of utilization of LTC insurance services can be ruled out. Still, utilization might be driven by morbidity trends on a trajectory approaching first-time LTC need [42]. Excluding the final year of the exposure period from the analysis showed that only estimates related to hospitalization are affected strongly by such morbidity trends. The robustness of the remaining estimates indicates that reverse causality through short-term morbidity trends is no major concern. The large nationwide sample enabled us to assess utilization of multiple health care services simultaneously despite their interrelation. In this way, we were able to measure the relationship of each utilization variable with first-time LTC need given the utilization pattern in terms of the other variables.

Nonetheless, this study faces some substantial limitations that confine the results to the domain of correlation. It is the nature of claims data that they lack information on disease severity, health-promoting behavior, social networks, and individual-level socioeconomic variables. These parameters need to be integrated to enable attainment of unbiased estimates, given that they are related to physical and social frailty, as well as the accessibility of health care [66,67]. Furthermore, despite the large sample size, results attained based on AOK-insured individuals cannot be generalized to the German population, as they tend to have lower socioeconomic status and higher comorbidity burden than people insured privately or with other SHI funds [68,69]. On top of that, our observation period coincides with the COVID-19 pandemic, whose effect on health care utilization limits the external temporal validity of our study.

Moreover, a range of health care services that may contribute to LTC need prevention, such as breast cancer screening, geriatric assessment, and rehabilitation, were not evaluated as part of this study. This study was designed to estimate associations of health care utilization with first-time LTC need without placing further restrictions on the study population than the criterion of being aged ≥60 years. Therefore, services such as breast cancer screening and geriatric assessment, access to which is specific to sex and age, could not be included. In Germany, rehabilitation services are covered by the statutory pension insurance scheme before retirement. Utilization of rehabilitation services can thus not be assessed on SHI claims data alone for a population partially still in employment. Furthermore, we primarily aimed to assess the association of health care utilization with first-time LTC need as a proxy for functional health. We must concede that claiming LTC benefits is itself an act of health care utilization that, besides functional health, is determined by access to health care and utilization behavior. As a determinant of health care accessibility and utilization behavior, individual-level socioeconomic variables could be a valuable addition in factoring out its confounding impact.

Conclusions

In conclusion, we have shown that the utilization of recommended screenings, vaccinations, specialist physician care, and physiotherapy displays substantial and significant associations with nonoccurrence of first-time LTC need in the German population aged ≥60 years. Our study provides an important foundation for future research. It is essential to address the limitations posed by unobserved confounding variables and the nonexperimental study design to generate evidence on how LTC need can be delayed or avoided. Such evidence could provide guidance on orienting health care toward preventing functional decline.

Acknowledgments

We thank Dr Antje Schwinger for her contributions during the initial phase of the study and Ms Hanna Müller for her assistance with literature review.

Funding

This study has been funded by the Federal Joint Committee (G-BA) as part of the WEGE project (grant ID 01VSF22047). The funder had no involvement in the study design, data collection, analysis, interpretation, or the writing of the manuscript.

Data Availability

The authors confirm that the statutory health insurance claims data used in this study cannot be made available in the manuscript, the supplemental files, or a public repository due to German data protection laws ("Bundesdatenschutzgesetz"). Therefore, AOK claims data are stored on a secure drive in the AOK Research Institute to facilitate replication of the results. Generally, access to data of statutory health insurance funds for research purposes is possible only under the conditions defined in German Social Law (SGB V § 287). Requests for data access can be sent as a formal proposal specifying the recipient and purpose of the data transfer to the appropriate data protection agency. Access to the data used in this study can only be provided to external parties under the conditions of the cooperation contract of this research project and after written approval by the SHI fund. For assistance in obtaining access to AOK claims data, please contact wido@wido.bv.aok.de.

Abstract

Background: Effective physician-patient communication is essential for building trust and sustaining positive relationships, yet becomes increasingly challenging in China's tertiary hospitals, where physicians face heavy workloads.

Objective: This study explored the barriers and facilitators of physician-patient communication by synthesizing perspectives from Chinese hospital-based physicians and patient relations coordinators.

Methods: A qualitative study using semistructured interviews was conducted with 17 participants (11 physicians and 6 patient relations coordinators) from tertiary hospitals in China (April-July 2025). Data were analyzed using thematic analysis following Braun and Clarke's framework.

Results: Barriers and facilitators of physician-patient communication were organized into a multilevel framework comprising patient-level, physician-level, and system-level factors. Patient-level barriers included individual background differences, inadequate expression and limited health literacy, and psycho-emotional states with expectation misalignment, whereas facilitators included effective expectation management, good health literacy and communication readiness, and trust in physicians with shared decision-making. Physician-level barriers involved communication style deficiencies, empathy gaps, and time pressure constraints; facilitators included active listening and patient-centeredness, empathy and emotional support, and clear explanations with cultural adaptability. At the system level, barriers included hospital environment and medical visit settings, legal and policy deficiencies, insufficient communication training, and media-driven distrust with digitally mediated information challenges, while facilitators included institutional support and security assurance, educational training and policy promotion, process optimization and patient health education, and artificial intelligence–assisted baseline knowledge.

Conclusions: Physician-patient communication is influenced by multiple factors, necessitating comprehensive intervention measures: enhancing patient education, improving physician communication skills, and strengthening organizational support systems. Notably, special attention should be directed toward addressing the unique challenges posed by digital technologies while concurrently leveraging the opportunities they present to optimize communication outcomes.

Introduction

As global health care systems increasingly contend with the challenges of aging populations, constrained resources, and growing patient expectations, effective physician-patient communication has become more crucial than ever, serving as a cornerstone of high-quality health care delivery [1,2]. A growing body of evidence shows that high-quality communication enhances patient satisfaction, improves treatment adherence, reduces medical errors, and ultimately contributes to better health outcomes [3-5]. Conversely, communication failures can have serious consequences; for instance, Humphrey et al [6] reported that an analysis of malpractice claims revealed that 49% involved communication failures and 53% specifically reflected physician-patient miscommunication.

Effective physician-patient communication is inherently a 2-way interaction in which both physicians and patients seek to understand and be understood [7-9]. However, current research on improving physician-patient communication has focused mainly on meeting patients' needs, with particular emphasis on improving physicians' communication skills [10-12]. This patient-centered approach has prioritized patient-reported experiences and satisfaction measures [13] while largely neglecting physicians' reciprocal need to be understood and their perspectives on physician-patient communication challenges.

Moreover, previous studies on physician-patient communication have mostly focused on Western family medical settings, with limited attention to the Chinese context. Yet the determinants of physician-patient communication vary significantly across cultural contexts [14]. Especially within China's inverted triangle health care system [15], tertiary hospitals serve as regional medical centers characterized by high patient volumes, short consultation times, and cross-regional patient mobility. Compared to secondary and primary hospitals, physicians at tertiary hospitals must balance heavy clinical workloads with patients' expectations for detailed explanations [16]. At the same time, the digital transformation of health care, including increased access to online health information, platform-based services, and emerging technologies such as artificial intelligence (AI), is reshaping the context in which physician-patient communication takes place. While these developments may create new opportunities for information exchange, they may also intensify misunderstandings, alter expectations, and introduce new communication challenges that remain insufficiently understood [17,18]. As frontline practitioners experiencing the dual pressures of system strain and digital transformation, physicians in tertiary hospitals may offer valuable insights into these evolving communication challenges. In addition, patient relations coordinators, who are directly involved in managing complaints and mediating disputes, can provide important perspectives on how these challenges manifest in practice and where systemic gaps may exacerbate tensions.

This study explored barriers and facilitators to physician-patient communication from the perspectives of frontline physicians and patient relations coordinators in Chinese tertiary hospitals. By integrating a dual-role perspective, this study aimed to develop a more nuanced understanding of the complex factors shaping physician-patient communication in contemporary hospital settings.

Methods

Study Design and Participants

We conducted a qualitative descriptive study using individual in-depth interviews to explore the perspectives of physicians and patient relations coordinators in Chinese tertiary hospitals regarding physician-patient communication. This study was situated within a critical realist ontological framework, which acknowledges that participants' experiences reflect real phenomena in clinical settings, while recognizing that our understanding of these phenomena is inevitably mediated by individual perspectives, social contexts, and the interpretive lens of the research team [19]. The study followed the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [20] and was conducted from April to July 2025 in Guangdong Province, China.

Participants were recruited from multiple tertiary hospitals through purposive sampling. Recruitment was initiated by the first authors through direct solicitation, under the guidance of the corresponding author, and was subsequently expanded during data collection to ensure diversity in institutional contexts and participant characteristics. The sampling strategy aimed to achieve variation in professional roles, gender, age, years of experience, and clinical specialty, thereby capturing a broad range of perspectives on physician-patient communication.

A total of 17 participants were recruited from tertiary hospitals, including 11 physicians from 7 tertiary hospitals and 6 patient relations coordinators from 5 tertiary hospitals, representing 11 tertiary hospitals in total across the full sample. The distribution of participants across institutions is detailed in Table 1. These 2 participant groups were purposively selected because they offered distinct yet complementary perspectives on physician-patient communication. Practicing physicians across different clinical departments were recruited to capture firsthand physician-patient communication experiences. Patient relations coordinators were included because of their roles in handling complaints, coordinating communication, mediating disputes, and identifying institutional barriers affecting physician-patient communication. Including both groups enabled the study to integrate direct clinical perspectives with insights from the hospital organizational level. All participants were currently employed, fluent in Mandarin, and had a minimum of 1 year of professional experience to ensure sufficient exposure to physician-patient communication dynamics. Retired practitioners were excluded from the study to ensure perspectives reflected current practice contexts.

Recruitment and data collection proceeded iteratively. The study sample size was informed by the concept of information power [21], which considers the study aim, sample specificity, theoretical framework, quality of dialogue, and analytic strategy. Given the focused aim of the study, the use of reflexive thematic analysis, and a purposively diverse sample drawn from 2 relevant participant groups with direct experience of physician-patient communication processes, we anticipated that a relatively modest sample would yield sufficient depth. Throughout data collection, we monitored the richness and

XSL•FO
RenderX

relevance of interview material in relation to the study aims. We concluded recruitment at 17 participants when the research team collectively assessed that the interviews had generated sufficiently rich and diverse data to develop coherent analytic themes addressing the research question, and that additional interviews were unlikely to substantially alter the developing analysis.

Data Collection and Procedures

Data were collected through semistructured, one-to-one interviews. Participants who could not meet in person were interviewed online via the Tencent Meeting platform, while others participated in face-to-face interviews. All interviews were conducted in Mandarin, lasted 45 - 90 minutes, and were led primarily by ZS, with HY moderating 3 interviews. Demographic data were collected verbally at the beginning of each interview. All interviews were audio- or video-recorded with participants' consent, transcribed verbatim by professional transcriptionists within 24 hours of completion to preserve contextual detail and support timely familiarization with the data. A random sample of 20% of transcripts was independently verified against original recordings by research team members to ensure transcription accuracy. Participant quotes selected for inclusion were translated into English by one bilingual research team member (ZS). To ensure conceptual equivalence and linguistic accuracy, a second independent bilingual team member (QJ) who had no prior exposure to the original Chinese text backtranslated all quotes into Mandarin. Discrepancies between the original and backtranslated versions were reviewed and resolved through consensus discussion among the research team until conceptual equivalence was confirmed. Participants received RMB 150 (approximately US $20) as compensation for their time.

A semistructured interview guide was developed collaboratively by the research team (Multimedia Appendix 1) and refined iteratively based on insights from initial interviews. The interview guide explored four core domains: (1) key physician behaviors and patient preparations that support high-quality interactions, (2) patients' main needs and expectations, (3) characteristics of effective patient-physician communication from the physician's perspective, and (4) personal, situational, and systemic barriers and facilitators to effective physician-patient communication. Throughout the interviews, the research team used techniques such as probing questions, clarification requests, and reflective listening [22] to elicit in-depth responses and encourage participants to share nuanced insights about the facilitators and barriers to physician-patient communication.

To ensure the scientific rigor and quality of data collection, several measures were implemented. All interviewers (ZS and HY) underwent training in qualitative interview techniques and conducted mock interviews prior to data collection to standardize approaches and ensure consistency. All interviews were conducted in quiet, private settings with standardized protocols, including consistent opening statements and informed consent procedures. For online interviews, technical equipment was tested beforehand to ensure optimal audio and video quality. Interviewers maintained brief reflective notes during and immediately after each interview to capture contextual observations, nonverbal cues where available, and preliminary reflexive insights.

Researcher Reflexivity Statement

Given the interpretive nature of reflexive thematic analysis, it is important to acknowledge the positionality and perspectives that the research team brought to this study [23,24]. The lead researcher and primary interviewer (ZS) is a doctoral researcher with training in qualitative research methods and prior professional experience in culture- and communication-related work at a tertiary hospital in China. This background provided familiarity with the dynamics of physician-patient communication in China's health care system, which facilitated rapport-building with participants and sensitivity to contextual nuances during interviews. At the same time, this proximity required reflexive awareness of potential assumptions about what constitutes "effective" communication, and ZS took care to remain open to perspectives that might differ from her own professional experiences.

The broader research team comprised members with expertise in clinical medicine, health communication, qualitative methodology, and health services research, which enriched the analytic process by bringing multiple interpretive lenses to the data. ZS maintained brief reflexive notes after each interview and met regularly with the supervisory team to discuss emerging interpretations, challenge assumptions, and consider how the team's positionality may have shaped the developing analysis. These reflexive practices were integral to the analytic process and supported the generation of themes that were grounded in participants' accounts while acknowledging the research team's active role in interpretation [19].

Data Analysis

Interview transcripts were analyzed using reflexive thematic analysis following Braun and Clarke's 6-step framework [23-25], which emphasizes the researcher's active and reflexive role in generating themes through deep engagement with the data. An inductive, data-driven orientation was adopted, whereby codes and themes were developed in response to participants' accounts without the imposition of a predetermined framework. Data management and coding were conducted using NVivo 20 (Lumivero LLC). Participant quotes were coded using alphanumeric identifiers: "Dr" followed by numbers (Dr01-Dr11) for practicing physicians, and "A" followed by numbers (A01-A06) for members from physician-patient relations management departments.

ZS led the analysis, conducting inductive coding of all transcripts through an iterative process of close reading, annotation, and code development. To deepen analytic reflexivity and broaden interpretive engagement with the data, XW independently coded a subset of transcripts (the first 2 transcripts from each participant group). These additional coding contributions informed collaborative discussions about alternative readings and emerging patterns, contributing to the refinement of the developing analytic framework. The purpose of this collaborative coding was not to achieve consensus or establish interrater agreement, but rather to bring multiple

XSL•FO
RenderX

interpretive perspectives to the data and to deepen the team's reflexive engagement with the analysis.

The team met regularly during the analytic process to discuss coding decisions, review evolving themes, and critically examine the developing analysis. DW provided an additional interpretive perspective during theme refinement. The final thematic framework was developed through an iterative process of deep engagement with the data across all phases of analysis, moving between data, codes, and candidate themes in a recursive manner. Themes were generated as interpretive patterns of shared meaning across the dataset, rather than predetermined categories [23]. In keeping with reflexive thematic analysis, analytic rigor was supported through sustained engagement with the full dataset, reflexive memoing, and regular interpretive discussions within the research team, rather than through coder agreement or the resolution of coding discrepancies to achieve consensus.

Trustworthiness and Quality

Several strategies were used to enhance the trustworthiness of the study, guided by considerations of credibility, transferability, dependability, and confirmability [26], while remaining attentive to the reflexive and interpretive nature of the analytic approach [23].

Credibility was supported through prolonged engagement with the data, purposive sampling to capture diverse perspectives across clinical specialties and professional roles, and the inclusion of 2 complementary participant groups (physicians and patient relations coordinators) to provide a multifaceted understanding of physician-patient communication. Collaborative coding of a subset of transcripts and regular team discussions further enriched the analytic process by introducing multiple interpretive perspectives.

Transferability was enhanced through a detailed description of the study context, participant characteristics, and analytic procedures, enabling readers to assess the applicability of the findings to their own settings. The purposive sampling strategy ensured diversity in institutional contexts, clinical specialties, and professional roles across the sampled tertiary hospitals in Guangzhou and Shenzhen, Guangdong Province, China.

Dependability was addressed through transparent documentation of all research decisions throughout the study. The interview guide, coding process, and thematic development were documented and discussed within the research team, creating an audit trail that traces the analytic journey from raw data to final themes.

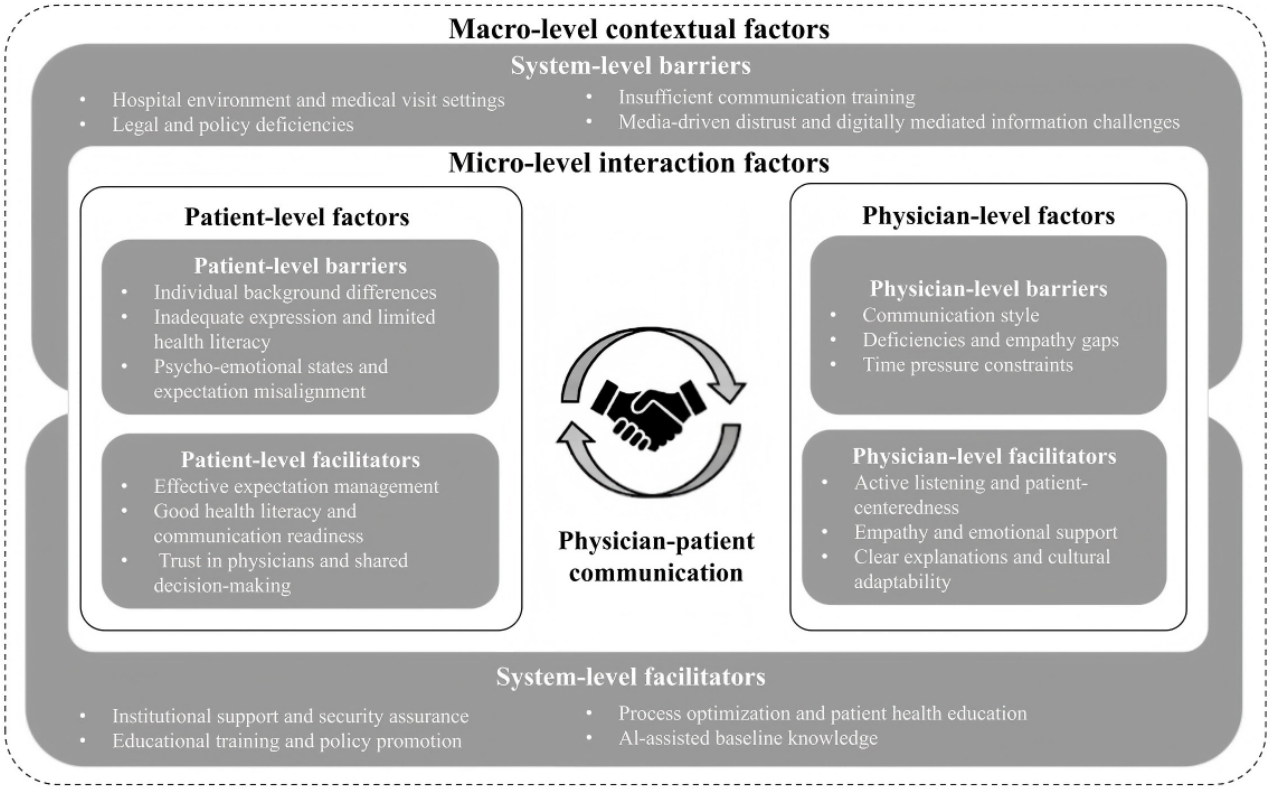
Confirmability was supported through reflexive practices, including the maintenance of reflexive notes by interviewers, regular supervisory discussions about emerging interpretations, and the explicit acknowledgment of the research team's positionality and its potential influence on the analysis. Within the framework of reflexive thematic analysis, we recognize that analysis is inherently shaped by the researcher's subjectivity; therefore, confirmability was pursued not through the elimination of researcher influence, but through transparency about the interpretive process [19,27].

Ethical Considerations

This study was approved by the Ethics Committee of Southern Medical University, Guangzhou, Guangdong Province, China (approval number NFYKDX003-2025-35), and was conducted in accordance with the Declaration of Helsinki. Prior to the interviews, participants were informed about the purpose of the study and the use of audio recording, and informed consent was obtained from all participants. Interviews were audio-recorded only with participants' permission. No personally identifiable information was collected or reported, and all data were kept confidential.

Results

Demographics of the Participants



We interviewed a total of 17 participants, comprising 11 physicians and 6 patient relations coordinators (Table 1). Among the physicians, there were 8 males and 3 females, with a mean age of 41.27 (SD 6.40; range 29‐50) years and a mean professional experience of 15.18 (SD 7.65; range 3‐30) years. They represented a broad range of specialties, including obstetrics and gynecology, cardiology, spinal surgery, general medicine, and other specialties. Given China's high patient-to-physician ratio and the central role of tertiary hospitals in delivering specialist care, physicians with senior roles (eg, department directors or deputy directors) remain active frontline clinicians regardless of administrative responsibilities. Three physicians with administrative roles reported conducting outpatient consultations on a regular basis, averaging 3 to 4 sessions per week. Among the patient relations coordinators, there were 1 male and 5 females, with a mean age of 34.00 (SD 4.12; range 27‐39) years and a mean professional experience of 8.67 (SD 5.61; range 1‐16) years.

Overview of Themes

Thematic analysis of the interview data identified 2 overarching themes: barriers and facilitators of effective physician-patient communication. As shown in Figure 1, these themes were organized into a multilevel framework comprising patient-level, physician-level, and system-level factors. Patient- and physician-level factors directly shaped the communication process, whereas system-level factors functioned as the broader context that could either hinder or enable effective interaction. The following sections discuss each theme and its constituent subthemes in detail.

XSL•FO
RenderX

Figure 1. Overview of the themes. AI: artificial intelligence.

Theme 1: Barriers to Effective Physician-Patient Communication

Patient-Level Barriers

Individual Background Differences

Physicians reported that patients' educational levels directly influenced communication effectiveness, with particularly notable differences between highly educated and less educated patients. Many highly educated patients tended to arrive with strong preformed views about their conditions, sometimes displaying overconfidence and questioning physicians' clinical judgments. Conversely, patients with limited education required extensive, repeated explanations to understand medical information, frequently resulting in miscommunication. For these patient groups, the standardized communication methods taught in medical schools were largely ineffective, and time constraints in high-volume outpatient settings made it difficult to tailor communication strategies to individual patients. As one physician explained,

> *For some well-educated patients, the problem lies in overconfidence; for others, I need to explain and rephrase multiple times before they can understand what I mean.* [Dr05]

Patient age also shaped communication dynamics. Younger patients demonstrated higher autonomous learning motivation and were more likely to form preliminary self-diagnoses before consultations, a tendency exacerbated by the digital information environment elaborated in the subsequent section (see "System-Level Barriers"). Furthermore, they often approached health care from a consumerist perspective, expecting guaranteed outcomes and engaging in what participants described as excessive rights protection behaviors, such as recording consultations and filing complaints. Such behaviors often prompted physicians to adopt defensive communication practices, including avoiding discussions of clinical uncertainty. As a member of the physician-patient relations office noted,

> *Many young patients treat medical consultations like 'online shopping,' expecting guaranteed treatment outcomes and a 'seven-day free return' policy. However, medicine is inherently fraught with uncertainty, and no one can guarantee outcomes...Some patients record every interaction, forcing physicians to speak with excessive caution and hesitate to discuss treatment uncertainties.* [A03]

Inadequate Expression and Limited Health Literacy

Inadequate symptom expression and limited health literacy are the primary patient-level barriers to physician-patient communication. Physicians reported that many patients lacked the ability to accurately describe symptoms and express their core consultation needs clearly. Patients often used colloquial language, requiring physicians to adjust their questioning strategies repeatedly and clarify complaints through follow-up inquiries. Even so, patients frequently provided irrelevant responses, resulting in the loss of key clinical information. One physician elaborated on the difficulty of obtaining effective clinical information:

> *When I ask under what specific circumstances the stomach pain occurs, they just repeat 'severe bloating' without answering the actual question...Sometimes we spend five minutes and still cannot obtain the necessary information, which leaves us feeling quite helpless.* [Dr07]

XSL•FO
RenderX

One physician further noted,

> *Patients who can clearly express their conditions and are quite professional are actually rare... The health literacy of most patients in China still has significant room for improvement.* [Dr01]

Beyond incomplete symptom descriptions, participants emphasized a significant disconnect between patients' surface-level expressions and their underlying needs. One physician added,

> *Some patients are unable to clearly articulate their true needs; in fact, what a patient says during a consultation may not reflect their actual needs. If the doctor cannot discern this, communication will still fail even if the diagnosis is correct.* [Dr05]

Psycho-Emotional States and Expectation Misalignment

Physicians described encountering contradictory patient demands and misaligned expectations during treatment processes. On one hand, patients' psycho-emotional status, such as disease-related anxiety, significantly disrupted communication. One physician provided a vivid example:

> *A patient might just have a sore throat, but it is accompanied by overwhelming anxiety, fearing they would be reprimanded by their boss, and might even lose their job.* [Dr03]

Such intense emotional states caused patients to talk excessively and pose repetitive questions, overwhelming the physician and impeding effective clinical communication. On the other hand, expectation misalignment was also evident when patients sought definitive diagnoses or guaranteed outcomes while resisting the examinations or costs required to support clinical decision-making. As one physician stated,

> *Some patients hope for both definitive diagnosis and cost savings, which is somewhat contradictory in certain situations. For example, to give a definitive diagnosis, I need to order some examinations to find the root cause. Naturally, this requires more examinations, but once examinations increase, patients feel that costs might be higher, so contradictions exist here.* [Dr01]

Physician-Level Barriers

Communication Style Deficiencies and Empathy Gaps

Physicians' professional capabilities directly influenced their ability to understand and manage patient conditions. Good professional competence helped enhance patient trust and treatment compliance; conversely, insufficient professional capabilities not only weakened therapeutic effects but also reduced communication effectiveness. As one physician noted,

> *If I cannot clearly explain or show confidence in diagnosis, patients will naturally doubt what I say.* [Dr02]

Some physicians exhibited authoritative tendencies in communication, often assuming patients could understand medical concepts while lacking the ability to translate professional information into accessible language. Communication involved excessive use of medical terminology and rigid language, tending toward unidirectional information delivery rather than shared decision-making with patients, sometimes displaying condescending attitudes. As a member of the physician-patient relations office observed,

> *Many physicians tend to dominate conversations. They use many professional terms, but patients often have no idea what they mean.* [A06]

This approach not only weakened patient participation but also exacerbated power imbalances between physicians and patients, making patients feel ignored or disrespected. Furthermore, when facing physician-patient conflicts, some physicians lacked awareness of appropriate vulnerability demonstration and empathy expression, requiring improvement in communication skills. A physician remarked,

> *Physician-patient conflicts often escalate from verbal confrontations. In some cases, some conflict escalations occur when physicians insist on verbal dominance and want to win the argument. When patients feel disadvantaged in communication process, they may turn to other forms of confrontation, such as calling 12,315 (Chinese consumer rights complaint hotline), or engaging in physical confrontation. In my view, physicians do not need to compete for victory; instead, they can show appropriate vulnerability and defuse conflicts before they escalate beyond verbal confrontation.* [Dr02]

Time Pressure Constraints

Insufficient time was the most frequently mentioned communication barrier by physicians. Participants' accounts showed that high patient volume, limited staffing, and heavy workload reduced the time physicians could allocate to each consultation. Several physicians described that, although they valued communication and recognized its importance in clinical care, time pressure often constrained them to provide detailed condition explanations. For instance, one physician stated,

> *Patients might wonder why physicians can't give them more time. I also want to give them plenty of time, but I need to see 50 patients in one morning, with over ten people still waiting. My work pressure is also enormous; I can only try my best to do well.* [Dr05]

Likewise, one physician noted,

> *it's almost time to clock out, and there are still 10 to 20 people are queuing behind you...objectively, there is simply no time.* [Dr09]

This perception was also echoed by a member of the physician-patient relations office, who commented,

> *Some physicians see 50 patients in a single morning. Do they realistically have the time to explain everything to each patient individually? Not possible.* [A06]

XSL•FO
RenderX

System-Level Barriers

Hospital Environment and Medical Visit Settings

Any problems in the medical care-seeking process, such as long waiting times or cumbersome examinations leading to poor visit experiences, could cause patients to project emotions onto physicians with whom they directly interacted. Emotional venting was one of the important causes of physician-patient communication conflicts. Some patients carried emotions from negative previsit experiences into communications with physicians. A member of the physician-patient relations office described,

> *The tipping point for a patient's emotional outburst is rarely an isolated incident; rather, it is the culmination of their preceding experiences. For example, patients waited one or two hours to see the physician, the consultation is over in just two or three minutes. After that, patients have to go through examinations, wait for reports, make payments, and return visits. The whole process is very exhausting.* [A02]

Insufficient Communication Training

Although medical education invested heavily in clinical skill development, physician-patient communication training remained relatively underdeveloped, with curriculum content primarily focused on diagnosis and technical operations, while communication training for high-complexity clinical scenarios and patient emotional and psychological needs remained insufficient. This problem was particularly prominent among young physicians. Limited by clinical experience, they often lacked confidence in communication and struggled to quickly establish trust; simultaneously, patients questioned the professional authority of junior physicians, further exacerbating communication barriers. A member of the physician-patient relations office noted,

> *In school, physician-patient communication was not a core curriculum. Although hospitals provide training after employment, genuine communication skill improvement still depends on personal understanding. Because communication scenarios are complex, merely teaching communication theory cannot actually solve practical problems. Communication is a capability requiring lifelong learning.* [A04]

Legal and Policy Deficiencies

Insufficient legal enforcement and protection mechanisms left both patients and physicians feeling vulnerable. Physicians reported that patients currently possessed numerous accessible channels for expressing demands; however, physicians lacked adequate advocacy channels when facing unreasonable demands, verbal abuse, or violence. This "legal vacuum" forced medical staff to adopt defensive postures, hindering honest dialogue about medical uncertainty or treatment limitations. Additionally, complex medical insurance policies (such as reimbursement scope and self-payment ratios) often became "noise" in physician-patient communication. Prescription authority restrictions, medical insurance reimbursement clauses, or hospital regulations often forced physicians to refuse patient requests. This "institutional rejection" was easily misunderstood by patients as physician indifference, exacerbating relationship tensions. As one physician stated,

> *If I cannot be certain of receiving protection when problems arise, I will avoid discussing any potentially controversial content.* [Dr11]

One physician expressed similar difficulties,

> *Sometimes I must say 'no' due to regulations, but patients think I simply don't care.* [Dr04]

Media-Driven Distrust and Digitally Mediated Information Challenges

Participants described media narratives and digital health information environments as important barriers to effective physician-patient communication. For one thing, biased media coverage of negative medical incidents was found to foster patients' preconceived distrust of physicians prior to consultations, which directly hindered the establishment of therapeutic rapport, mutual trust, and open communication. As one physician observed,

> *Some media's negative medical reporting affects patients' impressions of physicians. Patients believe physicians are making money from patients' illnesses, arriving with such preconceived notions before visits. In such situations, it's very difficult for physicians to change these prejudices through communication, so public opinion direction is extremely important.* [Dr07]

On the other hand, the growing use of digital technologies and the wide availability of online health information introduced new communication challenges. Physicians reported that patients increasingly searched for health information online and, in some cases, used AI tools such as DeepSeek (Hangzhou DeepSeek Artificial Intelligence Co, Ltd) before or after consultations. Patients were often described as becoming partially informed through fragmented online or AI-generated information, without fully understanding the broader clinical context. This increased the explanatory burden on physicians and sometimes shifted consultations away from treatment planning toward the correction of misinformation. As one physician explained,

> *More and more patients come with DeepSeek recommendations. Although I'm willing to maintain an open attitude to communication, each time I need to spend time mutually sharing materials and judging which side is more reasonable and has stronger evidence, it's quite exhausting. Sometimes I spend more time explaining why AI recommendations aren't suitable for patients than discussing actual treatment plans.* [Dr09]

XSL•FO
RenderX

Theme 2: Facilitators of Effective Physician-Patient Communication

Patient-Level Facilitators

Effective Expectation Management

Effective management of expectations was identified as a key characteristic of patients that facilitates constructive physician-patient communication. Participating physicians clearly preferred patients who understood the limitations of medicine, the complexities of diagnosis, and the uncertainties of treatment outcomes. As a member of the physician-patient relations office explained,

> *Many patients expect health to be a completely disease-free state. But medicine has its limitations. Physicians can only promise to improve conditions through treatment; a complete absence of disease is impossible. If patients can manage their expectations, we can have peaceful discussions about what is possible, rather than being forced to make promises that we cannot fulfill.* [A01]

Physicians noted that such patients enabled more open and honest discussions about treatment options, potential outcomes, and associated risks.

Good Health Literacy and Communication Readiness

Patients' strong communication skills and adequate health literacy helped improve physician-patient interaction quality. Patients who could clearly present medical histories, ask targeted questions, and demonstrate understanding of basic medical concepts enabled physicians to focus more on complex decisions and personalized treatment.

> *If patients can clearly describe symptoms and understand basic terminology, we can spend more time developing treatment plans rather than starting from scratch.* [Dr11]

Patients' strong sense of health responsibility was also emphasized as a valuable factor promoting physician-patient communication. Physicians valued well-prepared patients who maintained organized medical records, obtained information from reliable sources, and asked clear questions.

> *A patient who communicates well knows they are the primary person responsible for their own health, rather than believing that medical visits are entirely the physician's responsibility. Patients can prepare their past medical history materials as much as possible, allowing us to communicate and interact, examine disease development trends, making the entire diagnostic and treatment process smoother and more efficient.* [Dr09]

Trust in Physicians and Shared Decision-Making

Patient trust in physicians and shared decision-making more easily helped patients and physicians establish balanced and mutually trusting dialogue atmospheres. Physicians emphasized preferring patients who respected their professional knowledge while asking insightful questions, with shared decision-making during communication interactions being more aligned with patient needs.

> *Trust is the foundation. When patients trust physicians but still ask questions, this means they are actively participating in communication. This type of communication interaction more easily facilitates shared decision-making, helping patients choose treatment plans most suitable for their current personal situations.* [Dr01]

Physician-Level Facilitators

Active Listening and Patient-Centeredness

Participating physicians emphasized that active listening and patient-centeredness were foundations of effective medical communication. Through attentive listening, asking follow-up questions based on patients' verbal or nonverbal cues, and summarizing their core concerns, physicians not only made patients feel heard and valued but also reduced risks of missing important symptoms or worries. One physician mentioned,

> *I believe treating illness requires standing from the patient's perspective, first treating the heart. Many patients don't have physical illness but anxiety. When physicians patiently listen to their complete expressions, patients may feel half-better upon leaving the consultation room.* [Dr10]

Empathy and Emotional Support

Empathy and emotional support were repeatedly mentioned as core elements for building trust and enhancing treatment compliance. Physicians who could recognize patient fears, acknowledge their concerns, and provide comfort could establish relationships transcending clinical interventions. Such connections were viewed as key to alleviating anxiety and enhancing patient confidence in treatment processes.

> *I believe a very important aspect of being a doctor is having understanding and empathy, being able to comprehend why patients say what they do; additionally, being able to make patients feel 'this physician understands me' from the first words spoken.* [Dr05]

Clear Explanations and Cultural Adaptability

Using accessible language for clear explanations was viewed as key to bridging gaps between medical expertise and patient understanding. Physicians described the importance of translating professional terminology into colloquial language, using analogies or visual aids when appropriate, and confirming patient comprehension levels to improve communication. One physician emphasized,

> [Many medical professional terms are incomprehensible to patients; we need to translate professional terms into common people's language, making them understandable and clear. Dr02]

Maintaining transparency when discussing diagnoses, treatment options, and prognoses was also viewed as a hallmark of effective communication. Physicians who frankly discussed uncertainties, limitations, and potential complications could

XSL•FO
RenderX

maintain hope while setting realistic expectations, thereby avoiding disappointment and conflict. Many associated this transparency with more collaborative relationships, especially when combined with shared decision-making approaches that incorporated patient preferences and values.

> *I told them frankly what we knew, what we didn't know, and what the risks were, and then we decided together how to proceed.* [Dr11]

When interacting with diverse patient populations, cultural sensitivity and adaptive communication styles were viewed as crucial. Recognizing differences in health beliefs, communication preferences, and decision-making processes enabled physicians to adjust communication approaches accordingly, reducing misunderstandings and promoting respectful, culturally appropriate care. As one physician explained,

> *If you don't understand the patient's cultural background, you may be talking, but you're not really connecting.* [Dr11]

System-Level Facilitators

Institutional Support and Security Assurance

Physicians unanimously emphasized that institutional support and security assurance provided by medical institutions were important prerequisites for physicians to conduct effective communication. For example, hospitals' zero-tolerance policies toward violence and abuse, along with clear behavioral standards and response mechanisms, made physicians feel more secure and confident when communicating with patients, thereby reducing defensive behaviors and promoting open dialogue. Transparent and efficient complaint handling processes were highly valued for protecting physicians from unfounded accusations while ensuring reasonable patient grievances were addressed. Multidepartmental collaboration and information-sharing mechanisms, along with third-party coordinator intervention (such as physician-patient relations offices, AI assistants, and patient companions), could effectively reduce information gaps and misunderstandings, ensuring continuity and smoothness in diagnostic and treatment processes. As a member of the physician-patient relations office said,

> *Patients always feel that they are the weaker party, but in fact they already have multiple channels for providing feedback. Healthcare workers are quite difficult because various parties may make all kinds of demands on them. Medical institutions should provide health care workers with more psychological, financial, and other forms of support, and ensure their safety, so that healthcare workers can focus on clinical work and form a virtuous cycle.* [A03]

Process Optimization and Patient Health Education

Physicians believed that streamlined processes could help shorten patient waiting times and reduce information delays. Additionally, providing patient health education to empower them to play an active role in their treatment was crucial for maintaining high-quality communication. In particular, patient education and health literacy improvement programs could help patients better understand medical information and actively participate in medical discussions, thereby reducing communication barriers caused by information asymmetry. As one physician explained,

> *If the appointment and check-in processes are straightforward and patients receive basic guidance beforehand, they will arrive less stressed and better prepared. We can use that time for what truly matters, such as collaboratively determining the best next steps.* [Dr11]

Educational Training and Policy Promotion

Participants emphasized that education and policy interventions were key to maintaining and strengthening these facilitating factors. Embedding scenario-based communication training throughout medical education and professional development (such as role-playing, standardized patient simulations, and video reviews) could significantly enhance physicians' practical communication abilities. Mentorship and exemplary demonstrations helped continuously reinforce communication skills in clinical environments, forming positive transmission. At the policy level, through patient rights and responsibility education, health care worker protection legislation, and performance assessments incorporating communication quality indicators, effective communication could become an important measure of medical services, incentivizing physicians to continuously improve communication abilities and ensuring sincere exchanges in safe environments. A member of the physician-patient relations office explained,

> *Physician-patient communication is not just one-time learning, but requires reminders, feedback, and support at every stage of professional careers.* [A05]

AI-Assisted Baseline Knowledge

In contrast to the communication barriers posed by fragmented internet information (as displayed in Theme 1), some physicians hold positive attitudes toward AI-assisted diagnosis when used by patients with adequate health literacy. They viewed it as a superior alternative to traditional, unreliable information sources. Highlighting this nuanced perspective, one physician stated,

> *I generally welcome these learning-oriented patients; at least most AI information is accurate. I'd rather they consult AI than turn to Baidu platform or listen to neighbors.* [Dr08]

Simultaneously, some physicians emphasized that AI diagnosis required professional oversight to reduce risks and ensure patient benefits.

> *I maintain an overall positive attitude toward AI diagnosis. Relying solely on AI for diagnostic decisions carries risks, but these risks can be managed through professional oversight, ultimately benefiting patients at the patient level.* [Dr02]

This divergence illustrates that the digital information environment acts as a double-edged sword, where its impact heavily depends on the patient's underlying health literacy and the physician's guiding approach.

Discussion

Principal Findings

This qualitative study explored the barriers and facilitators of physician-patient communication in Chinese tertiary hospitals from dual perspectives of physicians and patient relations coordinators, and organized these factors into a multilevel framework covering patient, physician, and system levels. At the patient level, barriers included individual background differences, inadequate expression and limited health literacy, and psycho-emotional states with expectation misalignment; facilitators included effective expectation management, good health literacy and communication readiness, and trust in physicians with shared decision-making. At the physician level, barriers involved communication style deficiencies and empathy gaps as well as time pressure constraints; facilitators included active listening and patient-centeredness, empathy and emotional support, and clear explanations with cultural adaptability. At the system level, barriers encompassed hospital environment and medical visit settings, legal and policy deficiencies, insufficient communication training, and media-driven distrust with digitally mediated information challenges; facilitators included institutional support and security assurance, educational training and policy promotion, process optimization and patient health education, and AI-assisted baseline knowledge.

Consistent with the propositions of information ecology theory [28], our findings emphasize that physician-patient communication is not determined by individual factors alone but is embedded in contextual environments. This suggests that improving health care interactions cannot be achieved solely by enhancing physicians' professional skills. Similar to previous research [29-31], we found that excessive administrative burdens and conflict management responsibilities undermine physicians' ability to engage in effective communication with patients. Redistributing nonmedical responsibilities to appropriate administrative personnel or digital systems may alleviate physicians' workload, reduce communication fatigue, and ultimately foster more meaningful, patient-centered interactions. Administrators from patient relations coordinators emphasized systemic solutions, including third-party mediation mechanisms, cross-departmental coordination, and a zero-tolerance policy for violent behavior. These measures are often overlooked but are important drivers for improving communication between physicians and patients. These perspectives challenge the dominant focus on individual-level communication training. However, it allows physicians to focus on their core medical responsibilities with peace of mind.

Furthermore, our findings highlight the need to attend to patient-level barriers and facilitators that influence physician-patient communication. As proposed by Inui and Carter [32], physician-patient communication is a reciprocal exchange that demands active participation from both parties. While patient-centered communication requires balanced information exchange and complementary roles, the communication gap often extends beyond simple information asymmetry to include disparities in health literacy, shared understanding, and collaborative care capacity [33,34]. To bridge this gap, comprehensive patient education programs are essential and should address 2 key dimensions. First, education must narrow the knowledge divide between medical professionals and the general public. This entails moving beyond traditional paternalistic models toward a collaborative framework in which patients become informed partners, equipped with basic health literacy, a clear understanding of treatment options, and realistic expectations regarding therapeutic outcomes [35]. Second, such programs should build communication competencies, empowering patients to make the most of limited consultation time by articulating symptoms clearly, asking relevant questions, expressing concerns appropriately, and participating in shared decision-making [36]. When patients proactively express their expectations and concerns, physician-patient communication becomes more efficient and meaningful. This, in turn, fosters mutual tolerance, understanding, and respect, thereby promoting a supportive and reciprocal communicative dynamic [37].

Within a multilevel framework, AI functions as a digitally mediated environmental factor that introduces new challenges to physician-patient communication. Although existing studies have often compared patient preferences for AI- versus physician-generated communication [38], or evaluated the relative quality of AI-assisted and clinician communication [39], less is known about how physicians respond when patients bring AI-generated information into real-world consultations. Our findings address this gap by showing that physicians did not view AI-informed communication as uniformly beneficial or harmful, but evaluated it according to how patients used, interpreted, and communicated AI-generated information during clinical encounters. Consistent with recent scoping review evidence [39], our findings suggest that AI-informed communication was not perceived as uniformly harmful or beneficial. On the one hand, AI may improve patients' baseline knowledge and support more informed questioning, thereby creating conditions for more patient-centered communication. On the other hand, it may also introduce new communication pressures when AI-generated information is inaccurate, decontextualized, or treated by patients as a substitute for clinical judgment. Importantly, physicians in our study did not uniformly reject AI-informed patients. Rather, they distinguished between patients who used AI as a learning tool to better understand their condition and those who used AI-generated advice to challenge professional judgment. This finding suggests that the impact of AI on physician-patient communication depends less on the presence of AI itself than on how AI-generated information is interpreted, communicated, and managed within clinical encounters.

Strengths and Limitations

Grounded in the context of Chinese tertiary hospitals, this study breaks the limitation of single-stakeholder views by integrating the experiences of practicing physicians with the insights of patient relations coordinators. It bridges micro-level clinical encounter practices with macro-level organizational processes and further identifies the double-edged sword effect of digital transformation on physician-patient communication. Collectively, this work provides constructive reflections for

XSL•FO
RenderX

optimizing physician-patient interactions in high-workload clinical environments.

Several limitations should be noted. First, this study focused on tertiary hospitals in Guangzhou and Shenzhen, 2 economically developed cities in southern China. While these settings provide valuable insights into high-complexity health care environments, findings may not fully reflect communication dynamics in different hospital levels or geographic regions. Second, the qualitative design offers rich contextual understanding but cannot quantify the relative importance of identified factors or establish causal relationships. Third, the study was conducted during a specific timeframe and may not capture evolving digital health trends. Future research should examine communication patterns across diverse health care settings and incorporate mixed methods approaches to validate these findings and assess intervention effectiveness.

Conclusion

This qualitative study of frontline physicians and patient relations coordinators within tertiary hospitals in China identified the key barriers and facilitators to physician-patient communication. Our findings support that effective physician-patient communication is influenced by a variety of factors, including patient-, physician-, and system-level factors. In the modern era, physician-patient communication is challenged by consumerist medical attitudes, the internet age, and societal changes, but also benefits from new mechanisms such as third-party coordination and technological assistance. To achieve effective communication, it is necessary to understand these complex factors and establish a relationship based on mutual understanding and respect, while also implementing systematic education and training, policy support, and organizational improvements to optimize the communication environment.

Acknowledgments

The authors would like to express their sincere gratitude to all participants in this study. The authors declare the use of generative artificial intelligence (GenAI) in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to GenAI tools under full human supervision: proofreading and editing, and reformatting sentence structure in specific, limited portions of text. The GenAI tool used was ChatGPT-5.4. Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Funding

This research was supported by Basic and Applied Basic Research Foundation of Guangdong Province (grant number 2023A1515011124). The funder had no role in the study design; data collection, management, analysis, or interpretation; manuscript preparation, review, or approval; or the decision to submit the manuscript for publication.

Data Availability

The datasets generated and/or analyzed during the current study are not publicly available to safeguard participant confidentiality but are available from the corresponding author on reasonable request.

Abstract

Background: *Clostridioides difficile* infection (CDI) is the most common cause of health care–associated infectious diarrhea; however, variability in laboratory testing results in uncertainty in diagnosis and clinical decision-making. Recurrent CDI (rCDI), defined as the return of infection following initial treatment, continues to present significant clinical challenges due to limited therapeutic options. Although health care providers are familiar with vancomycin as first-line therapy for CDI, many are less familiar with fecal microbiota transplantation (FMT), despite its recommendation in clinical guidelines for rCDI management. Consequently, primary care providers (PCPs) may experience uncertainty regarding diagnostic test interpretation, treatment selection, and referral for FMT, highlighting the need for practical clinical tools to support evidence-based management.

Objective: This study will support the standardization of care and improve patient treatment experiences in Alberta by identifying barriers and facilitators encountered by PCPs in managing CDI and rCDI, using these findings to codevelop a provincial rCDI clinical pathway.

Methods: This qualitative study investigated the codevelopment process of a provincial rCDI clinical pathway between the study team and intended end users. A draft pathway was developed by the study team comprising gastroenterology and infectious disease specialists, followed by an iterative end user–centered design approach. PCP participants completed 2 rounds of 60 - to 90-minute virtual, one-on-one, semistructured interviews incorporating scenario-based usability testing with standardized clinical cases. Using a think-aloud approach, participants evaluated the pathway's clarity, diagnostic decision-making, treatment recommendations, referral processes, and integration into clinical workflows. Feedback was analyzed using thematic analysis, informed iterative revisions were made to the pathway and accompanying user guide, and they were reevaluated in a second round of interviews.

Results: Out of 30 invited PCPs, 3 (10%) participated in this study. During the first round of interviews, participants identified challenges interpreting PCR-positive vs toxin-positive test results, navigating the pathway layout, locating embedded hyperlinks, and understanding FMT referral processes. Iterative, feedback-driven revisions addressed these barriers by improving diagnostic guidance, simplifying navigation, increasing hyperlink visibility, and clarifying referral timing with a user guide. During the second round of interviews, all participants reported that modifications improved CDI test result interpretation, streamlined navigation, enhanced workflow integration, and increased confidence in applying the pathway to clinical scenarios. The final version of this pathway was well received for its clarity, readability, and clinical utility, and was viewed as a valuable educational resource for supporting evidence-based management of CDI.

Conclusions: This study demonstrated the feasibility and value of codeveloping a provincial clinical pathway with physician partners for managing CDI and rCDI. The resulting tool was clear, practical, and aligned with primary care workflows. This iterative, user-centered design was useful for developing clinically relevant decision support tools. Future research should evaluate the pathway's implementation and impact on physician practice, patient care, and clinical outcomes using quantitative and qualitative methods.

KEYWORDS

Clostridioides difficile infection; clinical pathway; codevelopment; primary care providers; fecal microbiota transplant

Introduction

Clostridioides difficile infection (CDI) is a significant health care priority, representing the most common causes of health care–associated infectious diarrhea, commonly triggered by antibiotic use [1]. Gaps in knowledge around CDI diagnosis and recurrent CDI (rCDI) management have contributed to suboptimal and delayed treatments [2,3]. Specifically, CDI is diagnosed in patients who have diarrhea and a positive stool test for toxigenic *Clostridioides difficile*. Diagnostic confusion arises because there are two main categories of laboratory assays: (1) an enzyme immunoassay for toxins A and/or B with high specificity but low sensitivity (33% - 65%) [4], and (2) a polymerase chain reaction (PCR)–based assay with higher sensitivity (approximately 90%) but much lower specificity, as it cannot differentiate between active infection and asymptomatic colonization [5]. While most practitioners are comfortable with vancomycin as the first-line therapy for CDI, most are not familiar with guideline-recommended fecal microbiota transplantation (FMT) for patients with at least 2 recurrences [6,7]. Not only is FMT an efficacious treatment option, it is also the most cost-effective strategy for treating rCDI [8]. In a retrospective study in Alberta, timely FMT, defined as administration after the second recurrence, was associated with mean per-patient cost savings of approximately CAD $29,842 (CAD $1=US $0.71 as of September 23, 2026) compared with delayed FMT [9]. Additional challenges exist as many primary care providers (PCPs) are unsure when to refer [10] or how to access FMT.

Clinical pathways are evidence-based tools designed to translate clinical practice guideline recommendations into routine practice while standardizing and coordinating patient care within a multidisciplinary health care setting [11]. A study evaluating the implementation of a clinical pathway for liver surgery found that its use significantly reduced hospital stays and postoperative costs without increasing postoperative morbidity [12]. However, traditional top-down dissemination of clinical practice guidelines often fails to address potential barriers to their development, dissemination, and implementation [13,14]. As such, it is crucial to involve end users in codeveloping this rCDI pathway to optimize guideline implementation and timely care for rCDI patients.

Methods

Study Overview

This study describes the process of cocreating a provincial clinical pathway to support physicians in the management of patients with CDI (including rCDI) in Alberta, Canada, while highlighting key aspects of CDI care, including diagnosis, treatment, and referral processes.

Ethical Considerations

Ethics approval was obtained from the University of Alberta Research Ethics Board (Pro00130489). All participants signed a written consent form and agreed to be video recorded during the interviews.

Physician Recruitment

A purposive sampling strategy was applied to recruit participants. PCPs were identified with the support of the Alberta Health Services (AHS) Primary Health Care Integration Network, interested primary care networks, the Alberta Medical Association, and the academic Department of Family Medicine at the University of Alberta. From this pool, PCPs with experience referring rCDI patients were contacted via email to assess their interest in participating. The FMT nurse navigator distributed consent forms and coordinated interviews.

Study Design and Codevelopment Process

We used a qualitative methodology to gather empirical data on the optimal format and clinical content of the proposed pathway. The draft provincial rCDI clinical pathway was first developed by the study team consisting of specialists in gastroenterology and infectious diseases in collaboration with the University of Alberta's Physician Learning Program. To facilitate use in clinical practice, the pathway incorporated direct links to existing provincial and Canadian clinical resources, including the Alberta Referral Directory, Bugs & Drugs [15], and other relevant guidance documents, allowing clinicians to access additional information as needed. This draft served as a low-fidelity prototype intended for iterative testing and refinement according to feedback from the end users. A user-centered design approach was also taken, as scenario-based usability testing and iterative prototyping can reveal cognitive and workflow mismatches that are not readily apparent through guideline development alone. Codevelopment activities consisted of 2 rounds of scenario-based usability testing conducted through one-on-one virtual 60 - to 90-minute interview sessions with PCPs. The sessions followed a semistructured format, framed by an interview guide with case scenarios in addition to open-ended questions. A separate interview guide was designed for each respective interview.

Prior to the first interview, PCPs were provided with the initial draft of the provincial rCDI pathway. During the interview, participants were asked to apply the draft pathway to 2 standardized patient case scenarios representing common but clinically challenging rCDI presentations. Using a think-aloud approach, PCPs described how they interpreted pathway steps, made treatment decisions, and determined referral appropriateness while navigating the tool.

The interviewer probed for clarity, decision confidence, points of hesitation, perceived ambiguities, and workflow misalignments. Particular attention was paid to how physicians interpreted diagnostic test results (PCR vs toxin), distinguished

XSL•FO
RenderX

recurrent cases from new infections, and identified when to reassess for alternative causes of diarrhea.

Following the first interview, usability findings were synthesized into structured summary tables and task success matrices capturing decision points, areas of confusion, drop-off locations within the pathway, and suggested revisions. These artifacts were used to guide iterative pathway redesign, including modifications to terminology, visual hierarchy, navigation cues, hyperlink visibility, and referral timing.

The revised pathway and an accompanying user guide were then retested with the same end user PCPs in a second round of interviews to assess whether prior usability issues had been resolved and to validate improvements in clarity, workflow integration, and clinical feasibility.

Data Collection and Analysis

The AHS Health System Knowledge and Evaluation team, acting as additional independent qualitative analysts, collaborated with the research team to design interview guides including sample case scenarios, facilitate interviews, and conduct data analysis. Verbatim transcripts generated from Microsoft Teams recordings were analyzed using a thematic analysis framework. To ensure methodological rigor, coding was conducted independently by a member of the study team and a member of the external AHS Health System Knowledge and Evaluation team. Discrepancies in code applications were resolved through consensus and consultation with the broader study team rather than using formal quantitative interrater reliability measures.

Theme derivation followed an inductive approach, progressing from initial open coding to group codes into broader, descriptive categories representing specific workflow barriers or design challenges. These categories were then structured into overarching thematic maps (Figures S1 and S2 in Multimedia Appendix 1) to visually map the relationships between diagnostic interpretation, pathway navigation, clinical workflow, and implementation feasibility.

In addition to thematic qualitative analysis, usability data were analyzed using task-based evaluation methods commonly used in human-centered design. Task success and failure were documented alongside qualitative observations and participant quotations. This dual analytic approach enabled triangulation between what physicians reported, how they navigated the pathway, and where design-related barriers emerged. Findings were iteratively mapped back to pathway revisions to ensure that identified usability issues directly informed design changes rather than remaining descriptive only.

Results

Participants

Of the 30 PCPs invited, 3 provided consent and subsequently participated in one-on-one interviews. Participant gender and practice history are presented in Table 1.

Table . Participant characteristics (N=3).

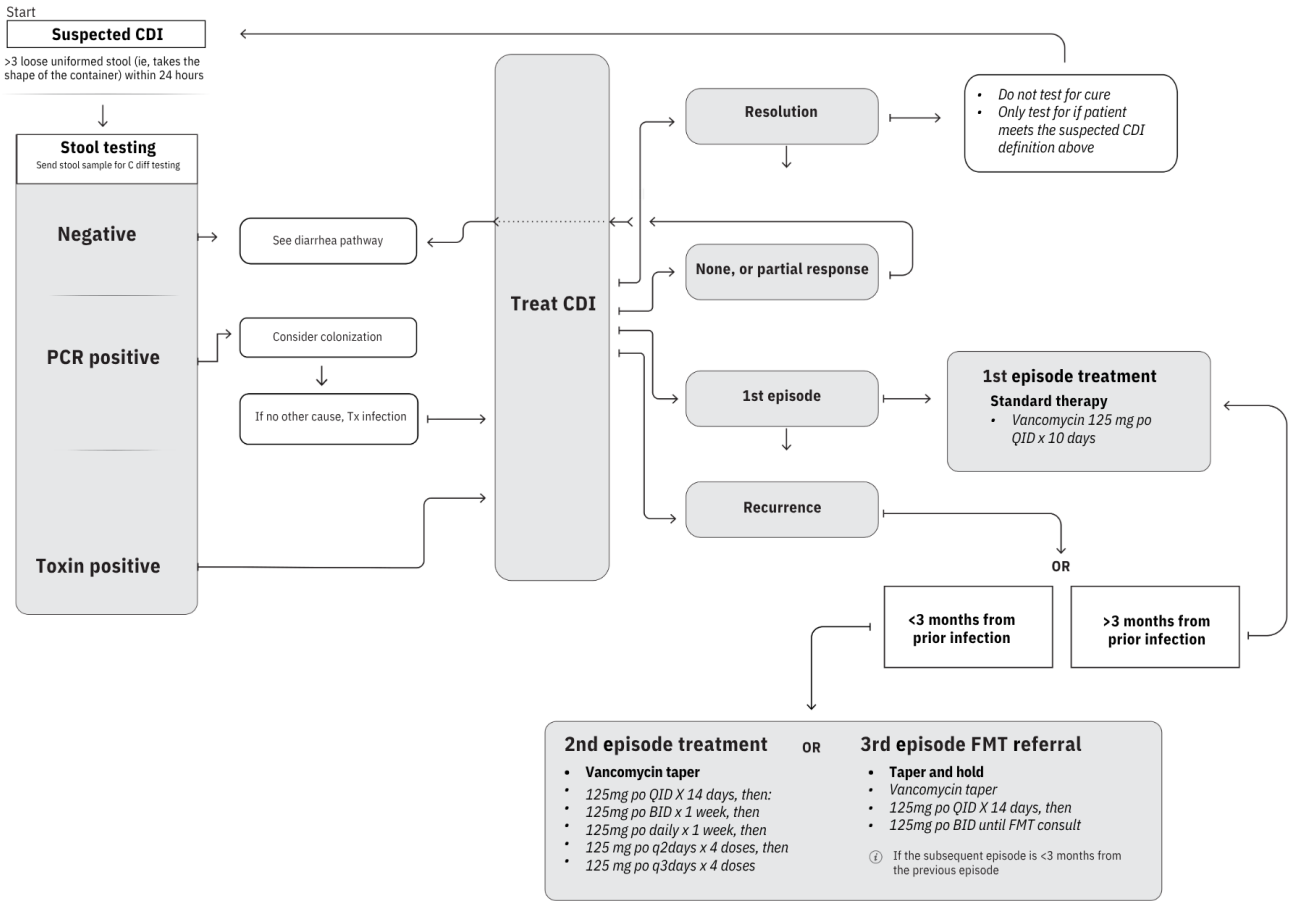
Characteristic	Participants, n (%)
Male	2 (66.7)
Health care specialty and practice setting	
Primary care	3 (100)
Plus emergency medicine	1 (33.3)
Plus geriatrics	1 (33.3)
Urban	2 (66.7)
CDI[a] patient volume (per year)	
<10 patients	2 (66.7)
>10 patients	1 (33.3)

[a]CDI: *Clostridioides difficile* infection.

Interview Sessions

PCP Interviews Round 1

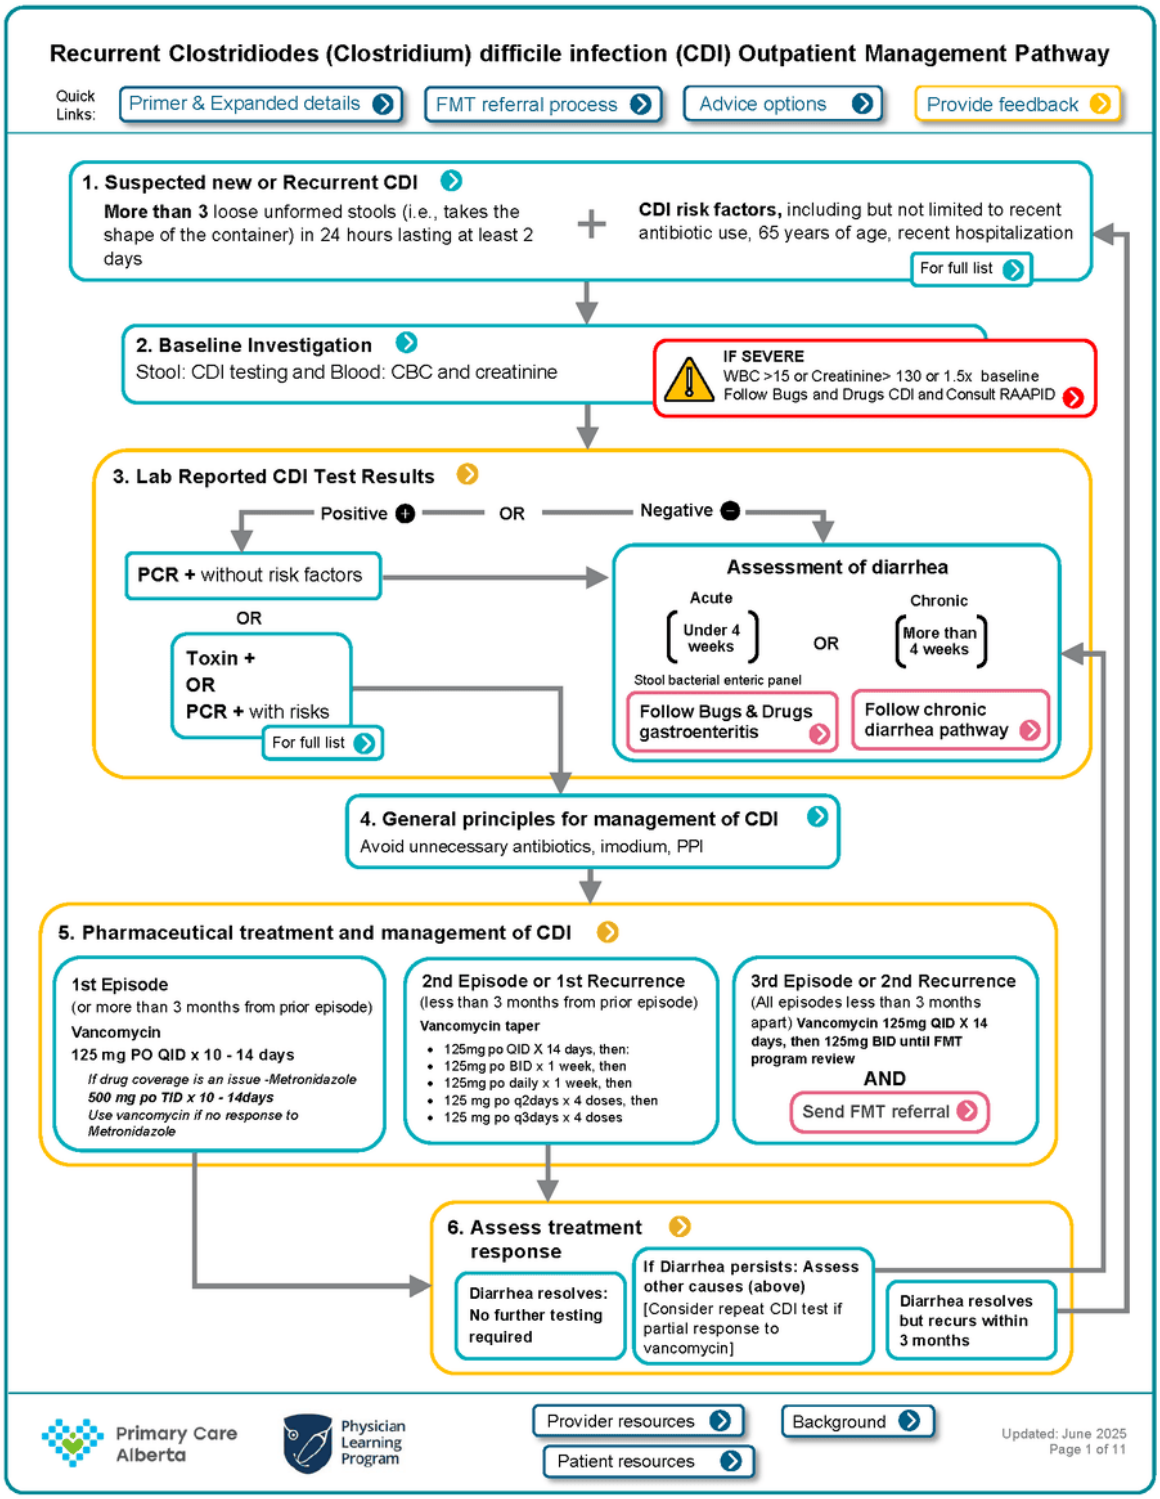
Three PCPs participated in 2 rounds of semistructured, one-on-one interviews. All 3 participants worked in primary care settings with annual patient volumes exceeding 500.



The first set of interviews were conducted between May 29, 2024, and June 6, 2024. The initial draft of the pathway incorporated direct access links to several resources: (1) Bugs & Drugs, an evidence-based antimicrobial reference guide for health care professionals in Alberta [15]; (2) the AHS diarrhea pathway, a clinical guide for managing diarrhea in primary care, including a step-by-step approach with investigations and management; and (3) patient education resources. A warning sign–flagged hyperlink was incorporated to distinguish fulminant CDI from severe nonfulminant CDI and to direct clinicians to the inpatient CDI management pathway for cases requiring urgent care. The pathway begins by outlining clinical criteria that define “suspected new or recurrent CDI,” followed by a recommendation to obtain a *C difficile* diagnostic test in the appropriate context. Subsequent management is guided by the test results, which may be (1) toxin positive, (2) PCR positive with additional risk assessment, or (3) both toxin and PCR negative. Based on these findings, the pathway specifies what treatment is required and outlines the recommended

XSL•FO
RenderX

clinical actions for CDI recurrence, including management for first, second, and third episodes. The pathway explicitly indicates FMT referral at the third episode (or second recurrence). Further recommendations are based on treatment response.



The initial and final versions of the pathway can be found in Figures 1 and 2, respectively. Visually, each major phase of decision-making is separated by dotted lines to delineate distinct stages of progression. Individual outcomes are presented in separate boxes to emphasize branching pathways. Embedded hyperlinks within the outcome boxes direct users to supplementary informational resources when required.

Figure 1. Initial draft of the recurrent *Clostridiodes difficile* infection (rCDI) clinical pathway prior to finalization. BID: twice a day (*bis in die*); C diff: *Clostridiodes difficile*; CDI: *Clostridiodes difficile* infection; FMT: fecal microbiota transplantation; PCR: polymerase chain reaction; po: by mouth (*per os*); q2days: every 2 days (*quaque* 2 days); q3days: every 3 days (*quaque* 3 days); QID: 4 times a day (*quater in die*); Tx: treatment.

XSL•FO
RenderX

Figure 2. Final version of the recurrent *Clostridiodes difficile* infection (rCDI) clinical pathway. BID: twice a day (*bis in die*); CBC: complete blood count; FMT: fecal microbiota transplantation; PCR: polymerase chain reaction; po: by mouth (*per os*); PPI: proton pump inhibitor; q2days: every 2 days (*quaque* 2 days); q3days: every 3 days (*quaque* 3 days); QID: 4 times a day (*quater in die*); RAAPID: referral, access, advice, placement, information, destination; WBC: white blood cell.

The first interview focused on eliciting participant feedback on the clarity and usability of the pathway. Participants were asked to apply the pathway to 2 patient scenarios and describe how they would manage each case, including the need for FMT referral and the appropriate timing and process for referral.

Task-based usability outcomes from the scenario-based interviews are summarized in Table 2. Participants completed a series of predefined clinical decision-making tasks, including distinguishing between new and recurrent CDI, interpreting diagnostic test results, selecting the appropriate management pathway, identifying the appropriate timing for FMT referral, and navigating the pathway to relevant supporting resources.

XSL•FO
RenderX

Areas of task difficulty identified during the first round of usability testing informed iterative revisions to the pathway prior to the second round of interviews.

Table . Participant performance on predefined usability tasks during pathway evaluation (N=3).

Usability task	Round 1	Round 2
Accurate classification of recurrence vs new infection	2/3 success; 1/3 partial success[a]	3/3 success
Interpretation of PCR[b]-positive vs toxin-positive results	0/3 success; 3/3 partial success[a]	3/3 success
Appropriate treatment selection	3/3 success	3/3 success
Correct identification of FMT[c] referral thresholds	2/3 success; 1/3 partial success[a]	3/3 success
Confidence[d] in next-step decision-making	2/3 success; 1/3 partial success[a]	3/3 success

[a]Partial success means the participant ultimately reached an appropriate decision but required clarification, showed significant hesitation, or completed only 1 of the 2 scenarios correctly.

[b]PCR: polymerase chain reaction.

[c]FMT: fecal microbiota transplantation.

[d]Confidence was not measured using a numerical scale during the interviews. This row is based on retrospective coding of participant hesitation, requests for clarification, and ability to independently identify the appropriate next step.

Complementary qualitative findings are presented in Figure S1 in Multimedia Appendix 1, which illustrates the thematic map generated from the first round of interviews. The thematic analysis identified barriers related to pathway design, structural organization, diagnostic test interpretation, navigation, and referral processes. Together, the usability and qualitative findings informed iterative refinements to improve the pathway's clarity, usability, and alignment with practitioner workflows.

> *I guess one of my questions would be about the testing. I think there needs to be something on this path...that talks about the difference between toxin testing and PCR testing, as I suspect I am not alone as a family physician in wondering when each of those happens.* [Participant 3]

> *That is a little bit ambiguous in terms of the PCR testing, that I would...clean that up, but just so that it makes it a little bit more clear cut that that's what you mean...I understand now that it's explained, but I wouldn't have thought that straight away.* [Participant 2]

Participants reported difficulty navigating the draft pathway, as the dotted lines gave the impression that sections were separate and did not allow users to circle back through the algorithm. Consequently, PCPs were uncertain about when to assess patients for alternative causes of diarrhea (Figure 1).

> *I'm wondering if...there's a way to link back from...this algorithm...it kind of makes it look like once you're in the "treat C diff" you don't go back, although I guess down at the bottom under treatment outcome you go down to "Assess other causes".* [Participant 1]

PCPs recommended clearer visual cues for hyperlinks, such as the use of consistent icons to indicate their presence. While the draft pathway clearly indicated when patients should be referred for FMT, 2 PCPs noted concerns about the referral process itself. Additionally, the placement of the FMT referral button did not clearly convey if the referral should occur concurrently with vancomycin treatment.

> *When I kind of first looked at the pathway it just kind of seemed a little bit out of place. Like I didn't know what, like where that kind of related, if you don't click the links.* [Participant 1]

> *Just in case there is anyone that perceives that as an ambiguity...If you send the FMT referral, if you put that as the first thing, and then you do that concurrently.* [Participant 2]

All participating PCPs reported that the pathway enabled them to distinguish between a new CDI infection and a recurrent infection. They also indicated that the pathway clearly outlined the treatment approach for both scenarios. Participants recommended including an appendix or user guide containing definitions and additional information to avoid having to consult an external source.

> *So on a lot of the specialist link pathways and provincial pathways and stuff they have the page like this, and then there's a link within here that just leads to almost an appendix that it details out risk factors or details out like higher risk features in more detail kind of things so that I don't have to go to a second source.* [Participant 1]

PCPs were asked whether their treatment approach differed when a patient's results were PCR positive vs toxin positive, and all indicated that it did. PCPs considered a PCR-positive result in patients without risk factors indicative of colonization and did not initiate CDI treatment. In cases where patients showed no response or a partial response to CDI therapy, PCPs reported extending treatment duration, conducting additional testing for alternative causes, and referring the patient as appropriate.

> *I would do more of a work up...broaden my differential and look at things again. If they were toxin-positive and didn't respond...I know the toxin*

XSL•FO
RenderX

> *takes a while to go away, even with treatment. So it would kind of depend how long, I might consider retesting for C diff, and...if the toxin was negative, [it] would be more helpful than if it's positive. But ultimately if I'm just really not sure what to do, I would usually do a connect MD phone consult or something like that.* [Participant 1]

When asked about the potential use of patient education materials linked to the pathway, all participating PCPs indicated they would use such resources. Additional feedback highlighted variability in clinical workflows, including differences between practices using provincially based electronic medical records or paper charts, which may affect how this clinical pathway is accessed. Some PCPs noted that certain pathway content was not fully aligned with information in Bugs & Drugs, which highlighted the need for consistency with existing reference materials.

> *That could be a very big hindrance in following this pathway [the misalignment with Bugs & Drugs]...I've dealt with some really recurrent C diff so I don't put people on Metronidazole. I put them on Vanco as my rule of thumb...whenever I have students and I teach them this because I'm also a precept at the university. I try and explain this and they said "no, no, but Bugs & Drugs says..." and I said "yeah, that's fine." But that's not what we should do...* [Participant 2]

Based on participant feedback, we incorporated additional resources, including links to alternative pathways for varying clinical scenarios and detailed information on the FMT referral process. The revised version was then presented to the same physicians during a second interview to further refine the pathway.

PCP Interviews Round 2

The second round of interviews was conducted between February 27, 2025, and March 11, 2025. Prior to these interviews, PCPs were provided with the revised provincial rCDI clinical pathway along with the user guide, which had been developed based on feedback from the first round of interviews.

Figure S2 in Multimedia Appendix 1 presents the thematic map derived from analysis of the second interview, focused on evaluating the revised pathway and assessing whether ambiguities were resolved. Overarching themes reflected improved diagnostic clarity, navigation, referral processes, and considerations related to workflow integration and implementation.

Task-based usability testing demonstrated improvements across all predefined tasks following pathway revision (Table 2), supporting the qualitative findings that participants experienced greater clarity in diagnostic interpretation, referral processes, and pathway navigation.

> *It was much more readable and more consistent with the other pathways.* [Participant 1]

The participating PCPs indicated that the revised pathway had improved clarity in diagnostic test interpretation, differentiation between new and recurrent CDI, referral timing, and overall ease of navigation.

> *It [the pathway] does [clarify test results]. Just the addition of the two categories on the third step is useful.* [Participant 3]
>
> *I think it makes it more clear about what's a recurrence versus what's a new infection...Yeah, I thought that section was definitely clarified. For sure, and easier to read.* [Participant 1]

One participant suggested removing the "If severe" box because the guidance provided in Bugs & Drugs was consistent with the information already in the pathway.

> *Because presumably, if your white blood cells are high and your creatinine's high, you also need the positive CDI test...if it's C. diff, then you go down to five. And it doesn't change what you do for that first episode, apart from the clinical assessment of maybe they need hydration or admission or something like that...but the instructions to follow Bugs & Drugs CDI, you're kind of doing that anyway. Going through the pathway, so you don't need to shunt someone else to a different source when it's exactly the same as what's later on in the pathway.* [Participant 1]

The user guide (Multimedia Appendix 2) was perceived as a comprehensive supplement to the pathway and was particularly helpful in diagnostic test interpretation, including the distinction between PCR-positive and toxin-positive results. However, participants indicated that the user guide added little additional value for CDI management or differentiating new vs recurrent infections, as the pathway itself already provided sufficient clarity.

> *That's [the User Guide] exactly what provides the clarity for sure.* [Participant 2]
>
> *Truthfully, it's pretty well laid out in the pathway. So really, in terms of the treatment itself, I don't know that the User Guide contributes a lot to the treatment component of it specifically...given that the pathway's quite clear on what the treatment would and should be.* [Participant 3]

This sample of PCPs viewed the pathway as a valuable educational resource and recommended several refinements to the accompanying user guide, including guidance for managing patients with a vancomycin allergy and providing contact information for physicians requiring further support. A recurring theme across interviews was how and when the pathway would be used. One suggestion was to attach or link the pathway to a positive CDI laboratory result, ensuring that physicians have the provincial rCDI clinical pathway and user guide available at the point of care.

> *That might be something to put on the PCR results of C diff testing at the bottom. Say, "please see Provincial Pathway for CDI, for recurrent CDI management." Because a lot of times someone comes in with diarrhea, you know, I think a lot of people are like, OK, C diff, I'm going to check for it and then they get the results back and they're like, "what do I*

XSL•FO
RenderX

> *do with this now?" And if you have the link directly there in the results...they're much more likely to look at it.* [Participant 1]
>
> *It's a good teaching tool in that sense, to physicians as well, because that will be implicit if someone follows the pathway and follows that course...it helps teach for the future.* [Participant 3]

Given the small sample size, thematic saturation may have been limited. However, recurring themes were consistently identified across interviews, supporting the credibility of the findings within this exploratory sample.

Discussion

Principal Result

Physician partners in our study identified important gaps in the current CDI clinical workflow, including inconsistencies in referral patterns and challenges in accessing consistent information. Through an iterative co-creation process with PCPs, we developed a physician-centered pathway to guide diagnosis, management, and referral for rCDI. The resulting pathway was perceived by participants as clinically relevant, practical, and easy to use, highlighting the feasibility of using a co-creation framework to design practical, end user–aligned clinical pathways. However, our participating physicians were all highly engaged, academically affiliated, and had prior experience referring rCDI patients, and results may differ if we had included participants in rural practices or those without prior experience with rCDI patients. Nevertheless, as a regional, qualitative development study, our results demonstrate the value of the co-design process. Future studies should evaluate pathway uptake and impact on clinical practice, referral patterns, health care utilization, and patient outcomes.

Current Landscape

Prior to this project, no provincial clinical pathway existed for CDI management in Alberta. While CDI practice guidelines have been published by professional societies, access to FMT in Canada remains limited, and most practitioners do not know when or how to access this treatment [16]. Clinical pathways may address these gaps by translating evidence into practice and improving access to emerging treatments. Integration of pathway content into electronic health records has been proposed as a low-effort strategy to enhance awareness [17], which informed the development of our clinical pathway.

Co-Creation Process

Co-creation is gaining recognition as a valuable way to bring together stakeholders to promote collaboration, support knowledge dissemination, and exchange perspectives [18]. In practice, coordinating multiple health care professionals during pathway development can be challenging. The complexity of the clinical problem, intervention, and implementation, including the need to align pathway goals across members of the health care team and ensure stakeholder engagement, may either facilitate or hinder both pathway development and implementation [19]. Also, a lack of leadership and limited intrinsic motivation can be barriers in a clinical setting [19]. Therefore, involving a specialist in a relevant health care field is essential for providing guidance and structure in the initial development of care pathways [20]. Across specialties, pathways have demonstrated effectiveness in standardizing patient care, improving timeliness, and reducing costs while not negatively affecting overall patient health outcomes [12,21]. For effective knowledge mobilization, particularly between specialists and PCPs, codevelopment provides an important mechanism for generating tools that are relevant and acceptable to stakeholders, more usable, and more likely to be successfully implemented within health care settings [22,23].

Embedding human-centered design methods allowed us to translate physician feedback into iterative refinements that improved our pathway's clarity and usability. Although the initial draft was developed by the multidisciplinary research team using existing evidence and specialist expertise, repeated engagement with PCPs allowed their perspectives to inform iterative pathway refinement. Future work could involve PCPs earlier in pathway conceptualization, enabling them to shape pathway content from the outset while further strengthening stakeholder ownership and supporting implementation.

Clinical Pathway Efficacy

The existing literature examining the co-creation of clinical pathways with PCPs is limited. However, studies evaluating clinical pathways more broadly demonstrate that their implementation can yield numerous positive outcomes across the journey of care, from diagnosis to treatment. One study assessing the impact of a clinical pathway reported a marked reduction in health care–associated CDI rates following the introduction of a mandatory pathway [24]. The investigators attributed this reduction to decreased rates of misdiagnosis, reducing the use of resources and health care costs and promoting the delivery of appropriate patient care.

Evidence from other studies further emphasizes the utility of clinical pathways in other areas. A study conducted in the United States found that implementing clinical pathways for nutritional management and lower airway inflammation in patients with cystic fibrosis resulted in more standardized and uniform care [25]. Additionally, a systematic review from Europe reported that care pathways enhanced health care staff knowledge, improved interprofessional documentation, and strengthened both communication and team relationships [26]. Across these studies, a recurring theme was the necessity of a multidisciplinary approach in developing and implementing care pathways, which can effectively support collaboration within interprofessional teams and enhance the quality of patient care [25,26].

Limitations

A key limitation in this study is the low number of participants. Potential participants may have been discouraged by the required time commitment of up to 4 hours, which can be a significant challenge for a busy clinician. Selection bias may also have been introduced in this exploratory codevelopment study; as participants were recruited through professional and academic networks, all 3 PCPs were academically affiliated and had prior experience treating and referring rCDI patients. Self-selection bias was also a concern, as those who agreed to participate may

XSL•FO
RenderX

have held stronger opinions regarding clinical pathways or a greater interest in quality improvement initiatives. Although this small sample size was appropriate for iterative pathway development, the findings may not fully reflect the perspectives of physicians practicing in other settings, those who have not managed rCDI patients, or other potential end users such as nurses, pharmacists, or patients. A greater diversity of participants may have provided valuable perspectives for further refining this pathway and its implementation. A higher number of participants would also permit specific feedback to be quantified to substantiate our qualitative analyses. As such, the findings should be viewed as exploratory and may not be transferable to community-based, rural-based, or less academically engaged practitioners and allied health care team members.

Supporting PCP engagement in research is essential to developing systemic interventions that mitigate clinical burdens and foster robust, interdisciplinary support networks across medical specialties [27,28]. Enhancing future PCP research participation requires a multipronged approach, which may include equitable financial compensation, reduced interference with daily practice routines, and enhanced institutional backing [29,30]. Future pathway refinement should also incorporate perspectives from additional stakeholders, including nurses, pharmacists, and a more diverse group of physicians, to strengthen the pathway implementation and transferability.

Methodological limitations should also be noted. The interview guides were not pilot tested, potentially limiting our ability to assess and refine the validity of their content [31]. Interviews are a valuable method for gathering information; however, the quality of data obtained through interviews can vary considerably depending on the researcher's qualifications, skills, and familiarity with the research topic.

Conclusions

The co-creation of clinical pathways with physician partners represents a feasible approach for developing clinically relevant decision support tools for the management of rCDI. Future research should explore the acceptability and effectiveness of alternative formats for the pathway to ensure these resources remain accessible and relevant across diverse primary care settings. As the rCDI clinical pathway is introduced into the provincial referral directory, prospective evaluation will be critical to assess its impact on clinical decision-making, referral practices, implementation, and patient outcomes, while informing future refinement of the pathway.

Abstract

Background: The rising cost of unscheduled acute health care, particularly for emergency department (ED) visits, poses significant financial burdens. In 2021, aggregate costs for treat-and-release ED visits in the United States accounted for an estimated US $80 billion, while the total annual cost of diabetes was US $412.9 billion in 2022—representing about 1 in every 4 health care dollars, 61% of which are directly linked to diabetes.

Objective: This study explores the impact of a mobile health (mHealth) intervention with augmented social support delivered via guided SMS text messaging on health care use among patients with diabetes through a secondary analysis of the TExT-MED+FANS (Trial to Examine Text-Messaging in Emergency Patients With Diabetes + Family and Friends Network Support) randomized controlled trial.

Methods: The trial involved 173 participants randomized into either a FANS mHealth-augmented social support or an active control group that received the same support curriculum via mailed pamphlet; “augmented” social support refers to recruiting both individuals with diabetes and a designated family member or friend (“supporter”) to participate. Supporters in the FANS arm received structured SMS guidance on how to assist the participant with diabetes in managing their condition. Health care use outcomes, including ED visits, hospitalizations, and clinic visits, were compared between groups during and after the intervention period using linear regression models on change in health care visits in the last year, with subgroup analysis by participant sex and supporter relationship.

Results: Results showed significant reductions in acute unscheduled care visits for both groups during and after the intervention, with the FANS group experiencing a reduction of 1.04 visits during the intervention and 1.10 visits after the intervention, while the mailed pamphlet group had reductions of 1.47 and 1.53 visits, respectively (both $P<.001$). Clinic visits increased by 1.78 during the intervention phase ($P=.01$) but were not sustained postintervention. Hospitalizations modestly decreased in both groups, but the decrease was statistically significant only for the mailed pamphlet group ($P=.002$). Sex and supporter relationship differences were observed, with females supported by spouses in the active control group showing the largest decrease in unscheduled care visits.

Conclusions: The findings suggest that mHealth interventions combined with structured social support can improve diabetes management and reduce health care costs. Although these conclusions are specific to this study, they align with prior research demonstrating the benefits of social support and mHealth interventions. These findings may inform future programs, including the design of low-cost, scalable interventions in resource-limited settings.

Introduction

The cost of unscheduled, acute health care, particularly for emergency department (ED) care, continues to rise, with the strain particularly evident among patients with diabetes. In 2021, aggregate costs for treat-and-release ED visits in the United States accounted for an estimated US $80 billion in costs, with the total annual cost of diabetes being US $412.9 billion in 2022, representing about 1 in every 4 health care dollars—61% of which are directly linked to diabetes [1,2]. Patients with diabetes may need frequent unscheduled care due to complicated care needs, difficulty accessing care, and lack of self-management skills that result in clinical decompensation [3,4]. The US health care system often faces heavy financial burdens resulting from unscheduled visits [2,5]. In addition, high medical bills and unpredicted lost productivity ultimately pose significant expenses to patients themselves [6]. This is compounded by the broader societal impact, where increased health care spending can affect economic stability. Finding strategies to minimize these costs is important to creating a more sustainable health care ecosystem.

Within the context of such challenges, mobile health (mHealth) interventions offer an approach to managing chronic diseases like diabetes, providing tools such as glucose monitoring, medication reminders, dietary tracking, and personalized coaching [7,8]. These platforms aim to reduce health care costs, improve accessibility, and enhance patient medication taking, engagement, and involvement [9-11]. Examining the impact of mHealth interventions on health care use is crucial for evaluating their feasibility and scalability across various health care settings and populations, as they can greatly reduce direct costs [12,13].

Social support plays an important role in diabetes management, with prior studies showing that family and friend involvement can improve medication taking, self-management behaviors, and glycemic stability [14-16]. Recent work has also examined mHealth-directed social support, suggesting that combining digital health tools with structured support may further enhance patient engagement and outcomes [16]. However, few studies have directly compared mHealth-augmented support with traditional in-person support or print-based approaches. Such comparisons are essential to inform comprehensive diabetes management strategies that effectively leverage both technology and social networks to improve patient care and reduce costs associated with unscheduled health care use.

To understand the impact of mHealth integrated social support on health care use, this study offers a detailed analysis of health care use trends as a secondary analysis of TExT-MEDS+FANS (Trial to Examine Text-Messaging in Emergency Patients With Diabetes + Family and Friends Network Support), a randomized controlled trial of mHealth-augmented social support (FANS) compared to standard social support (mailed pamphlet) added to a patient-focused mHealth curriculum for patients with diabetes. The primary research objectives were to assess the association between mHealth-delivered social support and its influence on health care–seeking behaviors, including the frequency and nature of health care use. We also examined whether the character of the existing support associations prior to the intervention modified the intervention effect.

Methods

Research Methodology

TExT-MED+FANS was a 12-month comparative effectiveness randomized controlled trial that investigated the impact of two exposures: (1) mHealth-augmented social support (FANS) and (2) standard social support (mailed pamphlet) on patient health care use outcomes. Participants were enrolled from June 2017 to December 2019. This study represents a secondary analysis of the original randomized trial data, focused on differences in health care periods and subgroup characteristics not examined in the primary publication. For further information on the methods used in TExT-MED+FANS and the specific mHealth program under study, please refer to the protocol study by Burner et al [17].

Ethical Considerations

The study received approval from the University of Southern California Health Sciences Institutional Review Board (HS-17 - 00406). All participants provided written informed consent. Data were stored in an encrypted dataset and were not deidentified to allow linkage to electronic medical record (EMR) information. Consent procedures were conducted in English or Spanish, depending on patient preference. Patients and supporters were provided with compensation ranging from US $20 to US $280, depending on the number of study visits completed [16].

Study Population

Study Protocol: Screening

Patients were eligible to participate if they had either type 1 or type 2 diabetes with elevated glycated hemoglobin (A_{1c}) levels ($A_{1c} \geq 8.5$), were aged 18 years or older, possessed the capability to send and receive text messages, could identify a supporter, and were able to provide informed consent.

Enrollment of Patient

Trained research assistants used convenience sampling by approaching eligible patients with diagnosed diabetes identified through their EMR during routine ED visits, regardless of the nature of the patient's visit. No public advertisement or broader outreach strategy was used. Patients provided informed consent and completed an intake interview in their preferred language (English or Spanish). They were then registered in the SMS text-messaging platform to access the TExT-MED patient curriculum. While in the ED, patients nominated a family member or close friend to serve as their supporter for the study, and research assistants collected contact information for up to 3 supporters.

Enrollment of Support Person

Support person enrollment took place concurrently in the ED or through telephone communication within a 2-week window following patient enrollment. Supporters completed the enrollment process by providing informed consent and verifying their ability to send and receive text messages.

XSL•FO
RenderX

Randomization

Following supporter enrollment, patient-supporter dyads were randomized to either mHealth-augmented social support through the FANS program or standard social support delivered via mailed pamphlets. If the dyad was randomized to the FANS arm, research assistants registered the family member in the SMS text-messaging platform to receive the mHealth-augmented support curriculum. A computer-generated simple randomization sequence was used, with allocation concealed via sealed envelopes until assignment.

Treatment Groups: Exposures

The main exposure variable was the type of social support intervention: mHealth-augmented support (FANS) versus standard support (mailed pamphlet). Every patient received the SMS text message–based patient curriculum (TExT-MED) regardless of their group assignment. This included automated, static (noninteractive) text messages delivered daily for 6 months. The content included education on diabetes self-management, encouragement, and reminders. Messages were not personalized. Supporters in the intervention group received a text message–based curriculum (FANS) guiding them to provide mHealth-augmented social support to their loved ones. These messages were also static and noninteractive, delivered twice weekly. Supporters in the active control group received standard social support through the same material and curriculum distributed via a mailed pamphlet. No additional support or follow-up beyond the pamphlet was provided to the control group supporters.

Measures: Outcomes and Assessments

The primary outcome was health care use, assessed through EMR review. Outcome variables that were included are given below:

1. Acute unscheduled care, defined as any visit to the Medical Center ED or urgent care.
2. Hospitalizations, defined as any inpatient stay recorded in the Los Angeles County Department of Health Services system.
3. Scheduled clinic visits, defined as fulfilled clinic appointments with a primary care provider within the Los Angeles County Department of Health Services.

All calculations underwent scrutiny by 2 reviewers, with any discrepancies resolved through consensus.

Measurement Phases

The following measurement phases were used to assess changes in health care use over time:

- Prior: 6 months prior to enrollment.
- Active: from the intervention start date to the intervention end date (a 6-month period).
- After intervention: end of intervention date to 6 months after intervention. Participants did not receive SMS text messages during this period.

At the time of enrollment, patients self-reported their sex, race or ethnicity, primary language, duration of diabetes, and access to primary care. Age and insurance status were extracted from the EMR. Insurance status was classified as means-tested (eg, Medicaid or other government insurance programs), non–means-tested (eg, Medicare or private insurance), or uninsured (no recorded insurance coverage at the time of the visit). The supporter's sex was reported by the supporter, and for analysis purposes, supporters identified as cohabitating significant others by the patient were considered spouses. Supporters other than spouses were categorized as nonspouse supporters, encompassing various relationships such as siblings, friends, or children.

Data Analysis

The intervention group assignment was otherwise examined with an intention-to-treat approach, regardless of patient or supporter dropping out of the TExT-MED or FANS text messages. Analysis was completed with STATA (version 17.0; StataCorp LLC). Data were examined with histograms and did not violate assumptions of heteroscedasticity. Baseline characteristics were examined descriptively as a whole and by intervention group (Table 1).

In our main effects analysis, we used linear regression models with outcomes of change scores of health care visits from (1) baseline to the end of intervention phases, and (2) from the end of intervention to the end of maintenance phase, examining differences in health care use by the FANS augmented versus traditional mailed pamphlet groups (Table 2). The main independent variable was intervention group assignment. No other independent variables were included in the main effects model. Differences between groups were estimated with the contrast and margins function. We individually examined unscheduled acute care visits (ED and urgent care visits), hospitalizations, and scheduled care (clinic) visits. For subgroup analysis, we used an interaction term for sex and supporter relationship to examine the moderating effect of supporter relationship and sex with the same procedures (Table 3).

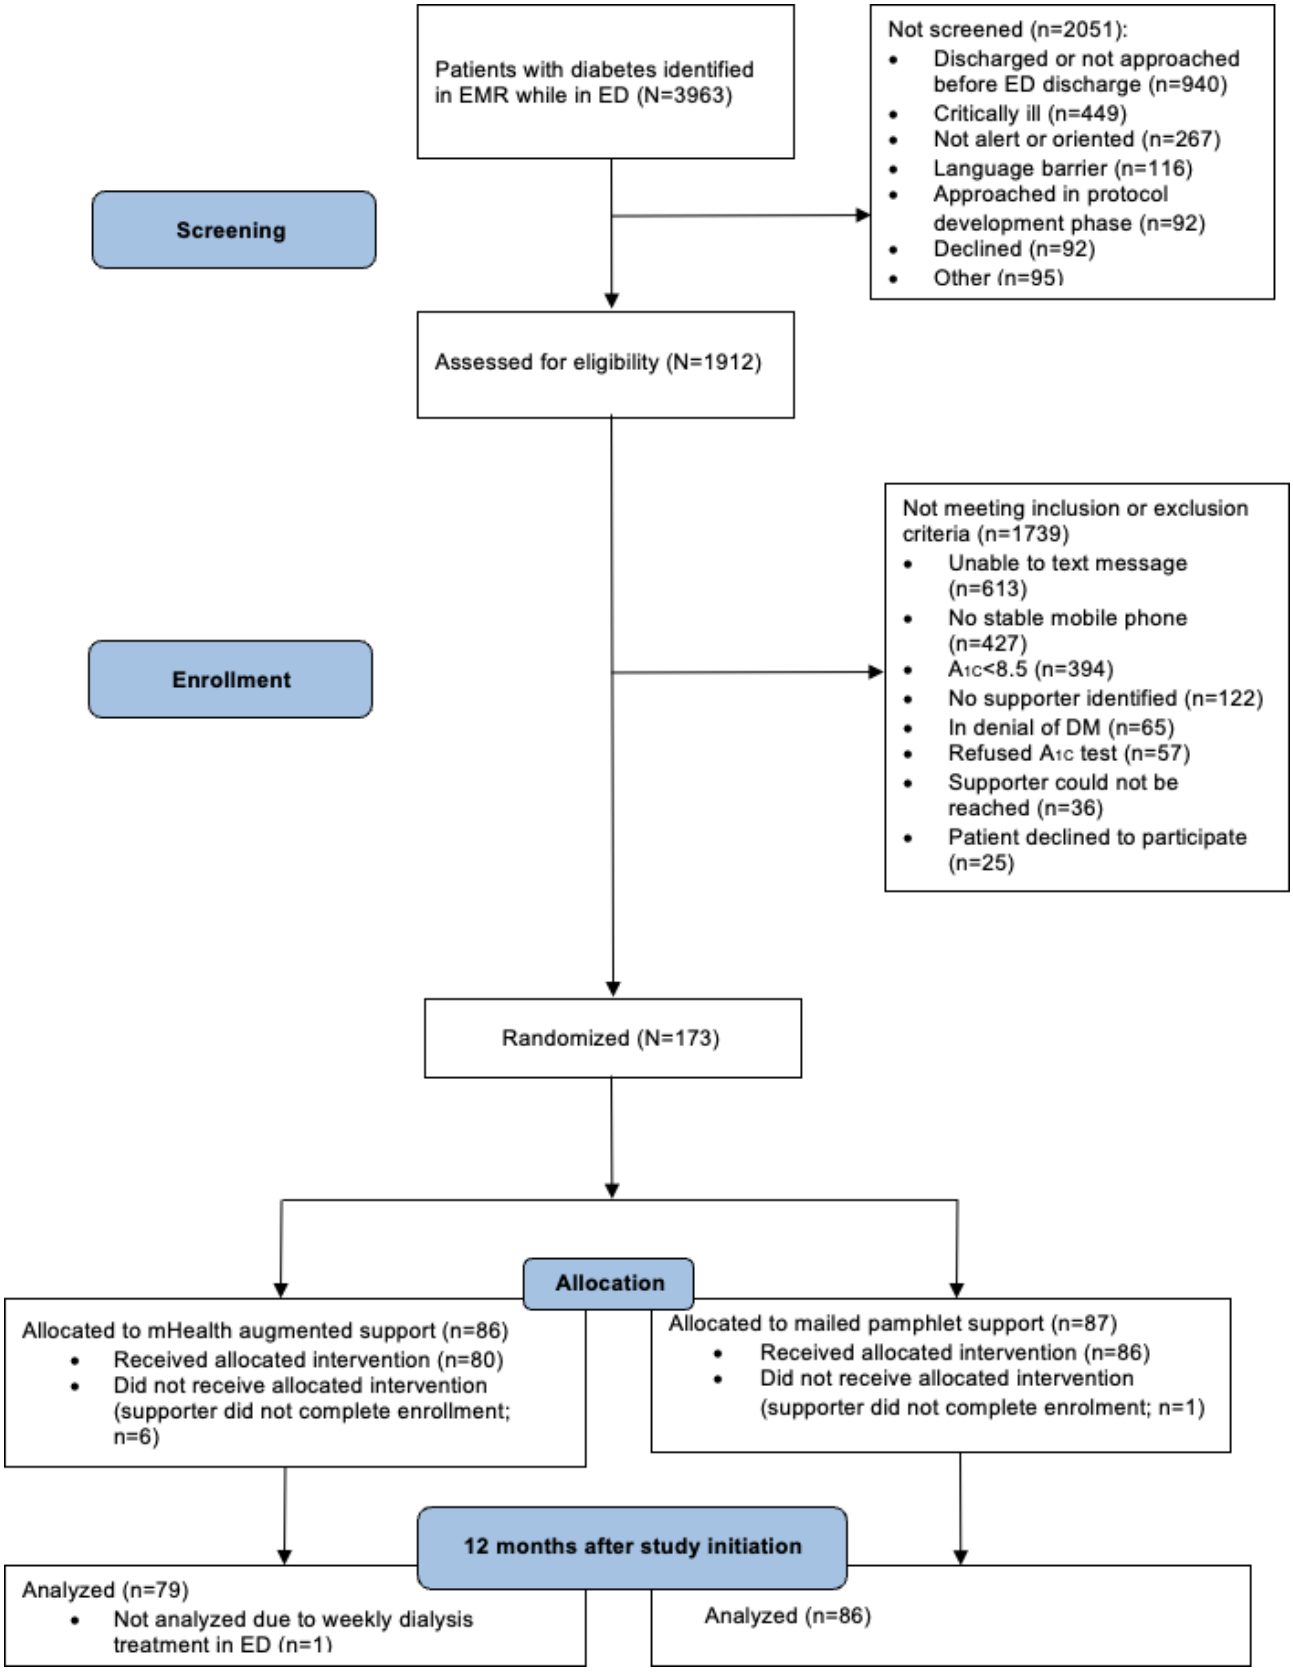
[a]Values represent the mean change in health care use (with 95% CIs) by sex and supporter relationship for each study period. *P* values indicate the significance of within-group changes.

[b]FANS: Family and Friends Network Support.



Results

In this study, a total of 3963 patients with diabetes were identified from electronic health records while in the ED (Figure 1). Of these, 12051 patients were not screened for various reasons, including critical illness, discharge or nonapproach before ED discharge, lack of alertness and orientation, language barriers, and other reasons. Among the screened individuals, 1739 were excluded due to inability to send SMS text messages, lack of a stable mobile phone, A_{1c} <8.5%, absence of a supportive individual, and other reasons (n=183; Figure 1). Ultimately, 173 patients were randomized into the study and allocated either to mHealth-augmented support (86/173, 49.7%) or standard social support (mailed pamphlet; 87/173, 50.3%). One participant in the mHealth-augmented group was excluded from this analysis because they were undergoing thrice-weekly dialysis treatment in the ED due to insurance limitations during the study period. The final analytic population was composed of 165 participants randomized into 2 intervention groups: FANS with 79 participants and a mailed pamphlet with 86 participants.

The average age of a patient was 47.59 (10.5) years, and males comprised approximately half of the study population, with a slightly higher proportion in the FANS group (45/79, 57%) compared to the mailed pamphlet group (37/86, 43%). The majority of participants self-identified as Latino or Hispanic (152/165, 92.1%), with small representations from Non-Latino or Hispanic White (2/165, 1.2%), Asian (2/165, 1.2%), and Black (9/165, 5.5%) backgrounds. A substantial proportion of participants primarily spoke Spanish (115/165, 69.7%). Insurance coverage was predominantly means-based (Medicaid or other means-based government insurance programs; 153/165, 92.7%), with a few participants either non–means-based insured (Medicare or private insurance) (7/165, 4.2%) or uninsured (5/165, 3%). Most participants had visited a primary care provider within the previous 6 months (127/165, 77%). The average duration of diabetes among the participants was 11.39 (9.7) years, indicating a long-standing condition of diabetes within the cohort (Table 1).

Figure 1. Participant flow diagram. DM: diabetes mellitus; ED: emergency department; EMR: electronic medical record; FANS: Family and Friends Network Support; mHealth: mobile health.

The results from the study indicated significant changes in health care use across different types of care visits during the intervention and postintervention phases (Table 2). During the intervention phase, there was a notable reduction in acute unscheduled care visits across both intervention groups. The FANS group experienced an average decrease of 1.04 visits (P<.001), while the mailed pamphlet group saw a larger average decrease of 1.47 visits (P<.001). This trend was sustained after intervention, with reductions of 1.10 and 1.53 visits, respectively, for FANS and mailed pamphlet groups, both

XSL•FO
RenderX

statistically significant (P<.001). The difference between the FANS and mailed pamphlet groups was not statistically significant in either period.

Clinic visits increased during the intervention phase, with the FANS group showing a mean increase of 1.78 visits (P=.01) and the mailed pamphlet group an increase of 1.00 visits (P=.02). However, this increase was not sustained after intervention, with the changes becoming statistically insignificant and the direction of change mixed. There was a difference of 0.62 visits between the intervention groups during the postintervention period; however, this was not statistically significant.

Hospitalization rates showed a modest decrease during the intervention phase with reductions of 0.24 visits in the mailed pamphlet group and 0.18 visits in the FANS group, with the former being statistically significant (P=.002). This decreasing trend in hospitalizations continued into the postintervention phase with similar reductions. There was a difference of −0.07 between the intervention groups, though this was not statistically significant.

During the 6-month interval, females with spouse supporters in the mailed pamphlet group experienced a significant decrease in acute unscheduled care visits, showing a reduction of 2.41 visits (P<.001). In contrast, males with spouse supporters saw a decrease of 1.19 visits (P=.002) in the FANS group and a similar decrease in the mailed pamphlet group. Females with nonspouse supporters and males with nonspouse supporters also showed significant decreases, though the effect was strongest in those with spouse supporters. Clinic visits increased significantly during the 6-month interval for both females and males with spouse supporters in the FANS group, with increases of 4 visits (P=.03) and 3.21 visits (P=.002), respectively.

Discussion

Principal Findings

In this study, we evaluated the impact of a mHealth-augmented social support intervention (FANS) compared to an active control (mailed pamphlet) on health care use among patients with diabetes, analyzing data from 165 participants to assess changes in acute unscheduled care visits, clinic visits, and hospitalizations. The main findings indicate a significant reduction in acute unscheduled care visits and hospitalizations for both intervention and active control groups, with this effect maintained after intervention. Moreover, an increase in clinic visits was seen during both the intervention and postintervention phases. In addition, we found that the type of supporter, particularly whether or not the supporter was a spouse, played a role in study participants' use of the mentioned health services.

The reduction in acute unscheduled care visits aligns with existing literature supporting the effectiveness of mHealth interventions and educational pamphlets in improving patient self-management [18]. Previous studies have shown that providing structured support and education to patients with chronic diseases can lead to better health outcomes [19]. Specifically for patients with diabetes, these interventions have been linked to improved diabetes care, glycemic stability, and reduced A_{1c} levels [20]. Moreover, the integration of mHealth technologies has facilitated more consistent monitoring and timely interventions, enhancing overall disease management. Such approaches not only empower patients but also foster a proactive engagement in their health care journey, ultimately reducing the burden on acute care services [21].

There is a notable gap in the literature regarding health care use following mHealth interventions, particularly concerning ED visits, hospitalizations, and clinic visits for patients with diabetes. While extensive data exists on the impact of such interventions on other chronic conditions, like chronic obstructive pulmonary disease (COPD), similar comprehensive studies on diabetes-focused mHealth interventions are lacking. Yang et al [22] demonstrated that an mHealth curriculum for patients with COPD significantly reduced the risk of hospitalizations, although it did not yield a substantial difference in the average length of stay. In this study focusing on diabetes, a marked reduction in the frequency of hospitalizations was observed both during and after the intervention; however, we did not examine the length of stay. While both conditions benefit from mHealth interventions, the nature and progression of diabetes and COPD may present unique challenges and opportunities for reducing healthcare utilization, emphasizing the need for more tailored research in diabetes-specific programs.

The subgroup analysis revealed that while acute unscheduled care visits decreased significantly across most supporter groups, females with spouse supporters in the FANS group showed no significant change. The type of supporter may influence the intervention's effectiveness, aligning with prior work indicating that spousal support by sex can vary widely in its impact on health behaviors [23]. These patterns underscore the complex role of social support dynamics, as highlighted in previous studies which have shown that the quality and type of support can differentially impact health outcomes [24,25]. Specifically, research has emphasized the effectiveness of spousal support in chronic disease management, including diabetes, due to the consistent and close nature of the support provided [26]. Clinic visits increased significantly for females with spouse supporters during the intervention phase in both groups, which aligns with studies indicating that females are generally more proactive in seeking preventive care [27-29]. In this study, this increase was only sustained in the FANS group, suggesting the potential for digital health tools to maintain engagement with health care services. This study's findings align with these insights, suggesting that while mHealth interventions can be broadly beneficial, their impact may be moderated by the type of support relationship involved.

The findings of this study have substantial implications for public health and policy. The reduction in acute unscheduled care visits among patients with diabetes through mHealth-augmented social support interventions highlights the potential of such technologies in enhancing chronic disease management. Policy makers should consider integrating mHealth solutions into standard care protocols, particularly for populations with limited access to care, to improve health care accessibility and outcomes [20,30,31]. In addition, investing in

XSL•FO
RenderX

mHealth platforms could alleviate the financial burden on health care systems by reducing the frequency of costly acute unscheduled care visits and hospitalizations [32,33]. Public health initiatives should also focus on promoting digital literacy and access to mHealth technologies, ensuring that communities that have been historically marginalized can fully benefit from these advancements. By incorporating mHealth interventions into broader health care strategies, a more sustainable and equitable health care system can be created that better addresses the needs of patients with chronic conditions like diabetes. Future research and policy initiatives should also consider incorporating structured family or supporter-based engagement as a mechanism to enhance intervention effectiveness and long-term adherence.

This study has several limitations that must be considered when interpreting the findings. First, the small sample size and the secondary analysis nature of the study may limit the internal validity of the results. Using secondary data introduces inherent limitations, including potential bias related to how the original study was designed and executed. Since this analysis was not prespecified in the original study protocol, there may be risks of selective reporting or post hoc interpretation. In addition, certain variables of interest may not have been collected or controlled for in the original trial design, potentially limiting the scope of inferences. Future research with larger, more diverse populations is needed to confirm these findings. Second, acute unscheduled care visits in this study included both urgent care and ED visits, due to the structure of the Los Angeles County Department of Health Service Electronic Health Record System. While urgent care visits are less costly than ED visits, they still are inferior to scheduled clinic care and are not the desired health care use pattern [34,35]. Third, the sample was predominantly composed of individuals from Hispanic or Latino and low-socioeconomic backgrounds who used means-based insurance. These findings may not be generalizable to populations with different demographic and socioeconomic characteristics. Despite these limitations, the study provides valuable insights into the potential benefits of mHealth interventions. Addressing limitations and exploring tailored approaches can enhance the efficacy and reach of such interventions.

Conclusions

This study contributes to the growing body of evidence examining the use of mHealth tools to support chronic disease management, reduce the burden on health care systems, and support the effectiveness of structured support systems and educational interventions in enhancing patient self-management and reducing health care use. mHealth-augmented social support interventions, such as the FANS program, may be able to reduce acute unscheduled care visits and hospitalizations among patients with diabetes. Though more work in this area is needed to identify who will most benefit, we saw indications that these interventions, particularly when involving spouse supporters, can lead to meaningful improvements in health care outcomes and engagement with preventive care services. The significant reductions in unscheduled care visits suggest that mHealth-augmented social support can effectively improve diabetes management, particularly for disproportionately affected groups. These findings underscore the importance of incorporating digital health solutions into chronic disease management social support strategies to improve health care outcomes and reduce acute care reliance.

Abstract

Background: This study presents a novel virtual health-humanities approach to collaborative online international learning, developed and delivered between 2023 and 2025. The approach, which we describe for the purposes of this study as a "Health Humanities Global Classroom" (HHGC), aimed to raise health professions students' awareness of intercultural perspectives, potentially fostering more interculturally attuned health professionals. In the HHGC, students across 3 international universities participated synchronously in a virtual object-based learning seminar using shared teaching expertise and digitized artworks and museum objects drawn from the universities' diverse art and cultural collections.

Objective: This mixed methods research study aimed to assess the HHGC's impact on encouraging a deeper awareness of intercultural perspectives in participants.

Methods: A mixed methods study was conducted, involving 58 health professions students from universities in Australia, Singapore, and Hong Kong in February 2025 and March 2025. All students participated in a 2-hour online seminar with the theme of global health and well-being, during which they undertook guided exploration of virtual museum objects and artworks. Data on students' seminar experiences were collected through presurveys and postsurveys, written reflections created during the seminar, and online focus groups conducted immediately afterward.

Results: All 58 students participated in the focus groups. Among the participants, 84% (49/58) completed the postseminar survey; 96% (47/49) agreed that the seminar increased their awareness of how they communicate and exchange meanings with peers from diverse cultures; 98% (48/49) agreed that engaging with the museum objects in the seminar with peers heightened their awareness of diverse perspectives; and 86% (42/49) agreed that the seminar increased their awareness of local health in interprofessional contexts. Four primary themes were identified through qualitative analysis, including (1) key learning outcomes (intercultural, analytical, and empathic capacities, and knowledge acquired), (2) enabling factors (pedagogy, environment, and peer interaction), (3) barriers to learning (pedagogical approach, learning resources, time factors, and virtual constraints), and (4) novel and distinctive experiences (international, arts-integrated learning).

Conclusions: This study provides early evidence for an innovative and accessible pedagogical approach. The HHGC is promising as a valuable educational activity, with positive student engagement in a safe environment for intercultural dialogue mediated by virtual museum objects and artworks. This approach may be useful to enhance participants' awareness of cultural humility.

Introduction

Background

Providing culturally sensitive and appropriate care is a cornerstone of modern global health equity. Medical and educational institutions increasingly seek curricula that foster intercultural competence [1-6]. While there is currently no consensus on the definition of "intercultural competence," it is widely understood as the "ability to communicate effectively and appropriately in intercultural situations based on one's knowledge, skills, and attitudes" [7,8]. Additionally, as a pedagogical objective, the acquisition of "intercultural competence" betrays an assumption that culture is a finite body of knowledge to be mastered, a view that risks reducing complex human worlds to a static checklist of traits [7].

A combination of methods such as lectures with simulations, role-playing, and community engagement with diverse populations has been found to enhance intercultural competence [9]. Experiential learning, such as international placements, has also made a positive impact on the development of cultural competence among health professional students [10]. However, these incur financial costs and logistical barriers, making them inaccessible for many. The reach of such interventions is further limited by packed, discipline-specific health curricula that relegate humanistic approaches that cultivate essential skills like empathy, observation, and comfort with ambiguity to their periphery. This creates a critical gap: a need for scalable, accessible, and pedagogically innovative methods to mainstream intercultural competence learning.

To address these pedagogical challenges, we designed a new humanities-based methodology which could be used as an intervention in an existing health professions curriculum. Our approach, which we describe as a "Health Humanities Global Classroom" (HHGC), builds on the known potential of 3 pedagogical approaches, specifically museum-based health education (MB-HE), object-based learning (OBL), and collaborative online international learning (COIL).

MB-HE

MB-HE uses carefully facilitated engagement with art and museum collections to support the development of transferable skills and ways of thinking among health professionals, such as visual observation, tolerance for ambiguity, awareness of bias and diversity of perspectives, empathy, and self-reflection. By connecting these experiences in the museum to clinical practice, the approach aims to promote more humanistic, patient-centered care, and simultaneously support well-being and reduce burnout [11,12]. MB-HE activities are commonplace in many universities' health education curricula around the world and are extensively reported as an effective pedagogical approach [11,12]. Particularly since the COVID-19 pandemic, this approach has been translated into online learning environments with varied success [13-15]. Online collaborative intercultural peer group activity in the global health educational context has been beneficial for student learning by complementing existing teaching in global health [16].

OBL

OBL is a student-centered, experiential pedagogy that uses direct engagement with artworks, museum objects, and artifacts, and other types of material culture such as archives or scientific instruments, to stimulate observation, enquiry, and knowledge construction [17]. Differing from MB-HE, it is applied in any disciplinary context and, in its simplest form, is taught as a small-group "hands-on" investigation of a single object, where meaning or interpretation is built through discussion [17]. OBL has been adopted globally and is increasingly recognized as a powerful tool to promote ethical considerations of material culture, collections, and power [18].

COIL

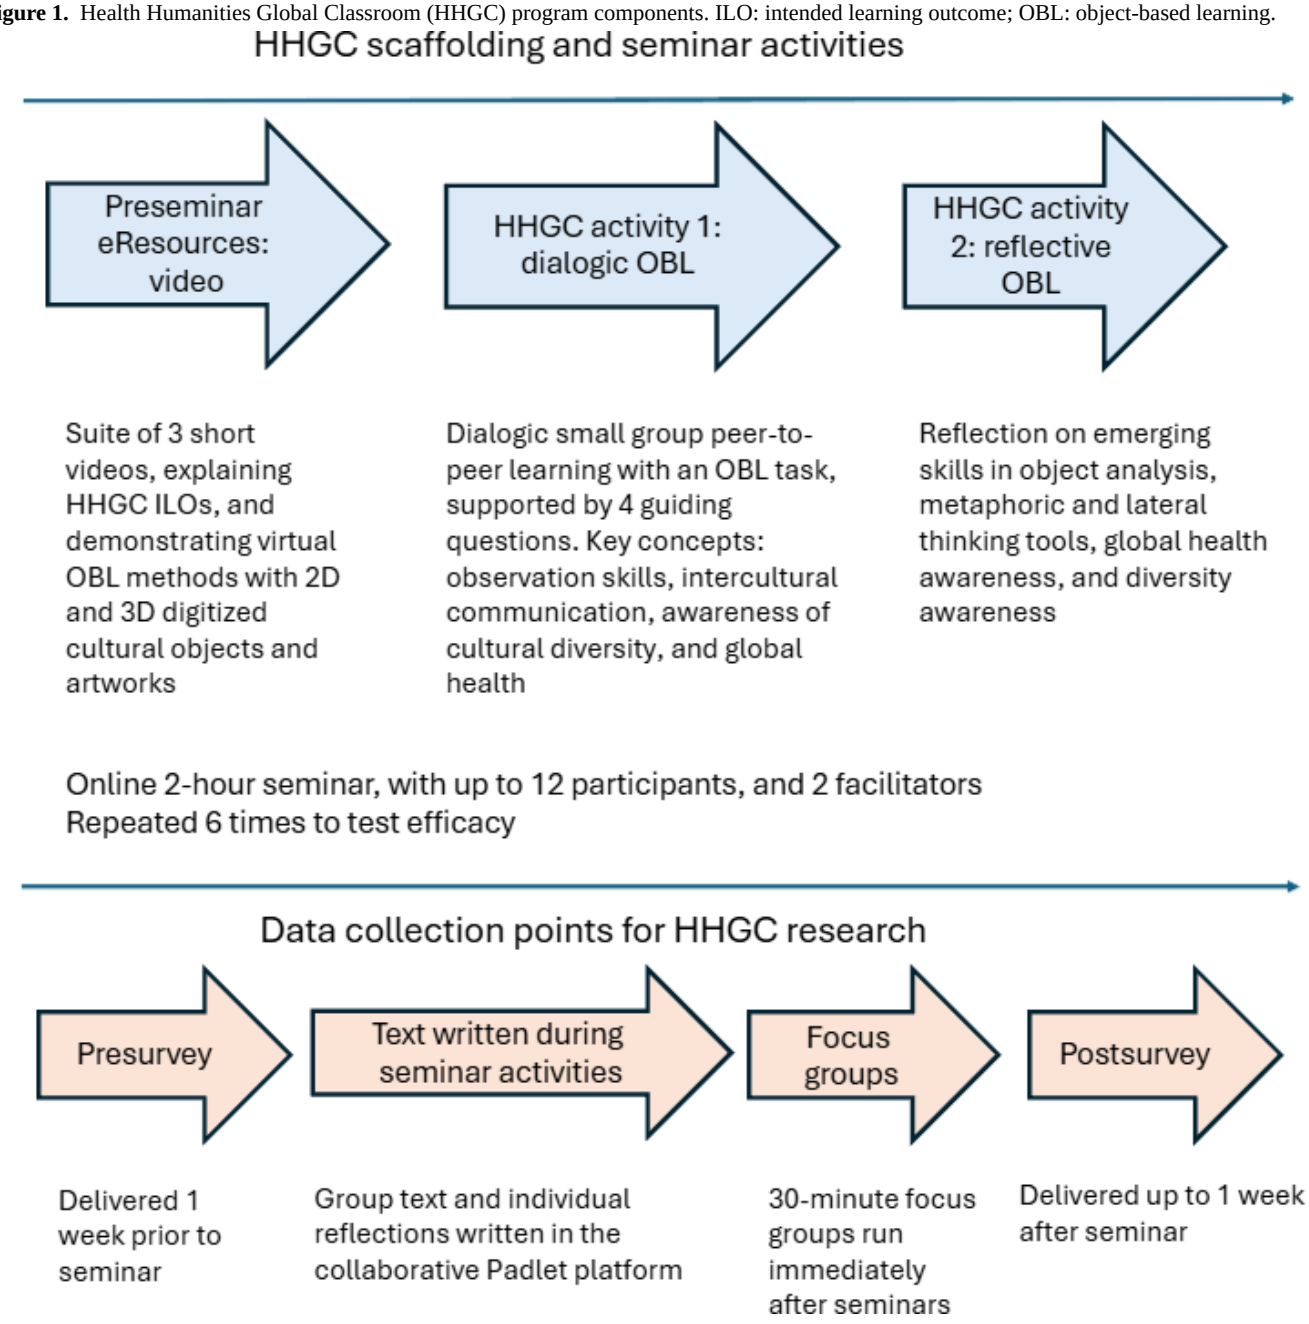
COIL is an internationalized educational approach in which educators from different countries and universities co-design and cofacilitate curriculum-integrated learning experiences that bring students together through real-time online interaction and collaborative inquiry. By engaging in sustained intercultural dialogue and joint academic tasks over the course of a "project" or part of a curriculum, students can potentially develop intercultural competence and understandings of global perspectives, as well as build collaborative and teamwork skills [19,20]. As Hackett et al [21] noted, measuring whether COIL programming successfully improves participants' intercultural competence is difficult, so further investigation is required to clarify its effectiveness in this area [21].

Objectives

Building on the aforementioned pedagogies, we hypothesized that a teaching and learning approach that privileges awareness of multiple perspectives on a relevant health topic across a global context, using OBL with diverse cultural artifacts as mediating objects, in a virtual COIL context, would allow students to develop a deeper awareness of aspects of intercultural competence. We shaped our HHGC methodology to create a "third space" for intercultural dialogue [22], where learning is a situated activity and where knowledge is coconstructed within a temporary "community of practice" formed by the international student group [23]. We speculated that, through the OBL approach, the shared (virtual) artwork or cultural artifact would function as a neutral ground upon which students could negotiate complex meanings and explore sensitive topics without feeling personally exposed. The approach would thus foster a mode of inquiry that was analytical and creatively engaged. We undertook a research study that aimed to give us a deeper understanding of participants' experiences of our HHGC methodology, and the potential of the methodology to support students' development of intercultural competence.

Methods

Overview



The development phase of our HHGC methodology has been published previously in brief [24]. In this article, we report the results of a pilot delivery of the HHGC methodology conducted in early 2025 with health students from 3 international universities: the University of Melbourne (UoM), the University of Hong Kong (HKU), and the National University of Singapore

XSL•FO
RenderX

(NUS). The full HHGC project, including the learning components and associated research to understand its impact, is shown in Figure 1, and described in detail below.

The identical HHGC seminar was delivered in English and ran for 2 hours. The seminar was delivered on 6 occasions, each attended by between 8 and 11 participants, and each participant took part in a single session. To maximize the cultural diversity of the learning experience, we allocated students as evenly as possible from each university site, according to student availability. The mix of students in each seminar is shown below (Table 1).

Figure 1. Health Humanities Global Classroom (HHGC) program components. ILO: intended learning outcome; OBL: object-based learning.

XSL•FO
RenderX

Table . Distribution of participants across 6 Health Humanities Global Classroom (HHGC) seminars (by university).

Seminar repeat delivery, n	Student from UoM[a], n	Student from HKU[b], n	Student from NUS[c], n	Total seminar participants, n
1	4	1	5	10
2	4	1	3	8
3	3	1	5	9
4	3	2	6	11
5	2	1	6	9
6	5	2	4	11
Total participants across all seminars:				58

[a]UoM: University of Melbourne.

[b]HKU: University of Hong Kong.

[c]NUS: National University of Singapore.

The seminars were facilitated by 2 members of the team, one with health professional expertise, and one with museum expertise, representing 2 different universities. Across the 6 occasions, all research team members contributed to facilitation at least once. Facilitators closely followed a script cocreated by all members of the team to ensure uniformity of the participants' experience. The seminar theme was broad, with discussions shaped around thoughtful comparisons of health and well-being in the contexts of each university's local and national environment. Using Anderson and Krathwohl's revision of Bloom's Taxonomy [25], our intended learning outcomes for the pilot HHGC (encompassing Levels 2 to 6 of the Taxonomy) were as follows: (1) use effective communication with students from different disciplinary backgrounds and cultures (Level 2: Understand and Level 3: Apply); (2) apply effective teamwork skills with students from different disciplinary backgrounds and cultures (Level 3: Apply and Level 4: Analyze); (3) develop an understanding of different cultural and global perspectives on health care (Level 2: Understand and Level 4: Analyze); and (4) build observational, creative, and critical thinking skills to discuss the presented artwork or museum object (Level 4: Analyze, Level 5: Evaluate, and Level 6: Create).

The OBL content for discussion consisted of a virtual group (e-Gallery) of 24 artworks and museum objects, which we selected in equal numbers from the cultural collections of the 3 universities (Figure 2).

Artworks were selected by the museum professionals on the team, who worked closely together online to curate the final group to provide a balance of cultural and historical contexts of the artworks' production and a rich potential to trigger discussions about the human body, health, or well-being.

Facilitators formed breakout-room teams of 3 to 4 participants at the start of each seminar, aiming, where possible, for each team to include at least 1 student from each university site. In the facilitated OBL activities, teams selected 1 object from the e-Gallery for in-depth exploration and discussion. Four guiding questions scaffolded the team discussions, encouraging students to move logically through a process: to undertake close observation of the object; to build a detailed, collective description; to consider and share their emotional responses; and to reflect on how their cultural perspectives might shape their observations. Teams documented their close observations on the collaborative online platform Padlet, including how they connected them to the HHGC's overarching theme of health [26]. In the final part of the seminar, students each selected a new object and crafted short reflective statements that captured their understanding of their object, and how the group discussion may have influenced or changed their analysis. Participants were encouraged throughout the seminar to use an enquiring approach, to make direct or lateral connections between the artworks and the broad theme of global health, and to contribute these actively to the group discussion.

Figure 2. Screen capture of a section of the e-Gallery resource of cultural objects and artworks.

Ethical Considerations

We designed a mixed methods research study to evaluate the impact of the HHGC on intercultural learning for participants. Ethical approval has been granted by all 3 universities where students were participating in this project: The University of Melbourne Office of Research Ethics and Integrity (reference: 2024-28502-54028-3; approval date: May 31, 2024), National University of Singapore Institutional Review Board (reference: NUS-IRB-2024-467; approval date: September 27, 2024), and The University of Hong Kong Research Ethics Institutional Review Board (protocol: UW 24-583; approval date: October 25, 2024). All participants provided informed consent through Qualtrics, and participation was entirely voluntary. All surveys were anonymous, and participants were not identifiable. All data from focus group recordings and text data created by participants during the HHGC activities were anonymized and deidentified to safeguard participant information. Participants were reimbursed for their time with a US $65 gift voucher.

XSL•FO
RenderX

Participants

Participants in the HHGC were diverse, drawn from students studying at different levels and in different curriculum contexts at the 3 universities. A convenient sampling approach was undertaken to recruit participants at each of the university sites, via a recruitment email posted on the learning management system from members of the research team to specific cohorts (for example, students studying an elective "Medical Humanities" topic at UoM). In the presurvey, delivered to participants via Qualtrics up to 2 weeks prior to the scheduled seminar, we sought to understand the participants' demographic and contextual (social, cultural, and historical) details, to learn more about their previous experiences in online learning and museum-based learning, and their current perception of confidence relating to intercultural communication ability (Table 2).

Table . Presurvey questions, Health Humanities Global Classroom.

Question number	Question	Response selection
1	Which university are you currently studying at?	University of Melbourne, University of Hong Kong, and National University of Singapore
2	Which of the following area(s) of health is the focus of your current tertiary study? Select one or more answers.	Medicine, nursing, pharmacy, optometry, dentistry, audiology, social work, and other
3	At what year level of your degree are you currently studying?	Years 1, 2, 3, 4, 5, and 6
4	Have you participated in an online international learning experience previously?	Yes/no
5	If you answered yes to the question above, briefly describe that experience.	Free-text answer
6	Have you participated in a museum-based learning experience as part of your tertiary education?	Yes/no
7	If you answered yes to the question above, briefly describe that experience.	Free-text answer
8	What language/s do you speak at home?	Free-text answer
9	Rate your response to the following question: "I am confident in my ability to communicate and exchange meanings with colleagues from diverse cultures in a variety of contexts."	Extremely confident, very confident, somewhat confident, not very confident, and not at all confident

Focus groups of approximately 30 minutes were conducted and recorded on Zoom following each seminar. We chose focus groups so that participants could build on each other's ideas in a collaborative context, continuing the open and safe environment for sharing that had already been created in the seminar [27]. Focus groups were facilitated by members of the research team who had not taught in the preceding seminar; each facilitator followed a script with ethics-approved questions and prompts (Textbox 1). Each focus group had 3 to 6 participants, depending on the total number attending the seminar; the focus groups ran simultaneously in new, separate Zoom meetings beginning ten minutes after the seminar concluded. Focus-group participants were predetermined during the allocation of seminar attendees, with the aim of including as even a distribution from each university as possible. During the focus groups, participants were asked questions designed to explore how they individually experienced the seminar's contextual factors. Focus groups' transcriptions were anonymized, and each participant was given a code number.

Textbox 1. The presurvey questions delivered to students who indicated interest in participating in the health humanities global classroom seminar.

- What was your experience of participating in this seminar with international peers?
- What was the experience of exploring the global health theme in this specific seminar context like for you?
- What was your experience of sharing your personal perspectives and observations during the seminar?
- What was your experience of hearing the perspectives of the other students during the seminar?
- What was the experience of working with virtual museum objects like for you?
- Has this seminar been a unique experience for you in any way?

Analysis

As noted in Figure 1, we collected quantitative data at the beginning and end of the data-collection phase using surveys, and qualitative data midstudy through in-seminar reflective texts on Padlet, and postseminar focus groups. Our surveys contained a mix of qualitative and quantitative items. We analyzed quantitative survey data in Qualtrics, reporting

XSL•FO
RenderX

percentages for categorical variables and means for Likert-scale items. GraphPad Prism 6.07 (GraphPad Software Inc) was used for graphical presentation of the data. We reported only descriptive statistics (percentages and means) because this pilot study was an exploratory evaluation of a novel pedagogical intervention, with a modest convenience sample and immediate postsession measurement. In this paper, we did not include data or analysis from the in-seminar reflective texts; that material will be included in a future paper that focuses on the impact of our virtual OBL approach, addressing the technical challenges and opportunities of the pedagogy. Qualitative data from the focus groups were analyzed thematically to categorize the major themes, using the qualitative data analysis software NVivo (version 15; Lumivero). We used a qualitative data analysis approach described by Fereday and Muir-Cochrane for text-based data [28]. An initial codebook was developed by HMG. Coding was legitimated when RS, HTC, and KMC (representing 2 of the 3 participating sites) each independently checked the coding on 4 focus-group transcripts. The platform Spark AI (UoM) was used by HMG to run queries across the qualitative data set of focus groups to explore potential additional subcodes. Themes and subthemes derived from the codes were discussed by the team via email and Zoom meetings. Any disagreements were resolved by HMG. The final consensus was shared with the full team as a report produced in NVivo, listing themes, related codes, theme descriptions, and statistics on the number of files and references for each.

Finally, we adopted a convergent mixed methods approach in which descriptive quantitative measures of participants' perceptions are interpreted alongside thematic qualitative data to provide complementary perspectives. Quantitative percentages describe the prevalence of positive perceptions across the cohort, while qualitative data explain how and why participants experienced these outcomes. In reporting, we therefore emphasized convergence (where high percentages aligned with recurrent qualitative themes) and complementarity (where qualitative data provided more nuance to the descriptive results).

All members of the research team were conscious of and reflected on their potential biases, recognizing that their diverse backgrounds as doctors, pharmacists, anthropologists, optometrists, clinical educators, museum curators, and educators may influence the interpretation of the results to some degree. Reflexive notes throughout the development and delivery of the pilot methodology and multiple discussions across the data analysis period ensured that coding decisions were anchored in the transcript data rather than researchers' *a priori* expectations, as much as possible.

Results

Participant Demographics

A total of 67 students were recruited for this study and completed the preseminar survey in the week prior to the seminars. Of the 67 students, 58 attended an HHGC seminar, and the 9 who did not attend were either unable to find a suitable seminar time or faced unforeseen personal circumstances. Because of survey anonymity, we were unable to identify which presurvey respondents did not continue in the study. All 58 students who attended an HHGC seminar participated in the focus groups; 84% (49/58) of seminar attendees completed the postseminar survey. The 67 participants in the presurvey ranged across first to fourth years of their current degree across the 3 university sites, with a few having recently graduated (Tables 3 and 4).

Table . Presurvey responses from 67 participants indicating location and current year of studies.

University	First year; n	Second year; n	Third year; n	Fourth year; n	Recently graduated; n	Total responses; n
NUS[a]	3	17	7	6	0	33
HKU[b]	3	3	1	3	0	10
UoM[c]	0	1	15	4	4	24
Total	6	21	23	13	4	67

[a]NUS: National University of Singapore.

[b]HKU: University of Hong Kong.

[c]UoM: University of Melbourne.

XSL•FO
RenderX

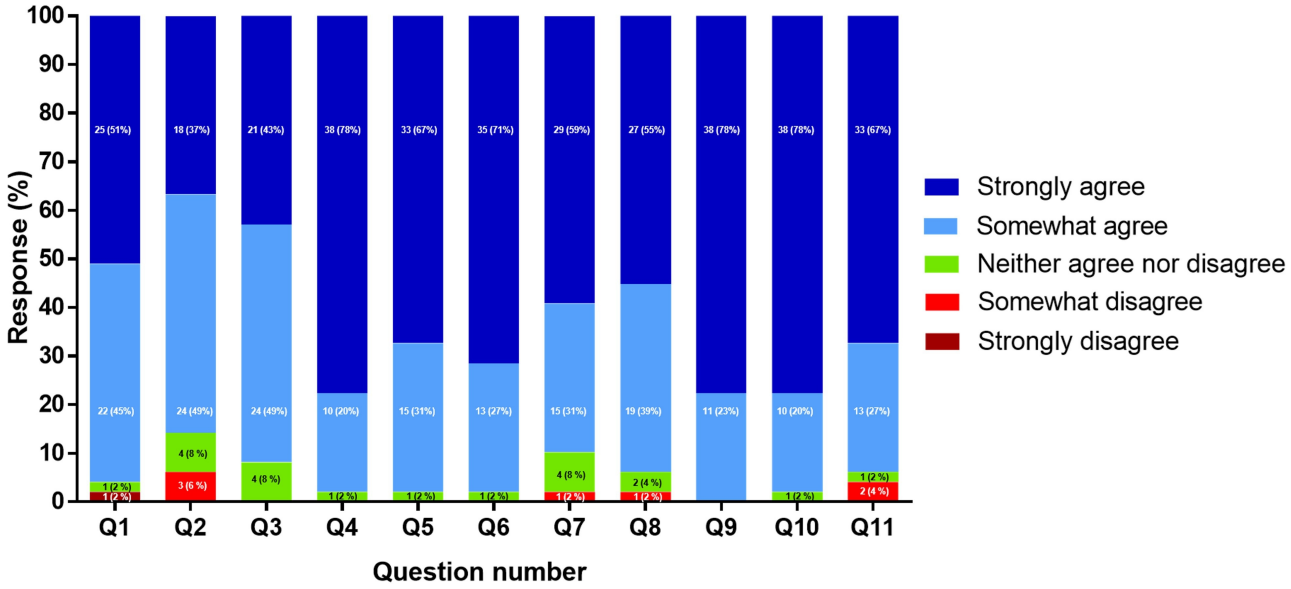
Table . Presurvey responses from 67 participants showing university site, and their current disciplinary focus/foci.

Site	Medicine; n	Pharmacy; n	Nursing; n	Population and global health; n	Nursing, population and global health, and health and well-being; n	Pharmacy and health and well-being; n	Other, n	Total, n
NUS[a]	4	21	3	0	0	3	2	33
HKU[b]	3	0	1	2	2	0	2	10
UoM[c]	23	0	0	0	0	0	1	24
Total	30	21	4	2	2	3	5	67

[a]NUS: National University of Singapore.

[b]HKU: University of Hong Kong.

[c]UoM: University of Melbourne.



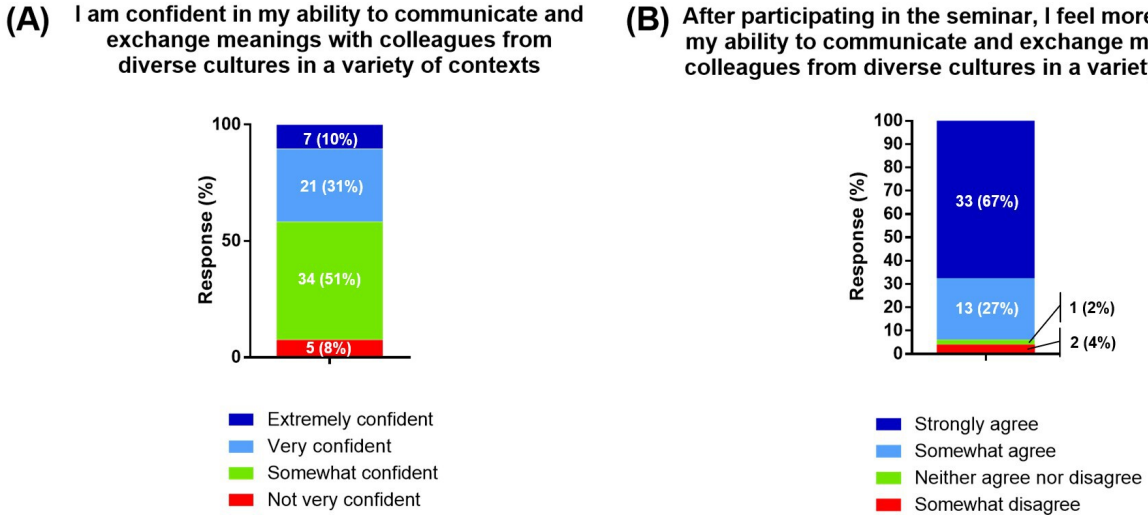
All participants were fluent in English, and a large proportion were multilingual, speaking other languages at home, including Sinhalese, Mandarin, French, and Italian. From the presurvey data, 18% (12/67) had previously participated in an online international learning experience; 45% (30/67) had participated in a museum-based learning experience as part of their tertiary education, including single sessions in local history, art, or anatomy museums, and in some cases, more extensive museum experiences through enrollment in medical humanities courses.

Quantitative Analysis

From the 58 students, 84% (n=49) of seminar participants completed the postseminar survey (Figure 3). In this survey, 96% (47/49) of respondents agreed that the seminar had increased their awareness of how they communicated and exchanged meanings with peers from diverse cultures. Relating to health knowledge, 86% (42/49) agreed that the seminar had increased their awareness of local health in interprofessional contexts, while 92% (45/49) agreed that they had an increased understanding of health from a global perspective. Relating to the virtual OBL experience, 98% (48/49) agreed that engaging with the diverse museum objects was thought-provoking and that engaging with these objects in a peer learning environment heightened their awareness of diverse perspectives. The same proportion of participants also agreed that this COIL experience with international peers was an effective way to increase their awareness of intercultural competence.

XSL•FO
RenderX

Figure 3. Participant responses to postsurvey questions.



Q1 This seminar has increased my awareness of how I communicate and exchange meanings with peers from diverse cultures.
Q2 This seminar has increased my awareness of local health in interprofessional contexts.
Q3 This seminar increased my understanding of health from a global perspective.
Q4 Engaging with virtual museum objects from different universities was thought provoking.
Q5 Engaging with virtual museum objects in the seminar allowed me to explore the health theme with peers in a way that was novel to me.
Q6 Engaging with virtual museum objects in the seminar with peers heightened my awareness of diverse perspectives.
Q7 The online platform for interaction with the virtual museum objects was easy to use.
Q8 I found the pre-seminar online resources useful to prepare me for my seminar experience.
Q9 I found the Seminar Facilitators helped create an environment conducive to learning.
Q10 Participating in an online seminar with international peers is an effective way of increasing my awareness of intercultural competence.
Q11 After participating in the seminar, I feel more confident in my ability to communicate and exchange meanings with colleagues from diverse cultures in a variety of contexts.

In the presurvey and postsurvey, participants were asked to describe their immediate perception of confidence in communicating across cultures (Q9: presurvey; Q11: postsurvey). While our presurvey question asked about their current self-perception of confidence in communicating in intercultural contexts, the postsurvey question sought to identify any change in their perception of their confidence after seminar participation. Prior to the seminar, 92% of students who completed the survey were confident to some degree ("somewhat confident," "very confident," or "extremely confident"), with around half of that group sitting in the "somewhat confident" category. In the postsurvey, we saw that 94% (46/49) perceived an increase in their confidence through the experience (Figure 4).

XSL•FO
RenderX

Figure 4. Side-by-side graphic comparisons of (A) preseminar and (B) postseminar survey questions that explored participants' immediate self-perception of confidence in their intercultural communication ability.

Thematic Analysis

Four key themes, with multiple subthemes, emerged from our thematic analysis of the textual data derived from transcriptions of the 12 focus groups and text-based responses in the postsurvey. The themes presented students' perceptions of their experiences of the seminar across three distinct areas, namely (1) their key learning outcomes, the enabling factors which allowed them to engage and learn effectively; (2) the barriers to learning they encountered; and (3) their articulation of what was unique or novel about the seminar experience. These themes are summarized in Table 5. The themes were listed in the order of frequency with which they occurred in the data. We also identified a fourth theme, which brought together their suggestions for improvements to the seminar, or future use of the methodology in health education. We did not include this fourth theme in the primary findings, as we considered that the data should be considered separately from that which reported their experience in the HHGC seminar itself.

XSL•FO
RenderX

Table . Students' experience of the Health Humanities Global Classroom (HHGC): qualitative themes and summary of subthemes.

Key themes	Subthemes
1. Key learning outcomes: intercultural, analytical, and empathic capacities, and knowledge acquired	• Self-perception of intercultural capacities enhanced, including new understandings of the influence of cultural lenses, effectiveness of diverse perspectives, and specific capacities regarding communication across cultures. • Self-perception of skills and capacities enhanced, including observation skills, analytic style, increased empathy awareness, and importance of emotions. • Knowledge acquired in health and global health, and personalized care. • Knowledge acquired about art or culture.
2. Enabling factors: pedagogy, environment, and peer interaction	• Exposure to diverse perspectives including from international peers. • Engaging e-resources, and application of OBL[a] pedagogy. • Safe, positive, comfortable, and inclusive learning environment. • Collaborative peer discussions and exposure to peer expertise. • Sense of commonality among peers. • Using art to understand health • Contribution of expert and supportive facilitators • Encouragement of exploratory lateral thinking • Small group size
3. Barriers to learning: pedagogical approach, learning resources, time factors, and virtual constraints	• Limitations of e-resources as compared to experiencing physical artworks or objects. • Unfamiliarity with the approach of using art to explore health. • Challenge of virtual learning environment (as compared to a physical environment). • Time constraints of a single seminar
4. Novel and distinctive experiences: international, art-integrated learning	• Confluence of multiple HHGC factors (including virtual OBL with art, international peer exposure, and linked health theme, and so on). • Difference of humanities learning environment compared with standard health education. • Intersection of humanities and health • Discussing art with international peers

[a]OBL: object-based learning.

Theme 1: Key Learning Outcomes

In terms of learning outcomes, participants expressed the acquisition of analytical, intercultural, and empathic capacities, and specific knowledge. The capacity most frequently identified by participants was an enhancement of their intercultural awareness. The second most common capacities we grouped as personal skills, such as observational skills, and critical or analytic thinking.

Theme 2: Enabling Factors

The second theme helped us to understand the enabling factors that contributed to participants' learning. The highest-cited factor we identified was the students' exposure to diverse perspectives (including those from international peers). Engagement with e-resources and the OBL pedagogy was the second-highest factor. A positive and inclusive learning environment was the third most common factor identified.

Theme 3: Barriers to Learning

This theme allowed us to understand the barriers students reported as interfering with their learning or engagement. The highest-cited factor focused on various limitations of the e-resources, mostly in comparison to a face-to-face experience with physical artworks or objects. The second highest barrier was unfamiliarity with the lateral approach of using art to explore health. However, all responses that cited this barrier included descriptions of how they were able to improve their confidence with the lateral approach during the seminar: what was initially experienced as a difficulty became a positive through the influence of other factors, including more time to work on a skill, learning from their peers, or effective facilitator interactions. As 1 participant observed:

> *For me, it was quite intimidating at first, because I didn't really have much experience with connecting humanities to health, and so I had to sort of come up with responses and opinions in such a short frame of time. … But once the flow, once the whole thing started rolling, and we each got more involved and then, it became smoother, the process of thinking and analyzing.* [2.1P2]

It is important to note that what some participants perceived as barriers were not perceived as barriers by others. For example, the online (Zoom platform) learning experience was identified by some participants as a highly effective way of engaging synchronously with international peers, while others found it to be less optimal than face-to-face learning.

XSL•FO
RenderX

Theme 4: Novel and Distinctive Experiences

The fourth theme focused on the uniqueness of the HHGC experience. Participants identified a range of factors that were novel to them, such as the opportunity to explore art in relation to health topics, accessing virtual galleries of artworks scanned in three dimensions, and synchronous learning with international peers from diverse backgrounds. The most highly cited aspect was the confluence of more than three HHGC factors. One participant described this as “the whole package” (6.1P4). We compare the quantitative and qualitative findings in Table 6.

XSL•FO
RenderX

Table . Side-by-side convergence of Health Humanities Global Classroom (HHGC) quantitative and qualitative data.

Analytic domain (theme)	Quantitative findings	Qualitative evidence (theme summary and representative quotes)
Key learning outcomes: intercultural, analytical, and empathic capacities, and knowledge acquired.	• 98% (48/49) agreed engaging with objects with peers heightened awareness of diverse perspectives. • 98% (48/49) agreed the COIL[a] experience was effective to increase awareness of intercultural competence. • 92% (45/49) increased understanding of health from a global perspective. • 86% (42/49) increased awareness of local health in interprofessional contexts.	• "[I] understood much more clearly - through personal experience obtained from completing the exercises - how culture informs how we see the world and how layered and complicated that can be." (PS.P7) • "I feel like …we … can also understand different perspectives from our own very different cultural contexts, like, from our international peers. And that I feel like such new perspective will allow us to gain a very holistic overview, which actually is something I feel like is very needed… given our current global landscape." (2.1P4) • "I learned to link my thought processes on health-related concepts to the culture in which the item in question is produced, beyond simply making links to the item itself." (PS.P22)
Enabling factors: pedagogy, environment, and peer interaction	• 100% (49/49) agreed that the seminar facilitators helped create an environment conducive to learning. • 98% (48/49) agreed engaging with virtual museum objects was thought-provoking. • 90% (44/49) agreed that the online platform for interaction with the virtual museum objects was easy to use. • 94% (46/49) agreed that the preseminar online resources were useful preparation for the seminar experience.	• "Engaging with peers from different linguistic and cultural backgrounds also strengthened cross-cultural communication skills and underlined the need for cultural sensitivity in global health work in the future." (PS.P38) • "I was quite fascinated with the way that we did the seminar... the 3D image that has been created, give us a lot of details, so we can have a deeper discussion on the artwork... this is really important because it facilitated our discussion later." (3.2P4) • "I definitely like the technology to support the exhibition, actually, because I think it's quite easy and convenient for us to access different resources and also we did like four or five questions, we have to post our ideas or comments on the Padlet, and that actually helps to connect with people from different cultural backgrounds or different locations." (6.2P4) • "I felt there was a safe space to really share more about our personal perspectives about the artworks, and how they relate to health as a whole" (3.1P3).
Barriers to learning: pedagogical approach, learning resources, time factors, and virtual constraints	• 2% (1/49) somewhat disagreed that the online platform for interaction with the virtual museum objects was easy to use. • 2% (1/49) somewhat disagreed that the preseminar online resources were useful preparation for the seminar experience.	• "I think scale plays a really big role in how you emotionally respond to something, and that is something that's lost through the digital gallery, unfortunately." (1.1P2) • "[It was] certainly difficult sometimes to [sic] looking at some of the pieces and trying to think of how it relates to health, and yeah, just bringing it back to the theme." (6.2P1)

Analytic domain (theme)	Quantitative findings	Qualitative evidence (theme summary and representative quotes)
Novel and distinctive experiences: international, art-integrated learning	• 98% (48/49) agreed that engaging with virtual museum objects in the seminar allowed me to explore the health theme with peers in a way that was novel to them.	• "But I think, generally, the virtual experience is really amazing, that you can actually get it all that work from different like different authors, different cultural backgrounds, that allow us to actually integrate it into the health care or into the humanity concept. So I think, yeah, it's generally very, very unforgettable." (6.1P4) • "Creativity is such a, like, nourishing thing for the human spirit… and it's something that in health care, you know, we don't spend much time reflecting on it, because we're so busy just getting the job done. So it's wonderful to have these experiences where we share our thoughts about the world, and look at it from a different perspective, like using art as the, sort of, talking point, around which we can focus the discussion." (2.1P3)

[a]COIL: collaborative online international learning.

Discussion

Principal Findings

A novel virtual health humanities approach for collaborative and international learning among health professional students, the HHGC, was developed. While the HHGC draws on established pedagogies (MB-HE, OBL, and COIL), its contribution to educational practice lies in their structured synthesis as a synchronous, virtual, cross-institutional seminar that uses shared, curated cultural objects as mediating tools. This integrated format creates an accessible "third-space" for intercultural dialogue that leverages material culture as a neutral focal point, supports small-group inquiry across institutions, and is designed for scalability and sustainable access. In this way, the HHGC offers a practicable model for embedding humanities-informed, intercultural learning into curricula where face-to-face exchanges or international placements are infeasible.

We found that the HHGC approach raised participants' awareness of diverse cultural perspectives and provided stimulating opportunities to consider intercultural contexts through a humanities lens. We believe the perceived benefits of the seminar can be attributed to its unique design, which addresses gaps in traditional health education through a form of situated learning. By creating a supported and safe environment for dialogue mediated by virtual museum objects and artworks, the HHGC provided a psychologically safe environment where knowledge could be coconstructed, rather than merely transmitted [29]. As we had hypothesized, the HHGC structure allowed students to explore sensitive topics without the defensiveness that can arise in unmediated conversations, mitigating the risk of stereotyping. The objects served as a neutral focal point, enabling students to discover both surprising commonalities and profound cultural differences in a low-stakes context. As one student noted, this allowed for a more holistic overview. Several participants closely connected the HHGC's discussions and focused analysis of artworks to their professional clinical experiences and appreciated the power of developing one's ability to observe closely as they recognized these as transferable skills. This personal experience was coupled with the newly gained knowledge for comparing observations with group members of different cultural backgrounds and appreciating these differences, shedding bias, and establishing a more neutral yet holistic assessment. Some reflections written by participants offered suggestions for curriculum integration in broader health education contexts and outlined some potential applications in health care delivery. This will be valuable as we develop the methodology further.

We were particularly struck by how intellectually and creatively engaged the students typically were during the seminar, despite their perceived barriers such as unfamiliarity with OBL or the virtual learning context. As facilitators, we noticed how breakout room conversations were consistently active and productive, and how participants were confident to express new ideas about artwork interpretations, often drawing on their emotional responses to the artists' themes or the appearance of the artworks. In the data, we found many instances where participants used adverbial intensifiers in their descriptions of the value or personal impact of the experience, such as "pretty eye opening," "very surprising," and "genuinely, really, shocked" (in a positive sense). We consider that this suggests that participants experienced moments of reflexive self-confrontation at points in the seminar, potentially signaling the beginning of greater awareness and humility that is foundational to authentic intercultural engagement [30].

Considering our experiences in delivering the HHGC, and the data from our study showing the students' experiences, we posit that the methodology could be valuable in promoting cultural humility in students. Cultural humility, as originally described by Tervalon and Murray-García [30], is a lifelong process of self-evaluation and critique of one's own cultural biases and limitations, oriented toward redressing power imbalances in the clinical encounter [31]. Bora et al [32] include cultural humility

XSL•FO
RenderX

as one of the key elements when setting up cross-cultural dialogue in psychiatry training, along with open-ended inquiry, reflective practice, active listening, didactic education, and a collaborative approach. As a distinct element in a suite of approaches such as those described by Bora et al [32], the HHGC could serve as a stimulating humanities-based context to access diverse cultural perspectives. Our HHGC methodology centers ambiguity, interpretation, and highlights the validity of multiple perspectives. For these reasons, it may be a fruitful pedagogical tool in a larger approach that pushes back against the "hidden curriculum" of biomedicine, which often privileges certainty and a single, objective truth [31,33].

Strengths and Limitations

We believe this study has provided evidence for the potential of our novel pedagogical approach to support participants' development toward the important educational goal of increased intercultural competence and awareness. The curriculum, through being delivered in virtual learning environments, supports the goals of sustainable and equitable access to internationalizing experiences for learners in the health professions. However, our study of this pedagogy faced limitations. Importantly, the outcomes reported in this study reflect participants' immediate, self-reported perceptions of learning following a single 2-hour seminar, rather than direct measures of demonstrated competence. These findings, therefore, indicate perceived changes in awareness, confidence, and analytic orientation, rather than objective or sustained changes in intercultural skills. Future work should assess demonstrated competence using validated performance-based measures and longitudinal follow-up to determine whether perceived gains translate into durable, observable changes in behavior and clinical practice. Further limitations include self-selection bias from the recruited cohort: the sample reflects students who were available and willing to participate in a humanities-oriented virtual seminar and may therefore be more favorably disposed to art-integrated learning and online learning than the broader student population. The geographic representation, including participants drawn from universities in Australia, Singapore, and Hong Kong, while offering some diversity, does not capture the full range of global health education contexts and cultures, while the recruitment of primarily English-fluent participants limits generalizability. These sampling constraints should be borne in mind when considering the transferability of results to other settings.

Finally, the application of the HHGC methodology into health education contexts has specific development and delivery factors, requiring expert facilitators who have the skills and inclination to collaborate across the disciplines of health professional education and museum-based tertiary education, as well as access to compelling digital art resources. Additional challenges for delivery into the curriculum in health education include complex scheduling for cohorts learning together across multiple international sites and time-zones, a characteristic common to COIL educational programming, but it is acutely the case in the very full curriculum common in health education contexts.

Future Directions

We believe that the methodology of the HHGC has the potential to be translated into a range of health education contexts, by shaping the OBL context around a range of health themes, or broader topics such as sustainability in health care provision, or interprofessional collaboration and leadership. The HHGC methodology may be embedded into educational activities in curricula, either as short single-seminar interventions or as multiweek COIL projects. However, further research on the impact of these embedded experiences, on their longitudinal impact on students' cultural awareness or development of cultural humility, and on how they might shape students' interactions with their patients in clinical environments would be highly valuable to identify areas in which the methodology would be most effectively implemented and where it can be improved. Implementation research could also compare virtual versus in-person OBL experiences to clarify the trade-off between accessibility and embodied engagement with objects.

Conclusions

The proposed HHGC methodology has the potential to be implemented in health professions learning, where there is an educational need to promote intercultural capabilities. This pilot study suggests that the HHGC could offer a sustainable, scalable, and replicable approach for educators as a resource to educate future health care professionals with the critical personal and intercultural awareness necessary to provide humane care in a globalized world.

Acknowledgments

The authors acknowledge the central contribution to the development and delivery of the entire Health Humanities Global Classroom project, of Prof Kit Wa Chan, Yueh Siang Chang, Eugene Koh, and Ben Loveridge. The authors used computer tools to identify and organize relevant scholarly work. The University of Melbourne Spark AI platform was used in this study as a check on aspects of the first round qualitative coding by HMG, prior to loading codes into NVivo (Lumivero) for subsequent coding. Specifically, AI was asked to find all quotes it considered to match the first-round codes across the whole dataset. These quotes were then compared with the original quotes found by HMG. AI was asked to suggest additional subcodes for the dataset, and these subcodes were considered by HMG as a comparison to subcodes created by HMG and other members of the research team.

Funding

This project received seed funding from Universitas 21 (no grant number), and The University of Melbourne (Chancellery International Global Classrooms Seed Grants 2023, no grant number).

Abstract

Background: Emerging evidence supports that women with histories of abuse have heightened stress and immune dysregulation. Few studies have examined the biological plausibility of this association in US Black women—a population disproportionately affected by gender-based violence (GBV), health disparities, and generally underrepresented in research. Biomarkers of stress and immune health remain challenging to study due to barriers in recruitment, retention, and protocol adherence.

Objective: This study developed and examined the feasibility of an at-home, self-collected, and minimally invasive salivary cortisol awakening response (CAR) collection protocol among Black women with histories of abuse in Baltimore City, Maryland.

Methods: Black women were recruited from November 2015 to May 2018 from Baltimore City sexually transmitted disease clinics. Participants received in-person instruction and demonstration on saliva self-collection using the passive drool method, and were provided study-issued cell phones for reminders and adherence tracking. Participants self-collected saliva samples upon waking and 30 minutes post waking on 3 consecutive days to assess CAR. Outcomes included protocol completion, self-reported adherence, and experiences (via saliva collection logs), a weighted protocol adherence score, and cortisol measures (waking, post waking, and CAR). Differences in sociodemographic characteristics and outcome measures were assessed by adult forced sex exposure status using chi-square tests and ANOVA. The Pearson correlation coefficient assessed the day-to-day reproducibility of cortisol measures among women with 2 full days of valid samples.

Results: Of the 305 women completing the study survey, 228 completed the saliva specimen collection protocol, with no significant differences in completion between women with and without forced sex histories. Protocol feasibility was high, with 84% (191/228) completing at least 1 full day of adherent saliva collection and more than half (132/228) completing 2 full days. While feasibility did not differ by exposure status, women with adult forced sex exposure demonstrated lower protocol adherence scores compared to their unexposed counterparts. Between-day cortisol measures demonstrated variable reproducibility across waking, post waking, and CAR measures.

Conclusions: This at-home salivary cortisol collection protocol was feasible in our robust sample of Black women with histories of abuse. The process of at-home collection of salivary biomarkers, including cortisol measures, was well-documented, and participants were able to adhere to it. The protocol yielded usable data that will facilitate the examination of the physiological and health repercussions of GBV.

Introduction

Background

Chronic social stress is increasingly recognized as a key contributor to health disparities [1]. The minority stress model posits that individuals exposed to intersecting forms of social disadvantage experience cumulative stress that can be biologically embedded over time and adversely affect health [2]. Black women may face particularly high levels of chronic stress due to the intersection of racism, sexism, and a disproportionate burden of gender-based violence (GBV) [3,4]. Despite these intersecting stressors, few studies have incorporated biological measures of stress in research with women exposed to GBV. Existing studies often rely on small sample sizes, lack racial and ethnic diversity, collect clinic-based biomarkers, limiting participation and generalizability to the social context, and lack measures of collection protocol adherence [5]. Developing and testing a feasible and acceptable trauma-informed protocol for at-home, self-collection of stress biomarkers is a critical step toward advancing health equity research on the physiological impacts of violence. In this paper, we establish a protocol of repeat salivary cortisol self-collection among a robust sample of Black women with experiences of violence and examine the feasibility and usability of the samples.

GBV is a pervasive public health problem. Globally, an estimated 30% - 60% of women experience physical and/or sexual violence during their lifetime [6]. In the United States, 42% of women experience physical intimate partner violence (IPV) and 20% experience sexual violence in their lifetime [7]. Black women experience disproportionately high rates of IPV, including physical, sexual, and stalking IPV, compared with their White and Latina counterparts [7]. The health consequences of GBV are substantial. Survivors of IPV are more likely to experience mental health conditions (eg, depression, anxiety, posttraumatic stress disorder, and suicidality) [7,8] and chronic physical conditions, including cardiovascular disease, chronic pain, gastrointestinal disorders, sexual and reproductive health disorders, and increased susceptibility to infectious diseases, than women without IPV experiences [9]. Population-based research further suggests that Black women survivors of severe IPV demonstrate higher rates of mental health disorders and report poorer overall health than their White counterparts [10].

Cortisol is a widely used biomarker of physiological stress. Researchers have measured cortisol levels among women with histories of abuse using plasma [11,12], hair [13], and saliva [11,14,15]. However, this research has yielded inconsistent findings associated with cortisol levels in the context of IPV, likely due to variation in measurement approaches and cortisol analysis [13]. Salivary cortisol has emerged as a valuable tool because it is minimally invasive, convenient, and well-suited for repeat sampling. Saliva collection enables participants to self-collect samples in naturalistic settings (eg, at home), facilitating the study of hypothalamic-pituitary-adrenal (HPA) axis activity within the context of their daily life rather than in clinical settings. This approach further supports the inclusion of larger and more diverse samples, including populations that may face barriers to participation in clinic-based research. However, salivary cortisol research among women with abuse histories has been limited by several methodological challenges, including insufficient attention to collection adherence measures, lack of racially and ethnically diverse samples, reliance on clinic-based collection, and inadequate sampling frequency within or across days, which is critical to accurately quantify cortisol levels and patterns [16].

Cortisol follows a diurnal rhythm, including a rapid increase within 30 - 45 minutes after waking, known as the cortisol awakening response (CAR) [17]. Alterations in the CAR have been linked to chronic stress exposure and a range of adverse health outcomes disparities [18,19], making it a critical index in stress research. Accurate assessment of CAR depends on precise timing of saliva collection immediately upon waking and at specific postwaking intervals [20,21], introducing challenges for at-home saliva self-collection protocol adherence [22]. Although previous work has attempted to standardize CAR measurement, issues of protocol adherence remain a significant concern, particularly in unsupervised settings. These challenges may be amplified in research among women with histories of abuse, for whom ethical, safety, and trauma-informed considerations are critical. No standardized protocol exists for at-home salivary CAR self-collection for women with histories of abuse.

Medical mistrust is a critical barrier to participation in research for women with abuse histories and among Black women, and must be addressed with trauma-informed practices. Women with abuse histories often distrust medical institutions due to previous negative experiences, fear of judgment, and concerns about confidentiality [23,24]. Gender and abuse biases within medical settings can lead to the dismissal of women's health concerns, while systemic failures in addressing abuse further exacerbate mistrust and discourage care-seeking. Among Black women, medical mistrust is rooted in both historical and ongoing discrimination within the health care system [25,26]. Black women have been disproportionately subjected to unethical medical practices, such as forced sterilization and nonconsensual experimentation, and report higher levels of perceived discrimination in health care settings [25]. Medical mistrust is linked to poorer health outcomes, contributes to health disparities, and likely reduces willingness to participate in research and specimen collection [27-30]. Addressing these barriers requires the implementation of trauma-informed care approaches. Developing an at-home, repeated measures saliva collection protocol requires attending to these barriers to ensure inclusive participation.

Objectives

The objectives of this study are 2-fold. First, we describe the at-home, salivary CAR self-collection protocol designed for Black women with histories of abuse. Second, we assess the feasibility of this protocol among Black women with histories of abuse.

XSL•FO
RenderX

Methods

Study Design

Data were drawn from the ESSENCE (Examining Stress, Sexual Experiences, and Neighborhood Correlates of HIV Risk among Black Women) project, a retrospective cohort study to examine how experiences of forced sex and physiological stress response contribute to HIV risk among Black women. This study focuses on the development and implementation of an at-home saliva CAR self-collection protocol embedded within the broader study.

Study Setting

The study was conducted in 2 publicly funded sexually transmitted disease (STD) clinics in Baltimore, Maryland, United States, from November 2015 to May 2018. Participants were recruited from neighborhoods that have historically experienced structural inequities, such as racism, residential segregation, and community disinvestment [31], as well as unethical research practices surrounding Henrietta Lacks that spurred medical mistrust in the communities [32]. Data collection occurred during a period of heightened community tension following the death of Freddie Gray in police custody in April 2015 and the subsequent criminal proceedings that ultimately exonerated the 6 officers who were involved in July 2016, and occurred in neighborhoods where the protests were most intense [33]. These contextual factors informed the study's trauma-informed and community-engaged approach to participant recruitment and saliva collection protocol development.

Recruitment and Eligibility

Black women seeking health services were recruited in the clinic waiting rooms by trained female research staff. To prioritize safety and confidentiality, staff discreetly approached women and invited them to participate in an anonymous study about "women's health and safety." Interested women were led to a private examination room where staff read the informed consent document.

After providing informed consent, participants responded to a short eligibility screening survey. Eligibility criteria included (1) biologically female, (2) between ages 18 - 44 years, (3) self-identified as African American or Black, (4) reported having sex with a man in the past 6 months, and (5) reported having either 2 or more sexual partners in the past year or having a sexual partner at high risk for HIV (ie, used injection or noninjection drugs, had sex with men, been to prison, had a concurrent sex partner, had an STD, was HIV-positive, or did not know if their sexual partner had any of these characteristics).

Ethical Considerations

The study protocol was approved by the institutional review boards of Johns Hopkins University and the University of California, San Diego. Participants provided written informed consent separately for the eligibility screening and study participation, including the survey and saliva collection components. Although the study collected geographic data and contact information for follow-up, confidentiality was maintained by storing consent forms and identifiable information separately from the survey responses and biomarker data. All study data were deidentified and linked to a participant ID. Participants received financial compensation totaling US $70 (US $10 for screening, US $25 for survey completion, and US $35 for returning saliva samples), a daily bus pass, and a list of community resources related to violence and health care service referrals.

Survey Data Collection

Participants completed a 60 - to 90-minute survey administered using audio computer-assisted self-interview software. The survey assessed sociodemographic characteristics, sexual health and behavior, violence and trauma history, mental health, substance use, and neighborhood and social environmental factors. A female research staff member was made available to the participants in case of any questions, concerns, or technical difficulties. Following survey completion, participants were trained on saliva collection procedures [34].

Salivary Cortisol Collection Protocol

In-Clinic Training and Demonstration

Overview

After completing the survey, participants received standardized training on saliva collection procedures from research staff using a scripted protocol. Training covered the passive drool technique, saliva collection timing to measure the CAR, adherence documentation procedures, sample storage, and sample retrieval process. Participants then observed a demonstration of the passive drool technique and were given the opportunity to practice. Participants then received a collection kit containing 6 straws, 6 barcoded cryovials (with color-coded caps to visually distinguish waking [green] and 30-minute postwaking [red] samples), a saliva collection log (with adherence instructions on the back), a pen, and a study-issued mobile phone with charger. Study staff used the mobile phones to maintain contact with participants during the collection period to provide reminders, troubleshoot issues, and coordinate sample retrieval.

Passive Drool Technique

Saliva samples were collected using the passive drool method developed by Salimetrics [34]. This method collects whole saliva rather than gland-specific saliva obtained from oral swabs. Participants generated saliva by thinking about a favorite food and generating saliva by gently moving their jaws as if chewing and allowing saliva to pool in the mouth. Using a straw attached to a cryovial, participants then gently allowed the saliva to flow into the vial until the 1 mL fill-line was reached.

CAR Collection

Participants were instructed to collect 2 saliva samples per day for 3 consecutive days (6 samples in total)—one sample immediately upon waking and a second sample 30 minutes post waking [35]. This schedule allowed the measurement of the CAR. Participants were instructed to avoid brushing their teeth, smoking, or eating before completing each morning's saliva collection.

XSL•FO
RenderX

Adherence Monitoring

The saliva collection protocol used multiple adherence monitoring strategies to measure the timing of saliva collection, as the accurate measurement of CAR requires precise timing of saliva collection relative to waking time. Participants were asked to record collection times using (1) a saliva collection log where wake times and saliva collection times were written in the log (Multimedia Appendix 1), (2) time-stamped photos of each saliva collection cryovial using the study-issued phone, and (3) text message responses to automated SMS text message prompts confirming sample collection times.

The saliva collection log included saliva protocol instructions, vial ID numbers, and space to document any stressors or other issues that may have impacted saliva collection. Study staff recorded participants' anticipated wake times and expected collection times for each study day on the saliva collection log. In the saliva collection log, participants were further instructed to report any mistakes or protocol deviations during saliva collection, as well as stressors experienced the previous night.

SMS text message reminders were delivered via an automated SMS digital platform and were scheduled based on participants' anticipated wake times. Messages prompted participants to confirm when they woke up and when they began collecting both the waking sample and the 30 minutes postwaking sample. These procedures were repeated across all 3 collection days.

Sample Storage

After each sample was collected, participants were instructed to place the vial in their home freezer until study staff retrieved the samples.

Sample Retrieval and Field Procedures

After completing the 3-day saliva collection period, study staff retrieved the frozen samples, saliva collection logs, and study phones from the participants' homes. Study staff also administered a brief survey assessing participants' understanding and adherence to the saliva collection protocol and reporting the study-issued phone condition (Multimedia Appendix 2). Participants received compensation (US $35) upon sample return.

Before the saliva retrieval home visit, study staff confirmed appointment times and assessed potential safety considerations. When safety concerns were present, alternative sample retrieval locations were arranged. Study staff documented any safety concerns in participant files, including a codeword that the participants could use to alert staff that they were unsafe and should call 911. Moreover, 2 study staff were present to conduct the retrieval visits, typically conducted on weekdays during daytime hours. Exceptions were made on a case-by-case basis for saliva sample retrieval visits during the weekend or at a location other than the participant's home (ie, their workplace or a friend's home).

At retrieval, study staff visually inspected each vial to verify the presence of at least 1 mL frozen saliva and recorded vial ID numbers, saliva collection information, and retrieval visit details. Study staff also administered a brief survey assessing participants' understanding and adherence to the saliva collection protocol. Samples were then transported in a small cooler with ice packs to a laboratory deep freezer at Johns Hopkins University, where they were stored at −80 °C until shipped out for assay.

Trauma-Informed Protocol

The saliva self-collection protocol was developed using trauma-informed principles to enhance feasibility, acceptability, and adherence among women with histories of abuse. Standardized procedures emphasized safety, autonomy, and privacy by allowing self-collection at home. Study materials were scripted with nonstigmatizing, culturally sensitive language and included explicit statements of voluntary participation, permitting participants to pause or discontinue at any time. Although collection schedules were standardized, the protocol allowed for flexible collection schedules, and reminders were delivered using preapproved methods. Participants were also provided with community and psychosocial support resources. Collectively, these procedures were designed to minimize retraumatization while supporting protocol compliance.

Field Coordination

A full-time field coordinator oversaw saliva collection procedures, maintained participant contact, and coordinated sample retrieval. The field coordinator was a Black woman who was a member of the local community, which facilitated trust and communication with participants and allowed her to understand the participants' lived experiences. Participants responded positively to the field coordinator's one-on-one supportive phone calls. This role was critical to providing support for adherence to the saliva collection protocol.

The field coordinator provided great insight into the facilitators and barriers to study participation and to saliva collection, helping to refine the saliva collection protocol in several instances. First, the protocol originally specified a collection schedule based on recruitment date (ie, those recruited into the study on a Monday would collect saliva on Tuesday through Thursday). The field coordinator reported that a predetermined saliva collection start schedule did not fit many participants' life demands. The protocol was adjusted to allow for a flexible collection start date. Second, the field coordinator was flexible to changes in call or text times and saliva retrieval schedules, often working outside of typical business hours to meet participants' unique needs and facilitate their study participation. This support and much-needed flexibility allowed participants to better adhere to the saliva collection protocol. Third, the field coordinator conducted in-home saliva collection demonstrations for participants who needed the extra support, adding further support for protocol adherence.

Sample Selection for Analysis

After saliva samples were retrieved, the 2 collection days most adherent to the protocol were chosen for shipping, assaying, and analysis. We developed a decision tree algorithm (Multimedia Appendix 3) to identify the 2 most protocol-adherent collection day samples to be assayed. Protocol adherence was evaluated using time data from saliva logs, time-stamped photographs, and SMS text messages. The algorithm prioritized samples collected closest to the target

XSL•FO
RenderX

timing (eg, immediately upon waking and 30-min post waking) and gave greater weights to samples in which collection time was only manually noted on the saliva log, and for every 5-minute delay in saliva collection. The 2 most adherent collection days (with the lowest total weight) were selected for assay.

Sample Storage and Shipping

Saliva samples were frozen immediately after collection and kept frozen for analysis. Samples retrieved from participants in Baltimore, Maryland, were stored at –80 °C at Johns Hopkins University until shipment and then batch shipped overnight on dry ice in accordance with federal regulations for biological materials to the Institute of Interdisciplinary Salivary Bioscience Research at the University of California, Irvine.

Cortisol Assay

At the Institute of Interdisciplinary Salivary Bioscience Research, on the day of assay, samples were thawed and centrifuged to remove mucins and other particulates. Cortisol concentrations were measured in duplicate using a commercially available enzyme immunoassay (Salimetrics). The assay had a lower detection limit of 0.007 µg/dL, a range up to 3.0 µg/dL, and average inter- and intra-assay coefficients of variation below 10% and 5%, respectively [36]. The average of duplicate assay results for each sample was used in the statistical analyses.

Measures

Outcome variables included (1) completing the saliva collection protocol, (2) saliva collection log, (3) saliva collection protocol adherence weight, and (4) cortisol levels. *Completing the saliva collection protocol* included women who provided at least 1 saliva sample that was sent off for assay. *Saliva collection log* survey measured participants' adherence, understanding, and experiences with the at-home saliva collection protocol. Items captured compliance with instructions (eg, reviewing logs and following precollection restrictions), the usefulness of study reminders (eg, SMS text messages), assessed challenges (eg, remembering collection times and storing samples), as well as documented field notes. *Saliva collection protocol adherence weight* was a weighted score derived from the decision tree algorithm. For each collection day, weights (range 6 - 14 points) were assigned to each of the 2 samples collected (ie, waking sample and 30-min postwaking sample) based on the method of time verification (eg, time-stamped photo or text vs manual log) and adherence to the protocol time sampling windows, with penalties applied in 5-minute increments for delays. The 2 weights were summed for a total daily sample adherence weight (range 12 - 28 points). Lower scores indicated greater adherence to the protocol. *Cortisol levels* were reported as waking cortisol levels (µg/dL), 30-minute postwaking cortisol levels (µg/dL), and CAR. CAR was calculated by the area under the curve between cortisol measures upon waking and 30 minutes post waking using the following equation: CAR=((Cortisol 30-min post-waking+cortisol waking)/2)×T1)–(cortisol waking×T1), where T1 represents time elapsed between sample collections.

Other variables included (1) adult forced sex exposure and (2) sociodemographic variables. *Adult forced sex exposure* status was measured as a positive response to one of the following questions: (1) "Since you turned 18, has a male sex partner: used threats to make you have sex when you did not want to or used force (like hitting, holding down, or using a weapon) to make you have sex?" and (2) "Since you turned 18, has any other male done any of the following: used threats to make you have sex when you did not want to or used force (like hitting, holding down, or using a weapon) to make you have sex?" *Socio-demographic variables* included age, education, employment status, housing instability, annual individual income, relationship status, number of children, and sexual orientation.

Statistical Analysis

All statistical analyses were conducted using Stata (version 15; StataCorp) [37]. Of the 305 women who participated in the study with complete survey data, 228 women completed saliva collection, with 191 (84%) women completing at least 1 full day of saliva collection that fell within acceptable range of time collection for CAR measurement (eg, waking sample collected within 15 min of wake time, 30-min postwaking sample collected between 30 - 45 min postwake time, and ≥20 min time difference between collection of waking and postwaking samples; data not shown).

We began our analysis with descriptive statistics of the sociodemographic characteristics of women in the overall sample who completed the saliva collection protocol. Chi-square statistic was used for categorical variables, and the *F* statistic from ANOVA was used for continuous variables to detect statistically significant differences by adult sexual violence exposure, using $P<.05$ for statistical significance cutoff. We then described the frequency distribution of responses to the saliva collection log, which gave insight into the feasibility and use of supports for adherence to the saliva collection protocol, and compared differences by adult sexual violence exposure. We then described the protocol adherence feasibility and reported the average sample adherence weights for the total sample and by adult sexual violence exposure. Finally, we reported the salivary cortisol levels for the total sample and by adult sexual violence exposure for the waking and 30-minute postwaking samples, and the CAR for the subsample of women who completed at least 2 full days of saliva collection within acceptable time ranges. We used the Pearson correlation coefficient to assess the significant correlation of cortisol levels between collection days.

Results

Overview

Overall, our results report on our saliva collection protocol results, and demonstrate the feasibility of saliva CAR self-collection among Black women with histories of abuse. Of the 305 women who were eligible and consented to the survey and saliva collection, 228 (75%) completed the saliva specimen collection protocol, 33 (11%) were lost at the survey, 23 (8%) refused the saliva collection, and 21 (7%) did not complete the saliva collection (refused mid-completion; data not shown). Of the women who completed the saliva specimen collection protocol, 93 (41%) had a history of forced sex since age 18

XSL•FO
RenderX

years (exposed women) and 135 (59%) had no history of forced sex since age 18 years (unexposed women).

Table 1 describes the demographic characteristics of the total study sample that completed the saliva collection protocol and compares differences by adult forced sex exposure. Among the total sample of Black women who completed the saliva collection protocol (n=228), participants were on average 26.6 (SD 6.45) years old, most had a high-school education or more (190/228, 83%), and over half were currently employed (133/228, 58%). Socioeconomic vulnerability was evident, with 61% (139/228) reporting annual incomes below US $10,000 and 7% (16/228) reporting housing instability. Most participants were single (160/228, 70%), had at least 1 child (118/228, 52%), and identified as heterosexual (192/228, 84%). Women exposed to adult sexual violence who completed the saliva collection were, on average, significantly older, were less likely to have a high-school education, were less likely to be currently employed, and were more likely to report housing instability than women unexposed to adult sexual violence who completed the saliva collection.

Table . Sociodemographic characteristics of Black women with violence experience completing repeated measures self-collection of saliva in Baltimore, Maryland (Source: The ESSENCE Project 2015-2018).

Characteristic	Total saliva (n=228), n (%)	Adult forced sex exposure status		
		Exposed (n=93)	Unexposed (n=135)	*P* value[a]

Saliva Collection Logistics

Analysis of the saliva collection log data (Table 2) demonstrates high levels of protocol feasibility, regardless of adult forced sex exposure. In terms of the saliva collection demo, most women reported receiving the saliva demo in the clinic 192/228, 84%), most reported that the saliva demo at the clinic was thorough enough to remember how to self-collect (190/228, 83%), and 99% (225/228) returned the saliva log, which was the standard protocol. In terms of protocol adherence supports, most women

XSL•FO
RenderX

reported referring to the instructions page provided to help remember how to collect the saliva sample (160/228, 70%). The most difficult part of the saliva collection reported was drooling (74/228, 33%) followed by taking pictures of the sample (46/228, 20%). Most women reported having a little or moderate difficulty refraining from drinking, eating, smoking, or brushing their teeth during the saliva collection (125/228, 55%). In terms of the study phones, most women reported receiving texts from the study phone (206/228, 90%), with most reporting that these texts were moderately useful (131/228, 58%) or very useful (56/228, 25%), and most using the study phone texts to wake up to collect their first sample (140/228, 61%). The majority of women reported taking pictures of the saliva vials (211/228, 93%). In terms of saliva storage, most women reported no problems storing the saliva samples in their freezer (217/228, 95%). There were no statistically significant differences observed between women exposed and unexposed to adult forced sex across the saliva collection log measures, indicating that the protocol was feasible across exposure groups.

[b]Not applicable.

Table 3 describes the feasibility of protocol completion and assesses protocol adherence using the protocol adherence weights generated by the decision tree algorithm. Protocol completion was highly feasible, with the majority (191/228, 84%) of the total sample successfully completing at least 1 full day of saliva collection within the specific timing necessary to measure CAR. Of the total sample, 26% (59/191) achieved 1 full day of adherence to protocol collection, and 58% (132/191) achieved 2 full days of adherence. This was consistent across adult forced sex exposure categories, with 83% (77/93) of exposed women and 84% (114/135) of unexposed women completing at least 1 full day of adherent saliva collection, with no significant differences. In terms of protocol adherence weights, the total sample maintained an excellent mean adherence weight of 16.25 (SD 6.303). There were statistically significant differences in the total protocol adherence weights by adult forced sex exposure status, with exposed women demonstrating significantly less adherence to the protocol (mean 17.85, SD 5.217) than unexposed women (mean 15.16, SD 6.750; *P*=.002). This discrepancy was most pronounced among women who completed the full 2-day protocol, where exposed women remained significantly less adherent to the protocol than their unexposed counterparts (mean 17.36, SD 4.986 vs mean 14.48, SD 6.126, respectively; *P*=.004). This finding suggests that, although feasibility was high across both groups, trauma history may influence women's ability to adhere to the protocol.

[b]Not applicable.

Table 4 reports the cortisol levels among women who completed 2 full days of saliva collection within the required time limits for CAR, comparing the Pearson correlation coefficient of between-day cortisol levels (waking, post waking, and CAR) for each of the 2 days. Among the total sample, day 1 and day 2 cortisol waking samples (r=0.276; P=.001) and the CAR levels (r=0.178; P=.04) were weakly but statistically significantly correlated, whereas the postwaking samples (r=0.411, P<.001) were moderately and statistically significantly correlated. When stratifying by adult forced sex exposure, waking cortisol samples for day 1 and day 2 were weakly but statistically significantly correlated among exposed women (r=0.316, P=.02) and unexposed women (r=0.258, P=.02). Postwaking cortisol samples for day 1 and day 2 were moderately and significantly correlated among exposed women (r=0.505, P<.001) and unexposed women (r=0.380, P=.001). CAR levels for day 1 and day 2 were not statistically correlated among exposed women (r=0.027, P=.85); however, CAR levels were weakly but statistically significantly correlated among unexposed women (r=0.273, P=.01). Overall, postwaking cortisol demonstrated the greatest reproducibility across the 2 days, while CAR demonstrated the least stability, particularly among women with adult forced sex exposure.

Discussion

Principal Findings

The study developed a standardized, trauma-informed protocol for multiple day at-home salivary CAR self-collection for women with histories of abuse and provides evidence supporting the overall feasibility of implementing the protocol among a hard-to-reach sample of US Black women with experiences of trauma and abuse.

Overall participants demonstrated high engagement with study procedures, with the majority returning saliva logs, using adherence supports (ie, SMS text message reminders and referring to instructional materials), and adhering to key protocol components (ie, documenting sample collection times and freezing samples). However, findings highlight critical differences in protocol feasibility and adherence among women who completed the full 2-day collection by adult sexual violence exposure status, with exposed women demonstrating lower protocol adherence scores than unexposed women. Future protocols may benefit from enhanced trauma-informed supports, such as more frequent reminders, simplified procedures, or real-time monitoring, to mitigate adherence challenges among this population.

The cortisol analyses provide additional insight into the reliability of the at-home self-collected salivary biomarkers. Postwaking cortisol levels demonstrated the strongest reproducibility across days, while CAR demonstrated weaker and less consistent correlations, especially among women exposed to adult forced sex. The lack of significant day-to-day correlation in CAR among exposed women may reflect both biological variability with trauma-related HPA axis dysregulation and the observed challenges with protocol adherence. These findings suggest that while home-based saliva self-collection for CAR measurement is a viable and inclusive approach for studying stress physiology in this population, careful attention to protocol adherence and collection day flexibility is warranted.

This study is innovative in developing a saliva collection protocol tailored for this underrepresented population. Best practices include the following: (1) the use of text reminders via cell phones to enhance participants' adherence to the saliva collection protocol; (2) the use of study staff who were representative of the community to retrieve saliva samples; and (3) the creation of a saliva sample decision tree, which automated the decision of which 2 of 3 saliva samples were most adherent in such a large sample. Research implications include the facilitation of the collection of salivary biomarkers (including stress and inflammation measures) to promote

XSL•FO
RenderX

research that examines the physiological and health repercussions of GBV within the context of women's everyday lives.

Strengths and Limitations

The protocol had several strengths. First, we established an at-home saliva self-collection (and storage) protocol with accommodations for women currently experiencing violence. Second, we had a large sample size of Black women with violence experience to demonstrate feasibility and acceptability in a diverse sample with safety considerations. Our protocol, importantly, demonstrated feasibility and acceptability in 2 populations (Black women and Black women with abuse histories) that have classically been mistrustful of the health care system and health care research. Third, we explored the use of study-issued cell phones to improve protocol adherence in terms of timing of saliva collection (as CAR is time-sensitive) and feasibility of sending a time-stamped picture documenting the time of the collected sample. Finally, collecting saliva at-home captures the interaction between biological and behavioral processes in the context of participants' everyday life, potentially enhancing the information collected compared with collecting biological markers in clinical settings.

Our protocol had several limitations that researchers implementing similar studies may wish to address. First, documenting the timing of saliva collection using the standard written log may have introduced self-report bias. To mitigate this, participants were instructed to send a time-stamped photo immediately after collecting each saliva sample. However, adherence to this protocol procedure was inconsistent due to logistical barriers (eg, uncharged or inaccessible study phone). Future studies could improve data accuracy by implementing automated time-stamping technologies (eg, mobile apps and electronic monitoring devices). Second, establishing regular wake times for participants for 3 consecutive days was challenging, particularly for participants who worked nights or with irregular sleep schedules. Although participants were provided with standardized instructions to plan sample collection based on their primary wake time, wake time ambiguity persisted among participants with fragmented sleep patterns. This variability may have introduced "noise" in terms of timing of sample collection relative to the cortisol diurnal pattern. Future research should consider more flexible, individualized collection protocols for women with abuse histories. Third, study-issued phones were intended to reduce the associated cost and participant burden of using their personal phone. However, some participants did not consistently use the study-issued phones, misused them for personal purposes, or reported loss or damage. Most participants had their own cell phone, and it was difficult for them to carry and use 2 cell phones. Additionally, for participants with histories of abuse, carrying a secondary phone may have posed safety concerns (ie, raising the suspicions of an abuser), which potentially affected protocol adherence. Future studies should carefully weigh the risks and benefits of providing study-specific devices and consider alternatives (eg, secure mobile app compatible with personal phones). Fourth, although access to a refrigerator was an eligibility requirement, participants who lived in settings with a shared refrigerator (ie, homeless or domestic violence shelter) had their samples erroneously thrown out. Other participants reported that family members found the samples and, not knowing what they were, threw them out. In these instances, staff issued new supplies. To mitigate this risk, future protocols should include more comprehensive participant education regarding sample storage, as well as considerations for discreet labeling. Finally, the use of cryovials with color-coded caps to visually distinguish waking sample (green) and 30-minute postwaking sample (red) vials may constitute a study limitation for individuals with red-green vision deficits. Future research should consider adopting alternative visual markers (eg, distinct patterns, textual labels, or uniquely shaped indicators) to enhance accessibility and ensure clarity for all participants.

Future Directions

Future studies that seek to obtain salivary samples among racial and ethnic minority women with histories of abuse should consider the context in which the women are living. In our study, we incorporated safe words and established safety plans with participants during key points of the protocol (ie, sample collection, phone usage, and sample pick-up). In addition, we preprogrammed community resources into the study phone contacts (ie, domestic violence shelters and study contacts) under aliases.

Acknowledging the reality and potential volatility of the context of participants' lives signals support for them and builds trust, which can strengthen protocol adherence. By strengthening adherence, we can advance research that examines the physiological and health repercussions of GBV.

Abstract

Background: Occupational e-mental health (OeMH) interventions emerged as a promising solution to prevent common mental health problems and enhance well-being and work performance. However, they must be subject to robust and reliable assessments for effectiveness.

Methods: A multimodal e-mental health intervention (EMPOWER [The European Platform to Promote Wellbeing and Health in the Workplace]) delivered over 7 weeks was developed and evaluated through a cluster randomized controlled trial conducted mainly in small to medium enterprises and public agencies from Spain (n=127), Finland (n=141), Poland (n=51), and the United Kingdom (n=389) between February 2022 and May 2024 (recruitment finalized in September 2023 and follow-up completed in May 2024). Inclusion criteria were being 18+ years, having a smartphone, sufficient language knowledge, and agreeing to participate. Clusters (companies or departments) were randomized to intervention or control conditions. The primary outcome

XSL•FO
RenderX

was presenteeism, and secondary outcomes were depression and anxiety symptoms, etc, all measured at baseline, postintervention, and in 21 weeks after program completion. The analysis was performed as an intention-to-treat approach using adjusted linear mixed models and as per protocol analysis comparing outcomes by level of engagement.

Results: A total of 347 participants were allocated to the intervention group and 361 to the control group. In the overall sample, the intention-to-treat analysis detected no statistically significant short-term (7 wk) or long-term (21 wk postintervention) effects of the EMPOWER intervention on presenteeism (postintervention β=2.186; 95% CI −2.424 to 6.796, follow-up β=1.294; 95% CI −3.608 to 6.396) and on other secondary outcomes such as depressive symptoms (postintervention β=−0.052, 95% CI −1.02 to 0.905, follow-up β=0.202, 95% CI −0.840 to 1.245), anxiety symptoms (postintervention β=−0.328, 95% CI −1.168 to 0.512, follow-up β=0.375, 95% CI −0.537 to 1.287), or general stress level (postintervention β=0.385, 95% CI −0.195 to 0.965, follow-up β=0.123, 95% CI −0.502 to 0.749). Subgroup analyses yielded several notable results, with significant differences between age groups, gender, and psychological symptoms at baseline. The per-protocol analysis showed no significant differences between participants who actively engaged with the intervention (119/347, 34%) and those who did not. Implementation challenges were related to technical problems, the complexity of this study's design, external factors, co-design strategy, and organizational barriers, which led to a smaller sample size, high attrition rates, and low adherence.

Conclusions: Our study provides evidence from a large cluster randomized controlled trial evaluating an OeMH intervention implemented in workplace settings, including small to medium enterprises and public agencies in Europe. Although no overall effectiveness was observed, this study contributes important methodological and implementation insights, highlighting the challenges of evaluating OeMH interventions. These findings suggest that future interventions should prioritize feasibility testing, organizational readiness, user engagement, and more targeted and pragmatic evaluation approaches to enhance real-world impact.

Introduction

Common mental health conditions, such as depression, anxiety, or other stress-related disorders, constitute approximately 40% of work-related illness cases, and these conditions are mostly manageable and avoidable with appropriate treatment and prevention [1,2]. On a global scale, around 12 billion workdays are forfeited annually due to the impact of depression and anxiety, resulting in an economic cost of approximately US $1 trillion per year attributed to reduced productivity [3]. In Europe, productivity loss due to mental health conditions has an estimated annual cost of €400 billion (≈US $460.4 billion) [4,5]. This productivity loss is a consequence of working with limitations due to an illness (ie, presenteeism) and absence from work due to the illness (ie, absenteeism) [6].

Occupational mental health interventions have been increasingly delivered through digital platforms, described as being more flexible, anonymous, and convenient [7]. This has the potential to increase the accessibility of evidence-based interventions and to reduce costs compared to face-to-face interventions [8]. There is evidence for moderate effects of occupational e-mental health (OeMH) interventions to reduce stress, insomnia, and burnout, and small treatment effects on depression, anxiety, well-being, and mindfulness [9-11]. Results regarding work-related outcomes, such as presenteeism and absenteeism, are scarce and inconclusive [10,12]. In general, there is a high heterogeneity between studies on OeMH interventions in terms of the type of intervention delivered, outcomes, and the quality of their methodology [13,14]. Furthermore, these mixed results underscore the complexity of assessing the outcomes of digital interventions and indicate that organizational culture, intervention design, and implementation serve as critical mediating factors.

In fact, the implementation of e-mental health interventions in the workplace has some important barriers. Challenges include adapting to new and changing regulatory frameworks, ensuring compatibility with existing systems, addressing employee privacy and security concerns, the rapid change of the digital ecosystem, and managing costs [15]. Additionally, maintaining treatment adherence and preventing attrition are also recognized as challenges. e-Mental health interventions have usually been associated with high attrition rates [8]. A recent scoping review indicates that potential successful implementation strategies for OeMH interventions include providing incentives to participants, sending reminders, providing support to users during the intervention, conducting educational meetings, and the involvement of senior management [16]. The scoping review also concludes that there is an urgent need to enhance the reporting of implementation strategies and to integrate common implementation frameworks with more technology-focused ones to comprehensively address the complexities of e-health implementations [16].

Several factors can potentially affect the effectiveness of OeMH interventions, such as the mode of delivery, the content, the approach (eg, tailored and universal), duration of intervention, the use of interventions in combination, and the characteristics

XSL•FO
RenderX

of the target population [17]. Digital interventions that are tailored to users' needs tend to foster higher engagement [17]. On the other hand, stigma against individuals with mental illness can deter participation in such interventions [18]. Finally, the cultural adaptation of workplace interventions is a critical factor for successful implementation, with more favorable outcomes for linguistically and culturally adapted interventions [19] and those that consider organizational cultural elements [20]. Culturally adapted e-mental health interventions seem to have a moderately higher effect in reducing depressive and anxiety symptoms when compared to interventions that are not culturally adapted [19].

While occupational mental health interventions delivered via digital platforms have emerged as promising tools for addressing workplace mental health issues, these interventions often lack contextual adaptation to workplace-specific needs and exhibit high variability in outcomes due to differences in design, content, and target populations. A systematic review by Moe-Byrne et al [12] highlighted this variability in the effectiveness of digital workplace mental health interventions and emphasized the need for context-sensitive, tailored approaches. Additionally, although digital mental health interventions are growing, many existing programs do not sufficiently consider organizational cultural factors or provide tailored support for small to medium enterprises (SMEs) [21].

The EMPOWER [The European Platform to Promote Wellbeing and Health in the Workplace] platform is a multimodal eHealth intervention delivered through a website and an application that was designed to address mental health issues in the workplace and enhance employees' well-being [22]. It follows a 3-tiered intervention structure: universal (primary) prevention; targeted (secondary) prevention, and tertiary prevention, focusing primarily on preventing mild mental health problems and promoting well-being in the workplace rather than treating mental disorders. It was specifically designed for SMEs and public agencies (for a comprehensive view of the design and rationale of the current study, please see references [22,23]), filling a critical gap identified in recent literature. EMPOWER integrates organizational readiness assessments and user-centered design principles to enhance feasibility and effectiveness, aiming to improve outcomes such as presenteeism, anxiety, depression, and well-being. We conducted a cluster randomized controlled trial (RCT) with employees from SMEs and public agencies in Finland, Poland, Spain, and the United Kingdom to evaluate the effectiveness of EMPOWER on various mental health and work-related outcomes, both immediately postintervention and at follow-up, and explored several factors that could impact the effectiveness through subgroup analyses. The rationale behind using a cluster randomized design was the organizational nature of the intervention and the high risk of contamination between employees within the same workplace. The primary and secondary outcomes were assessed at the individual employee level, while randomization and intervention allocation were performed at the organizational (cluster) level. Additionally, we discuss the challenges encountered during the implementation process and interpret our results in light of these difficulties.

Methods

Study Design

This study was conducted as a multicountry cluster RCT with 2 parallel arms (intervention and wait-list control), following an initial stepped-wedge trial design in Spain, Finland, Poland, and the United Kingdom. Clusters (ie, companies or departments) were randomly assigned to A, B, and C groups, differing in the time when participants had access to the intervention. Participants from the 3 groups were invited to download the application at the same time, that is, at the beginning of the RCT (T0). Participants in group A had access to the intervention after completing the baseline questionnaires (T0), participants in group B had access after completing 2 rounds of questionnaires (after T1), and participants in group C had access after completing 3 rounds of questionnaires (after T2). A total of 2 additional rounds of questionnaires were delivered to the participants as follow-up measures (T3 and T4). As such, data were collected at the individual level at 5 time points [22]. Each data collection wave took place with a span of approximately 7 weeks of difference. The first study protocols were approved by the ethics committees of Fundació Sant Joan de Déu (PIC-39‐20), Turku University Hospital (PIC-993966082), University of York (HSRGC250321), and Institute of Occupational Medicine, University of Lodz (9/2020).

Periodic reports and meetings were held among the consortium partners to monitor the progress of the fieldwork. We faced several barriers and challenges throughout the trial period, particularly during the first months (February 2022 to September 2022). During this time, various contingency measures were implemented to increase participation, including the inclusion of new companies, improvements in local dissemination activities, and sending reminders to workers. In Table S1 in Multimedia Appendix 1, we present the contextual barriers (at the country, company, and individual levels) as well as the facilitators identified throughout the trial.

In September 2022, the number of recruited participants was still lower than expected, despite the contingency actions that we took (see section Sample Size Calculation; 461 had consented to participate, 295 had completed baseline questionnaires, 100 had answered T1, 45 had answered T2, and 14 had answered T3). Feedback from participants, collected through qualitative interviews, revealed that one of the main reasons for not completing the planned assessments was the length of the questionnaires and the high number of assessment points. After careful consideration, the consortium agreed to modify the design from a stepped-wedge to a cluster RCT with 2 parallel arms: an intervention arm and a wait-list control arm. Following this change, each newly recruited cluster (company or department) was randomized to either intervention or control, regardless of size, type of workers, or sector. We also reduced the number of assessment points from 5 to 3 in all groups: T0 (baseline), T1 (postintervention, 7 weeks), and T2 (follow-up, 21 weeks). In addition, the number of questionnaires at T1 was reduced to minimize participant burden.

Participants recruited before September 2022, and therefore under the initial stepped-wedge design, were reallocated to

XSL•FO
RenderX

either the intervention or control group depending on their study status. Specifically, participants from group A, who had already completed the intervention between T0 and T1, were directly assigned to the intervention group. Participants from group B were reassigned to the intervention group, with their T1 data treated as preintervention, T2 as postintervention, and their follow-up postponed by 7 weeks to ensure comparability with group A. Finally, participants in group C continued their original assessment schedule, with the exception that they did not gain access to the intervention until the follow-up assessment (21 weeks).

This study's design modification was approved by Fundació Sant Joan de Déu in October 2022. The trial was registered at ClinicalTrial.gov (NCT04907604). The trial ended as planned after completion of follow-up assessments.

This cluster RCT was reported in accordance with the CONSORT (Consolidated Standards of Reporting Trials) 2010 statement [24], the CONSORT extension for cluster randomized trials [25], and the CONSORT extension for abstracts [26] (Checklist 1).

Recruitment Process and Randomization

Before the recruitment of participants, we approached several SMEs and public agencies from Finland, Poland, Spain, and the United Kingdom to participate in this study. Large companies were also considered for the RCT. Clusters were eligible if they were SMEs, public agencies, or large organizations willing to participate in this study and able to provide access to their employees for the duration of the trial. There was no limitation on the size or economic sector. Participant recruitment took place between February 25, 2022, and September 30, 2023; data collection lasted until May 30, 2024. New companies or departments could be included during the course of this study.

Different strategies were used by the local research teams to recruit companies (such as press release and media, employers' organizations, and face-to-face and online meetings). A formal agreement was signed between the EMPOWER consortium and the employer before recruiting their employees. In a first round of randomization (January 2022) and under the stepped-wedge trial design, clusters (ie, SMEs or departments) were randomly allocated into group A, B, or C, considering strata to reduce imbalance issues [27]. This was done separately in each country, considering, when possible, the cluster size, type of workers (blue vs white collar), and type of company (SME, public agency, and large). A second round of randomization was repeated in April 2022. We used the runiform module from Stata (StataCorp LLC) to randomize newly recruited companies or departments. After the design modification with 2 parallel groups (from September 2022), newly recruited clusters were randomly allocated to the intervention or control group by using randomly generated numbers in Excel (Microsoft Corp). In this case, variables such as cluster size, type of workers, and type of company were not taken into account when randomizing the companies. Randomization was performed by this study's coordinator. Moreover, due to the nature of the digital intervention, neither participants nor researchers were blinded to group allocation. Allocation concealment was not feasible due to the cluster-level nature of the intervention and the pragmatic implementation of the trial.

A total of 25 clusters were assigned to the intervention group and 19 to the control group. Initially, email invitations to the employees using the EMPOWER email address were sent, which provided a nontransferable, one-use link for downloading the application and a company-specific code to access it. This allowed us to have control over participants, but at the same time, did not allow participants to share the link with other workmates and increased the chance of technical problems. Thus, in April 2022, we created QR codes for each country to download the application, together with a company code to sign in. All procedures followed the General Data Protection Regulation [28].

Participant inclusion criteria were (1) being aged 18 years or older, (2) having a mobile phone with internet access, (3) having sufficient knowledge of the local language, and (4) providing informed consent.

All participants were invited to download the application and provide informed consent, which was integrated into the application. After providing consent, participants were asked to answer the baseline assessment questions. Employees of localities assigned to the intervention group were able to access and use the intervention part of the application directly after completing the baseline questionnaires; application access lasted for a duration of 7 weeks. All participants were asked to complete additional rounds of questionnaires 7 weeks after baseline assessment completion (postintervention) and 21 weeks after postintervention assessment completion (follow-up). Once the 3 rounds of questionnaires were completed, participants in both groups (intervention and control groups) had full access to the intervention part of the application. Participants with severe mental health conditions (including people reporting suicidal thoughts) requiring immediate treatment were advised to seek professional help and were warned that the EMPOWER application was not an intervention; however, they were not excluded from this study.

The assessment protocols were delivered through the application with no time limit for participants to complete the questionnaires. Participants received automatic reminder emails and/or pop-up messages from the application to notify them when an assessment protocol was available for them to complete. To increase retention rates, weekly reports were used to follow up on the number of responses, and the local researchers actively sent personalized email reminders to participants to encourage them to answer the questionnaires. Local researchers in each country had a coordination handbook that covered topics such as study design, data management and security, ethical aspects, responsibilities and good practices, solving problems during the fieldwork, and the incidental findings policy. No specific procedures were implemented to monitor adverse events, as the intervention was low-intensity and self-guided. Any potential unintended effects were assessed descriptively. Participants were provided with the contact details of the local research teams.

XSL•FO
RenderX

Sample Size Calculation

A cautionary approach was adopted to detect small changes and effect sizes and was based on a review that assessed the impact of mental health programs on presenteeism in the workplace [29]. The calculation also accounted for potential loss to early and late follow-ups (25%). The sample size calculation was based on detecting changes in presenteeism, based on a review of the impact of mental health programs on presenteeism in the workplace [30]. Considering an expected effect size of d=0.30, a bilateral type I error of 0.05, and a power of 80%, a total sample of 729 participants was required. However, due to the implementation of multilevel analyses resulting from cluster randomization, the sample size needed to be adjusted by a factor of 1.2, leading to a final sample size of 874 participants [29].

Ethical Considerations

This study was conducted in compliance with ethical guidelines for research involving human participants. Ethical approval was obtained from the relevant ethics committees in each participating country: Clinical Research Ethics Committee of Fundació Sant Joan de Déu (PIC-39-20), Ethics Committee of the Hospital District of Southwest Finland (PIC-993966082), Health Sciences Research Governance Committee, University of York (HSRGC250321), and the Institute of Occupational Medicine and the Bioethics Committee of the Nofer Institute of Occupational Medicine (Łódź, Poland; 9/2020). The trial was registered at ClinicalTrials.gov (NCT04907604). This study's design modifications made in response to recruitment challenges were approved by Fundació Sant Joan de Déu in October 2022.

All participants provided informed consent before enrollment in this study. Consent was integrated into the EMPOWER application, where participants were required to review study information and explicitly agree to participate before accessing the baseline questionnaire. Participants had the right to withdraw from this study at any time without consequence. Participants who completed all 3 rounds of questionnaires (baseline, post intervention at 7 wk, and follow-up at 21 wk) received a €20 (US $22.94) voucher as compensation for their time and effort in this study.

All data collected in this study were anonymized and stored securely in compliance with the General Data Protection Regulation. Each participant was assigned a unique identification code to ensure confidentiality. Identifiable personal data was not collected, and all responses were encrypted during data transmission and storage. Employers had access only to aggregated, anonymized workplace risk assessments, ensuring that individual participant data remained confidential.

Intervention

The EMPOWER digital intervention has been previously described in detail [23]. The intervention included components delivered at both the individual employee level (self-guided application modules) and the organizational level (employer web portal and aggregated psychosocial risk feedback). The website is public and offers a company-level mental health awareness campaign that assists both employees and employers in addressing work-related stress and mental health challenges. The application is available for use by individual employees and contains triage assessment tools and an algorithm to tailor content modules based on their symptomatology and work functioning. The application follows a self-guided approach, and the content is based on cognitive behavioral therapy (CBT) techniques, including psychoeducational material, tracking your mood, self-guided goal setting, problem solving, relaxation, and breathing exercises. The different modules of the application were designed to increase awareness about mental health, reduce stress, anxiety, and other psychological symptoms, screen for psychosocial risk factors and recommendations, and include a return-to-work module. From an organizational level, employers could access a restricted web portal that provided an anonymous brief assessment of psychosocial risk factors in the workplace as reported by employees, accompanied by tailored recommendations for employers. The readiness of the website and application was evaluated using the technology readiness level adapted for implementation sciences [31] as part of the impact assessment, which is described elsewhere [32]. During the RCT, we collected feedback from employees, employers, and local researchers as part of a qualitative assessment and impact analysis, described elsewhere [32].

Outcome Measures

All primary and secondary outcomes were assessed at the individual employee level. A summary of the outcome measures used in this study can be found in Table 1. Levels of anxiety and depression were categorized using cutoff scores from the GAD-7 (Generalized Anxiety Disorder Questionnaire) and PHQ-9 (Patient Health Questionnaire-9) scales, where scores greater than 5 are considered as having at least mild anxiety symptoms [33] or mild depressive symptoms [34].

XSL•FO
RenderX

Table . Variables and measures for this study.

Outcome	Measure	Description
Primary outcome measure		
Presenteeism	iMTA[a] Productivity Cost Questionnaire (iPCQ) [35]	Scores start at 0 and measure total hours lost due to being unproductive at work
Secondary outcome measures		
Depression	Patient Health Questionnaire-9 (PHQ-9) [34]	Its total score ranges from 0 to 27, ranging from no depression to severe depression.
Anxiety	Generalized Anxiety Disorder Questionnaire (GAD-7) [33]	This questionnaire ranges from 0 to 21, meaning from no anxiety to severe anxiety.
Insomnia	Insomnia Severity Index (ISI) [36]	The ISI ranges from 0 to 12, where 0 indicates no presence of insomnia, and 12 indicates a severe presence of insomnia.
Work stress	Mini-Psychosocial Stressors at Work Scale (Mini-PSWS) [37]	The total score ranges from 0 (no stress) to 48 (maximum stress)
General stress	Perceived Stress Scale (PSS-4) [38]	The total score of the PSS-4 ranges from 0 to 16, where 0 indicates no stress and 16 indicates severe stress.
Well-being	World Health Organization Well-Being Index (WHO-5) [39]	It scores from 0 to 100, where higher scores indicate better well-being, and a clinically significant change was defined as a difference of 10 points or more.
Momentaneous well-being	Visual analog scale from 0 to 10	Higher scores represent better well-being
Mental Health Quality of Life	Mental Health Quality of Life Questionnaire (MHQoL) [40]	Ranging from 0 to 21, where 21 represents the best possible mental health and quality of life.
Physical activity	International Physical Activity Questionnaire (IPAQ) [41]	Reported as total METs[b], with higher values indicating greater activity levels.
Sitting	International Physical Activity Questionnaire (IPAQ) [41]	Was recorded in minutes per day spent sitting
Somatization	Patient Health Questionnaire (PHQ-15) [42]	Scores from 0 to 30, where 30 indicates the worst health
Absenteeism	iMTA Productivity Cost Questionnaire (iPCQ) [35]	Scores start at 0 and measure total hours lost due to being absent from work
Unpaid labor	iMTA Productivity Cost Questionnaire (iPCQ) [35]	It calculates the hours lost due to needing assistance with tasks

[a]iMTA: Institute for Medical Technology Assessment.

[b]MET: metabolic equivalent of task.

Level of Engagement (Active vs Inactive Application Users)

In our analysis of the intervention group, participants were categorized as either active or inactive application users based on several key criteria. For each participant, we evaluated whether they earned more than 5 badges, engaged with any content by reading pages, began working on any problems, consistently tracked their mood for more than a week (7 d), or acquired any badge through application interaction. Participants were assigned a score of 1 if a condition was met and 0 if it was not. We then summed these scores for each participant. Those who met none or only one of these conditions were classified as inactive, while participants who met more than 1 condition were classified as active.

Statistical Analysis

For descriptive analysis, we used mean and SD, and frequencies and percentages (%) for continuous and categorical variables, respectively. Differences between groups were calculated using chi-squared and *t* tests. We also calculated a correlation matrix between the main outcomes at baseline to assess the relationships between those variables (see Table S2 in Multimedia Appendix 1).

As a first step, we followed an intention-to-treat approach to maintain the comparability between participants in the intervention and the control groups and avoid selection bias [43]. We calculated linear mixed models (LMMs) to separately analyze the primary and secondary outcomes. The independent variables were the participant's group (intervention vs control) and the intervention time (baseline, postintervention, and follow-up). Each model was adjusted for the covariates gender,

XSL•FO
RenderX

age, and country to account for potential confounding factors. Additional analyses were also performed, adding the same baseline measure as a covariate, to control for potential group differences at baseline. For each outcome, a *P* value and CIs are provided. LMMs were calculated for the whole sample. To investigate potential moderators for the effectiveness of the intervention on several outcomes, we conducted subgroup analyses where LMMs were estimated separately for different subgroups: gender, age groups (18 - 35, 36 - 49, and 50+ years), low and high levels of anxiety, depressive and somatization symptoms (using the clinical cutoff point of 5), low and high levels of work stress (using median as cutoff). For each subgroup, LMMs were adjusted for sex, age, and country to account for potential confounding factors (these covariates were held constant in each of the models; information about the coefficients for each covariate in the LMM models is available upon request).

Statistics that compared participants who dropped out with those who did not were also described with mean (SD) or n (%), depending on whether the outcomes were numeric or categorical. Finally, we conducted a per-protocol analysis as a secondary analysis, in which we conducted LMMs differentiating between active and inactive participants (see section Level of Engagement (Active vs Inactive Application Users)), comparing them to the control condition and between each other. As such, the per-protocol analyses in our study did not handle missing data. Per-protocol analysis estimates the effect of receiving the treatment (efficacy). Missing data were handled by using LMMs, which allow inclusion of participants with incomplete data under the missing at random assumption.

Results

Descriptive Analyses

A total of 877 employees accepted the informed consent, and 708 answered the baseline questionnaires. A total of 44 clusters were randomized, with 25 allocated to the intervention group and 19 to the control group. No clusters were lost or excluded after randomization, and all of them were included in the primary analyses. A total of 333 participants completed postintervention questionnaires and 267 follow-up questionnaires (Figure 1). Table 2 shows the descriptive statistics for the total sample and by intervention group, 78% (544/697) were females, and the average age was 45.05 (SD 10.50) years, 18% (127/708) of participants were from Spain, 7% (51/708) from Poland, 55% (389/708) from the United Kingdom, and 20% (141/708) from Finland. Most participants were working in public agencies (584/685, 85%) and were white-collar workers (663/696, 95%). The intervention and control groups significantly differed for sex, country, company, and workers' type. All participants who completed baseline assessments were included in the intention-to-treat analyses for the primary outcome.

[a]Chi-square test.

[b]*t* test.

[c]SME: small to medium enterprise.

In general, the correlation matrix showed high correlation coefficients between most outcomes at baseline (except for the variables sitting and absenteeism, see Table S2 in Multimedia Appendix 1). Table 3 shows the mean values for the outcomes at preintervention, generally, and divided by intervention and control groups. At preintervention (T0), the intervention group had significantly lower levels of depressive symptoms (t=2.031, P=.043), anxiety symptoms (t=2.169, P=.03), and general stress (t=3.104, P=.002), and higher levels of well-being (t=−3.412, P=.001), mental health quality of life (t=−2.166, P=.031), and momentaneous well-being (t=−2.438, P=.015), as compared with the control group. No statistically significant differences between groups were found for insomnia, work stress, physical activity, sitting, somatic health, absenteeism, presenteeism, and unpaid labor (all P>.05).

[b]IG: intervention group.

Adjusted Main Model for Postintervention Effects

All analyses were conducted following an intention-to-treat approach, including all participants according to their original group allocation. The results from models for the different outcomes adjusted by age, gender, and country are displayed in Table 4. The displayed value is the regression coefficient for the interaction effect from group (control vs intervention) by time (pre- to postintervention), therefore representing the intervention effect. Overall, the intervention had no significant effect on any of the outcomes of this study (all $P>.05$). Moreover, due to the significant differences at baseline between the intervention and control group, we also conducted the analyses adjusting for baseline levels. These additional analyses led to similar results except for a lower well-being in the intervention group as compared to the control group ($\beta=-3.289$, $P=.034$, 95% CI −6.331 to −0.247); however, this reduction in well-being is not considered clinically relevant.

Adjusted Main Model for Follow-Up Effects

As there was no limit to when the participants could respond to the follow-up questionnaire, the follow-up time had a mean value of 48.84 (SD 24.77) weeks. When looking at the intervention effect at follow-up, no significant intervention effects were found for any of the outcome variables (all *P*>.05; see Table 5). Again, due to the significant differences at baseline between the intervention and control group, we conducted the analyses adjusting for baseline (values or levels), finding no significant differences between the intervention and control group at follow-up.

Table . Generalized linear model adjusted results for follow-up effects.

Outcome	β-value (95% CI)[a]	*P* value
Depressive symptoms	0.202 (−0.840 to 1.245)	.70
Anxiety symptoms	0.375 (−0.537 to 1.287)	.42
Insomnia symptoms	−0.148 (−0.619 to 0.323)	.54
General stress	0.123 (−0.502 to 0.749)	.70
Work stress	−0.610 (−2.387 to 1.166)	.50
Well-being	−1.022 (−5.019 to 2.975)	.62

Results From Subgroup Analyses

Analyses conducted separately by subgroups yielded several significant results (tables with all the outcome variables for the different subgroup analyses can be found in Tables S3-S8 in Multimedia Appendix 1).

First, comparing men and women, we only found that the intervention group had decreased well-being at postintervention (β=−4.796, *P*=.029, 95% CI −9.109 to −0.482) in women. No significant intervention effects were found in men. The subgroup analysis by age groups showed that participants aged 18 - 35 years were less sedentary, spending less time sitting at postintervention (β=283.325, *P*=.004, 95% CI −477.588 to −89.062). Participants aged 50 years and older showed increased presenteeism at postintervention (β=10.016, *P*=.007, 95% CI 2.714 to 17.317). Comparing participants with low and high depression scores at baseline showed that participants with low depressive levels had decreased well-being (β=−4.901, *P*=.029, 95% CI −9.304 to −0.497) and lower mental health quality of life (β=−0.964, *P*=.028, 95% CI −1.822 to −0.105) at postintervention. Conversely, participants with high depressive symptoms at baseline spent less time sitting at T1 (β=−147.023, *P*=.047, 95% CI −292.164 to −1.882). As for low and high levels of anxiety, we observed that those with low anxiety levels at baseline also experienced decreased well-being (β=−4.523, *P*=.048, 95% CI −9.011,−0.036) and reduced mental health quality of life (β=−1.246, *P*=.007, 95% CI −2.148 to −0.344) at T1. Participants with high anxiety levels had increased somatization at follow-up (β=1.413, *P*=.025, 95% CI 0.181 to 2.646). As for low and high levels of somatization at baseline, participants with low somatization at baseline were found to have a decrease in mental health quality of life at T1 (β=−2.095, *P*=.003, 95% CI −3.498 to −0.692), whereas they experienced less insomnia symptoms at follow-up (β=−0.855, *P*=.026, 95% CI −1.606 to −0.103). Participants with high levels of somatization at baseline had decreased well-being (β=−4.489, *P*=.049, 95% CI −8.962 to −0.017) and spent less time sitting at T1 (β=−103.532, *P*=.029, 95% CI −196.746 to −10.318). Finally, considering low and high levels of work stress, individuals with low work stress were found to report less well-being at follow-up (β=−6.673, *P*=.042, 95% CI −13.102 to −0.244), while individuals with high work stress reported less insomnia at follow-up (β=−0.822, *P*=.024, 95% CI −1.534 to −0.110).

Attrition Analysis

The attrition analysis revealed several significant baseline differences between the participants who dropped out from this study and those who did not drop out (Table S9 in Multimedia Appendix 1). Age was slightly lower in the dropout group (mean 44.17, SD 10.03) compared to the not-dropout group (mean 44.23, SD 11.01), with a significant difference (*t*=3.201, *P*=.001). There were also significant differences in country distribution (χ^2=13.135, *P*=.004), with a higher proportion of participants from the United Kingdom and a lower proportion from Spain and Poland in the dropout group. Depressive symptoms, anxiety symptoms, general stress, and work stress levels were significantly higher in the dropout group (depressive symptoms: *t*=−2.092, *P*=.037; anxiety symptoms: *t*=−2.784, *P*=.005; general stress: *t*=−3.101, *P*=.002; work stress: *t*=−2.133, *P*=.033). Absenteeism was also higher in the dropout group (*t*=−2.942, *P*=.003). Other variables did not show significant differences between the groups. Moreover, of the participants in the intervention group, only 34% were considered active users of the intervention, implying an overall low intervention adherence.

Per-Protocol Analyses

Due to high dropout rates and low engagement, we performed additional analyses to assess the impact of those biases. We divided participants in the intervention group into active and inactive users depending on their level of interaction with the application. We conducted LMM analyses and found that, again, none of the outcome measures was significantly different from the control group for both inactive and active groups, and for postintervention and follow-up measurement time (all *P*>.05, Table S10 in Multimedia Appendix 1). Additionally, when comparing active participants to inactive participants, no significant differences in any of the outcomes were found (all *P*>.05, Table S11 in Multimedia Appendix 1).

Sample Size and Sensitivity Analysis

The final sample comprised 708 participants (347 in the intervention and 361 in the control group). Considering the corrective factor of 1.2 used in the a priori calculation (to account for the cluster design), the effective sample sizes are approximately 289 and 303 per group. With these numbers, the minimum detectable effect size for 80% power and 2-sided α=0.05 is 0.24-0.25 [44]. Thus, the current study would show adequate power to detect small-to-moderate effects (≥0.25-0.30) but would be underpowered for very small effects (≤0.20).

In a per-protocol comparison between intervention users (n=119) and controls (n=363), the effective intervention sample would drop to approximately 99 participants after the corrective factor, yielding a minimum detectable effect size of *d* between 0.34-0.35. This would considerably reduce the statistical power to detect small effects and should therefore be taken into account when interpreting our null findings.

Harms or Unintended Effects

No adverse events or unintended effects related to the intervention were reported.

Discussion

Principal Findings

In this cluster RCT, we investigated whether a multimodal, digital platform, consisting of a website and an application, improved mental health, well-being, and work-related outcomes of employees from SMEs and public agencies in 4 European countries.

Effectiveness Results

Overall, we did not find evidence of effectiveness of the intervention in the short (7 wk) or long term (21 wk post intervention), but some positive effects were observed for certain outcomes and subgroups of employees. We did not observe the expected effectiveness of the intervention to improve depressive

XSL•FO
RenderX

symptoms, anxiety symptoms, general and work-related stress, insomnia symptoms, physical activity, well-being, presenteeism, or absenteeism. However, different effect patterns were found when analyzing different subgroups. Previous literature showed small, significant effects of digital interventions in the workplace [9]. In the Carolan et al [9] meta-analysis (2017), 9 of the 21 studies included did not find an effect of the digital intervention on mental health. Additionally, 8 of 13 included studies did not find an intervention effect on work outcomes. It is possible that longer follow-up assessments (more than 21 weeks) are needed to detect an effect of an intervention like that proposed by EMPOWER.

As previously stated, when analyzing the effectiveness of the intervention in different subgroups, we found some significant results. For younger participants (18 - 35 y), those with high levels of depressive symptoms at baseline and with high baseline somatization, the intervention showed a positive effect to reduce sedentary behavior. Additionally, insomnia improved at follow-up for participants with low baseline somatization. However, in other subgroups, the intervention had the opposite effect. These findings suggest that demographic factors and initial health conditions could significantly influence the effectiveness and outcomes of interventions, highlighting the need for tailored approaches in mental health and well-being programs. Previous evidence has shown that tailored digital interventions did not reduce anxiety and depressive symptoms in the general working population, but significantly alleviated these conditions in employees with higher psychological distress [12]. More research is needed to determine which characteristics of employees could moderate the effectiveness of OeMH interventions.

Contrary to our expectations, some subgroups (eg, women, participants with low baseline depressive and anxiety symptoms, and those with high baseline somatization) showed a short-term decrease in well-being post intervention, which disappeared at follow-up. Temporary declines in well-being and mental health after a psychological intervention are not uncommon and could result from increased self-awareness of one's own issues and challenges. This is in line with the prevalence inflation hypothesis, which suggests that greater introspection and symptom monitoring can increase perceived distress before improvement occurs [45].

Indeed, the prevalence inflation hypothesis posits that heightened awareness during interventions can lead to increased reporting of mild symptoms as significant issues, potentially exaggerating perceived prevalence. According to this, while mental health awareness efforts are beneficial as they lead to more accurate reporting of previously unrecognized symptoms, these efforts may also cause individuals to interpret and report mild distress as mental health problems, potentially exacerbating symptoms through self-fulfilling behaviors and creating a cyclical and intensifying effect [45]. One could speculate that immediate benefits of an intervention such as EMPOWER might not always be observable and thus, longer follow-up assessments are needed to observe positive effects.

A recent review [12] suggests that personalized digital interventions demonstrated positive outcomes when it comes to reducing presenteeism, alleviating stress, improving sleep, and addressing physical symptoms associated with somatization. Nevertheless, their effectiveness in reducing absenteeism is somewhat limited. Moreover, another systematic review reported that the content of the intervention based on stress management and mindfulness seems more effective than CBT-based content. This suggests that CBT may be less useful for preventive approaches and for workplace settings [46]. All in all, the findings suggest that a universal approach to digital mental health interventions may not be effective in addressing the nuanced needs of workplace populations. Future implementations should consider a targeted approach, focusing on individuals with expressed mental health challenges or higher baseline distress.

Challenges During the RCT

Given the various challenges we faced during the trial, we cannot dismiss the possibility that the EMPOWER results may be attributable to chance rather than reflecting the effectiveness of the EMPOWER intervention. Some of these challenges included external contextual factors, such as the COVID-19 pandemic or the Ukraine war, organizational barriers, complexity of the initial design and length of questionnaires, and technical problems with the application affecting accessibility and adherence.

On the one hand, several contextual challenges were encountered during the RCT. For instance, in Finland, there were large reforms of health care, social welfare, and rescue services at the beginning of 2023. In Poland, there was a lack of company involvement in promoting the project among employees and a fear of discussing mental health with employees. In the United Kingdom, there were several strikes, and in Spain, we observed a certain level of stigma in the workplace to openly talk about mental health in the workplace. Overall, the COVID-19 pandemic hindered the successful completion of this trial, and the Ukraine war has had a significant impact on the small and medium companies both in Finland and in Poland.

On the other hand, we faced several challenges related to this study's design and the technical problems of the application itself. During the design phase, we conducted a prepilot study with volunteers who tested the beta version of the application [23]. However, there was no proper validation of the prototype in a real-world context (ie, employees), which hindered the early identification of technical problems with the design and functionality of the application. As such, during the RCT, users reported software bugs of the application, which interfered with the participants' accessibility to the intervention. However, we did not collect information on whether users who reported malfunctioning of the application were less engaged with the intervention. Several users contacted local researchers to report a bug in the registration process. To solve it, we provided them with a 1-use link to register. This bug could not be fixed, and we believe this could have also led to a loss of potential participants who did not contact us.

Moreover, the first study design (stepped-wedge design) required participants to answer many questionnaires at specific times. This resulted in a burdensome task, especially for those workers on the waiting list who complained about the number

XSL•FO
RenderX

of questionnaires with no obvious positive return. The design was then modified to a 2-parallel cluster control trial in September 2022, which helped increase the number of participants and retention. Additionally, invitation emails were initially sent by employers through a specific back-end system. We observed that this method, despite providing us with more control over who was participating in this study, did not result in an optimal recruitment rate. Thus, we created flyers with QR codes to directly download the application. While these changes were necessary to address low recruitment and high attrition, they introduced additional complexity in the interpretation of findings.

Only 34.3% of participants from the intervention group actively interacted with the application. The application contained a simple gamification system (ie, medals) that might not be enough to achieve an optimal engagement. During the qualitative data collection, participants indicated that the application was easy to use and enjoyable, but there was too much text and suggested the convenience of using more interactive and visual content and more feedback about one's progress. Additionally, the application was designed as a web application, which could introduce some problems in installing and receiving push-up notifications. Dropout rates were also high in our study, especially at T1 (postintervention) with 49% and 57% of loss to follow-up in the intervention and control group, respectively. Interestingly, the rate of retention was higher for the last round of questionnaires, with 70% from the intervention group and 91.7% from the control group ending questionnaires at follow-up. This could have affected the statistical power needed to find significant effects of the intervention.

Lessons Learned and Future Perspectives

During this study's process, we collected information about several challenges that provided a better understanding of barriers and facilitators of OeMH in the workplace. As such, we believe the lessons learned from the EMPOWER project can provide critical insights for future adaptations and evaluations of similar interventions.

Concerning this study's design, 1 significant challenge was ensuring that both employees and employers understood that EMPOWER was still in the research phase and not a finalized implementation. This issue was compounded by the need to balance strict RCT protocols with practical workplace application, a tension exacerbated by disruptions from the COVID-19 pandemic and the war in Ukraine's impact on neighboring countries such as Finland and Poland. Emergency protocols would have facilitated the recruitment process and adherence to the intervention. Flexibility in research design was crucial to completing the RCT amid unforeseen circumstances, preserving the scientific integrity of the effectiveness evaluation, and underscoring the importance of contingency planning in complex settings. Indeed, a restrictive RCT with multiple repeated measures may not be the most effective method for evaluating educational and skills-based interventions aimed at improving mental health and quality of life in the general worker population. Related to this, flexible trial approaches, including adaptive trial designs, have been suggested as alternatives to the traditional fixed-design trial. They allow for prospectively planned modifications to one or more aspects of the design based on data accumulated over the course of this trial as part of this study's protocol [47] and are thought to offer several benefits compared to the traditional fixed designs [48]. These benefits include greater statistical efficiency, which can be considered more ethical in some cases, and can be used to answer broader questions and increase acceptance from participants and trial funders. On the other hand, flexible trials can also add higher complexity because they require more planning and methodological considerations [48]. They should preserve statistical rigor, ensure transparency, and add prespecifications at the planning phase of the current study.

Another barrier was the omission of direct involvement from actual end users (managers and employees) in the design phase, highlighting the need for a more inclusive, bottom-up co-design process. However, early engagement with a broad range of stakeholders, including labor physicians, psychologists, union representatives, and HR managers, was initially beneficial [30]. Future implementations should follow a multistep approach to readiness that could integrate the development of the proof of concept, prototyping, and validation, piloting in a relevant environment, demonstration in real-world settings, and release of the tool, as suggested in the technology readiness level framework [32]. It is important to collect direct input from real-world end users, tailoring the tool to their specific contexts and needs using a co-design approach. In this context, it is crucial to assess the organizational readiness before OeMH interventions, including technological capacity and capability, commitment from both employers and employees, management support, and attitudes toward mental health. Implementing a brief, systematic, and standardized workplace assessment, such as the EMPOWER checklist [49], can help identify and address key threats to the RCT or pilot implementations. This could facilitate recruitment and adherence to the intervention, setting the stage for future uptake.

Privacy concerns were another identified barrier in our study. Indeed, concerns regarding privacy and data security necessitate clear and transparent privacy policies detailing data collection, usage, storage, and employees' rights, ensuring employers have no access to personal data. Developing a brief and structured guide for researchers and participants without a legal background can help identify privacy and security red flags early on.

The low adherence observed in our study may also reflect a poor user experience with the application and technical problems. Adherence to self-guided apps for depression and anxiety has been reported to range from 7% to 42% after 4 weeks, and 0.5% - 28.6% after 6 weeks [50]. In our study, some barriers mentioned by employees included a lack of time to use it, long questionnaires, unclear instructions of how to use it, and long text, whereas the application was referred to as easy to use and enjoyable. Several elements have been suggested to increase adherence to OeMH interventions, such as offering tailored and interactive content, peer support, monitoring and feedback about one's emotional state, and the possibility of contact with a coach [7].

XSL•FO
RenderX

Finally, policy support should focus on the continuous improvement and testing of existing platforms, such as the EMPOWER eHealth platform, rather than developing new tools. The lessons learned and infrastructure developed during the project provide a strong basis for further development, which is more sustainable and cost-effective compared to creating new tools from scratch. By following these recommendations, future OeMH interventions can be more effectively implemented and evaluated, ensuring better outcomes for both organizations and employees.

Study Limitations

As previously mentioned, our results should be interpreted cautiously due to the several challenges encountered during the RCT. Additional limitations that need to be considered are, first, that this study aimed for a conservative target sample size of 874 participants. Although 877 employees agreed to participate and 81% (n=708) answered the baseline assessments, only 333 (47%) and 249 (35.2%) answered the follow-up assessments. Attrition bias is generally a concern in the case of OeMH interventions, with unsupervised interventions having a mean of 32.85% (SD 22.21%) of attrition at postintervention [51]. Thus, selection and attrition bias could have played a role too in the effectiveness results, as there were significant differences in the baseline characteristics of participants who dropped out of this study compared to those who did not. Second, adherence to the EMPOWER intervention was notably low, with only about 34% considered as active users. Comparison of active and inactive users with the control group did not show any positive intervention effects. Given that only 1 in 3 participants continued using the intervention after 7 weeks, it is probable that the observed results are due to chance rather than the effectiveness of the EMPOWER intervention and do not reflect the potential of the intervention to improve mental health problems in the workplace. Third, because randomization was performed at the cluster level (companies or departments) rather than the individual level, this study was vulnerable to baseline imbalances between groups. Indeed, the intervention group showed significantly lower levels of depression, anxiety, and stress, and higher levels of well-being and quality of life at baseline. These differences may have limited the scope for observable improvement and introduced bias despite adjustment in analyses. Moreover, the relatively modest number of clusters (25 in the intervention arm and 19 in the control arm) increased the likelihood of imbalance. As such, the randomization process might not have succeeded in creating 2 comparable samples, adding to the potential floor effect. This can often happen in clustered RCT's, as when not having a large number of individuals to randomize but rather a limited number of clusters, the result of the randomization is more prone to cause imbalances between trial arms [24]. In our study, baseline imbalances between intervention and control groups were observed, with the intervention group showing significantly lower levels of depression, anxiety, and stress, and higher levels of well-being and mental health quality of life. These differences could potentially introduce bias, as the intervention group's baseline characteristics may limit the scope for observable improvements. Additionally, our failure to find significant differences between groups could be due to the regression to the mean effect [52]. To address this, all models were adjusted for baseline levels of these variables, and subgroup analyses were conducted to further account for these imbalances. These subgroup analyses revealed some significant results, such as the fact that women in the intervention group had worse well-being at postintervention, or that participants with higher stress levels at baseline had better insomnia scores in the follow-up after using the intervention. Additionally, baseline-adjusted analyses reflected similar results to the ones from unadjusted models. Despite these efforts, the imbalances underscore the challenges of achieving comparable groups in cluster randomized trials, particularly when working with smaller samples and diverse organizational contexts. Fourth, the modification from a stepped-wedge design to a 2-arm parallel cluster RCT, while approved by ethics committees and justified by recruitment and attrition challenges, may have further complicated comparability between groups. Participants initially enrolled under the stepped-wedge design were reassigned to the new trial structure, which could have affected trial integrity and interpretation of results. Fifth, the use of self-reported measures could introduce response bias and thus also be more prone to the prevalence inflation hypothesis. Sixth, there were statistical differences at baseline between both the intervention and control groups in demographic and outcome measures, which could have added bias to the results. Seventh, it is also important to interpret subgroup analyses with caution, as wide CIs for effect estimates indicate variability and uncertainty. These findings emphasize the need for tailored strategies and robust feasibility assessments in future trials. Eighth, as the intervention was delivered in a nonclinical population, individuals in a generally healthy population tend to start with lower initial levels of psychological symptoms, which means there is limited potential for further reduction [53]. As a result, the minimal observed improvements in these symptoms may be explained by a floor effect, where the initial low scores leave little room for noticeable change ("floor effect" refers to a scenario where baseline scores on outcome measures are so low that further reductions are difficult to detect, limiting the potential for improvement). Related to this, measuring significant changes in clinical outcomes (such as depression and anxiety symptoms) within a predominantly healthy population can be challenging. Preventive interventions often yield small effect sizes, and detecting statistically significant changes requires large sample sizes and sensitive measurement tools [54]. Finally, although the initial sample size calculation was conservative, the final effective sample size was lower than planned. The study had sufficient power to detect small-to-moderate effects ($d \geq 0.25$-0.30), but not very small effects ($d \leq 0.20$). Moreover, adherence was low, with only 119 of 347 participants in the intervention group actively using the program. This reduced the power of per-protocol analyses and likely diluted the effect sizes observed under ITT. Therefore, null results should be interpreted with caution, as this study cannot rule out the presence of smaller effects.

Conclusion

This study represented a large, multicountry cluster RCT evaluating the effectiveness of the EMPOWER platform, a digital OeMH intervention. Its main contribution lies in the

XSL•FO
RenderX

rigorous assessment of both effectiveness and implementation challenges across diverse organizational contexts, particularly within SMEs and public agencies. In contrast to many studies conducted in more controlled or clinical samples, EMPOWER targeted a predominantly healthy working population, highlighting the difficulties of detecting effects in preventive workplace interventions.

While the intervention did not demonstrate significant effects on primary or secondary outcomes, the findings provide valuable guidance for future research and practice by emphasizing the importance of feasibility testing, organizational readiness, and strategies to enhance user engagement. From a real-world perspective, the results support the need for conducting comprehensive feasibility studies, ensuring organizational readiness, and adopting flexible trial designs to enhance engagement and adherence in diverse workplace settings.

Acknowledgments

During the preparation of this work, a generative artificial intelligence (AI) tool (ChatGPT, OpenAI) was used solely to check the grammatical accuracy of selected parts of the manuscript. The authors reviewed all outputs and take full responsibility for the final content.

Funding

This project has received funding from the European Union's Horizon 2020 research (https://cordis.europa.eu/project/id/848180) and innovation program under grant agreement No 848180, and the National Health and Medical Research Council (NHMRC) of Australia under Grant Agreement APP1195937. CdM has received funding in form of a predoctoral grant from the Generalitat de Catalunya (PIF-Salut grant, code SLT017/20/000138). AR is supported by the Italian Ministry of Health (RRC). BO is supported by the Miguel Servet (CP20/00040) contract, funded by the Instituto de Salud Carlos III (Spain). The funders had no involvement in this study's design, data collection, analysis, interpretation, or the writing of this paper.

Data Availability

Requests to access the dataset should be directed to the corresponding author.

Authors' Contributions

BO and CdM handled the analysis, interpretation, and paper writing. JR-B worked on the analysis. All authors have engaged in paper drafting and have approved the final version for publication.

Conflicts of Interest

None declared.

Abstract

Background: Nonalcoholic fatty liver disease (NAFLD) and its progressive form, nonalcoholic steatohepatitis (NASH), represent an increasing clinical and public health burden in India. Despite their high prevalence, there are limited data on their diagnostic and management approaches among Indian health care providers. Real-world evidence on how Indian gastroenterologists and hepatologists diagnose and manage these conditions remains limited.

Objective: This study aimed to understand the current disease perspectives, diagnostic modalities, and management practices for NAFLD and NASH among Indian hepatologists and gastroenterologists.

Methods: A nationwide, web-based cross-sectional survey was conducted online between May 2023 and July 2023 among practicing gastroenterologists and hepatologists from health care setups, clinics, and hospitals located across India. The structured, self-administered questionnaire included 34 items covering 3 domains: disease perspectives (n=16), diagnostic modalities (n=4), and management strategies (n=14). Descriptive statistics were used to summarize responses as counts and percentages.

Results: A total of 609 physicians completed the online survey (gastroenterologists: n=556, 91.3%; hepatologists: n=53, 8.7%). For 336 (55.2%) physicians, NAFLD accounted for 25% to 50% of the patients consulted per month, and 220 (36.1%) physicians reported that 10% to 20% of patients with NAFLD had NASH. Obesity (n=583, 95.7%) and diabetes (n=579, 95.1%) were cited as leading risk factors for NAFLD. Transient elastography was the diagnostic tool preferred by 558 (91.6%) physicians, followed by NAFLD fibrosis score (n=378, 62.1%) and Fibrosis-4 score (n=356, 58.5%); only 154 (25.3%) physicians used liver biopsy. For treatment, 414 (68%) physicians managed patients using pharmacotherapy and dietary and lifestyle modifications, while 195 (32%) relied on lifestyle modification alone. Antioxidant vitamins (n=543, 89.2%) and saroglitazar (n=522, 85.7%) were the most frequently prescribed therapies. The main barriers to optimal NASH management reported were lack of patient awareness (n=466, 76.5%) and limited availability of effective pharmacological options (n=303, 49.8%).

Conclusions: This large, nationwide survey highlights that NAFLD and NASH constitute a major part of gastroenterology and hepatology practice in India. Although transient elastography and pharmacological agents such as saroglitazar and vitamin E are widely used, considerable heterogeneity exists in diagnostic and management approaches. The lack of patient awareness and effective treatment options remain the major hurdles in managing NAFLD and NASH. These findings underscore the need for the wider implementation of existing India-specific consensus recommendations, continued physician education, and future research focusing on tailored interventions in the management of NAFLD and NASH for the Indian population.

KEYWORDS

nonalcoholic fatty liver disease; NAFLD; nonalcoholic steatohepatitis; NASH; gastroenterology; elastography

Introduction

Nonalcoholic fatty liver disease (NAFLD) is the most prevalent cause of chronic liver disease that encompasses a broad spectrum of clinical liver pathologies, including simple steatosis and nonalcoholic steatohepatitis (NASH), which could advance to fibrosis and cirrhosis, and may lead to liver failure or hepatocellular carcinoma (HCC) [1]. The worldwide prevalence of NAFLD is estimated to be 24% to 30% [2,3]. However, estimates for India vary and range from 9% to 53%. In India, NAFLD and NASH have been identified as predominant causes of cirrhosis, HCC, and liver transplantation [4]. A total of 20% of patients with NASH were reported to develop cirrhosis, and 30% to 40% of the patients with NASH cirrhosis died from liver-related causes [5,6].

In June 2023, an international consensus panel recommended revising the nomenclature of NAFLD and NASH to *metabolic dysfunction–associated steatotic liver disease (MASLD)* and *metabolic dysfunction–associated steatohepatitis (MASH)* to better reflect the underlying metabolic basis of the diseases [7,8]. However, the Indian National Association for Study of the Liver (INASL; 2023) continues to recommend the use of NAFLD or NASH terminology in India until broader consensus and implementation are achieved [9]. Importantly, INASL cautions that the new nomenclature "may create confusion not only among hepatologists but also among physicians and non-hepatologists who manage these patients or conduct research in this area."

Various comorbidities have been reported among patients with NAFLD and NASH, such as diabetes, obesity, and hypertension [10]. NASH affects up to 30% of patients with obesity, which poses a serious risk to their liver and cardiovascular health [11]. Although various diagnostic strategies are available for the diagnosis of NAFLD and NASH in hepatology and gastroenterology practices, it is estimated that fewer than 20% of patients with NAFLD have been diagnosed [12,13]. In addition, among the diagnosed patients, very few are referred to hepatologists and gastroenterologists [14]. The mainstay of NAFLD treatment is lifestyle changes, including weight loss and physical exercise; however, many patients with NAFLD fail to lose weight [15,16].

The growing prevalence and limited number of approved medications for NAFLD and NASH remain a challenge in the management of these conditions [17]. In addition, long-term data on improvement in fibrosis with the existing therapies are lacking [18]. Therefore, it becomes imperative to understand the challenges faced by hepatologists and gastroenterologists in the diagnosis and management of NAFLD.

In a recent global survey, 68% of physicians reported lack of awareness as the most common reason for the limited screening of NAFLD, which can worsen the burden of NAFLD in the future [19]. The major barriers to NAFLD management include the lack of Indian data on the management of patients with NAFLD, low screening rates of vulnerable populations, and the paucity of suitable treatment options [9,17].

Therefore, to understand real-world perspectives of Indian hepatologists and gastroenterologists on NAFLD and NASH, a cross-sectional questionnaire-based disease perspective (DRIVE) survey was carried out between May 2023 and July 2023. As this survey was conducted *before* the global shift to MASLD and MASH terminology (June 2023), the survey questionnaire continued to use the NAFLD and NASH terms; therefore, these terms are retained throughout this paper for accuracy and consistency in reporting survey data.

This survey sought to capture the current clinical practices and perspectives on NAFLD and NASH management across India. The increasing global burden of metabolic liver disease and the variability in health care infrastructure and clinical practices across countries present significant challenges to standardized care. Evaluating diagnostic and therapeutic strategies from large-population settings such as India—where MASLD prevalence is rising rapidly—can provide critical insights, which can offer valuable lessons to other low- and middle-income countries facing similar implementation barriers [7,8].

Methods

Participants and Procedures

This web-based, cross-sectional survey was conducted online between May 15, 2023, and July 31, 2023, among practicing gastroenterologists and hepatologists across India to understand their perspectives on NAFLD and NASH. Eligible participants included practicing gastroenterologists and hepatologists working in various health care setups such as multispecialty hospitals, clinics, nursing homes, and government hospitals or medical colleges across the country who voluntarily agreed to participate in this survey. Invitations to participate were distributed electronically. Details on the number of invitations distributed and the source of the contact list were not recorded. The online survey questionnaire link was distributed electronically (via email), and gastroenterologists who provided a full response to the survey were included (N=609) in the analysis.

Survey Questionnaire

A predefined, structured, and self-administered questionnaire was developed by the study investigators based on national (INASL) [9] and international clinical practice guidelines for NAFLD and NASH management [7,20]. The questionnaire included 34 questions distributed across 3 domains: disease perspectives (16 items), diagnostic modalities (4 items), and management strategies (14 items). Items were reviewed by hepatology experts to ensure relevance and clarity. Both closed-ended questions with predefined response options and open-ended questions for additional comments were included.

XSL•FO
RenderX

The "Disease Perspectives" section included 16 questions on the monthly NAFLD caseload, the percentage of patients with NAFLD who had NASH, biopsy rates among patients with NASH, common fibrosis stages at presentation, the likelihood of progression to cirrhosis within 5 years, and actions taken upon incidental NAFLD detection. It also covered risk factors, comorbidities, and symptoms commonly associated with NAFLD.

The "Diagnostic Modalities" section encompassed 4 questions focused on recommended tests for NAFLD diagnosis, additional laboratory data considered, scoring systems used, and indications for liver biopsies.

Finally, 14 questions in the "Management Strategies" section included referral patterns to dietitians, commonly prescribed medications, follow-up frequencies, monitoring methods, guidelines followed, challenges in managing NASH, and anticipated future treatment options. The pharmacotherapy domain of the questionnaire included the following response options: vitamin E or antioxidant formulations, saroglitazar, pioglitazone, and a separate category labelled "hepatoprotective agents," which referred to ursodeoxycholic acid (UDCA), silymarin, and related antioxidant or herbal formulations commonly used in India [14,19].

The questionnaire included both open- and closed-ended questions to capture detailed insights. Demographic data on participants' practice settings, clinical experience, the number of patients with NAFLD consulted within a given time frame, and specialty referral patterns for patients with NAFLD were also collected (Multimedia Appendix 1).

Reporting Standards

This survey is reported in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines (Multimedia Appendix 2).

Statistical Analysis

Survey data were analyzed using descriptive statistics, with results summarized as frequencies and percentages to illustrate the distribution of responses across different categories. Responses to open-ended questions were also summarized descriptively to identify common themes. Summary statistics were used for numerical variables wherever applicable. All analyses were conducted using SPSS software (version 16.0; IBM Corp).

Ethical Considerations

This survey was reviewed and approved by the Royal Pune Independent Ethics Committee, Pune, Maharashtra, India (RPIEC110123; dated January 10, 2023). This was a physician-based survey with no involvement of patients or collection of patient-identifiable data. Hence, patient informed consent was not applicable.

Participation in this survey was voluntary and anonymous. Before accessing the survey, each participant was presented with an electronic informed consent form describing the survey objectives, the confidentiality of responses, the voluntary nature of participation, and the right to withdraw before final submission. Only those who provided electronic consent could proceed to complete the questionnaire. No personal identifiers were collected, and data were analyzed in aggregate.

No monetary or nonmonetary compensation was provided to the participants.

Results

Survey Participants' Demographics

A total of 609 physicians (gastroenterologists: n=556, 91.3%; hepatologists: n=53, 8.7%) participated in this survey from various centers across India. All the participating physicians had completed the survey in full. Most of the participating physicians were male individuals (n=574, 94.3%). In this survey, most physicians (n=213, 35%) had 6 to 10 years of experience in clinical practice. Overall, 341 (56%) physicians predominantly practiced in multispecialty hospitals, while 120 (19.7%) worked in mixed settings (Table 1).

Table 1. Demographic details of the participants (N=609).

Variable	Participants, n (%)
Sex	
Male	574 (94.3)
Female	35 (5.7)
Intersex	0 (0)
Duration of clinical practice (y)	
<5	149 (24.5)
6-10	213 (35)
11-20	178 (29.2)
>20	69 (11.3)
Predominant type of practice	
Multispecialty hospital	341 (56)
Mixed	120 (19.7)
Clinic or nursing home	95 (15.6)
Government hospital or medical college	53 (8.7)

Disease Perspective

Of the 609 physicians, 336 (55.2%) reported that the proportion of patients with NAFLD out of total patients examined each month was 25% to 50%. Furthermore, 220 (36.1%) physicians responded that 10% to 20% of their patients with NAFLD had NASH, and 523 (85.9%) physicians reported that less than 5% of their patients with NASH underwent biopsy. Patients with NAFLD presented to their physicians at varying stages of fibrosis. Most physicians (n=319, 52.4%) reported that majority of their patients with NAFLD first presented at stage 2 of fibrosis, while 204 (33.5%) physicians reported that 5% to 10% of patients with NASH progressed to cirrhosis over the course of 5 years.

Consulting physicians (n=491, 80.6%) were the most common specialties that referred patients with NAFLD to gastroenterologists and hepatologists (Table 2). According to 227 (37.3%) of the physicians, 25% to 50% of their patients with NAFLD were diagnosed incidentally. Among the patients with incidentally diagnosed NAFLD, various actions undertaken by physicians included investigation for the presence of metabolic alterations and the absence of other liver diseases (n=426, 70%), assessment for cardiovascular risk and liver disease (n=346, 56.8%), assessment for the risk of metabolic alterations and liver function with a noninvasive scoring system (n=499, 81.9%), investigation for presence of alcohol consumption (n=394, 64.7%), advice on lifestyle modification and follow-up (n=487, 80%), and initiation of pharmacotherapy (n=145, 23.8%), as reported by physicians.

Most physicians considered obesity (n=583, 95.7%) and diabetes mellitus (n=579, 95.1%) as the risk factors for NAFLD (Table 3). A total of 295 (48.4%), 149 (24.5%), and 300 (49.3%) physicians reported that 20% to 40% of their patients with NAFLD had diabetes, obesity, and dyslipidemia, respectively.

Of the 609 physicians, 331 (54.3%) reported that 10% to 30% of their patients with NAFLD required a multispecialty management approach. The proportion of lean NASH diagnosed among all patients with NASH per year was 3% to 5%, as reported by 224 (36.8%) physicians. Approximately 370 (60.8%) physicians recommended screening the family members of patients with NAFLD. Most physicians (n=345, 56.7%) reported that fewer than 10% of their patients with NAFLD were symptomatic. The most common symptoms reported to physicians by their patients with NAFLD were right upper quadrant pain (n=425, 69.8%), fatigue or tiredness (n=421, 69.1%), a feeling of fullness (n=286, 47%), and bloating (n=270, 44.3%; Table 4).

Table 2. Predominant specialties referring patients with nonalcoholic fatty liver disease to gastroenterologists or hepatologists (N=609).

Referring specialties	Survey responses, n (%)
Consulting physician	491 (80.6)
Endocrinologist	85 (14)
Cardiologist	16 (2.6)
General practitioner	7 (1.1)
Surgeons	3 (0.5)
Gynecologists	2 (0.3)
Others	5 (0.8)

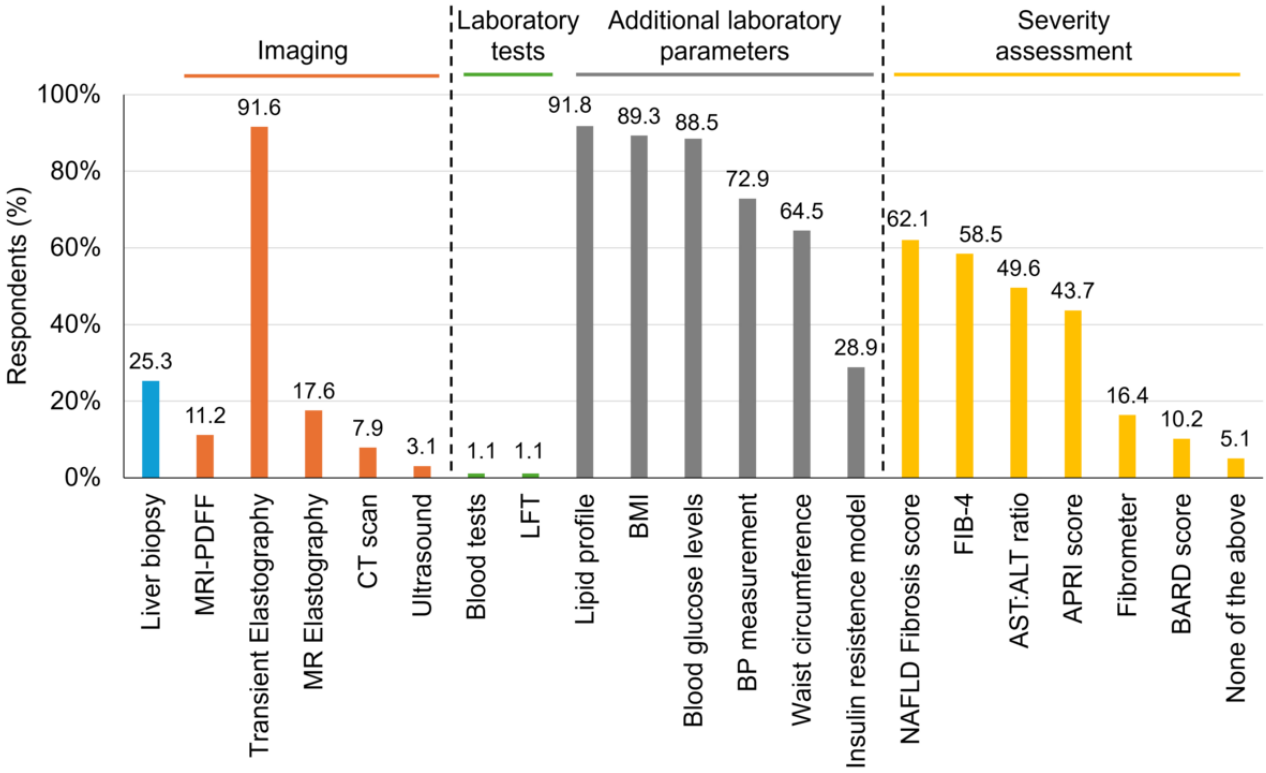
Table 3. Risk factors for nonalcoholic fatty liver disease (NAFLD) as reported by survey participants.

Risk factor	Respondents, n (%)
Obesity	583 (95.7)
Diabetes	579 (95.1)
Dyslipidemia	547 (89.8)
Hypothyroidism	381 (62.6)
Polycystic ovary syndrome	367 (60.3)
Hypertension	335 (55)
Sleep apnea	281 (46.1)
Ischemic heart disease	189 (31)

Table 4. Symptoms commonly reported by patients with nonalcoholic fatty liver disease (NAFLD) as reported by survey participants (N=609).

Symptoms commonly reported by patients with NAFLD	Respondents, n (%)
Right upper quadrant pain	425 (69.8)
Fatigue or tiredness	421 (69.1)
A feeling of fullness	286 (47)
Bloating	270 (44.3)
Weakness	184 (30.2)
Asymptomatic	4 (0.7)
Other symptoms[a]	9 (1.5)



[a]Other symptoms include gastroesophageal reflux disease, incidental detection, incomplete evacuation of bowel, lethargy, loss of appetite, low mood, poor appetite, sense of indigestion, discomfort or pain after meals, and other complaints.

Diagnostic Modalities

For the diagnosis of NAFLD, most physicians preferred transient elastography (TE; n=558, 91.6%) followed by liver biopsy (n=154, 25.3%), magnetic resonance elastography (n=107, 17.6%), and magnetic resonance imaging–proton density fat fraction (n=68, 11.2%), computed tomography scan (n=48, 7.9%), and ultrasound (n=19, 3.1%). Additional tests or assessments routinely advised in patients diagnosed with NAFLD were lipid profile, BMI, blood glucose levels, and so on. To assess the severity of NAFLD, scores such as the NAFLD fibrosis score, Fibrosis-4 (FIB-4) score, aspartate aminotransferase-to-alanine aminotransferase ratio, and aspartate aminotransferase-to-platelet ratio index score were used (Figure 1). A total of 286 (47%) of the physicians reported that the main intent of advising a biopsy in patients with NAFLD was to determine the stage of fibrosis for prognostic purposes, while 236 (38.8%) of the physicians advised biopsy to differentiate NASH from steatosis for diagnostic purposes.

Figure 1. Summary of the clinicians' preference for various diagnostic modalities to diagnose and differentiate between nonalcoholic fatty liver disease (NAFLD) and its subtypes in patients. ALT: alanine aminotransferase; APRI: aspartate aminotransferase-to-platelet ratio index; AST: aspartate aminotransferase; BARD score: BMI, AST:ALT ratio, and diabetes mellitus; BP: blood pressure; CT: computed tomography; FIB-4: Fibrosis-4; HOMA-IR: homeostatic model assessment of insulin resistance; LFT: liver function test; MR: magnetic resonance; MRI-PDFF: magnetic resonance imaging–proton density fat fraction.

Management Strategies

Of the 609 physicians, pharmacotherapy, along with dietary and lifestyle modifications, was prescribed by 414 (68%) physicians for the management of patients with NAFLD, while 195 (32%) physicians used only dietary and lifestyle modifications to manage their patients. It was reported that more than 30% of the patients were referred to a dietitian for dietary management by 278 (45.6%) physicians. A total of 499 (81.9%) physicians allowed no alcohol consumption for patients with NASH, and 110 (18.1%) physicians allowed 10 to 30 g of alcohol per day.

Antioxidant vitamins were the most often prescribed drugs (n=543, 89.2%) for the treatment of NAFLD and NASH. Other commonly prescribed drugs were saroglitazar (n=522, 85.7%), hepatoprotective agents (n=366, 60.1%), obeticholic acid (n=255, 41.9%), and pioglitazone (n=141, 23.2%; Table 5).

In this survey, of the 609 physicians, 525 (86.2%) reported prescribing vitamin E for treating NASH, and UDCA was prescribed by 341 (56%) physicians, while 26 (4.3%) physicians recommended alternative medicine or herbal preparations. Aside from pharmacotherapy, dietary and lifestyle modifications were also recommended to more than 30% of the patients with NAFLD.

Of the 609 physicians, 498 (81.8%) reported that they followed up with their patients with NAFLD every 3 months. To monitor the response of patients to pharmacotherapy, 558 (91.6%) physicians reported using liver function tests, while 477 (78.3%) preferred elastography, 234 (38.4%) used different scoring methods based on serum markers, and 188 (30.9%) used ultrasonography (Table 6).

Of the 609 physicians, most (n=347, 57%) referred to the American Association for Study of Liver Diseases (AASLD) guidelines, while 148 (24.3%) physicians referred to the Asian Pacific Association for the Study of the Liver (APASL) guidelines for diagnosing and managing patients with NAFLD. In terms of treatment barriers, most physicians (n=466, 76.5%) considered lack of patient awareness as a major barrier to managing NASH. Additionally, 303 (49.8%) physicians reported a lack of availability of effective drugs, and 264 (43.3%) reported the cost of evaluation and treatment as barriers (Table 7).

The drugs considered by physicians as potential future therapeutic options for the management of NAFLD and NASH included peroxisome proliferator–activated receptor α and γ agonists (n=348, 57.1%), glucagon-like peptide-1 (GLP-1) agonists (n=271, 44.5%), farnesoid X receptor agonists (n=262, 43%), and sodium-glucose cotransporter-2 inhibitors (n=219, 36%).

Time constraint	105 (17.2)
No barriers	9 (1.5)

Discussion

Principal Findings

This nationwide survey of 609 Indian gastroenterologists and hepatologists provides a comprehensive understanding of real-world practices in the diagnosis and management of NAFLD and NASH. The findings highlight that NAFLD accounts for a substantial proportion of liver disease cases seen in daily practice, with obesity and diabetes being the most frequently coexisting metabolic comorbidities, consistent with the well-documented pathophysiologic overlap between metabolic syndrome and NAFLD in Indian patients [1,2,4]. Notably, this survey was conducted between May 2023 and July 2023, before the official nomenclature change from NAFLD and NASH to MASLD and MASH was announced globally; therefore, the previous terminology was used throughout the questionnaire and data reporting to ensure consistency.

Although TE was the most frequently used diagnostic modality in our survey (reported by 558/609, 91.6% of the physicians), its diagnostic value lies primarily in the noninvasive assessment of liver fibrosis rather than the differentiation between simple steatosis and steatohepatitis (MASH). Current international guidelines from AASLD, European Association for the Study of the Liver (EASL), and APASL recommend an initial screening with simple serum-based fibrosis indices such as FIB-4 or the NAFLD fibrosis score, followed by TE as a secondary assessment in patients at intermediate or high risk [9,20,21]. The predominant reliance on TE observed in our cohort likely reflects its availability and routine use in tertiary centers, where most patients are referred cases from consulting physicians or secondary-care facilities. In such settings, TE serves as a valuable tool for fibrosis staging and risk stratification. However, optimizing its use in accordance with global stepwise algorithms—including initial screening with low-cost serum indices—would ensure more efficient resource use and enhance adherence to international best practices across all levels of care in India.

In contrast, pharmacological management patterns were dominated by saroglitazar (n=522, 85.7%) and vitamin E (n=525, 86.2%), and hepatoprotective agents such as UDCA and silymarin remained frequently prescribed despite limited supporting evidence [17,22]. These findings illustrate the diversity of real-world clinical approaches in India and highlight opportunities to further align everyday practice with evolving evidence and guideline-based recommendations.

XSL•FO
RenderX

Comparison With Prior Work

Our findings are consistent with previously published Indian studies and surveys showing variability in NAFLD diagnosis and treatment pathways [3,5,17]. Similar reliance on TE and limited use of validated scoring systems was reported by Singh et al [6] and Duseja et al [9], emphasizing the need for broader adoption of noninvasive fibrosis indices for early risk stratification. Internationally, AASLD, EASL, and APASL recommend a tiered diagnostic pathway beginning with simple serum-based scores, followed by elastography or imaging only when advanced fibrosis is suspected [20,21].

The predominance of saroglitazar use (n=522, 85.7%) in this survey reflects its availability and regulatory approval for NAFLD in India. However, current global guidelines have not endorsed saroglitazar as a first-line therapy, and its approval outside India remains limited [15,17]. Although Indian real-world studies report biochemical and metabolic improvements, long-term histological and outcome data remain limited. Our survey did not capture details regarding cost, accessibility, or physician perceptions influencing prescription behavior; therefore, these findings should be interpreted as descriptive of current practice rather than indicative of comparative efficacy or cost-effectiveness. This finding underscores the need to examine economic and awareness factors shaping therapy choices in future research.

GLP-1 receptor agonists (RAs) such as semaglutide show histological improvement in NASH and metabolic benefits in global phase 3 trials [23,24]. When the DRIVE survey was conducted, injectable semaglutide was not approved in India; therefore, questions on its clinical use were not included. Instead, GLP-1 RAs were listed among potential future therapeutic options, for which only a small proportion of clinicians expressed interest. Given that semaglutide is still not approved for NASH in India and requires parenteral administration, widespread use is currently limited. Future studies should assess the real-world uptake, feasibility, and outcomes associated with GLP-1–based therapies in Indian clinical practice.

The term “hepatoprotective agents” in our questionnaire encompassed widely used drugs such as UDCA, silymarin, and antioxidant formulations. These agents are not recommended by AASLD, EASL, or INASL for NAFLD management due to the absence of histological benefit [9,21]. Their continued use by more than half of the surveyed clinicians (n=366, 60.1%) likely reflects therapeutic inertia, overreliance on empirical, perceived safety, and patient demand. However, this pattern must also be interpreted in the context of limited pharmacological options available in India during the survey period—till early 2025, saroglitazar remained the only approved agent for NASH, and no other globally validated drugs had received regulatory clearance. In the absence of alternative evidence-based therapies, clinicians may have continued to rely on hepatoprotective agents to provide symptomatic or biochemical improvement. These findings suggest opportunities to strengthen clinician education; wider dissemination of updated practice guidelines; and accelerated access to effective, evidence-based therapies to address the unmet clinical needs in NAFLD management.

Globally, there has been a paradigm shift in nomenclature from *NAFLD* and *NASH* to *MASLD* and *MASH* [7,8]. This change was formally endorsed in June 2023 by major international societies, including AASLD and EASL, reflecting a conceptual move away from alcohol exclusion criteria toward emphasizing metabolic dysfunction as the central driver of disease. The DRIVE survey was conducted before this global transition; therefore, it used NAFLD and NASH terminology, which has been retained in this study to maintain accuracy and continuity of the survey data.

In the INASL 2023 Guidance Paper, it was explicitly acknowledged that the recent nomenclature change “may create confusion not only among hepatologists but also among physicians and non-hepatologists who manage these patients or conduct research in this area” [9]. Accordingly, INASL continues to recommend the use of NAFLD and NASH terminology within India until uniform adoption of the MASLD and MASH framework is achieved.

In addition to metabolic drivers of steatotic liver disease, HCC may arise in patients with MASLD even in the absence of cirrhosis. Onzi et al [25] reported that a significant proportion of HCC cases in NAFLD occur in noncirrhotic livers, suggesting that hepatocarcinogenesis in MASLD involves metabolic and inflammatory pathways independent of advanced fibrosis. Soldera et al [26] further emphasized the need to integrate risk factors such as diabetes and obesity into HCC surveillance frameworks, highlighting the relevance of the Barcelona Clínic Liver Cancer protocol for risk-based screening. Given India’s rising burden of diabetes and obesity, these findings support reconsidering surveillance criteria to include selected patients with MASLD who are noncirrhotic at elevated risk for HCC.

Strengths and Limitations

This survey has several notable strengths. First, it captured perspectives from a large, nationally representative cohort of 609 practicing gastroenterologists and hepatologists across diverse health care settings in India, providing a robust overview of real-world diagnostic and therapeutic approaches. Second, it used a structured, predefined questionnaire based on national and international clinical guidance, ensuring consistency and comparability of responses. Third, the survey included both hepatologists and gastroenterologists, reflecting multidisciplinary viewpoints and providing a realistic picture of current clinical practice. Fourth, because the survey was conducted immediately before the global transition from NAFLD and NASH to MASLD and MASH terminology, it provides a baseline on physician practices before the nomenclature change—information that will be valuable for future longitudinal comparisons.

However, several limitations merit mention. First, responses were self-reported and may be subject to recall or social-desirability bias. Second, as participation was voluntary and the total number of invitations sent was not recorded, representativeness and the response rate could not be assessed. Third, as this was a noncomparative, exploratory survey aimed

XSL•FO
RenderX

at describing clinical practice patterns, only descriptive statistical analyses were conducted, and inferential statistics were not performed; hence, causal inferences cannot be drawn. Fourth, this survey reflects physician perceptions and may not fully represent patient-level practice data. Fifth, newer pharmacological agents and diagnostic technologies may have been underrepresented, given the survey's cross-sectional design and timing before the MASLD nomenclature shift. Sixth, the survey did not include specific questions on HCC risk assessment or surveillance practices, an important area of growing relevance given the emerging evidence of HCC development in noncirrhotic MASLD. Finally, the survey did not include questions on drug affordability, availability, or rationale for therapy selection, which limits the interpretation of the observed preference for therapeutic options. Therefore, while the survey provides valuable insights into prevailing clinical practices, the findings should be interpreted cautiously and may not be fully generalizable to all health care settings, including primary care.

Future Directions

Future research should explore longitudinal changes in diagnostic and treatment practices as the MASLD and MASH terminology and updated clinical frameworks become integrated into Indian hepatology practice. Strengthening implementation and adherence to existing India-specific consensus guidelines such as those issued by INASL [9] will be critical to ensure diagnostic accuracy and affordability, particularly by promoting the stepwise use of noninvasive scores (FIB-4 and NAFLD fibrosis scores) before TE. Educational interventions and continuous medical education programs can be instrumental in promoting rational pharmacotherapy and evidence-based management [18]. However, a major barrier in the Indian context remains the limited availability of approved, effective agents for NAFLD and NASH. Addressing this gap will require focused research and development on novel therapies—particularly those demonstrating antifibrotic effects—along with timely regulatory approval and improved access to such agents once available.

National liver societies should prioritize promoting evidence-based treatment practices and gradually phase out the use of hepatoprotective agents with limited clinical benefits, alongside structured dissemination of MASLD nomenclature and risk-adapted HCC surveillance even in noncirrhotic metabolic liver disease [7,26]. Establishing multicenter registries and real-world databases can further support health-economic evaluations and inform locally relevant guideline updates. Although this survey focused on Indian clinicians, its findings have wider international relevance, as the challenges identified—limited patient awareness leading to delayed diagnosis, few effective or approved treatment options, and discrepancies between drugs approved in India (eg, saroglitazar) and those endorsed internationally (eg, GLP-1 RAs)—mirror challenges faced by other low- and middle-income countries [13]. These insights can help inform global implementation strategies for MASLD management in diverse health care settings.

Conclusions

This nationwide survey highlights considerable variability between prevailing clinical practices in India and international guidelines for the diagnosis and management of metabolic dysfunction–associated liver disease. While TE has become the most widely used noninvasive test, reliance on it without previous application of simple scores such as FIB-4 or the NAFLD fibrosis score indicates gaps in stepwise risk stratification. Saroglitazar remains the most commonly prescribed drug owing to its domestic approval and availability, but its long-term histological efficacy and cost-effectiveness require further evidence. The continued use of hepatoprotective agents such as UDCA and silymarin highlights the persistence of non–evidence-based treatments.

The transition from NAFLD and NASH to MASLD and MASH nomenclature provides an opportunity for India to harmonize diagnostic frameworks, enhance physician education, and modernize treatment algorithms. Future national efforts should focus on stepwise noninvasive staging, rational pharmacotherapy, risk-adapted surveillance for HCC—including in selected patients with MASLD who are noncirrhotic—and large-scale real-world registries to monitor outcomes. Harmonizing Indian clinical practice with evolving international standards is imperative to enhance diagnostic accuracy, consistency, and patient outcomes in metabolic dysfunction–associated liver disease.

Abstract

Background: Global population aging places an increasing burden on health care systems. This is driven by multimorbidity, frailty, and polypharmacy. Older adults, particularly those aged 65 years or older, use emergency departments (EDs) more frequently and experience poorer outcomes. In this population, decisions regarding admission to monitored acute care units—intensive care units, intermediate care units, and operating rooms—are frequent and complex. While ED and intensive care unit use are well documented, data on monitored acute care units as a whole remain limited. Evidence on admission trends, patient characteristics, and outcomes in older adults is scarce.

Objective: This study aimed to describe temporal trends in monitored acute care unit admissions, identify predictors of such admissions, and assess outcomes following these admissions.

Methods: We conducted a retrospective cohort study using routinely collected electronic health record data. We included patients aged 65 years or older who visited the EDs of the Geneva University Hospitals, Switzerland, between 2009 and 2019. The primary outcome was admission to a monitored acute care unit. The secondary outcomes were hospital length of stay, 7-day mortality, and 1-year mortality. Logistic regression models were used to identify factors associated with monitored acute care unit admission and to assess the association between age and mortality.

Results: During the 10-year period, 701,838 ED visits were recorded. Annual visits increased from 56,944 to 76,368 (+34.1%). The increase was greater among patients aged 65 years or older (+56.1%) than among younger patients (+26.5%). A total of 180,189 older patients presented to the ED. Of these, 887 (0.5%) died in the ED, 97,238 (54.0%) were discharged home, 63,025 (35.0%) were admitted to a ward, and 19,039 (10.6%) were admitted to a monitored acute care unit. Monitored acute care unit admissions increased from 1379 (10.3%) in 2009 to 2240 (11.1%) in 2019. This represented an absolute increase of 62.4% and a relative increase of 0.8%. Predictors of monitored acute care unit admission included younger age, male sex, ambulance arrival, higher triage level, being married or in a relationship, not residing in a nursing home, and French as the primary language. Among patients admitted to a monitored acute care unit, mortality was 5.8% (1105/19,039) at 7 days and 22.3% (4251/18,039) at 1 year. Older age was associated with higher 7-day mortality (adjusted odds ratio 1.55, 95% CI 1.14 - 2.10) and 1-year mortality (adjusted odds ratio 1.28, 95% CI 1.08 - 1.51).

Conclusions: Admissions to monitored acute care units among older patients increased over time. These findings indicate a growing demand for high-level care in this population. Hospitals should adapt infrastructure and resource allocation to address the needs of an aging population.

Introduction

The global population is aging rapidly, exerting substantial pressure on health care systems [1,2]. With increasing life expectancy, older adults present with a higher burden of chronic illnesses, polypharmacy, and biological frailty. However, only limited data exist on the use of monitored acute care units within this population.

Individuals aged between 65 and 79 years exhibit the highest prevalence of comorbidity, while those aged 80 years and older have a 30% likelihood of presenting with at least one chronic condition [3]. This demographic shift places considerable strain on health care services. In the United States, studies have shown that patients aged older than 65 years account for 15% of all emergency department (ED) admissions, with these consultations increasing by 25% over the past decade [4,5]. These patients typically present with more severe emergencies, requiring extensive hospital resources [6]. Moreover, they experience poorer outcomes following admission compared to younger patients, particularly in the intensive care unit. In-hospital mortality rates are markedly higher for older patients during the postintensive phase [7,8], with the majority of deaths occurring within 3 months after intensive care unit discharge [9]. Furthermore, survivors frequently experience a substantial decline in quality of life, with age and frailty being crucial factors that affect the recovery of functional capacity [10].

These age-associated challenges necessitate careful consideration when evaluating older patients for admission to high-level care. Understanding these aspects is essential for health care providers in developing strategies that effectively address the specific needs of older patients, ensuring that the allocation of high-level care resources is both efficient and beneficial. While extensive research exists on ED use and intensive care unit admissions in older patients, there is a notable gap in data regarding the trends in monitored acute care unit admissions over time. Furthermore, research on monitored acute care unit admissions, encompassing intensive care units, intermediate care units, and operating rooms, as a whole entity, remains limited. Finally, intermediate care units have only recently been introduced in health care systems, and their impact on patient disposition and role as acute care providers remains to be determined.

This study aimed to address this gap by analyzing ED and monitored acute care unit admissions among patients aged 65 years or older over the past decade in a Swiss tertiary care institution. Our primary objective was to describe the trends in monitored acute care unit admissions during this period. Our secondary objectives were to identify predictors of monitored acute care unit admission, describe patient outcomes following monitored acute care unit admission, and explore the association between patient age and mortality at day 7 and 1 year postadmission.

Methods

Study Design

This single-center retrospective cohort study used routinely collected data from patients who visited the ED between 2009 and 2019. The study was approved by the institutional ethics committee of Geneva, Switzerland, and patient consent was waived based on Article 34 of the Swiss law on human research.

Study Setting and Population

The study was conducted at Geneva University Hospitals (HUG), the largest medical complex in Switzerland. The HUG is a tertiary care institution with 2 adult EDs located at different sites. The main ED, which operates 24/7, handles approximately 80,000 visits annually and includes a stretcher bay and a walk-in sector, providing comprehensive emergency care. The second ED, opened in 2016, is situated at a geriatric hospital and handles approximately 5000 visits annually. It operates only during daytime hours and is dedicated to patients aged older than 75 years with low-severity conditions. Although this geriatric ED is equipped with a full radiological division, it has limited access to specialty consultants, sometimes requiring the transfer of patients who need urgent specialized consultation or surgical procedures. Hospitals within the HUG network share the same computer system, and patients' medical data are accessible in each hospital.

HUG provides specialized care across all medical fields, serving as a reference center for regional hospitals and often receiving patients from smaller centers. The main location offers 24-hour cardiac catheterization services and is the only trauma and stroke center in the region, providing immediate care for patients requiring intravenous thrombolysis, interventional radiology, or the management of life-threatening injuries.

The HUG's critical care infrastructure includes a medical-surgical intensive care unit and several specialized intermediate care units. These intermediate care units serve as an intermediary level of care between the intensive care unit and regular wards and include a cardiac intermediate care unit, a neurological and neurosurgical intermediate care unit (with a stroke unit), a surgical intermediate care unit, and 2 medical intermediate care units (one located at the main hospital and one at the geriatric hospital).

The HUG is funded through a mixed financing model, with approximately half of the budget provided by the State of Geneva and the remainder generated from hospital revenues (including patient care and insurance reimbursements) as well as dedicated research funding from national grants and private foundations. Health care financing in Switzerland is based on mandatory basic health insurance (LAMal), which ensures equal access to care for all residents and is funded through individual premiums, complemented by regulated cost-sharing mechanisms (eg, deductibles and co-payments) and optional supplementary insurance.

Participants

We included all adult patients (aged ≥18 y) who visited either of HUG's EDs between January 1, 2009, and December 31,

XSL•FO
RenderX

2019. Patients were excluded if they (1) were aged younger than 65 years, (2) were transferred from another hospital or ED outside of HUG, or (3) refused the use of their data for research purposes. The age cutoff of 65 years was selected, as it is a widely recognized threshold for defining "older patients" and aligns with the retirement age in Switzerland.

Variables and Data Sources

The primary outcome was monitored acute care unit admission, defined as an admission to an operating room (including surgical rooms, interventional radiology, or a cardiac catheterization laboratory), an intermediate care unit, or the intensive care unit. This outcome was based on patient trajectories within the institution. The secondary outcomes included hospital length of stay, mortality at day 7 after monitored acute care unit admission, and mortality at 1 year. Owing to the lack of linkage between the electronic health record and the national death registry, data were missing for patients who did not die in the hospital and were not readmitted beyond 1 year after the initial admission.

Patient variables extracted included age, sex, marital status (married or in a relationship vs single, divorced, or widowed), primary language, emergency triage level (based on the Swiss Emergency Triage Scale [11], ranging from 1 [highest priority] to 4 [lowest priority]), triage motive category, nursing home residence, and means of transportation to the ED (ambulance or nonambulance).

Data were electronically extracted from the hospital's data warehouse by a dedicated team, which contains all information routinely gathered for clinical use in the patient's electronic health record. These structured data can be retrieved for quality assessment or research purposes after approval from the research ethics board. Each care episode is assigned a unique number, facilitating linkage between different database subsets. There was no linkage with other databases.

Study Size

The sample size was determined based on the study's objective to describe trends over a decade rather than on power calculations for statistical significance. With an expected inclusion of more than 150,000 patients, the sample size was considered sufficient to perform a multivariable logistic regression analysis without the risk of overfitting, based on established methodological recommendations regarding events per variable. Previous studies have shown that logistic regression models are unlikely to be overfitted when at least 10 events per predictor variable are available and that model performance remains robust even with fewer events per variable in large datasets with stable estimates. Given the large number of observations and outcome events in this study, the risk of overfitting was therefore considered minimal [12-14].

Statistical Analysis

Data cleaning and statistical analysis were conducted using the integrated statistical software Stata/SE (version 18; StataCorp LLC).

First, the data were cleaned and standardized. Variables were reformatted to facilitate analysis. Outcomes were constructed based on patients' trajectories through the institution. To evaluate trends in monitored acute care unit admissions over time, we graphically computed the number of ED visits for patients aged 65 years or older and the number and type of monitored acute care unit admissions by year. The absolute and relative changes over time were reported. A linear regression model was used to evaluate trends over time and determine the statistical significance of the observed changes.

To explore predictors of monitored acute care unit admission, baseline variables were summarized using descriptive statistics for the overall population. Mean and SD (or median and IQR) were used for continuous variables, whereas frequency and proportion were used for categorical variables. Patients admitted to a monitored acute care unit were compared to those not admitted to a monitored acute care unit using standardized mean differences (SMDs). We used SMDs rather than *P* values, as these comparisons are descriptive and not inferential. An absolute SMD greater than 0.2 was considered to reflect a potentially meaningful imbalance. The association between age and monitored acute care unit admission was graphically represented using restricted cubic splines, a flexible regression method, with the number of knots determined by the Akaike information criterion and their placement based on recommended quantiles [14]. Independent predictors of monitored acute care unit admission were identified using a multivariable logistic regression model, with monitored acute care unit admission as the dependent variable. Potential predictors were selected based on previous literature or clinical relevance and included sex, age, marital status, nursing home residence, primary language, arrival by ambulance, emergency triage level, and triage motives. Relationships modeled with restricted cubic splines were presented as odds ratios (ORs), comparing older patients (75th percentile of age) to younger patients (25th percentile of age) [14]. A sensitivity analysis using age as a categorical variable was also performed.

To explore patient outcomes following monitored acute care unit admission, outcomes were summarized using descriptive statistics.

Finally, to explore the association between patient age and mortality at day 7 and 1 year following monitored acute care unit admission, restricted cubic splines were used. Subsequently, multivariable models similar to those used previously were applied.

Missing data frequency was reported for each variable. For the initial logistic regression model, a complete case analysis was performed. A subsequent analysis included variables with higher levels of missingness without imputation to assess changes in the coefficient estimates.

Ethical Considerations

The study was conducted at HUG in accordance with the principles of Good Clinical Practice (the Declaration of Helsinki, 2002). This study was approved on July 11, 2022, by the institutional ethics committee of Geneva, Switzerland (project ID 2022 - 00987). Patient consent was waived by this committee. No compensation was offered to participants Data extraction generated deidentified data used for the analysis.

These data were subsequently anonymized for online publication.

Results

Inclusion of Patients and Characteristics

Between 2009 and 2019, a total of 701,838 ED visits were recorded at our institution (Multimedia Appendix 1). Of these, 180,189 (25.7%) patients met our inclusion criteria (Figure 1). The median age was 79 (IQR 72-86) years. Patient characteristics and the proportion of missing data are presented in Table 1.

Figure 1. Flowchart of our retrospective cohort study conducted at the Geneva University Hospitals (HUG) over a 10-y period (2009 - 2019). All adult patients (aged ≥18 y) who visited the HUG's emergency departments (EDs) were candidates for inclusion. Patients were excluded if they (1) were aged <65 y, (2) were transferred from another hospital or ED outside of HUG, or (3) refused the use of their data for research purposes. Of the 701,838 patients in our dataset, 180,189 met our inclusion criteria, representing 90.3% of all patients aged ≥65 y admitted to the ED during the study period. Of these patients, 19,039 (10.6%) were admitted to a monitored acute care unit (MACU).

Monitored Acute Care Unit Admissions and Evolution Over Time

Over the study period, 887 (0.5%) patients died in the ED, 97,238 (54.0%) patients were discharged home, 63,025 (35.0%) patients were admitted to a ward, and 19,039 (10.6%) patients were admitted to a monitored acute care unit. Of these, 4499 (23.6%) patients were admitted to the intensive care unit, 10,835 (56.9%) patients were admitted to an intermediate care unit, and 3705 (19.5%) patients were admitted directly to an operating room (Table 2).

[a]MACU: monitored acute care unit.

Over the 10-year study period, monitored acute care unit admissions increased by 62.4% in absolute terms (from 1379 in 2009 to 2240 in 2019) and by 0.8% in relative terms (from 10.3% in 2009 to 11.1% in 2019, *P*=.02; Figure 2A). This increase was mainly driven by a rise in intermediate care unit admissions, from 450 of 1379 (32.6%) in 2009 to 1436 of 2240 (64.1%) in 2019. In contrast, operating room admissions remained stable, from 328 of 1379 (23.8%) to 450 of 2240 (20.1%). Intensive care unit admissions decreased, from 601 of 1379 (43.6%) to 354 of 2240 (15.8%; Figure 2B). Notably, while the proportion of patients who died in the ED remained stable, the proportion of patients admitted to hospital wards increased over the 10-year period, from 4026 of 13,377 (30%) in 2009 to 7996 of 19,990 (40%) in 2019.

Figure 2. (A) Trends in emergency department (ED) visits and monitored acute care unit (MACU) admissions for patients aged ≥65 years and (B) distribution of MACU admissions to different types of MACUs over time. Over the 10-year study period (2009 - 2019), ED visits at the Geneva University Hospitals from patients aged ≥65 years increased by 56.1%, from 14,705 to 22,955. MACU admissions increased by 62.4%, from 1379 to 2240. The increase in MACU admissions primarily involved intermediate care units (IMCUs), from 450 of 1379 (32.6%) in 2009 to 1436 of 2240 (64.1%) in 2019. ICU: intensive care unit.

Predictors for Monitored Acute Care Unit Admission

Patients admitted to monitored acute care units were more frequently male, younger, and more often in a relationship (Table 1). Figure 3 shows the unadjusted association between age and monitored acute care unit admission among older patients. Patients admitted to a monitored acute care unit more frequently arrived by ambulance. They also had a higher triage level, with only 2817 (14.8%) of monitored acute care unit admissions having a lower triage level (3 or 4). In our multivariable analysis, younger age, male sex, marital status, absence of nursing home residence, arrival by ambulance, and higher triage level were all identified as independent predictors of monitored acute care unit admission (Table 3). A sensitivity analysis using age as a categorical variable did not significantly change these findings (Multimedia Appendix 2)

Figure 3. Association between age and monitored acute care unit (MACU) admissions among older patients. Older patients are less likely to be admitted to a MACU, with an inflection around 80 to 85 years old. In our multivariable analysis, younger age was identified as an independent predictor of MACU admission (75th vs 25th percentile, adjusted odds ratio 0.73, 95% CI 0.69-0.76).

Outcomes

Seven days following monitored acute care unit admission, 1105 (5.8%) patients had died, 6184 (32.5%) patients had been discharged or transferred to long-term care, 10,139 (53.3%) patients were hospitalized in a ward, and 1611 (8.5%) were still in a monitored acute care unit (Table 4). Patients initially admitted to the intensive care unit had the highest mortality (584 patients, 13.0%) and the lowest discharge rate. Only 135 (1.2%) patients admitted to an intermediate care unit required transfer to a higher level of care. The average hospital length of stay ranged from 11.2 to 13.8 days, depending on the admitting unit. One-year mortality following monitored acute care unit admission was 22.3% (4251 patients), with 23.9% (4553 patients) of data missing for the cohort. Compared to patients admitted to an intermediate care unit or the operating room, patients initially admitted to the intensive care unit had worse outcomes (Table 4). After adjustment for other variables, there was a significant association between age and mortality at day 7 (adjusted OR 1.55, 95% CI 1.14-2.10) and at 1 year (adjusted OR 1.28, 95% CI 1.08-1.51), as illustrated in Figure 4.

XSL•FO

Figure 4. Association between age and (A) mortality at day 7 and (B) mortality at 1 year. For patients aged ≥65 years or older with monitored acute care unit admission, there was a significant association between age and mortality at day 7 (adjusted odds ratio 1.55, 95% CI 1.14-2.10) and at 1 year (adjusted odds ratio 1.28, 95% CI 1.08-1.51). Seven-day mortality was 5.8% (1105 patients), whereas 1-year mortality was 22.3% (4251 patients), with 23.9% (4553 patients) of data missing for the cohort (19,039 patients).

Discussion

Principal Findings

This retrospective cohort study, spanning from 2009 to 2019, revealed a significant increase in monitored acute care unit admissions among older patients. Key predictors of monitored acute care unit admission, such as age, sex, and arrival by ambulance, were identified. While short-term outcomes were relatively good with a 7-day mortality rate of approximately 5%, long-term outcomes were poorer, with more than 20% mortality at 1 year.

Over the study period, monitored acute care unit admissions increased by 62%. This increase was not uniform and can be primarily attributed to the growing number of older patients presenting to the ED with a more modest rise in the proportion of these patients being admitted to a monitored acute care unit, from 10.3% (1379 patients) in 2009 to 11.1% (2240 patients) in 2019. Notably, this overall increase in admissions was primarily driven by a substantial rise in intermediate care unit admissions. Although changes in unit capacity over time could not be assessed, the increase in intermediate care unit admissions and the decrease in intensive care unit admissions are likely to be related. This trend may reflect a redistribution of patients and the development of new competencies within the intermediate care units. Such units can also be seen as a more tailored approach to managing older patients, providing an intermediate level of care that is perhaps more suitable for the needs of this population. Additionally, these units benefit from economic advantages, supporting their use as a cost-effective strategy to prioritize health care resource allocation.

Intensive care unit admission rates among older patients have been extensively studied, with the available literature reporting considerable variability. Some studies have found annual increases of up to 5.6% in patients over 80 years old [15], whereas others have found no significant change [16]. In contrast, data on intermediate care unit admissions are more limited, likely due to the wide variety of formats of such units (including intermediate care units, step-down units, and high dependency units), making it challenging to standardize the data [17-19]. The observed rise in intermediate care unit admissions in our study is closely linked to the overall increase in ED visits by older patients, which has directly led to higher demand for monitored care. Beyond this, several other factors may have contributed, including the growing prevalence of chronic diseases among older patients that require a level of care beyond general ward care but less than intensive care unit, along with advances in medical technologies, interventions, protocols, and admission criteria that allow for safer and more effective management of these patients in intermediate care units [20-24].

As anticipated, older patients were less likely to be admitted to a monitored acute care unit, with a notable decrease in admissions and an increase in mortality observed around the age of 85 years. This age threshold may be due to higher comorbidity rates and the presence of advanced care directives in this patient population [25,26]. Age is known to be associated with both a decrease in intensive care unit referral by emergency physicians and an increase in admission denial by intensive care physicians [27]. It might make sense, as intensive care unit admission for patients aged older than 80 years has not been shown to affect 2-year survival rates [28]. However, critical care societies recommend that decisions regarding monitored acute care unit admissions should be based on illness severity, comorbidities, and baseline functional status rather than age alone [29]. It is crucial for physicians to engage in discussions with patients and their next of kin about the potential implications of a monitored acute care unit admission, although the final decision rests with the receiving physician [30].

Our study also identified other predictors of a monitored acute care unit admission. Arrival by ambulance, which is up to 4.6 times more frequent for older patients [31] and serves as an indicator of higher clinical severity, was a strong predictor of monitored acute care unit admission. Nursing home residents were less likely to be admitted to a monitored acute care unit, likely due to higher levels of comorbidities and frailty levels,

XSL•FO
RenderX

often associated with a diminished quality of life and cognitive impairment [32-34]. Neurology-psychiatry–related triage motives were the strongest predictors of monitored acute care unit admission, likely due to conditions such as strokes, which typically require a monitored acute care unit–level care. Interestingly, the French language, male sex, and marital status were also associated with monitored acute care unit admission. Language barriers are well documented as contributing to worse health outcomes, including longer hospital length of stay, higher readmission rates, and limited access to health care systems, regardless of socioeconomic status [35,36]. While female patients were predominant in the ED, they were 21% less likely to be admitted to a monitored acute care unit compared to male patients, a finding consistent with existing literature [37-39]. This disparity may be influenced by more comorbidities in men, and the tendency for female patients to set medical limitations and have advanced directives, especially when divorced or widowed [40]. However, sociocultural factors and implicit or explicit biases may also contribute to this disparity. Unmarried patients often presented with more severe illness at admission [41], possibly due to delayed medical intervention, whereas patients with a partner are more likely to receive high-level care to meet family expectations. Physicians must be aware of such disparities and strive to mitigate them in their practice.

Short-term outcomes for patients admitted to a monitored acute care unit are quite encouraging, with one-third of patients discharged and more than half transferred to the ward by day 7. However, long-term outcomes were less favorable, particularly for patients admitted to the intensive care unit, who had a 1-year mortality rate exceeding 30%. While intensive care unit mortality in older patients is well documented [42], outcomes for intermediate care unit patients have been less studied, especially among ED patients. Torres et al [43] reported no significant difference between demographics regarding in-hospital mortality after intermediate care unit admission and a 34% mortality after 2 years for patients aged older than 65 years, significantly higher than the 10% for younger patients. In a secondary analysis of the ICE-CUB2 trial focusing on ED patients, Thietart et al [44] reported 6-month mortality rates of 44% and 31% for intensive care unit and intermediate care unit patients, respectively, which were higher than those reported in other studies, including this one, which the severity of the patients can explain, as they did not include uncomplicated acute coronary syndromes and strokes. Finally, D'Andrea et al [45] found a 43% 1-year mortality rate in patients aged older than 75 years admitted to a geriatric intermediate care unit, with a significant association between age and 1-year mortality.

Clinical and Scientific Implications

This study highlights the need to adapt health care structures to meet the growing demands of an aging population. Developing specialized geriatric acute care units or intensive care units, along with training physicians specifically to address the needs of older patients, could help raise awareness of these needs while addressing potential biases related to gender, language, and marital status. Further research should explore patient and family satisfaction and the alignment between care provided and patient wishes. Previous studies have shown that quality of life in older intensive care unit survivors is initially worse [46] but tends to improve within a year, with many older patients willing to undergo intensive care unit admission again if necessary [47,48]. Further studies could focus on developing clinical guidelines or tools specifically tailored to older patients to aid in the shared decision-making process regarding monitored acute care unit admission. These guidelines should incorporate measures such as the Functional Independence Measure or the Clinical Frailty Scale, which have been shown to correlate with resource use and outcomes [45,49,50].

Strengths and Limitations

Some strengths and limitations need to be acknowledged. The study analyzes a large cohort over a decade, providing a robust dataset for analysis. The innovative and comprehensive approach of considering all monitored acute care unit admissions offers a broad view of high-cost care, which has not been extensively studied. Additionally, we used a rigorous statistical plan, including restricted cubic spline models to account for the nonlinear relationship between age and outcomes, to enhance the robustness of our results. The primary limitations of this study are related to the design. As a retrospective cohort, the study is prone to bias and missing data, notably the variation in monitored acute care unit beds per unit over the years, which may influence patient disposition based on unit saturation. The second major limitation is the lack of information on comorbidities, place of residence (rural vs urban), and polypharmacy. These variables are either not available as structured data in our electronic health record or are at high risk of bias. To preserve high data quality, we chose not to report them. The authors acknowledge this as a limitation of the study, with a risk of residual confounding. Results involving mortality should be considered cautiously, as mortality data were missing for 1 in 4 patients. Our study is monocentric; however, its findings are likely generalizable to other university hospitals in Switzerland and Europe, given the similar monitored acute care unit admission criteria. The exclusion of private hospitals with minimal monitored acute care unit capacity is a minor limitation, as their patients tend to be younger than 65 years. The change in the slope of the association between age and monitored acute care unit admission, as well as age and 1-year mortality, may be driven by only a small number of patients in the oldest age group, potentially distorting the true association. Finally, this study did not cover the periods of the COVID-19 pandemic, which could limit the generalizability of the results, as monitored acute care units were particularly strained during this period.

Conclusions

This study highlights the sharp increase in monitored acute care unit admissions among older patients, reflecting the growing demand for high levels of care in this population. The rise was primarily driven by a substantial increase in intermediate care unit admissions, whereas intensive care unit admissions remained stable. These findings emphasize the need for hospitals to adapt health care infrastructure, clinical procedures, and resource allocation to meet the evolving needs of an aging population. Future work should focus on the importance of developing specialized geriatric acute care units, refining clinical guidelines, and engaging in shared decision-making to ensure equitable and effective care for all older patients.

Abstract

Background: Frailty increases with age and is associated with increased vulnerability to adverse health outcomes. International guidelines recommend screening for frailty in primary care; however, this is not routine practice in Australia. Once identified, frailty progression has the potential to be halted or reversed with early intervention. The FRAIL (Fatigue, Resistance, Ambulation, Illnesses, Loss of weight) Scale Tool, a simple and validated screening and management tool, offers a feasible approach for integration into the Australian health assessment for those aged 75 years and older (75+HA), which can be performed annually by primary care providers.

Objective: This study explores the rates of frailty, resources required to support management, and the determinants of implementing frailty screening and providing management for older Australians at the 75+HA.

Methods: A mixed methods evaluation was conducted in 24 general practices across 2 Australian Primary Health Network regions, Sydney North and Brisbane South. The FRAIL Scale Tool was implemented during the 75+ health assessment, and data were collected on FRAIL Scale scores, hospitalization rates, recommended frailty interventions, and barriers to frailty management. Practice staff perceptions of the long-term sustainment of the FRAIL Scale Tool were assessed using the Provider Report of Sustainment Scale. Semistructured qualitative interviews were conducted with practice staff and patients, exploring barriers and enablers to implementing frailty screening and management. Guided by the Consolidated Framework for Implementation Research, transcripts were coded and themes developed.

Results: Of the 1484 patients aged ≥75 years who were screened, 223 (15%) patients were frail, 616 (41.5%) patients were prefrail, and 645 (43.5%) patients were robust. People who were frail were more likely to be female, older, and have more prescribed medications. Of those screened as frail, 23 (11%) had a nonelective hospitalization in the 3 months prior to screening compared with 28 (5%) who screened as prefrail and 5 (1%) who screened as robust (*P*=.012). Management recommendations commonly included medication reviews, aged care packages, assessment for depression, and exercise programs. Barriers identified to accessing interventions included health, transport, cost, and time. Survey and qualitative findings highlighted that the FRAIL Scale Tool was easy to use, integrated well into existing workflows as part of the 75+HA, and sustained use would be supported by software integration. Patients valued the assessment and tailored health support offered by trusted primary care providers.

Conclusions: Incorporating the FRAIL Scale Tool into the annual health assessment for people aged 75 years and older provides a funded opportunity for addressing frailty in general practice. Patients and staff value the Tool's simplicity and the opportunity to raise awareness and manage frailty proactively. Incorporating the Tool into practice software systems would enhance adoption. Broader implementation research in diverse settings and with Aboriginal and Torres Strait Islander populations is needed to improve frailty prevention and management.

Introduction

Worldwide, the population is aging with an increasing proportion of people aged 60 years and older, and the number of people aged 80 years or older is expected to triple between 2020 and 2050 [1]. In response, health care systems and models of care must focus on the health needs and priorities of older people. Frailty and its precursor, prefrailty, affect more than half of the adults older than 50 years worldwide [2]. Characterized by physiological decline and increased vulnerability to stressors, frailty is a dynamic state associated with an increased risk of adverse health outcomes [3]. While not an inevitable part of aging, the risk of developing frailty increases with advancing age, with the prevalence of frailty and prefrailty climbing to 31% and 52% respectively, in people older than 80 years [2]. With the gradual loss of muscle mass and decline in physical condition, frailty is associated with falls and acute illnesses. Hospitalization or prolonged recovery can contribute to further physical deconditioning, with people experiencing frailty often requiring substantial support and resources to return to their prior health state or prevent further deterioration [4]. Importantly, causes of frailty can be managed, and in some cases reversed, highlighting the importance of early identification of older people who are living with prefrailty [5].

International guidelines highlight the opportunity for frailty prevention and early intervention in primary care [6]. This can be challenging as prefrailty develops subtly and may go unnoticed without targeted examination. While screening of older adults in primary care has been recommended for early identification of prefrailty to initiate preventative management strategies [7], screening is not routinely recorded and tracked in practice in Australian primary care [8]. This presents a missed opportunity as validated screening tools have been found to assist health care professionals with identifying risk of frailty and monitoring any changes in health status [6].

The FRAIL (Fatigue, Resistance, Ambulation, Illnesses, Loss of weight) Scale (Figure 1) has been validated [9,10] as a screening tool for community-dwelling adults. A recent pilot study found the Tool was feasible for general practitioners (GPs) and practice nurses to administer in a busy clinical setting and appropriate for screening older people at the time of routine appointments [11]. It is based on the phenotype of frailty elements of Fried et al [12]: exhaustion (fatigue), weight loss, measured grip strength and walking speed, and low energy expenditure. The FRAIL Scale includes 5 simple questions about fatigue, resistance, ambulation, illnesses, and loss of weight to identify risk of frailty [9]. FRAIL Scale scores range from 0 to 5 (with 1 point for each component) to give one of three outcomes: (1) frail (3 or more components present), (2) prefrail (1 to 2 components present), or (3) robust (0 components present).

Figure 1. The FRAIL Scale. FRAIL: Fatigue, Resistance, Ambulation, Illnesses, Loss of weight.

FRAIL SCALE Risk Assessment

	Question	Scoring	Result
F	**Fatigue** How much of the time during the past 4 weeks did you feel tired? A = All or most of the time B = Some, a little or none of the time	A = 1 B = 0	
R	**Resistance** In the last 4 weeks b y yourself and not using aids, do you have any difficulty walking up 10 steps without resting?	Yes = 1 No = 0	
A	**Ambulation** In the last 4 weeks by yourself and not using aids , do you have any difficulty walking 300 meters?	Yes = 1 No = 0	
I	**Illness** Did your Doctor ever tell you that you have? ☐ Hypertension ☐ Diabetes ☐ Cancer (not a minor skin cancer) ☐ Chronic lung disease ☐ Heart Attack ☐ Congestive heart failure ☐ Angina ☐ Asthma ☐ Arthritis ☐ Stroke ☐ Kidney disease	0 – 4 answers ✓ = 0 5 – 11 answers ✓ = 1	
L	**Loss of weight** Have you unintentionally lost more than 5kg or 5% of your body weight in the past year?	Yes = 1 No = 0	
		Total Score	
Scoring: Robust = 0, Pre-frail = 1-2, Frail = ≥3			

Once identified, frailty progression has the potential to be halted or reversed with proper management [5]. Clinical guidelines suggest a multifaceted management approach to address physical function, nutrition, polypharmacy, and fatigue [6,13,14]. However, according to health professionals, the management of frailty can be hindered by a lack of defined protocols and care pathways to guide evidence-based intervention in practice [15,16]. To address this issue, the bespoke Frailty Management/Decision Tool (the Tool) was developed by Sydney North Health Network (SNHN) and Northern Sydney Local Health District for primary care staff to assess and track FRAIL Scale scores and provide associated management suggestions and interventions recommended within the Tool (Figure 2). The tool was successfully piloted by general practices in Sydney North and Brisbane South, with 80% (860/1071) of those screened identified as frail or prefrail [11]. Staff feedback

XSL•FO
RenderX

highlighted that the Tool was patient-focused, easy to use, and a formalized assessment for risk of frailty. To fit with practice workflows, this pilot research supported screening for frailty risk in conjunction with the annual Medicare-funded preventive health assessment for those aged 75 years and older (75+HA), which is conducted with more than 600,000 older Australians in general practice annually [17]. While the 75+HA assesses falls risk, vision, hearing, current weight, and cognitive assessment, it does not currently include a formalized frailty assessment.

XSL•FO
RenderX

Figure 2. The Frailty Management Decision Tool (The FRAIL Scale Tool).

FRAILTY MANAGEMENT/DECISION SUPPORT TOOL

	Assessment Score	Intervention	Referral/follow up
	FRAIL scale 0= robust	• Encourage ongoing activity levels. • Provide physical activity and nutrition resources	• Re-do FRAIL Scale in 12 months • Community exercise with balance/resistance component. Provide physical activity and nutrition resources.
	FRAIL scale 1-2 = Pre-frail >3 = Frail	**If FRAIL Score is positive, address underlying causes as suggested below**	
F	Feeling fatigued most or all of the time	• Consider screening for reversible causes of fatigue (sleep apnoea, depression, anaemia, hypotension, hypothyroidism, B12 deficiency). • Use EPWORTH scale, K10 or Geriatric Depression Scale in Health Assessment.	• Consider referral to Geriatrician/Specialist for complex care patients • Consider referral to Occupational Therapist for functional and home review • Consider referral to Psychologist using Mental Health Care Plan • Consider referral to Aged Care organisation for loneliness support (isolation can be a cause of fatigue).
R	Resistance against gravity - difficulty walking up 10 steps without resting	• Consider referring to an individualized progressive exercise program with resistance and strength component.	• Physiotherapist or exercise physiologist for exercise prescription. • For diabetes – group session Medicare funded exercise physiologist • Community exercise with balance/resistance component. • Telephone-based health coaching
A	Ambulation - difficulty walking 300 meters unaided		
I	Having 5 or more illnesses	• Review indication, side effects and use of medication (evidence for use of some medicines change after 75). • Consider discussing with pharmacist. • Consider reducing/de-prescribing superfluous medication.	• Pharmacist for comprehensive medication review (HMR item 900). • Occupational Therapist for functional and home safety review. • Self-management support from aged care organisation volunteer
L	Loss of >5% weight in 12 months	• Consider screening for reversible causes of weight loss • Consider protein and caloric supplementation/food fortification (75mg protein per day required – range of products available at pharmacy). • Advice and encourage healthy eating; provide nutrition resources.	• Weight and assess BMI – record in patient record • Dietitian for diet review and management • Meal Delivery Services • Speech Pathologist for swallowing review • Dentist for dental review (pain/infection/ill-fitting dentures) • Occupational Therapist for functional and home cooking ability/review.

This study aims to determine:

XSL•FO
RenderX

1. The rates of risk of frailty/frailty in the general practice population aged 75 years and older when screened at the time of the 75+HA.
2. The resources required to support those identified as frail or at risk of frailty.
3. Barriers and enablers to implementing frailty screening and management for community-dwelling older Australians in primary care.

Methods

Design

A convergent mixed methods study design was used. FRAIL Scale scores, recommended resources for frailty management, and barriers to accessing these were tracked prospectively by general practice staff. Semistructured qualitative interviews were conducted with practice staff and patients to understand (1) the determinants of implementing frailty screening and (2) the barriers and enablers to frailty management in primary care. Interview questions and analysis were guided by the Consolidated Framework for Implementation Research (CFIR) [18]. CFIR provides a framework for assessing determinants of implementation at multiple contextual domain levels: inner and outer setting, intervention, individual, and implementation process.

Researcher Positionality

DC is a Primary Health Network (PHN) stakeholder who worked with Sydney North primary care centers to introduce the FRAIL Scale tool. AP contributed as a biostatistician, and the remainder of the research team has worked clinically with older persons (JJ: Dietitian, CN: Physiotherapist, RS: Sleep Technician, CJ: GP). All have extensive experience implementing health services in the primary care setting and are acutely aware of the time and workforce challenges faced by primary care.

Ethical Considerations

Ethics was approved by The University of Queensland HREC (Project IDs: 2021/HE001441 and 2021/HE002398), and informed consent was obtained from participants. Participant data was protected by unique study codes and secure servers with limited access to ensure confidentiality, and only deidentified data was shared with the researchers. General practice incentive payments supported the general practice staff time for the data collection (70 frailty screens/practice at Aus $40 [US $26.652]/assessment for new practices). Participants were reimbursed for their time for a semistructured interview at Aus $120 (US $79.956)/interview for practice staff and Aus $50 (US $33.315) for patients.

Recruitment

As previously described, the research team partnered with 2 PHNs—SNHN and Brisbane South Primary Health Network (BSPHN)—to pilot [11] and more broadly implement the Frailty Management Decision tool. PHNs are not-for-profit organizations funded by the Australian Government to improve access to primary care services for patients, particularly those at risk of poor health outcomes, and coordination of care.

SNHN is a predominantly metropolitan region that is ranked the least socioeconomically disadvantaged PHN in Australia. In contrast, BSPHN is a diverse region that includes metropolitan, rural, and remote island locations, and 2.8% of residents are Aboriginal or Torres Strait Islander. There are 292 general practices in SNHN [19] and 336 in BSPHN [20], with people aged ≥65 years making up 17.3% of SNHN residents and 14.2% of BSPHN residents.

Practices that participated in the pilot program between April 2021 and June 2023 were invited to join this study. Additional practices were recruited between July 2023 and February 2024 via a PHN practice newsletter, expressions of interest, and PHN/researcher practice networks. The Tool was implemented by 24 enrolled practices (14 SNHN, 10 BSPHN).

Tool Implementation

Patients were screened using the FRAIL Scale tool during the 75+HA. GPs, nurses, and other practice staff completing 75+HA were encouraged to use an optimized health assessment template incorporating the FRAIL Scale questions (Multimedia Appendix 1) or add the FRAIL Scale to their existing practice templates. The frailty score was calculated, and practices referred to the associated management suggestions and interventions recommended within the Tool (Figure 2). Practice staff could download the results of the questionnaire and save them to the patient's medical record.

Training for the practices included (1) an in-person, phone, or web-based video session outlining the aims of the study, how to complete data collection, and use of the FRAIL Scale tool, and (2) check-in visits, or phone/video calls, and emails with the project researcher. Data collection commenced in July 2023 and was completed in January 2025.

Data Collection

Implementation Evaluation

During the study, practice staff conducted FRAIL Scale screening with patients aged 75 years and older and collected deidentified data via a REDCap (Research Electronic Data Capture; Vanderbilt University) data collection tool developed for the research. Data collected included date of screening, time to complete the screen, patient characteristics (age, BMI, sex, and Aboriginal or Torres Strait Islander background); whether the patient had been hospitalized (planned or unplanned) or attended the emergency department in the previous 3 months; current medication number; patient FRAIL Scale scores; suggested management/referral options; and any barriers identified by patients or caregivers for accessing suggested management/referral options from a picklist (cost, time, transport, or health) or a free text option.

Practices provided data on the active practice population and the total number of GPs and nurses working in the practice. Practices were classified on location (ie, metropolitan or regional) using the Modified Monash Model [21].

Staff Survey

Staff perceptions of the long-term sustainment (continued use) of the FRAIL Scale were assessed using the Provider Report

XSL•FO
RenderX

of Sustainment Scale (PRESS), a pragmatic, reliable, valid 3-item survey [22]. The 3 items were rated on a scale from 0 (not at all) to 4 (to a very great extent), with the mean score calculated and higher scores indicating more sustainment. An additional free-text option was included: "Do you have any other feedback regarding the implementation of the FRAIL Scale tool in your practice?"

Qualitative

Qualitative interviews were conducted with (1) practice staff who had used the FRAIL Scale tool during implementation, and (2) patients who had been assessed for risk of frailty to understand determinants (barriers and enablers) to (1) implementing the FRAIL Scale tool and (2) risk of frailty management in primary care.

Staff conducting the FRAIL Scale tool assessments during the study were invited to be interviewed, and practice staff recruited potential patients for interview at the time of the 75+HA. Invitations were emailed or mailed to staff and patient participants, with information describing the rationale for the research provided via an information sheet. Participants were sent the interview questions in advance, allowing them time to consider their viewpoints. Interviews were semistructured and informed by the CFIR [18,23]. The relevance of each CFIR determinant to the implementation of the FRAIL Scale tool was rated by the research team members (CN, JJ, and DC), and those with the highest rating were used to determine interview questions [24]. Interview questions Multimedia Appendix 2) were developed using the Interview Guide Tool available via the CFIR website [25] and with a focus on patient views on the FRAIL Scale assessment tool, barriers to accessing management options and resources, and preferences for suitable options and resources. All interviews were conducted via telephone by an implementation scientist with extensive experience in qualitative research (JJ). As an alternative to data saturation, the process of Malterud et al [26] was used to inform the sample size. Sample size was determined to be met once the purpose and goals of the analysis were achieved, with information power considered strong, since the interviewer was experienced, the research questions were specific, and the interview guide was informed by theory [26]. The interviewer recorded notes during and after interviews to identify barriers and enablers to implementing screening and management for risk of frailty/frailty (JJ). Interviews were audio-recorded, transcribed verbatim using Microsoft Word, cross-checked against the recording (JJ), and anonymized.

Data Analysis

FRAIL Scale

Data were summarized using median (IQR) for continuous nonnormally distributed variables and frequency (percent) for categorical variables. The associations between frailty (frail, prefrail, and robust) and patient demographics were explored using chi-square tests for categorical characteristics and Mann-Whitney *U* tests for continuous nonnormally distributed characteristics. Statistical significance was indicated at a *P* value of <.05 (2-sided). These analyses were performed in STATA (version 18; StataCorp LLC) and IBM SPSS Statistics (version 29.0.0.0 241).

PRESS Survey

Survey data were presented using descriptive statistics (median and IQR) and tabulated with free-text responses.

Qualitative interviews

A deductive, thematic analysis was used to understand barriers and enablers to implementation of frailty screening and management in general practice with a view to guiding ongoing implementation [27]. Interview transcripts were coded by 2 researchers (JJ and RS), using a deductive process guided by CFIR [18], and themes were developed (JJ and RS). The aim of having 2 coders was not to reach consensus, but to develop richer and more complex insights into the data. As every participant has their own experience and view of frailty screening and management, member checking of results was not conducted [28].

The qualitative feedback was used to explore, in greater depth, the (1) results of the PRESS survey on sustainment of the Tool and (2) data collected by GPs and nurses from patients regarding the barriers they identified to accessing frailty management resources [29].

Results

Overview

The characteristics of the Sydney North and Brisbane South practices that implemented the FRAIL Scale tool at the time of the 75+HA are presented in Table 1. All practices were in a metropolitan region (MMM1) [21]. Screening was conducted by 61 staff (57 nurses, 3 GPs, and 1 nondispensing pharmacist) from the practices who used the FRAIL Scale tool.

Frailty Screening Results

Practice staff screened 1484 patients for risk of frailty at the time of the 75+HA (Table 2). The median time taken by staff to complete the FRAIL Scale tool was 3.9 minutes (IQR 2.2 - 7.6 minutes, n=1458).

Table . Patient demographics for Brisbane South and Sydney North primary health networks.

	Total (n=1484)	Brisbane South (n=588)	Sydney North (n=896)
Patient sex, n (%)			
Male	650 (43.8)	256 (43.5)	394 (44.0)
Female	834 (56.2)	332 (56.5)	502 (56.0)
Age in years at screen (years), median (IQR)	80 (77-85)	79 (77-84)	81 (77-85)
BMI (kg/m^2), median (IQR)[a]	26.8 (23.7-30)	27.6 (24.4-30.8)	26.2 (23.3-29.6)
Aboriginal or Torres Strait Islander, n (%)[b]	7 (0)	2 (0)	5 (1)
Prescribed medication count, median (IQR)[c]	5 (3-8)	5 (3-8)	5 (3-7)
Frail score, median (IQR)	1 (0-2)	1 (0-2)	1 (0-2)
Nonelective hospitalization in prior 3 months, n (%)[d]	56 (4)	20 (4)	36 (4)
Emergency department attendance in prior 3 months, n (%)[e]	90 (6)	38 (6)	52 (6)

[a]Missing data, n=271

[b]Missing data, n=40.

[c]Missing data, n=5.

[d]Missing data, n=26.

[e]Missing data, n=5.

At the time of screening, 43.5% (n=645) of all patients (n=1484) were classified as robust (score 0), 41.5% (n=616) as prefrail (scores 1 - 2), and 15.0% (n=223) as frail (scores 3 - 5) (Table 3). People who were frail were more likely to be female, older, have more prescribed medications, and to have had a nonelective hospitalization in the prior 3 months. Although those who were robust had a lower BMI than those who were prefrail or frail (statistically significant), the median BMI did not differ greatly between the frail groups.

The predominant frailty management or resources suggested are outlined in Table 4, with GP medication reviews most frequently recommended (17.3%).

Table . Management recommendations and resources (10 most frequent for prefrail and frail patients who had recommendations made of the 1484 screened).

Recommendation or resource	Values, n (%)
GP[a] medication review (medication indications/side effects/usage)	256 (17.3)
My Aged Care packages	194 (13.1)
Use depression assessment in 75+HA[b] tool	141 (9.5)
Activity program/ exercise classes	108 (7.3)
Fatigue - screen for sleep apnea, depression, anemia, hypotension, hypothyroidism, B12 deficiency	107 (7.2)
Exercise program with resistance/strength component	101 (6.8)
Support services	97 (7)
Physiotherapy or exercise physiologist for exercise prescription	95 (6)
Pharmacist for comprehensive medication review (Home Medication Review item 900)	95 (6)
Occupational therapy for functional/home review	66 (4)

[a]GP: general practitioner.

[b]75+HA: health assessment for those aged 75 years and older.

PRESS Survey

The PRESS survey was completed by 15 staff (13 nurses, 1 GP, and 1 Practice Manager) from 11 practices (Table 5). All practices had used the FRAIL Scale tool for greater than 6 months prior to survey completion. Free-text comments to the request for other feedback regarding the implementation of the FRAIL Scale tool in the practice are outlined in Multimedia Appendix 3 .

XSL•FO
RenderX

Table . PRESS survey feedback (n=15) regarding long-term sustainment (continued use) of the FRAIL (Fatigue, Resistance, Ambulation, Illnesses, Loss of weight) Scale rated on a scale from 0 (not at all) to 4 (to a very great extent).

Feedback	Median (IQR)
Staff use the FRAIL Scale tool as much as possible when appropriate	3.0 (2.0 - 3.0)
Staff continue to use the FRAIL Scale tool throughout changing circumstances	2.0 (1.0 - 3.0)
The FRAIL Scale tool is a routine part of our practice	2.0 (1.5 - 4.0)

Qualitative Interviews

Overview

Of the 16 people who consented and were sent the interview questions, 15 took part in the interviews (94% participation rate): 4 practice nurses, 1 GP, and 10 patients (aged 75 years and older). The qualitative results related to the determinants of implementing the two components of the Tool: (1) frailty screening at the time of the 75+HA and (2) risk of frailty/ frailty management.

Determinants of Implementing Frailty Screening at the Time of the 75+HA

Overview

Qualitative feedback highlighted that the FRAIL Scale Tool focused patient and GP attention on aspects of health and aging. Staff identified that screening at the time of the 75 and over health assessment fit with the general practice workflows, and that the FRAIL Scale tool was easy to use, formalized screening, and allowed tracking of frailty over time. However, the PRESS survey comments suggested key factors would support the adoption of the Tool in the long term.

The FRAIL Scale Assessment is Recipient-Centered

Patients reported that they appreciated the opportunity to reflect on their health.

> *nobody asks you questions .. like that, usually it's just whatever you're going to the doctor (for) ….the fact that you know at my age 75…I'm still doing well… So I was kind of quite happy with my assessment.* [PS14 (Pt)]

> *I think it's great that they do ask those questions because a lot of times you don't mention those sort of things to your doctor when you're there.… those sort of questions .. remind you you're not 21 anymore and your body is not as agile as what it used to be.* [PS22 (Pt)]

> *I probably was pleased with what they went through and thought that the questions give me assurance that I'm doing the right thing.* [PS15 (Pt)]

> *These questions just remind me that …. I have to pay more attention on my … my daily life. And maybe if no one asked me this, maybe something happening that I didn't notice.* [PS27 (Pt)]

> *it's good learning for me …feeling I have to learn more to keep my body healthy.* [PS28 (Pt)]

Embedding the FRAIL Scale Tool in Practice Processes

GPs and practice nurses reflected on the benefits of having a process for screening for risk of frailty and a method to record and track risk of frailty in the patient chart over time.

> *I think.. often there's an insight to the doctor because we don't always ask those questions.* [PS17 (GP)]

> *they can get an actual number score. Says how frail someone is. If you can look at someone and you can think about their history and everything and they're like, OK, they might be frail. They're becoming a bit frail. But having a number to it makes a difference.* [PS20 (Nurse)]

The FRAIL Scale tool is easy to use, and although it takes extra time to complete, the Tool improves the care for patients.

> *I don't find using the tool complicated at all. I .. it's easy for us to access. It's very self-explanatory.* [PS21 (Nurse)]

> *It takes a bit of extra time.. but it means .. we can provide better care for that person… so we have allowed an extra 15 minutes into our appointment.* [PS20 (Nurse)]

> *it's worthwhile for the government to do this because you get … better outcome(s)..and the frail elderly, definitely you would save a lot more in preventative care.* [PS17 (GP)]

Staff felt the FRAIL Scale screen fit with the workflows for the 75+HA, and some practices incorporated a link to the Tool from the 75+HA templates in the medical practice software (Best Practice).

> *it's part of the auto fill for the 75+HA. So we do .. daily living and then we go through .. risk factors for osteoporosis. And then falls risk and (the) Frail Scale Tool so it works in perfectly.* [PS18 (Nurse)]

Introduction of the FRAIL Scale tool, which included management recommendation prompts based on the score in each FRAIL domain, was seen as an advantage by staff.

> *much easier because it … gives you prompts … we're actually. .. suggesting actions, whereas before we might have just said that they were frail and .. left it at that, whereas now we're sort of discussing with them .., maybe you should be thinking about doing some balance and falls programs.* [PS18 (Nurse)]

Some staff found the paper-based FRAIL Scale tool useful as a quick guide to screening and management.

XSL•FO
RenderX

> *the frailty management decision tool is quite good.. it's got the words FRAIL down the side and then it's got intervention and referral follow up prompts for things that you can do for each section and that's quite useful. .. easier to look at as an overview.* [PS18 (Nurse)]

> *I do print off recommendations for (management) and (say to the patient) if you want to, you can have a read. You don't have to. I'm not forcing you to do anything, but this information is here for you when you want it and let us know if you want us to refer (you) to anyone.* [PS20 (Nurse)]

With the current format of the Tool, documentation and communication within the practice is part of the process of implementing the Tool.

> *it's in the patient notes.…… this is what the score number was, .. what it meant. And we also save… the whole thing with the recommendations and everything into their notes as well into correspondence* [PS20 (Nurse)]

> *I do find it is a great resource because..then I'll document it in ..the patient notes. But I will also hand it over then to the GP … they will always see the GP after they see me* [PS21 (Nurse)]

However, PRESS survey feedback (Multimedia Appendix 3) highlighted that use of the Tool is not business as usual, and building the FRAIL Scale Tool into the practice management software would automate the recording process and make the Tool "more user friendly".

Patients identified trust in the medical team that facilitated the implementation of screening.

> *[Dr] has been my GP for quite some time and she looks after me and my wife really well. So whatever she asks, I'm very happy to discuss with her.* [PS27 (Pt)]

Some staff felt that completing the risk of frailty screening with robust patients was unnecessary.

> *if they're doing.. 3-4 hours of physical activity a week, you possibly don't need to carry on filling the questionnaire.* [PS21 (Nurse)]

Determinants of Implementing Risk of Frailty/Frailty Management

Overview

While the FRAIL Scale tool raised awareness of the importance of healthy aging, patients identified barriers to accessing management resources. Access to frailty management interventions and resources was limited due to patient motivation and capability related to health, and limited opportunity due to transport issues, cost of resources, or caring duties. Accessing web-based resources was identified as a challenge for those who may not be savvy with technology, and in this case, face-to-face programs were the preferred option. Data recorded by practice staff at the time of frailty screening is presented in Table 6, with further context provided by quotes from the qualitative interviews.

XSL•FO
RenderX

Table . Barriers to accessing frailty management and resources: quantitative (673 prefrail/frail patients who had a recommendation made) and qualitative (10 patients, 1 general practitioner [GP] interview).

Barriers	Quantitative, n (%)	Qualitative
Health	81 (12)	• *I've got blocked arteries in both legs…. I could go out for a walk right now, but I get a certain distance, and I'd have to stop and wait till the… cramps and things in my legs so I can walk home* [PS14 (Pt)]
Transport	81 (12)	• *at over 75, .. it's very difficult for them to access the care either because cost or no one's taking them. They don't want to trouble their family, and so they often don't want to follow through* [PS17 (GP)]
Cost	57 (8)	• *at over 75, .. it's very difficult for them to access the care either because cost or no one's taking them. They don't want to trouble their family, and so they often don't want to follow through* [PS17 (GP)]
Time	57 (8)	• *You gotta have the time and the desire to go walking. So I don't do it too much.* [PS16 (Pt)]
Other (caregiver duties, language, grieving, motivation, technology)	53 (8)	• *I've been with the gym for about 15 years, but .. these days I only….go there every once a week… because of my wife, she has dementia... so I don't have much time to do that* [PS27 (Pt)] • *I'm here by myself… so you sometimes get a little bit lazy* [PS15 (Pt)] • *I haven't been doing them (exercises for shoulder from physio). I've been very lazy, it's been too cold* [PS19 (Pt)] • *another barrier is because we are not IT people. So sometimes ..the programme .. from online .. is a bit difficult for us to join. But if the community can have more practical programmes like face to face .. led by the leader that will be… easy for us to join* [PS28 (Pt)]

The interviews with patients highlighted other determinants of frailty management in primary care that were not identified by practice staff at the time of frailty screening. These included (1) lack of patient knowledge of management options and resources available, (2) social support enhancing participation in physical activity, and (3) location of resources enhancing access.

Knowledge of Available Resources

Some patients were unaware of resources available locally or were interested in learning more about healthy lifestyle behaviors.

> *They did suggest that maybe that I should… see an exercise Physiologist which .. I've never even heard of before.* [PS26 (Pt)]
>
> *Teach me… the benefit of .. food and how to eat it better. And how to keep the body .., easier to go to the toilet every day ... That would be helpful.* [PS28 (Pt)]

Relationships and Social Connectedness Were a Facilitator to Exercise

Family, friends, and social interaction were identified as supporting physical activity for several people.

> *I go to the gym. I walk with my son every weekend. We have coffee and sometimes, if my daughter can, I walk with her. I see the family all the time. I'm in a good place.* [PS25 (Pt)]
>
> *My daughter gets onto me about that "do your exercises", and my other daughter says the same thing.* [PS19 (Pt)]
>
> *I do Tai chi three times a week…. go to a park with a group… After the Tai Chi we have coffee time and chat.* [PS28 (Pt)]

XSL•FO
RenderX

Access to Resources and Local Programs, and Motivation to Attend

Patients and providers recognized the benefits of local resources for providing access to frailty management.

> *In the retirement village where I am, on Tuesday we have exercises, Wednesday we have a bus which takes us shopping, Thursday I play indoor bowls…. And then Friday night I have tea with the neighbours next door…We have a nursing section in the village and they have.. a gym up there* [PS15 (Pt)]

Discussion

Principal Findings

Incorporating the FRAIL Scale tool into the annual health assessment identified 56.5% (839/1484) of the 75 years and over general practice population in this study as frail/at risk of frailty. The predominant frailty management interventions recommended were medication reviews, aged care packages, assessments for depression, and exercise programs. Compared with those who were robust/prefrail, those identified as frail were 4 times more likely to have had a nonelective hospitalization in the 3 months prior to the assessment. Older people living with frailty occupy a large proportion of hospital bed days, at a significant health care cost, and have an increased risk of death [30]. Implementing the FRAIL Scale tool with the annual health assessment provides a funded opportunity to screen for frailty in general practice, prior to onset, and enact prevention/lifestyle interventions to slow or prevent development. Patient feedback highlighted that being involved in the screening process provided an opportunity to reflect on their health, raised awareness of frailty, and prevention and management strategies. Ease of use with screening results linked to actionable management interventions was identified by staff as a valuable component of the FRAIL Scale tool. Patients expressed trust in the primary care team, which may facilitate implementation and highlight the benefits of screening where people receive their usual health care. However, this research has identified individual and health system enablers and barriers experienced by patients to accessing support and services required for effective frailty prevention and management. Determinants of frailty management related to the availability of local resources and the capability, opportunity, and motivation for patients to access these resources. Increasing knowledge for patients and providers on frailty management, providing social support for healthy aging activities, and improving access to management resources were highlighted as potential facilitators to healthy aging.

Comparison to Prior Work

The rates of prefrailty and frailty (839/1484, 56.5%) in this study are lower than those identified in the pilot study (860/1071, 80%), where both opportunistic screening (at the time of routine procedures) and structured screening were conducted with those aged 75 years and older [11]. This suggests routine screening has the potential for early identification of prefrailty and presents an opportunity for health promotion in early aging.

Other researchers, however, have identified that primary care frailty screening and management tools must have usability and fit with practice workflows and have highlighted the importance of resources or funding for the team to complete frailty assessment [31-34]. This study supports previous findings that implementing the FRAIL Scale tool at the time of the Medicare-funded 75+HA fits with practice workflows, formalizes processes, and renumerates staff time to screen for frailty in this population [11]. In addition, as found in the pilot study, some staff adopted strategies to facilitate the workflow, including incorporating the Tool in the 75+HA templates [11]. However, survey feedback highlighted that embedding the screening tool within practice software was needed to support broader adoption and sustainability of the FRAIL Scale tool in primary care.

In addition, supporting frailty prevention and management for older people in primary care requires knowledge of resources available [15]. While practitioners appreciated the management prompts incorporated in the FRAIL Scale tool, practitioner skill is required to use and encourage behavior change techniques [35] such as social support [36] and goal setting [37] to support healthy aging.

Strengths

With limited research on prefrailty and frailty in community-dwelling adults in Australia [2,38], this research has highlighted the association of hospitalization with increasing rates of frailty in 2 diverse PHN regions in Australia [39].

The Implementation Research Logic Model [40] has been used throughout the research process to guide planning for the implementation of the FRAIL Scale [41]. The use of the Implementation Research Logic Model has enhanced the implementation process and understanding of implementation determinants framed by CFIR and informed strategies for broader implementation.

Limitations

First, screening was conducted across only 24 general practices in regions with larger metropolitan populations of older persons and may not be representative of all patients aged 75 years and older. While participation was offered to all practices in each study region, recruitment of metropolitan practices may reflect those practices that had the opportunity to be involved due to adequate staffing, which is often limited in regional, rural, and remote general practices [42]. Preliminary pilot work by the research team in rural and remote Queensland suggests rates of frailty may be higher in nonmetropolitan regions. Second, as risk of frailty screening was completed as part of the 75+HA in primary care settings, the rates of frailty and prefrailty found in this study may not reflect the rates in the broader population of community-dwelling adults aged 75 years or older. Evaluating screening through other avenues, such as community organizations, will be important to reach a broader representation of this age group. Third, the rates of screening for the Aboriginal and Torres Strait Islander population were low in this study. Frailty is known to occur more frequently and at a younger age in the Aboriginal and Torres Strait Islander population [38], and the acceptability of the FRAIL Scale tool to this population

XSL•FO
RenderX

was not assessed [38]. Fourth, only 25% (n=15) of staff completed the PRESS survey, with just under 50% (n=11) of practices represented, and qualitative interviews were conducted with only 5 staff. While these results may not reflect all users of the FRAIL Scale, after considering the results from previous interviews with practice nurses and GPs conducted in the pilot study [11] and the free text feedback from the PRESS survey, we did not feel we were gathering any further information and focused on the patient interviews. Finally, while practice staff recorded the management recommendations provided to patients based on the Tool, data was not collected on recommendations adopted by patients following their appointment. In addition, qualitative interviews with patients indicated that social relationships are a facilitator to healthy aging, yet social connectedness was not considered in the FRAIL Scale.

Future Research

Screening and management with the Tool is currently being evaluated in Western Queensland, where 20% of the population has an Aboriginal or Torres Strait Islander background [43], to understand rates of frailty and the appropriateness of the Tool for other populations and in rural and remote settings. Screening and management recommendations for addressing social connectedness have been incorporated into the Tool for this ongoing research.

While the FRAIL Scale tool can be readily incorporated into the 75+HA, broader implementation requires the Tool to be incorporated into practice software systems. Endorsement of FHIR (Fast Healthcare Interoperability Resources) standards by the Australian Digital Health Agency [44] has provided an opportunity for the research team to develop and evaluate a FHIR-compatible prototype of the FRAIL Scale tool in conjunction with CSIRO researchers [45]. This will improve interoperability across health systems and allow appropriate sharing of data between practice nurses, GPs, and health providers in other health care settings [46].

Importantly, further research is required to understand the effect of screening for risk of frailty in general practice on frailty awareness in the population and whether management recommendations increase adoption of health behaviors to prevent and reverse frailty, encourage proactive self-management, and slow or reverse frailty progression [47]. Consumer engagement will be vital in the development of appropriate, accessible resources for promoting the benefits of frailty prevention and management [7].

While NSPHN and BSPHN are relatively well-resourced regions with accessible programs and support networks, many regions of Australia lack the accessible, coordinated, multidisciplinary workforce required to effectively identify and manage the risk of frailty. This is made more difficult by the poor integration of Commonwealth, state, private, and not-for-profit services [48,49], identified in the aged care sector [50], and exacerbated in rural Australia by a limited local workforce to deliver effective care [42]. Frailty management would benefit from an alliance governance approach, an internationally accepted methodology, effective in binding such diverse health organizations contractually to collectively deliver an agreed program of work [51]. The research team is currently evaluating the implementation of an alliance governance model to support healthy aging in Western Queensland.

Conclusions

Screening and management of frailty and risk of frailty are not routine in general practice in Australia. A structured approach, using the FRAIL Scale tool at the time of the annual health assessment, has identified 56.5% of the general practice population aged 75 years and older as frail/at risk of frailty. With higher rates of nonelective hospitalization associated with those identified as frail compared with those who were robust/prefrail, routine screening that fits with practice workflows is important in the primary care setting. Importantly, the FRAIL Scale tool provides staff with intervention options to support healthy aging.

Acknowledgments

We would like to acknowledge the contribution of the partner organizations, the Northern Sydney Primary Health Network trading as Sydney North Health Network (SNHN) and Brisbane South Primary Health Network (BSPHN), and the general practices that conducted the data collection.

Funding

This research was funded by a Translational Research Grant from the HCF Research Foundation.

Data Availability

The datasets analyzed for this study are available from the corresponding author on reasonable request.

Authors' Contributions

JJ, CN, RS, DC, AP, and CJ are the principal and associate investigators of the project. JJ, CN, DC, RS, and CJ were extensively involved in the development of the study concept and design and provided project governance. RS and DC collected the data, and JJ and AP designed and conducted the analysis. JJ, RS, CN, and CJ drafted the manuscript. All authors were involved in critically revising the manuscript and read and approved the final manuscript for submission to your journal.

Abstract

Background: Frailty is a complex syndrome characterized by diminished physiological reserves, resulting in increased vulnerability among older adults. Scalable tools that leverage routinely collected laboratory data could enable earlier risk stratification in aging populations.

Objective: The aim of the study is to model frailty risk using Frailty Trait Scale (FTS)-12 scores and biochemical or hematological parameters, and to examine sex-specific patterns in predictors and performance.

Methods: This study analyzed data from a population-based cohort of 1485 individuals aged 65 years or older, drawn from the Toledo Study for Healthy Aging (TSHA). Multiple and logistic regression analyses were used to investigate the relationships between biochemical and hematological parameters, and the FTS-12 score. Predictive models were developed separately for female and male participants, incorporating both single and composite risk factors. Model performance was evaluated using correlation coefficients, coefficients of determination, Akaike information criterion, log-likelihood values, and receiver operating characteristic curves, which summarize how well the models distinguish between higher and lower frailty risk.

Results: The regression models accounted for approximately 40% of the variability in FTS-12 scores, revealing distinct risk factors for each sex. Gamma-glutamyl transferase, albumin, and age were kept as key predictors in the selected models. Several composite risk factor functions were also significantly associated with the FTS-12 score. Correlations between observed and predicted FTS-12 scores were moderately strong, with values of 0.621 (P<.001) for female participants and 0.615 (P<.001) for male participants. Logistic regression models showed moderate-to-good discriminative performance for high frailty probability, achieving receiver operating characteristic area under the curve values of 0.799 for female participants and 0.824 for male participants.

Conclusions: This analysis is an exploratory proof-of-concept study, and the developed models do not constitute validated clinical prediction tools. Routine laboratory profiles demonstrate moderate, sex-specific predictive performance for FTS-12–defined frailty and may, in principle, complement comprehensive geriatric assessment by facilitating the early identification of patients who could benefit from further evaluation and closer clinical follow-up. External validation in independent cohorts is required before any clinical use, alongside longitudinal designs with repeated biomarker measures and integration of additional biological layers, to enhance generalizability and confirm clinical utility. Within these limits, the analysis highlights the potential of routine laboratory data to support digitally enabled frailty screening and workflow-integrated risk stratification in primary care and remote geriatric care settings.

Introduction

Frailty is a multifaceted clinical syndrome characterized by diminished strength, endurance, and physiological function, leading to increased vulnerability to dependency and mortality [1-3]. Its complexity stems from several subtypes, including physical, cognitive, oral, and social frailty [4-6]. Physical frailty and physiological decline have been the most extensively studied. Fried et al [3] distinguished frailty as a condition separate from aging, comorbidity, and disability, noting its clinical reversibility and its role as a precursor to dependency in older adults. While unhealthy aging provides a context for frailty development, it is not an inevitable outcome, as individuals may exhibit varying levels of frailty over time [1,7-9]

Assessment tools such as the Fried Frailty Phenotype and the Frailty Index (FI) are routinely used in clinical practice to evaluate frailty. The Fried Frailty Phenotype identifies 5 dimensions—weakness, low endurance, slowness, low physical activity, and weight loss—and classifies individuals as frail if they perform poorly in 3 or more domains [3]. In contrast, the FI conceptualizes frailty as the accumulation of deficits that predispose individuals to adverse outcomes, including mortality and hospitalization [10]. Despite their widespread validation, both methods have limitations in clinical settings, such as being time-intensive and challenging for monitoring subtle changes over time [11,12]. To address these gaps, newer approaches have expanded the conceptualization of frailty. García-García et al [11,13] introduced the Frailty Trait Scale (FTS)-12, which considers frailty as a biological trait encompassing additional domains, including vascular and nervous system health and nutritional status. The FTS has 3 validated versions (FTS-12, FTS-5, and FTS-3), each capturing different dimensions of frailty. These scales exhibit high sensitivity and accuracy in detecting frailty and predicting adverse health outcomes, such as hospitalization, fractures, and mortality. Among these, FTS-12 is effective in comprehensively assessing frailty and its associated risks [11].

Since 2022, we have pursued a screening-oriented approach to investigate whether routinely available laboratory data can help identify older adults at increased risk of frailty. In this study, we examined whether common biochemical and hematological parameters could be used to predict the FTS-12 score and to identify individuals more likely to fall within the highest frailty range. Beyond its statistical relevance, this approach may contribute to health care innovation by evaluating whether low-cost, routinely available laboratory data can support practical frailty risk stratification within digitally enabled geriatric care. In this context, this study aims (1) to develop an equation to predict an FTS-12 score of an older individual based on their biochemical profile; (2) to determine whether frailty, as assessed by the FTS-12 scale, can be predicted to fall within the upper range of the distribution using routinely available blood-based biomarkers; and (3) to establish exploratory criteria for selecting predictive equations based on observed frailty estimates.

This study is conceived as an exploratory, proof-of-concept analysis, and the resulting models should not be regarded as validated clinical prediction tools. The approach is not intended to replace comprehensive clinical assessment of frailty; rather, it explores whether routinely available laboratory data carry meaningful frailty-related signals that could, pending external validation, eventually support preliminary screening of older individuals with a high probability of frailty.

Methods

Data Origin

This analysis used data from the Toledo Study for Healthy Aging (TSHA), a prospective, population-based cohort study investigating the determinants and consequences of frailty syndrome in older adults living in Toledo, Spain [14]. The study included 1972 participants who completed a home-based interview and physical evaluation, with biological samples provided by 1752 individuals for laboratory analysis. Baseline data were collected between June 2006 and September 2009, and participants were followed for an average of 3.5 (SD 1.19; range 0.30 - 4.79) years to evaluate study outcomes [11].

FTS-12, Blood Collection, and Measured Traits

The FTS-12 served as the dependent variable in statistical analyses. This scale includes 12 items across 7 dimensions. To calculate the FTS-12 score for each participant, the TSHA collected data in the following areas: (1) self-reported comorbidities, (2) basic and instrumental activities of daily living, (3) depressive symptoms, and (4) cognitive function. Trained nurses conducted physical examinations and clinical tests at participants' homes to supplement these data. Detailed assessment methods are provided in García-García et al [11].

Participants also provided 12-hour fasting blood samples, from which two primary categories of variables were derived: (1) 15 variables assessing blood characteristics (hemogram) and (2) 19 variables measuring biochemical characteristics (biochemical profile), along with an added 12 unique biochemical traits not included in the standard profile. In total, 46 blood-related variables, combined with participants' age, were included in the original database.

Ethical Considerations

The TSHA was approved by the clinical research ethics committee of the Complejo Hospitalario de Toledo, Toledo, Spain. The original cohort study ("Estudio Toledo de Envejecimiento") received ethics approval on March 30, 2005 (application 22). In addition, the specific research project entitled "Predictors of frailty, disability, cognitive impairment, vascular events, hospitalization, and mortality in a cohort of adults older than 64 years. Toledo Study for Healthy Aging" was approved on July 14, 2010 (application 93). All participants provided written informed consent before enrollment. This study is a secondary analysis of previously collected cohort data.

Statistical Analysis

Exploratory Data Analysis

The software programs JMP (version 13.2) and SAS Enterprise Guide (version 7.1; SAS Institute Inc) were used to perform descriptive statistical methods for each sex independently and to identify potential data anomalies [15,16]. Descriptive statistics included (1) examining data dispersion for individual variables and correlations between potential explanatory variables, (2) identifying plausible probability distributions for each variable, (3) detecting potential outliers mainly by using box plot analysis, and (4) analyzing the relationship between the main dependent variable (FTS-12) and possible explanatory variables. The final database included measurements from 1485 individuals aged 65 years and older, comprising 848 female participants and 637 male participants.

Missing Data

Missing data were present in less than 5% of observations across study variables. Analyses were conducted using complete cases only (listwise deletion). This approach is valid under the reasonable assumption that data were missing completely at random. Since the small amount of missingness was mostly caused by small problems during blood sample collection, this assumption was deemed reasonable. Given the low proportion of missingness, potential bias due to exclusion of incomplete cases was considered negligible. The exclusion of missing data is the default procedure in SAS Enterprise Guide (version 7.1) software.

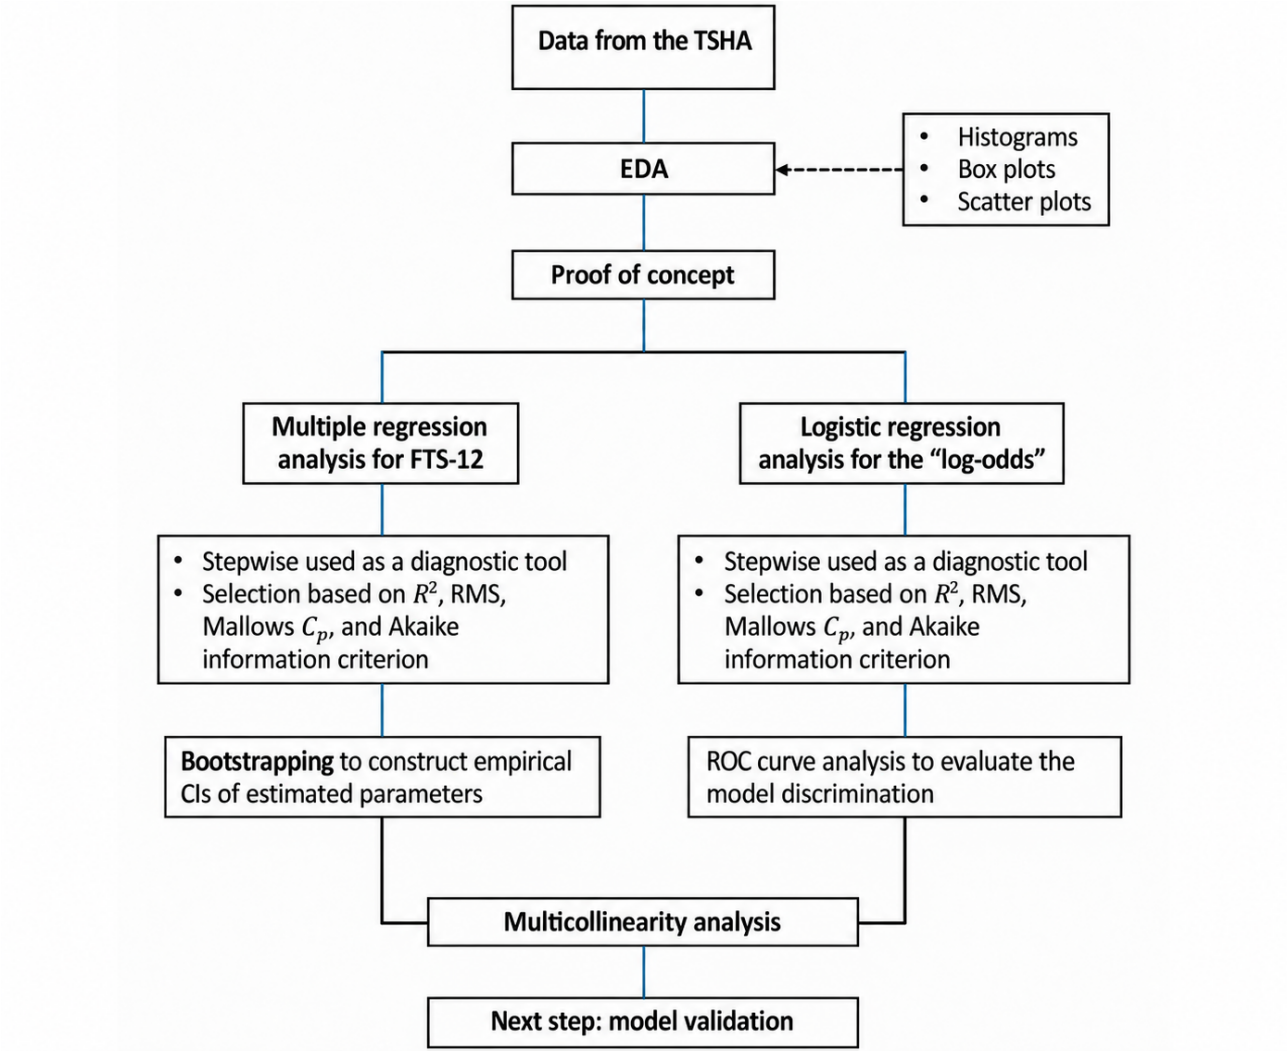
Modeling Regression Equations to Predict the FTS-12 Score

Two predictive models of FTS-12 scores were developed based on the following criteria: (1) sex and (2) available biological information, which included data from the biochemical profile and hemogram. The models were constructed using the theory of linear models in the framework of multiple regression analysis [17-19]. The mathematical formulations of the regression models are provided in Multimedia Appendix 1. Additional details regarding the model and its underlying assumptions are provided in Multimedia Appendix 2. We used a 2-stage, data-driven selection process. Predictors were initially screened based on their Pearson correlation with the outcome $r \geq 0.18$. A stepwise multiple regression was then applied to the remaining variables [17,18]. This approach was used for exploratory purposes, and the results should be interpreted cautiously. This approach was selected and justified because (1) we have a very large number of predictors (n=46); (2) this is a proof-of-concept analysis for predictive purposes (FTS-12 score and high-frailty probability, as described below), rather than an inferential analysis; (3) results must be treated as "exploratory and preliminary," and the stepwise was used as a diagnostic tool, not a decision rule; and (4) the final model will be validated on independent data. Selection criteria included the coefficient of determination, residual mean square, Mallows C_p statistic, and Akaike information criterion (AIC). All statistical calculations were performed using the PROC REG procedure in SAS (version 9.4).

Bootstrapping in multiple regression can be used to support statistical inference when classical assumptions are questionable or when sample size is limited. Bootstrapping was unnecessary in our multiple regression analysis. The size of the database is large; residual effects followed a normal distribution, and there were no heteroscedasticity problems. Here, bootstrapping is optional. However, we considered performing bootstrapping as a complement to the selection process. We used the stepwise selection procedure, and bootstrapping was applied to construct empirical CIs for the parameter estimates. The "bootstrapping" analysis was then conducted for the selected multiple regression models using the PROC SURVEYSELECT and PROC REG procedures in SAS (version 9.4). We generated 1000 subsamples of size 500 from the dataset and fitted a regression model for each subsample. From these models, 95% CIs for each parameter and the model's coefficient of determination were computed by calculating the 2.5% and 97.5% percentiles. A summary of bootstrapping is shown in Multimedia Appendix 2. Because the multiple regression model predicts a continuous outcome, calibration in the probabilistic sense was not applicable; instead, model performance was evaluated using goodness-of-fit measures (eg, R^2) and residual diagnostics and agreement between observed and predicted values. These approaches provide an assessment of model performance analogous to calibration in probabilistic models.

Modeling the Odds of Reaching Maximum FTS-12 Scores

FTS-12 scores ranged from 1 to 100. To analyze frailty levels, the 3 quartiles of the distribution were calculated, dividing frailty data into 4 distinct quarters [11]. Each individual's FTS-12 score was assigned to one of these 4 quarters, treating an individual's FTS-12 value in any quarter as a binomial (binary) variable. The fourth quarter—standing for the highest frailty levels—was of primary interest in this study. This quarter included FTS-12 values above the third quartile (scores >55), representing the highest frailty scores in this cohort. This upper-quartile definition was used as a cohort-specific analytical threshold to identify the subgroup with the highest frailty burden within the present sample and should not be interpreted as a universal clinical cutoff for the FTS-12 scale. For any individual in the original TSHA data with an FTS-12 value equal to or above 55, a "1" was assigned under a newly created "fourth quarter" column, while scores below this threshold were assigned a "0." We defined a binary response variable, Y, such that $Y=1$ if an individual's FTS-12 score exceeded the third quartile (ie, fell within the highest—fourth—quarter), and $Y=0$ otherwise. Therefore, a multiple logistic regression analysis was conducted for the binary variable representing the fourth quarter, following the approach described by Hosmer et al [20]. Logistic regression enables the prediction of the odds of a particular event occurring as a function of observed values for a set of potential explanatory variables. Depending on the context, these variables are referred to as independent variables, risk factors, predictors, or regressors. Additional details regarding the logistic model and its underlying assumptions are provided in Multimedia Appendix 2. Regression analysis was conducted using JMP (version 13.2) software, along with the LOGISTIC procedure in SAS (version 9.4) and SAS Enterprise



XSL•FO
RenderX

Guide (version 7.1). A stepwise regression approach, as outlined by Hosmer and Lemeshow [20], was applied as the selection method. Selection criteria included the coefficient of determination, residual mean square, Mallows C_p statistic, and AIC. Finally, we generated receiver operating characteristic (ROC) curves to illustrate how well the binary models distinguished between higher and lower frailty probability. As in the multiple regression analysis, this approach was used for exploratory purposes, and the results should be interpreted cautiously. Bootstrapping was not performed in the logistic regression analysis because of the large sample size and the fact that the number of events per variable exceeded 20 in the binary outcome. Instead, ROC curve analysis was used to assess how well the models distinguished between higher and lower frailty probability. This analysis provided area under the curve (AUC) estimates for the selected variables and allowed comparison of their discriminatory performance.

Multicollinearity was assessed to determine whether some independent variables carried overlapping information that could make coefficient estimates unstable. Collinearity in both the multiple and logistic regression models was evaluated using variance inflation factors (VIFs). Values of 5 or higher were considered indicative of problematic collinearity. In this study, no relevant multicollinearity was detected, as all VIF values were below 2.0. A summary of this analysis is provided in Multimedia Appendix 2.

Figure 1 shows a flowchart summarizing the analysis steps. As proof of concept, we conducted this preliminary analysis to assess the feasibility of the proposed approach. This analysis was not intended to provide definitive inference, but rather to demonstrate that the proposed method can be implemented and yield meaningful results under realistic conditions.

Figure 1. Flowchart summarizing the methodological workflow of the proof-of-concept study using data from the TSHA. EDA included histogram, box plot, and scatter plot visualizations. The FTS-12 score was analyzed using multiple linear regression, while the binary log-odds outcome was analyzed using logistic regression. A stepwise variable selection method was applied as an exploratory diagnostic tool, together with added model selection criteria. Bootstrapping procedures were incorporated into the multiple regression analysis, and ROC curve analysis was applied within the logistic regression framework. Multicollinearity assessment was conducted for both regression approaches. External model validation is pending and will be addressed in future work to further improve the variable selection process. EDA: exploratory data analysis; FTS-12: Frailty Trait Scale 12; RMS: residual mean square; ROC: receiver operating characteristic; TSHA: Toledo Study for Healthy Aging.

Results

The results presented in this section correspond to an exploratory, proof-of-concept analysis and should be read accordingly: the estimates and discriminatory measures reported are intended to characterize the frailty-related signal contained in routine laboratory data, not to define validated clinical prediction tools. Their interpretation is therefore conditional on external validation in independent cohorts.

Age and FTS-12 Values

The mean age of participants included in the selection process was 75.04 (SD 5.84; range 65 - 95) years for female participants and 74.95 (SD 5.63; range 65 - 99) years for male participants. The mean FTS-12 scores observed in the study were 46.68 (SD 15.99; range 6 - 92.11) for female participants and 39.62 (SD 15.43; range 0 - 84) for male participants. The original database comprised 847 (57%) female participants and 637 (43%) male participants.

Models Based on FTS-12 Values: Selected Risk Factors and Functions

Tables S1 and S2 in Multimedia Appendix 3 summarize the variables retained in the regression models for female participants and male participants, respectively. In both sexes, the selected models combined individual laboratory markers with composite functions derived from clinically relevant variables. Table 1 presents the diagnostic statistics for the models stratified by sex. The *F*-statistics for both models were highly significant ($P<.001$), and the root mean square error ranged from 12 to 12.45. These findings highlight the relevance of both individual risk factors and their combined effects in modeling FTS-12 scores. Overall model performance was moderate, with R^2 values of approximately 0.39 in female participants and 0.38 in male participants. The parameter estimates and associated statistics for the selected multiple regression models in female and male participants are presented in Tables 2 and 3, respectively. The definitions and mathematical expressions of the composite risk factors used across the regression models are provided in Table 4.

Figures 2 and 3 further illustrate the modeling quality of the models. A moderately strong Pearson correlation was observed between the observed and modeled FTS-12 scores for both sexes, with correlations of 0.621 for female participants and 0.615 for male participants. The predicted FTS-12 scores were reasonably aligned with the observed scores in both sexes, supporting the feasibility of this approach while also indicating that substantial prediction uncertainty remains. The scatter plots visually represent this positive relationship, with a colored ellipsoid enclosing 90% of the data points. Higher correlations indicate better agreement between observed and predicted FTS-12 values.

Table . Descriptive characteristics and diagnostic analysis of selected multiple regression models for female and male participants[a].

Statistics	Case study	
	Female	Male
F value	46.81 (10, 744)	37.22 (9, 550)
P value	<.001	<.001
Root MSE[b]	12.45	12.00
R^2	0.39	0.38
Percentile 97.5% for R^2	0.436	0.493
Percentile 2.5% for R^2	0.298	0.312
Adjusted R^2	0.38	0.37
Total of observations read	847	637
Total of observations used	755	560
Simple Pearson correlation between observed and expected values of FTS-12[c]	0.621	0.615

[a]Percentiles 97.5% and 2.5% for R^2 were obtained by using the Bootstrapping technique. See the Modeling Regression Equations to Predict the FTS-12 Score section for further details.

[b]MSE: mean square error obtained from the ANOVA table of regression analyses.

[c]FTS-12: Frailty Trait Scale 12.

[a]CRF2 and CRF3 are composite risk factors defined in Table 4. Simple Pearson correlations between each risk factor in the selected reduced model and the FTS-12 score are also shown.

[b]FTS-12: Frailty Trait Scale 12.

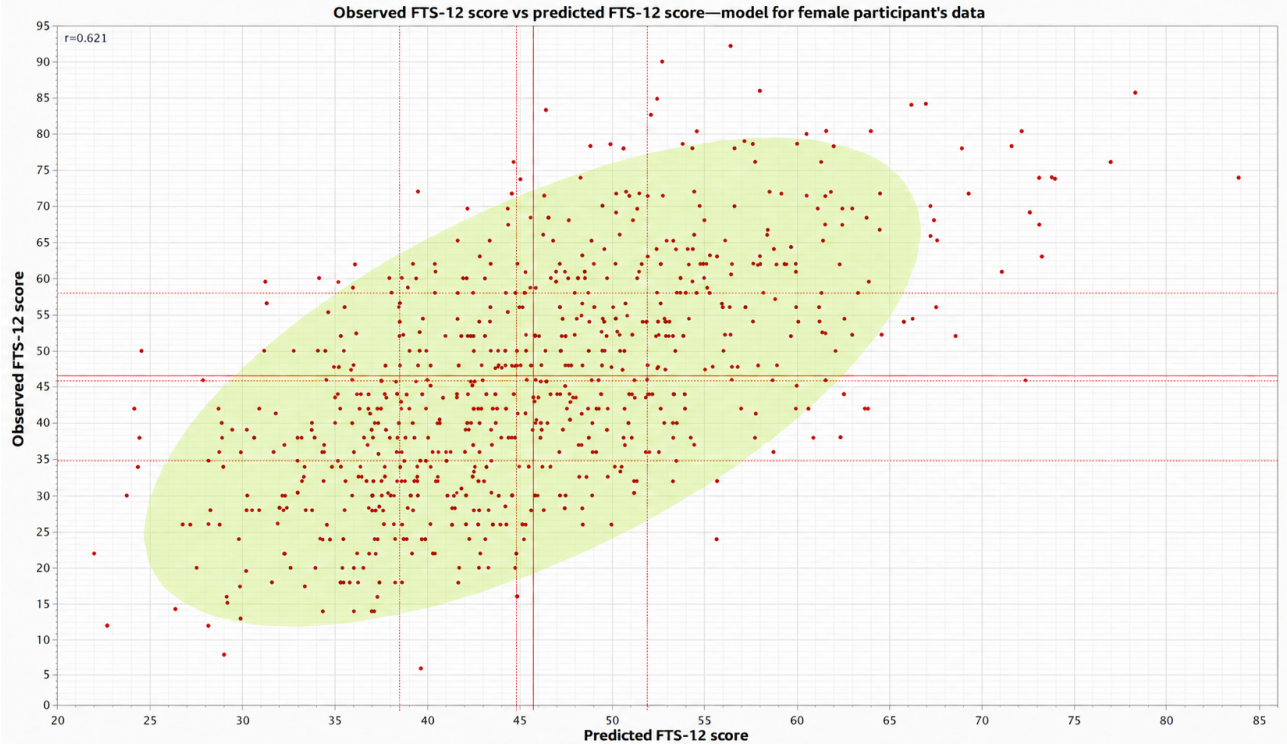
[c]Not available.

[d]CRF: composite risk factor.

[e]GGT: gamma-glutamyl transferase.

Table . Definitions of composite risk factors (CRFs) used in the regression models[a].

Label	Descriptor	Formula	Selected in model
CRF1	RDW[b]-age-albumin composite	$\ln(RDW \times age^3/albumin)$	Female participants, multiple regression
CRF2	Alkaline phosphatase-age-albumin composite	$\ln(AlkPhos^c \times age/Albumin)$	Female and male participants, multiple regression
CRF3	Albumin-age composite	ln(albumin)×00/age	Male participants, multiple regression; female participants, logistic regression
CRF4	Hemoglobin-age composite	$Hemoglobin \times 10^5/age^3$	Male participants, logistic regression



[a]Logarithmic transformations were applied to better capture nonlinear relationships between predictors and the Frailty Trait Scale 12 score, consistent with standard practice in regression modeling [21]. CRF identifiers are used throughout the paper; full mathematical definitions appear only in this table.

[b]RDW: red cell distribution width.

[c]AlkPhos: alkaline phosphatase.

Figure 2. Observed versus modeled FTS-12 score using the selected multiple regression model in female participants (n=848). The horizontal axis shows the FTS-12 score predicted by the sex-specific multiple regression model (which retained age, albumin, gamma-glutamyl transferase, and selected composite risk factors as predictors; Table 2), and the vertical axis shows the FTS-12 score observed for each participant. The simple Pearson correlation was 0.621 (P<.001). Continuous vertical and horizontal red lines show the mean values for the modeled and observed FTS-12. Dashed vertical and horizontal red lines are the first (lower), second (median), and third (upper) quartiles. The shaded ellipse is the region encompassing 90% of the plotted data. A higher correlation, and closer alignment of points along the diagonal, indicate better agreement between observed and modeled FTS-12 values. The moderate dispersion observed is consistent with the multidimensional nature of frailty, only part of which is captured by routine laboratory data. FTS-12: Frailty Trait Scale 12.

XSL•FO
RenderX

Figure 3. Observed versus modeled FTS-12 scores using the selected multiple regression model in male participants (n=637). The horizontal axis shows the FTS-12 score predicted by the sex-specific multiple regression model (which retained age, albumin, gamma-glutamyl transferase, and a composite risk factor as predictors; Table 3), and the vertical axis shows the FTS-12 score observed for each participant. The simple Pearson correlation was 0.615 (P<.001). Continuous vertical and horizontal red lines show the mean values for the modeled and observed FTS-12. Dashed vertical and horizontal red lines are the first (lower), second (median), and third (upper) quartiles. The shaded ellipse is the region encompassing 90% of the plotted data. A higher correlation, and closer alignment of points along the diagonal, indicate better agreement between observed and modeled FTS-12 values. The moderate dispersion observed is consistent with the multidimensional nature of frailty, only part of which is captured by routine laboratory data. FTS-12: Frailty Trait Scale 12.

Regression Analysis of Statistical Models

Tables 2 and 3 present the regression parameter estimates and related statistics for the 2 selected models. The composite risk functions were more strongly related to the FTS-12 score than most single laboratory variables. This suggests that frailty is better captured by combinations of biologically related markers than by isolated biomarkers alone. In female participants, the strongest association was observed for the function combining red cell distribution width (RDW), age, and albumin, whereas in male participants, the strongest association involved albumin- and age-related composite terms. These findings support the idea that frailty risk is influenced by interacting physiological processes rather than by a single laboratory abnormality. To enhance visualization, colored ellipsoids enclosing 90% of the data points are included in both figures. These ellipsoids highlight the trends that informed the selection of these functions for the models. Notably, the relationship is not strong enough to approximate a straight line. If they were, each value of the function composite risk factor (CRF) 1 (Figure S1 in Multimedia Appendix 4) or CRF3 (Figure S2 in Multimedia Appendix 4) would correspond to only 1 or a few closely related FTS-12 values. Instead, the ellipsoids suggest a broader range of FTS-12 scores for a specific value of each function. Nonetheless, a positive trend is evident for CRF1 (Figure S1 in Multimedia Appendix 4), while a negative trend is observed for CRF3 (Figure S2 in Multimedia Appendix 4). Comparatively, correlations with single risk factors were moderate. For female participants, the highest correlation was 0.187 (P<.001) for uric acid, with a positive correlation observed for gamma-glutamyl transferase (GGT; 0.120; P=.001). In contrast, GGT showed a negative correlation in male participants (−0.128; P=.001).

Correlations between FTS-12 and key variables such as age, RDW, albumin, and alkaline phosphatase were also examined. Age and albumin were of particular interest, as they were included in all CRF functions, regardless of sex. For age, the correlation was 0.515 (P<.001) in female participants and 0.476 (P<.001) in male participants. For albumin, the correlation was −0.389 (P<.0001) in female participants and −0.427 (P<.001) in male participants. Despite its moderately high correlation, albumin was not selected as an "individual variable." Plausible reasons for this exclusion are discussed later in the text.

Models Based on High Frailty Probability: Selected Risk Factors and Functions

Tables S3 and S4 in Multimedia Appendix 3 summarize the statistics for the predicted probabilities (hereafter referred to as "the probabilities") and the independent variables, including individual risk factors and composite functions, incorporated into the selected logistic models for female participants and male participants, respectively. These tables also include information on "age" and several other risk factors. Although these variables were not selected as individual predictors, they are components of the CRF functions named through the selection process.

XSL•FO
RenderX

Table 5 provides descriptive statistics and diagnostic parameters for the selected logistic models. Among the participants, 200 of 735 (27%) in the female participants and 100 of 564 (18%) in the male participants had FTS-12 scores in the fourth quarter (above the third quartile, showing a high probability of frailty). The remaining participants in each group were distributed across the lower 3 quarters.

Table . Descriptive characteristics and diagnostic analysis of selected logistic regression models for female participants and male participants.

Statistics	Case study	
	Female participants	Male participants
Observations read, n	847	637
Observations used, n	735	564
Observations with an FTS-12[a] value located in the fourth interval (larger than the third quartile), n	200	100
Observations with an FTS-12 value not located in the fourth interval (larger than the third quartile), n	535	464
Model fit statistics criterion		
AIC[b]	696.4	421.8
−2 Log *L*	682.4	403.8
Max-rescaled R^2	0.312	0.323
Testing global null hypothesis: only intercept		
Likelihood ratio		
Chi-square (*df*)	178.0 (6)	123.3 (10)
P value	<.001	<.001

[a]FTS-12: Frailty Trait Scale 12.

[b]AIC: Akaike information criterion.

Tests of the global null hypothesis were highly significant (*P*<.001), showing that at least 1 independent variable—whether a single risk factor or a composite function of risk factors—was significantly associated with the probability of FTS-12 falling into the uppermost range.

Tables 6 and 7 summarize the estimated parameters and associated statistics for the selected models applied to female and male participants, respectively. The model for female participants includes 5 single variables and 1 composite function of risk factors. In contrast, the model for male participants comprises 7 single variables and 1 composite function of risk factors.

[a]Simple Pearson correlations between each risk factor included in the selected model and the estimated probability of the FTS-12 values greater than the third quartile of the distribution are also presented. CRF4 is a composite risk factor defined in Table 4. Pearson correlations between each risk factor and the modeled probability of falling above the FTS-12 third quartile are also presented, together with odds ratio estimates.

[b]Not applicable.

[c]CRF: composite risk factor (Table 4).

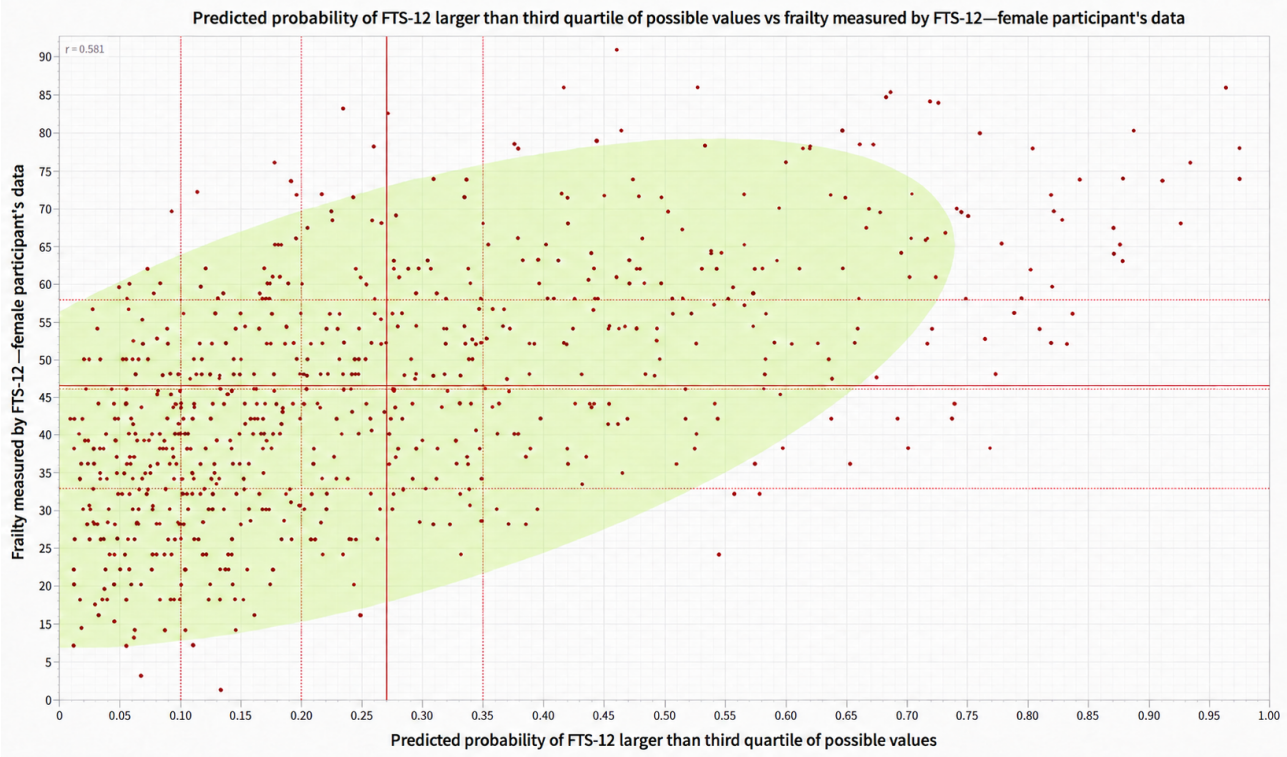
[d]CHCM: mean corpuscular hemoglobin concentration.

[e]FTS-12: Frailty Trait Scale 12.

Considering the Wald chi-square statistics, the presence of CRF3, granulocytes, and GGT is highly significant and essential in the model for female participants. For male participants, CRF4, albumin, hemoglobin, triglycerides, and phosphorus are identified as highly significant and critical associated factors. Tables 6 and 7 also present Pearson correlations between each selected independent single variable or composite function of risk factors and the modeled probability. Additionally, these tables include correlations between the modeled probability and both age and FTS-12 scores within the working datasets. In absolute terms, correlations involving composite functions of risk factors exceeded 0.64 (*P*<.001). Notably, the function CRF3 in female participants showed particularly strong correlations. Among the single risk factors, albumin showed a highly negative correlation in the selected model for male participants.

Figures S3 and S4 in Multimedia Appendix 4 illustrate the functional relationship between the modeled probability and the composite functions of risk factors with the highest correlations. However, these associations were nonlinear. For the logistic model applied to female participants, the relationship between the observed values of the function and the predicted probability followed an inverted logistic S-curve (Figure S3 in Multimedia Appendix 4), with a simple correlation of −0.871 (*P*<.001). When the value of the function exceeded 2.20, the probability fell below .20 (odds of 1 to 4). Conversely, when values of the function were less than 1.55, the probability exceeded .70 (odds of 7 to 3).

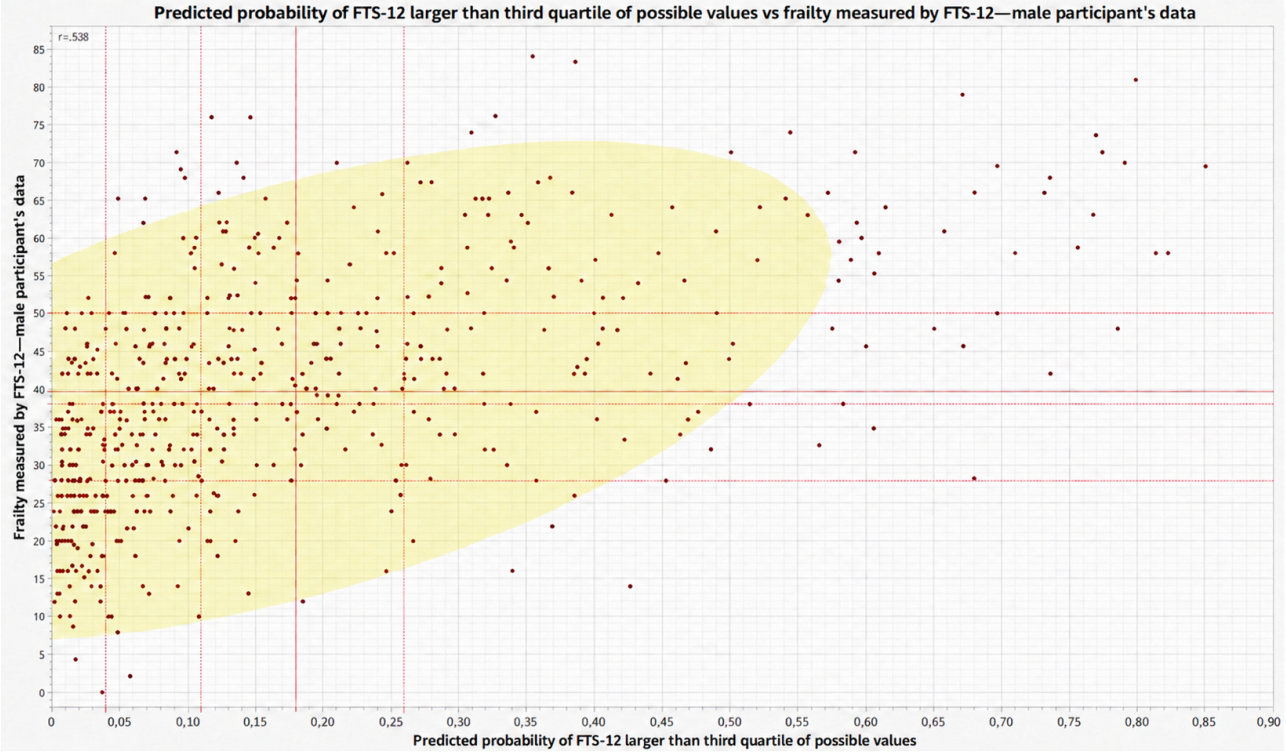
Similarly, for the logistic model in male participants, the relationship between function CRF4 and the modeled probability also followed an inverted logistic S-curve (Figure S4 in Multimedia Appendix 4), with a simple correlation of −0.641 (*P*<.001). Here, values of the function above 4.75 corresponded to probabilities lower than .20 (odds of 1 to 4), whereas values below 1.50 were associated with probabilities exceeding .70 (odds of 7 to 3). We also estimated the simple correlations between the modeled probability and both patient age and observed FTS-12 values in the original datasets. Age was consistently included in all composite functions of risk factors selected by the selection process. All correlations were highly significant (*P*<.001), irrespective of sex. Notably, correlations



XSL•FO
RenderX

with age were stronger than those with FTS-12 (Tables 6 and 7).

Multimedia Appendix 4 also illustrates the functional relationship between the modeled probability and age in the selected models. For female participants, the scatter plot in Figure S5 in Multimedia Appendix 4 demonstrates that the distribution of values aligns closely with a logistic S-curve. Similarly, for male participants, Figure S6 in Multimedia Appendix 4 exhibits a positive trend, also resembling a logistic S-curve.



Positive correlations between the observed FTS-12 values and the modeled probabilities are clearer in the scatter plots presented in Figures 4 and 5 for male and female participants, respectively. While the dispersion of points in both plots shows a moderate correlation, a clear trend appears, highlighting the prediction capability of the selected models. This consistency in predictive performance is clear across both sexes.

Figure 4. Scatter plot of observed FTS-12 values versus the modeled probability of the frailty scores larger than the third quartile of the distribution of possible FTS-12 values, based on the selected logistic model in female participants (n=848). The horizontal axis shows the modeled probability returned by the sex-specific logistic regression model (which retained albumin- and age-based composite risk factors and selected single biomarkers as predictors; Table 6), and the vertical axis shows the observed FTS-12 score for each participant. The probability quantifies the model-estimated likelihood that an individual falls within the highest-burden frailty subgroup of the cohort (ie, above the FTS-12 third quartile), used here as an internal analytical cutoff rather than as a clinical threshold. The Pearson correlation coefficient is 0.581 (P<.001). Continuous red lines are the mean values of the observed FTS-12 values and the modeled probability, while dashed red lines mark the first (lower), second (median), and third (upper) quartiles. The shaded ellipse is the region encompassing 90% of the plotted data. FTS-12: Frailty Trait Scale 12.

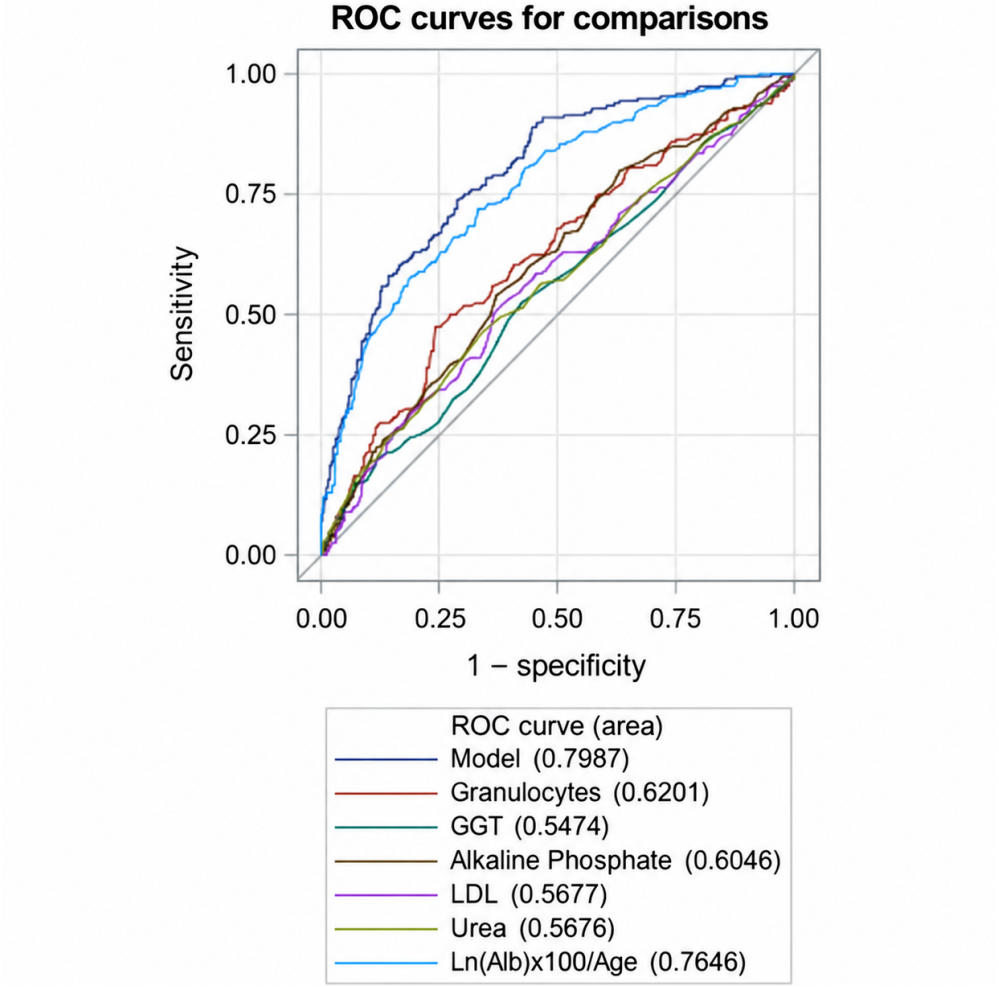
Figure 5. Scatter plot of observed FTS-12 values versus the modeled probability of the frailty scores larger than the third quartile of the distribution of possible FTS-12 values, based on the selected logistic model in male participants (n=637). The horizontal axis shows the modeled probability returned by the sex-specific logistic regression model (which retained hemoglobin- and age-based composite risk factors and selected single biomarkers as predictors; Table 7), and the vertical axis shows the observed FTS-12 score for each participant. The probability quantifies the model-estimated likelihood that an individual falls within the highest-burden frailty subgroup of the cohort (ie, above the FTS-12 third quartile), used here as an internal analytical cutoff rather than as a clinical threshold. The Pearson correlation coefficient is 0.538 (P<.001). Continuous red lines are the mean values of the observed FTS-12 values and the modeled probability, while dashed red lines mark the first (lower), second (median), and third (upper) quartiles. The shaded ellipse is the region encompassing 90% of the plotted data. FTS-12: Frailty Trait Scale 12.



Discriminatory Performance of the Logistic Models (ROC Analysis)

Using the AIC and −2Log *L* (minus 2 log-likelihood) to assess goodness-of-fit, the model for male participants proved a better fit compared to the model for female participants. Additionally, chi-square statistics derived from the likelihood ratio test provided strong evidence that the independent variables significantly influenced both selected models. The intercept alone was insufficient to explain the observed log-odds—the logarithm of the ratio between the probability of a FTS-12 value being larger than the third quartile of the distribution, and the probability of it not doing so. In addition to goodness-of-fit metrics, ROC curve analysis was used to evaluate the discriminatory performance of the selected logistic models. Tables S5 and S6 in Multimedia Appendix 3 provide statistics from the ROC analysis of the selected logistic models for both sexes. The ROC curves align closely with the goodness-of-fit statistics. For female participants, the AUC was approximately 0.799. Table S5 in Multimedia Appendix 3 and Figure 6 show that the function CRF3 was the most influential risk factor, accounting for 76% of the total AUC and closely approximating the model's overall AUC. For male participants, the AUC was approximately 0.824. Table S6 in Multimedia Appendix 3 and Figure 7 reveal that CRF4 and albumin were the most influential risk factors, contributing 73% and 71% of the total AUC, respectively.

Figure 6. ROC curves for the selected logistic regression model and partial models in female participants (n=848). The ROC curve for the selected logistic regression model is shown alongside the ROC curves of partial models that include individual or composite risk factors for comparison. The curves illustrate the discriminatory power for the log-odds (and related probability) of an FTS-12 score in the uppermost range (above the third quartile) of the cohort. The horizontal axis shows 1–specificity (false positive rate), and the vertical axis shows sensitivity (true positive rate); the diagonal represents a noninformative classifier. The AUC for the selected model was 0.799, indicating moderate-to-good discrimination, and was substantially higher than the AUC of any model built on a single biomarker. The largest contribution among the partial models came from CRF3, accounting for approximately 76% of the total AUC. Key statistics, including the AUC for each model, highlight the improvement in predictive performance when combining risk factors in the selected model. CRF3 (the albumin-age composite) is defined in Table 4. AUC: area under the curve; CRF: composite risk factor; FTS-12: Frailty Trait Scale 12; GGT: gamma-glutamyl transferase; LDL: low-density lipoprotein; ROC: receiver operating characteristic.

Figure 7. ROC curves for the selected logistic regression model and partial models in male participants (n=637). The ROC curve for the selected logistic regression model is shown alongside the ROC curves of partial models that include individual or composite risk factors for comparison. The curves illustrate the discriminatory power for the log-odds (and related probability) of an FTS-12 score in the uppermost range (above the third quartile) of the cohort. The horizontal axis shows 1–specificity (false positive rate), and the vertical axis shows sensitivity (true positive rate); the diagonal represents a noninformative classifier. The AUC for the selected model was 0.824, indicating moderate-to-good discrimination, and was substantially higher than the AUC of any model built on a single biomarker. The largest individual contributions to the model AUC came from CRF4 (approximately 73% of the total AUC) and albumin (approximately 71%). Key statistics, including the AUC for each model, highlight the improvement in predictive performance when combining risk factors in the selected model. CRF4 (the hemoglobin-age composite) is defined in Table 4. AUC: area under the curve; CHCM: mean corpuscular hemoglobin concentration; CRF: composite risk factor; FTS-12: Frailty Trait Scale 12; ROC: receiver operating characteristic.

Discussion

Principal Findings

This exploratory study aimed to identify and refine sex-specific predictive equations for the FTS-12 score using routinely available biochemical and hematological data, including an analytical strategy to estimate the likelihood of belonging to the highest frailty range of the cohort. In line with these aims, the study showed that sex-specific multiple regression models could estimate the FTS-12 score with moderate accuracy, and that sex-specific logistic models could identify predictors associated with being in the upper range of the FTS-12 distribution. Across both approaches, age, albumin, GGT, and several composite variables emerged as recurrent contributors, suggesting that frailty-related laboratory signals are better captured through combinations of markers than through most single biomarkers alone. Taken together, these findings support the feasibility of a low-cost, laboratory-based approach for exploratory frailty risk stratification, but the present models do not constitute validated clinical prediction tools and would require external validation in independent cohorts before any clinical application can be considered.

Interpretation of Findings and Comparison With Previous Literature

Our findings suggest that routinely available biochemical and hematological data can provide a meaningful, although still imperfect, estimate of frailty burden as measured by the FTS-12 score, as well as of the likelihood of being in the highest frailty range of the cohort. Some uncertainty in prediction is expected, as the FTS-12 reflects a multidimensional construct integrating 7 dimensions, including energy balance, nutrition, and vascular system components [11], rather than a single biological process. In this context, combinations of laboratory variables performed better than most isolated biomarkers, consistent with the stronger associations observed for the selected composite risk functions in both sexes (Tables 2 and 3 and Figures S3 and S4 in

XSL•FO
RenderX

Multimedia Appendix 4). The logarithmic transformations applied to variables such as albumin, age, and hemoglobin should be understood as a way to capture nonlinear clinical relationships and improve model fit, rather than as an end in themselves [21]. For example, combinations involving age and albumin may reflect the joint contribution of aging-related vulnerability and reduced nutritional or systemic reserve, in line with literature linking low albumin and hypoproteinemia to frailty, inflammation, and nutritional vulnerability in older adults [22,23]. Likewise, functions including RDW, hemoglobin, or albumin may capture overlapping signals related to erythrocyte heterogeneity, oxygen-carrying capacity, anemia-related vulnerability, and physiological resilience, consistent with evidence associating RDW and lower hemoglobin status with frailty in older populations [24,25]. In the logistic models, composite risk functions showed the strongest associations with higher frailty probability; and in male participants, albumin also emerged as an important contributor, supporting the interpretation of frailty as a multidimensional state of vulnerability shaped by interacting biological processes.

The models explained about 40% of the variability in FTS-12 scores, indicating moderate predictive performance. This level of explanation is clinically meaningful for an initial screening-oriented approach, while also showing that a substantial part of frailty remains influenced by factors not captured in laboratory-based models—a multidimensional syndrome reflecting biological, functional, cognitive, psychosocial, and environmental factors. The unexplained variance is therefore expected and reinforces that these models should be viewed as complementary tools rather than substitutes for comprehensive geriatric assessment, with future improvements depending on incorporating additional clinical, behavioral, and social determinants of frailty. Notably, albumin and age emerged as key associated factors consistently included across all composite functions, with logarithmic transformations capturing nonlinear relationships more effectively than models based solely on individual risk factors.

Recent literature includes only a few studies that model frailty risk using biochemical traits in older adults [21,23,26]. Several recent works have developed statistical models for frailty and frailty-associated outcomes such as mortality, most of them using logistic regression [27-30]. For example, Bencivenga et al [31] examined a FI composed of 38 multidimensional health deficits—including comorbidities, laboratory and diagnostic data, and symptoms and signs of disease—using procedures outlined by Searle et al [32]; the independent variables in their multiple regression model included sex (binary), age, BMI, and muscle thickness of the vastus intermedius and rectus femoris. Logistic regression is a widely used technique for modeling binary dependent variables in this setting [33-35]. Wang et al [36] provide a recent example using logistic regression and ROC curve analysis to compare 2 FIs in classifying binary mortality outcomes: the first based on routine physical assessments and laboratory tests, the second on self-reported data encompassing 30 health problems (“health deficits”) such as diseases, symptoms, disabilities, and psychological issues. In their study, FI values were used as independent variables to model the log-likelihood of dying. The clinical relevance of laboratory-based frailty stratification was further supported by Pasternak et al [37], who demonstrated that a laboratory-based FI was significantly associated with all-cause mortality in hospitalized older adults.

In contrast, our study used FTS-12 measurements to generate a new binary dependent variable, categorizing scores as exceeding the third quartile of the distribution or not. This allowed us to model the likelihood that an observed FTS-12 value would fall within the uppermost range, with logistic regression then applied to assess the log-likelihood of these outcomes. Liu et al [38](2021) also used logistic regression, but with a different approach: a binary outcome representing the presence or absence of frailty in older patients with nutritional risks, with frailty status determined from previous research. However, Liu et al [38] focused on exogenous (environmental) predictors such as age, sex, ethnicity, educational level, BMI, walking ability, activities of daily living, and cognitive functioning, whereas our study prioritized “endogenous” biochemical variables to identify both the “most reasonable” model and the “most influential” risk factors.

Álvarez-Sánchez et al [39] used logistic regression to evaluate the association between 2 inflammatory biomarkers—high-sensitivity C-reactive protein and homocysteine—and prefrailty in Spanish adults aged 65 years and older [3], underscoring the role of inflammation in age-related physical decline. Although neither biomarker was selected in our models, our findings on GGT and albumin are consistent with emerging geriatric evidence. In a Korean population-based cohort, Kang et al [26] reported that elevated GGT levels were 26% higher in frail male participants than in nonfrail male participants, with higher GGT quartiles showing a 2.08-fold increased odds of frailty. Elevated GGT has also been associated with poorer muscle function—including reduced jump power and diminished handgrip strength—independent of body-composition factors [40], and with increased risk of hip fracture in postmenopausal female participants, irrespective of alcohol consumption or chronic liver disease [41]. Because both diminished handgrip strength and elevated risk of hip fracture are strongly associated with frailty in older adults, these observations support the potential relevance of GGT in frailty risk estimation [3,11]. A recent systematic review further emphasized that hypoalbuminemia is associated with a significant risk of frailty and adverse health consequences in hospital and community contexts [24]. Together, these findings strengthen the biological plausibility of our results, suggesting that GGT and albumin reflect convergent pathways of oxidative stress, malnutrition, and chronic inflammation that are central to geriatric syndromes [42].

From a model-performance perspective, the diagnostic criteria used to compare candidate logistic models suggested acceptable exploratory fit [20,33,43]. More importantly, from a clinical standpoint, the models showed that higher frailty probability was better captured by combinations of laboratory variables than by most isolated biomarkers alone. This supports the idea that frailty-related vulnerability reflects interacting biological domains rather than a single abnormal test result and helps explain why composite terms contribute more consistently than most individual variables. Notably, the strongest correlations

XSL•FO
RenderX

were seen between CRF functions and both FTS-12 values and the associated probabilities, regardless of sex. However, substantial dispersion in observed FTS-12 values persisted for each value of the composite risk functions, highlighting the complex interplay of factors across the 7 dimensions underlying frailty assessment.

Placed in the context of existing approaches for laboratory-based frailty screening, the discriminatory performance reported in the Results section falls within the moderate-to-good range typically described for tools that rely exclusively on routine biochemical and hematological variables [11,21]. AUC values close to 0.80 for both sexes are consistent with what may reasonably be expected when functional, cognitive, and self-reported components are not incorporated, and they reinforce the view that the present models should be regarded as a complementary first layer of risk stratification rather than as a stand-alone diagnostic instrument. Beyond their overall discriminatory performance, the biological composition of the dominant composite functions is also informative: the prominence of the albumin-age composite in female participants is consistent with the well-established association of hypoalbuminemia and anemia with adverse outcomes in older adults [24,25], while the relevance of the hemoglobin-age composite in male participants is compatible, with erythropoietic decline acting as a sex-sensitive marker of physiological reserve. The recurrent involvement of GGT and alkaline phosphatase further suggests that subclinical hepatobiliary and oxidative pathways contribute to the laboratory signature of frailty [26], in line with the broader role of inflammatory, nutritional, and oxidative mechanisms previously implicated in the syndrome [3,39,42].

Limitations

Variable selection was conducted using stepwise multiple regression guided by the AIC and Mallows C_p statistic. Although stepwise procedures have recognized limitations, this approach was used for exploratory purposes within a proof-of-concept framework, and the results should therefore be interpreted with appropriate caution.

This study has several limitations that should temper the interpretation of its findings. First, its cross-sectional design prevents causal inference and may be susceptible to reverse causation; for example, elevated GGT could reflect unmeasured liver disease or alcohol intake rather than etiological pathways to frailty [26,44]. Second, all biochemical measurements were obtained at a single baseline visit, so temporal fluctuations and dynamic changes in frailty status were not evaluated. Third, the cohort was drawn from a single European population (Toledo, Spain), which may limit external validity in ethnically diverse or resource-limited settings. Finally, model development and internal validation were performed using the same dataset, which may increase the risk of overfitting despite the application of bootstrapping procedures. Future studies should therefore prioritize external or independent validation to assess model performance on unseen data and the generalizability of the proposed models.

Furthermore, rather than serving as a general clinical cutoff for the FTS-12 scale, the binary logistic analysis based on the upper quartile should be understood as an internal analytical technique to identify the subgroup with the highest frailty burden within this cohort. We recognize that dichotomization may reduce information and affect apparent model discrimination. The current proof-of-concept study did not include formal calibration analyses (calibration plots, calibration slope/intercept, and Brier score), threshold-specific sensitivity and specificity, decision-curve analysis, or net-benefit evaluation, although discrimination was investigated using ROC curve analysis and multicollinearity was confirmed to be nonproblematic using VIFs.

As noted in the Methods section, calibration in the probabilistic sense did not apply to the multiple regression model, for which performance was instead evaluated through goodness-of-fit measures and residual diagnostics. For the logistic models, formal calibration was not assessed. The present models should therefore be interpreted as exploratory, discrimination-based tools to determine whether routinely available laboratory data contain meaningful frailty-related signals, rather than as deployment-ready clinical prediction instruments. Further development toward clinical implementation will require calibration-focused evaluation, external validation, and implementation-oriented testing. Although bootstrap procedures were used to estimate CIs for selected model parameters, this does not constitute a full internal validation; optimism-corrected evaluation of overall model performance was beyond the scope of this secondary exploratory analysis.

More stringent development and validation techniques—penalized regression (eg, least absolute shrinkage and selection operator), repeated cross-validation, formal calibration evaluation, clinical utility analyses, and benchmarking against parsimonious and machine-learning alternatives—should be incorporated into model refinement in later phases. These procedures were outside the scope of the current work because the study was not preregistered and was intended as a secondary exploratory proof-of-concept analysis based on an existing cohort dataset. Complete-case analysis was used due to low missingness, and sex-stratified modeling was given precedence over formal interaction testing. Variables such as alcohol use, liver disease, medication exposure, inflammatory markers, nutritional variables, and comorbidity burden were not available in sufficiently complete form for inclusion, so part of the observed signal for biomarkers such as GGT and albumin may reflect unmeasured clinical contexts rather than direct frailty-specific pathways. The present revision does not yet provide TRIPOD (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis)-compliant reporting, optimism-corrected full model validation, or direct benchmarking against simpler baseline models (eg, age-only or age-plus-albumin), all of which should be incorporated in future validation-oriented refinement.

Broader Implications

Our proof-of-concept analysis supports the viability of this modeling approach, and the next logical step is model refinement. A prospective, multicenter cohort with repeated biomarker assessments and adjudicated clinical outcomes would provide a more appropriate framework to confirm temporality

XSL•FO
RenderX

and improve generalizability. External validation in Latin American populations, integration of additional biological data layers, and comparison with machine-learning approaches may further improve predictive performance. Because the proposed models rely on routinely available laboratory parameters, they are particularly suitable for implementation in primary care and resource-limited settings, where they could help prioritize older adults for further geriatric assessment when specialized frailty evaluations are not immediately available. Embedding the frailty-probability equations within electronic health record dashboards or mobile screening tools could enable real-time, low-cost risk stratification in primary care and remote geriatric care. By facilitating earlier identification of risk patterns from routinely available laboratory data, this approach may contribute to more individualized and sex-sensitive frailty management strategies, consistent with the broader goal of precision geriatric care.

Recent discussions in clinical AI emphasize that real-world implementation requires explainability, fairness, human oversight, and careful workflow integration, so computational models should be developed to augment clinicians through earlier detection, smarter triage, and more targeted prevention rather than replace clinical judgment [45]. Likewise, work in adjacent computational health fields reinforces the need for interpretable pipelines, rigorous validation, and multicohort generalizability before routine implementation [46]. Taken together, these considerations position the present work not only as a statistical proof of concept but also as an early translational step toward clinically embedded, digitally supported frailty screening in aging care.

Conclusions

From routinely available biochemical and hematological data, frailty, operationalized using the FTS-12 score, was modeled with moderate accuracy; sex-specific models demonstrated consistent predictive performance in both male and female participants. The final models included albumin, age, GGT, and a few composite risk functions that are biologically plausible correlates of frailty-related risk. For transparency and future validation, the final equations (albumin in g/dL and GGT in U/L) are given in Multimedia Appendix 1. Currently, these models should not be viewed as nomograms or screening tools with clinically useful biomarker thresholds, but rather as instruments for continuous frailty-risk estimation.

The models offer clinically interpretable signals that could support future workflow-integrated frailty risk stratification, despite the modest explained variance. This strategy may support digitally enabled screening, earlier frailty-oriented assessment, and prioritization for comprehensive geriatric assessment in primary care, geriatric care, and remote care settings following appropriate external and prospective validation. Rather than establishing definitive clinical decision rules, this work was designed to evaluate feasibility, computational stability, and interpretability as a secondary exploratory proof-of-concept analysis based on an existing cohort. Before regular clinical use, additional validation, calibration, and implementation-focused research will be necessary.

Abstract

Background: Objective indicators are urgently needed to evaluate and monitor disease progression in patients with psoriasis.

Objective: This study aimed to verify the correlations between blood count–derived inflammatory markers and the Psoriasis Area and Severity Index (PASI) among patients with psoriasis and explore the value of applying the PASI in combination with proinflammatory factors.

Methods: This was a cross-sectional observational study that enrolled 719 patients from 2 tertiary hospitals. Receiver operating characteristic curve analysis and binary logistic regression models were applied to assess the evaluative power of blood count–derived inflammatory markers and their consistency with the PASI for stratifying psoriasis severity. The association with the PASI and the combination with proinflammatory factors of the blood count–derived inflammatory markers in 60 patients were analyzed. The exploratory association between blood count–derived markers and proinflammatory factors was analyzed using product terms. To ensure robustness, multivariable combined models were evaluated using receiver operating characteristic curves and decision curve analysis. Model performance was further validated via calibration plots and a predictive nomogram, with the decision curve analysis net benefit axis increased to 1.0 for comprehensive visualization.

Results: The area under the curve showed that the systemic immune-inflammation index (SII), systemic inflammation response index (SIRI), and aggregate index of systemic inflammation (AISI) were effective in reflecting psoriasis severity and showed advantages in patients with psoriasis complicated by arthritis and cardiovascular metabolic diseases. The comprehensive test showed quite appropriate consistency of the SIRI and PASI in distinguishing severity. The SII, SIRI, and AISI were significantly correlated with interleukin (IL)-6 in lesions (all P<.05), and the combinations of these indices with IL-6, IL-1, and IL-17 were also significantly correlated with the PASI (all P<.05).

Conclusions: Blood count–derived inflammatory markers could better reflect the inflammation of patients with psoriasis. The SII, SIRI, and AISI have important clinical significance in evaluating disease severity. The combination with proinflammatory factors showed an advantage.

Introduction

Background of Psoriasis and Its Clinical Challenges

Psoriasis is a common chronic inflammatory skin disease that is associated with psoriatic arthritis (PsA), obesity, dyslipidemia, hypertension, type 2 diabetes, and cardiovascular disease [1]. Blood cells interact with proinflammatory factors to regulate the progression of psoriasis. The increase in and prolongation of the systemic inflammatory state in patients may be important determinants of the severity, progression, comorbidities, and outcome of psoriasis. Presently, the treatment model for psoriasis is reactive; therefore, a more proactive and risk-stratified management approach is needed. Early intervention and effective treatment can alleviate the severity of psoriasis by reducing inflammation levels and may also reduce or prevent diseases such as cardiometabolic diseases, as

XSL•FO
RenderX

well as irreversible damage and disability. There is increasing acknowledgment that a single variable is rarely likely to be a good predictor of disease progression [2]; therefore, new parameters are required due to the lack of objective evaluation criteria, insufficient evaluation of chronic inflammation–causing disease, and differences between clinicians.

Blood Count–Derived Inflammatory Markers: Research Status

Complete blood count parameters have gained recognition as valuable biomarkers for a range of inflammatory conditions, primarily because of their widespread availability and cost-effectiveness. In one study, compared with the healthy control group, patients with psoriasis had higher total white blood cell, neutrophil, and platelet count; neutrophil-to-lymphocyte ratio (NLR); and platelet-to-lymphocyte ratio (PLR) but lower lymphocyte counts. However, there was no significant correlation between the Psoriasis Area and Severity Index (PASI) score and either the NLR or PLR [3]. In another study, the systemic immune-inflammation index (SII) and systemic inflammation response index (SIRI) were powerful prognostic indicators of poor outcomes in patients with cancer and were promising tools for treatment strategy decisions [4,5]. The SIRI and aggregate index of systemic inflammation (AISI) can be useful for the early identification of patients at risk of prolonged hospital stay in open elective thoracic surgery [6]. In another study, the NLR, PLR, monocyte-to-lymphocyte ratio (MLR), SII, SIRI, and AISI were referred to as the blood count–derived inflammatory markers [7]. Both the SII and SIRI have been shown to statistically significantly decrease in patients with psoriasis after only 3 months of treatment with biologics [8,9], and a low correlation between the reduction in PASI scores and PLR, SII, and SIRI values has been observed [9]. The AISI was first reported to be correlated with liver fibrosis severity in psoriasis vulgaris [10]. The AISI, SII, and SIRI have been positively correlated with disease severity in psoriasis [7].

Research Gaps and Study Rationale

Overall, there are limited studies on the correlation between blood count–derived inflammatory markers and psoriasis. Some studies have had small sample sizes, and there are limited studies that have stratified patients with psoriasis by severity based on PASI score and investigated blood count–derived inflammatory markers. Conventional severity assessment tools, including PASI and body surface area, are insufficient to reflect the underlying pathophysiological features and comprehensive disease course of psoriasis [11]; moreover, the combination of blood count–derived inflammatory markers of psoriasis and proinflammatory factors remains under-studied.

Methods

Patients and Data Sources

This study enrolled patients with psoriasis between June 2, 2021, and February 2, 2024, from the Department of Dermatology and Venereology of the First Affiliated Hospital and Fourth Affiliated Hospital of Guangxi Medical University. All patients were diagnosed based on clinical or histopathological manifestations of chronic plaque-type psoriasis. Data on baseline demographics; clinical characteristics; concomitant joint arthritis; and scalp, genital, lower leg, and nail involvement were recorded in the clinic. The disease duration was defined as the period from the first diagnosis of psoriasis by a dermatologist until the present. The inclusion criteria for patients were as follows: (1) patients with chronic plaque-type psoriasis and (2) age of more than 18 years. The PASI was assessed by 3 clinical physicians who had undergone unified training. Exclusion criteria included pregnancy or breastfeeding, acute systemic infection, immunodeficiency, malignant tumors, hematologic disorders, and clinically significant anemia (eg, iron deficiency anemia). Additionally, patients receiving systemic treatments within 1 month preceding enrollment were excluded to ensure a stable baseline and complete blood counts. Standard blood tests were performed for all patients before initiation of treatment, and the results were obtained from the Department of Clinical Laboratory, First Affiliated Hospital and Fourth Affiliated Hospital of Guangxi Medical University. The First Affiliated Hospital cohort served as the derivation set, whereas the Fourth Affiliated Hospital cohort functioned as the independent validation set.

Ethical Considerations

This study was approved by the ethics committee of the Fourth Affiliated Hospital of Guangxi Medical University (approval KY2024508) and conducted according to the principles of the Declaration of Helsinki. Written informed consent was obtained from all participants.

Definition of Blood Count–Derived Inflammatory Markers

The NLR was calculated as absolute neutrophil count ($\times 10^9$/L)/absolute lymphocyte count ($\times 10^9$/L), the PLR was calculated as absolute platelet count ($\times 10^9$/L)/absolute lymphocyte count ($\times 10^9$/L), the MLR was calculated as absolute monocyte count ($\times 10^9$/L)/absolute lymphocyte count ($\times 10^9$/L), the SII was calculated as absolute neutrophil count ($\times 10^9$/L) × absolute platelet count ($\times 10^9$/L)/absolute lymphocyte count ($\times 10^9$/L), the SIRI was calculated as absolute neutrophil count ($\times 10^9$/L) × absolute monocyte count ($\times 10^9$/L)/absolute lymphocyte count ($\times 10^9$/L), and the AISI was calculated as absolute neutrophil count ($\times 10^9$/L) × absolute platelet count ($\times 10^9$/L) × absolute monocyte count ($\times 10^9$/L)/absolute lymphocyte count ($\times 10^9$/L).

Materials

An antibody against interleukin (IL)-17A (catalog number GB11110-1-50; 1:300) was purchased from ServiceBio, an antibody against IL-1β (cat. no. GB11113-50; 1:300) was purchased from ServiceBio, an antibody against IL-6 (cat. no. YT5348; 1:300) was purchased from Solarbio, and a goat antirabbit secondary antibody (cat. no. 23303-100; 1:200) was purchased from ServiceBio.

XSL•FO
RenderX

Histomorphometric Analysis and Immunohistochemical Staining

The skin lesions were biopsied at the Department of Dermatology and Venereology of the First Affiliated Hospital of Guangxi Medical University. The lesions were immediately fixed in 4% paraformaldehyde. The samples were embedded in paraffin, and 4 μm thick sections were obtained. Immunohistochemical staining was performed to detect the level of IL-17, IL-1β, and IL-6 from a consecutive sample of 60 patients with psoriasis using the respective antibodies (1:300 dilution) according to the manufacturer's protocol. The histochemistry score (H-score) was adopted for the standardized evaluation of the histological expression of immunohistochemical markers. The specific calculation method was as follows: H-score ($\sum (pi \times i)$ = (percentage of weakly positive cells × 1) + (percentage of moderately positive cells × 2) + (percentage of strongly positive cells × 3), where *i* represents the classification of positive cell grades (strongly positive brownish cells count for 3 points). Positive cells were counted using the ImageJ software. Assessors were blinded to PASI score and blood count–derived inflammatory markers during H-score evaluation.

Statistical Analysis

Statistical analysis was performed using SPSS (version 25.0; IBM Corp). Statistical descriptions of normal or approximately normal measures were expressed as means and SDs; significantly skewed measures were expressed as medians and IQRs. Furthermore, categorical variables were presented as absolute counts and percentages. Categorical variables were compared using the chi-square test. The optimal cutoff values were determined using the Youden index within the derivation cohort only. Agreement between marker-based and PASI-based classifications in the validation cohort was further assessed using the Cohen κ (with 95% CI) and Pearson chi-square test. The Youden index was calculated as sensitivity − (1 − specificity). The differences between the groups were evaluated using the Mann-Whitney *U* test. Kolmogorov-Smirnov and Shapiro-Wilk tests were used for inspecting the normal distribution. Binary logistic regression analysis was used to further test the results of the Mann-Whitney *U* test. Binary logistic regression included adjustments for BMI, smoking status, and comorbidities (Multimedia Appendix 1). To verify the robustness of these conclusions, a sensitivity analysis was conducted by re-evaluating the inflammatory markers exclusively in a subgroup of patients without any comorbidities (n=571). Due to the skewed distribution and disparate unit scales of the inflammatory markers, natural log-transformation (ln) was applied to improve model stability and interpretability. Extended multivariable models additionally adjusted for study center, disease duration, and PsA. To address potential institutional bias, a stratified receiver operating characteristic (ROC) curve analysis was performed for each hospital cohort, and study center was included as an additional covariate in the sensitivity analysis of the regression model. Comparisons of area under the curve (AUC) values between markers were performed using the DeLong test, with the Benjamini-Hochberg procedure applied to control the false discovery rate (FDR) for multiple comparisons. The Hosmer-Lemeshow test was used to evaluate the goodness of fit of the logistic regression model. Correlations were evaluated using the Spearman correlation coefficient. A *P* value of less than .05 was considered statistically significant. Granular subgroup and correlation analyses were designated as exploratory in nature. A PASI score of 10 or higher vs a PASI score of less than 10 was used as the reference standard for ROC and logistic regression analysis.

Results

Baseline Clinical and Demographic Characteristics

The clinical and demographic characteristics of all participants included in the study are shown in Table 1.

Overall, 545 patients were recruited from the Department of Dermatology and Venereology of the First Affiliated Hospital of Guangxi Medical University, and another 174 eligible patients were enrolled from the Department of Dermatology and Venereology of the Fourth Affiliated Hospital of Guangxi Medical University. Among the 719 patients, the lesions involved the scalp in 427 (59.4%) patients, arthritis in 59 (8.2%) patients, the nails in 171 (23.8%) patients, the genital area in 83 (11.5%) patients, and the lower leg in 106 (14.7%) patients. Overall, 148 participants had chronic systemic comorbidities, of whom 97 (65.5%) had cardiometabolic disorders.

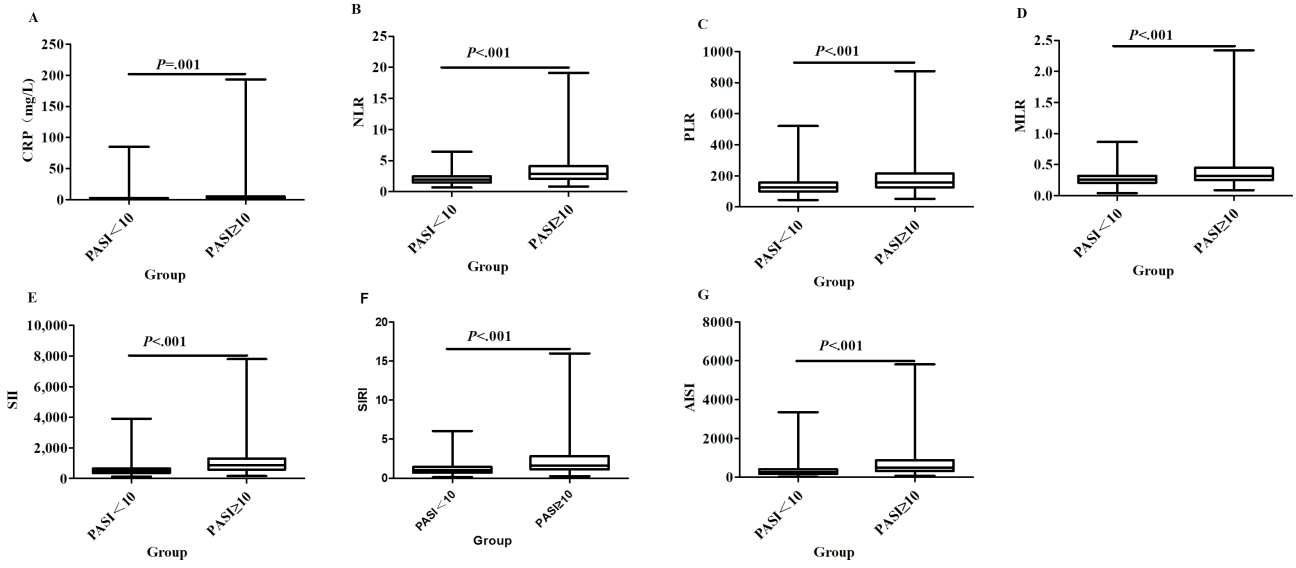
[a]PASI: Psoriasis Area and Severity Index.



Blood Count–Derived Inflammatory Markers and Psoriasis Severity

Of the 545 patients with psoriasis in the First Affiliated Hospital, 298 (54.7%) were in the group with a PASI score of less than 10, and 247 (45.3%) were in the group with a PASI score of 10 or higher. NLR, PLR, MLR, SII, SIRI, and AISI were all significantly higher in the group with a PASI score of 10 or higher than in the group with a PASI score of less than 10 (P<.001 in all cases; Figure 1). The higher the blood

XSL•FO
RenderX

count–derived inflammatory markers, the higher the psoriasis severity. The results of the ROC curve analyses evaluating the ability of blood count–derived indexes (NLR, PLR, MLR, SII, SIRI, and AISI) to be associated with psoriasis disease severity are presented in Figure 2. The AUC values were 0.58 (95% CI 0.53-0.63) for C-reactive protein (CRP), 0.75 (95% CI 0.70-0.79) for NLR, 0.70 (95% CI 0.66-0.75) for PLR, 0.66 (95% CI 0.62-0.71) for MLR, 0.79 (95% CI 0.75-0.83) for SII, 0.73 (95% CI 0.69-0.78) for SIRI, and 0.77 (95% CI 0.73-0.81) for AISI (P<.01 in all cases). The cutoff values were 6.55 for CRP, 2.80 for NLR, 147.85 for PLR, 0.31 for MLR, 662.39 for SII, 1.48 for SIRI, and 443.34 for AISI. The AUC values for NLR, PLR, MLR, SII, SIRI, and AISI were statistically significantly superior to those of CRP (FDR-adjusted P<.05 in all cases; Table S1 in Multimedia Appendix 1), suggesting that the blood count–derived indexes were associated with psoriasis severity, although their discriminative performance remained modest. On the basis of the optimal cutoffs from the derivation cohort, the validation cohort showed consistent patterns of association (Table S2 in Multimedia Appendix 1). A consistency test was conducted in 2 groups: those with a PASI score of less than 10 and those with a PASI score of 10 or higher. The comprehensive diagnostic performance, including AUCs with 95% CIs, cutoff values, and Cohen κ analysis, is summarized in Table S3 in Multimedia Appendix 1. The results of the distribution of moderate to severe psoriasis between the SII, SIRI, PLR, and MLR and the PASI score are shown in Table S4 in Multimedia Appendix 1. There were no significant differences in the distribution of moderate to severe psoriasis between the SII, SIRI, PLR, and MLR and the PASI score (P>.05 in all cases). Moreover, as shown in Figure S1 in Multimedia Appendix 2, PASI scores were significantly higher among the groups with inflammatory marker values (NLR, MLR, SIRI, SII, and AISI) above the cutoffs compared to those below. However, no statistically significant difference was observed between the CRP and PLR groups. All 719 patients were divided into groups with a PASI score of less than 10 and a PASI score of 10 or higher for binary logistic regression analysis. The Hosmer-Lemeshow test showed a good fit. As shown in Table 2, the NLR, MLR, and SIRI values were higher in the group with a PASI score of 10 or higher. The odds ratios were 1.704 (95% CI 1.483-1.959), 38.132 (95% CI 12.161-119.572), and 1.914 (95% CI 1.605-2.282), respectively (P<.001 in all cases). The odds ratios of PLR, SII, AISI, and CRP were close to 1 (P<.01 in all cases). In summary, higher NLR, MLR, and SIRI values were independently associated with greater psoriasis severity independent of BMI, smoking status, and comorbidities. To account for scaling effects, log-transformed multivariable analysis was also performed, yielding robust and more interpretable odds ratios (Table S5 in Multimedia Appendix 1). These markers remained independent predictors even after further adjusting for study center, disease duration, and PsA (Table S6 in Multimedia Appendix 1). These associations remained robust after adjusting for study center in the sensitivity analysis (Table S7 in Multimedia Appendix 1). Furthermore, stratified ROC analysis showed consistent predictive performance across both hospital cohorts (Figure S2 in Multimedia Appendix 2).

Figure 1. The differential expression of the blood count–derived indexes in patients with moderate and severe psoriasis. AISI: aggregate index of systemic inflammation; CRP: C-reactive protein; MLR: monocyte-to-lymphocyte ratio; NLR: neutrophil-to-lymphocyte ratio; PASI: Psoriasis Area and Severity Index; PLR: platelet-to-lymphocyte ratio; SII: systemic immune-inflammation index; SIRI: systemic inflammation response index.

[a]NLR: neutrophil-to-lymphocyte ratio.

[b]PLR: platelet-to-lymphocyte ratio.

[c]MLR: monocyte-to-lymphocyte ratio.

[d]SII: systemic immune-inflammation index.

[e]SIRI: systemic inflammation response index.

[f]AISI: aggregate index of systemic inflammation.

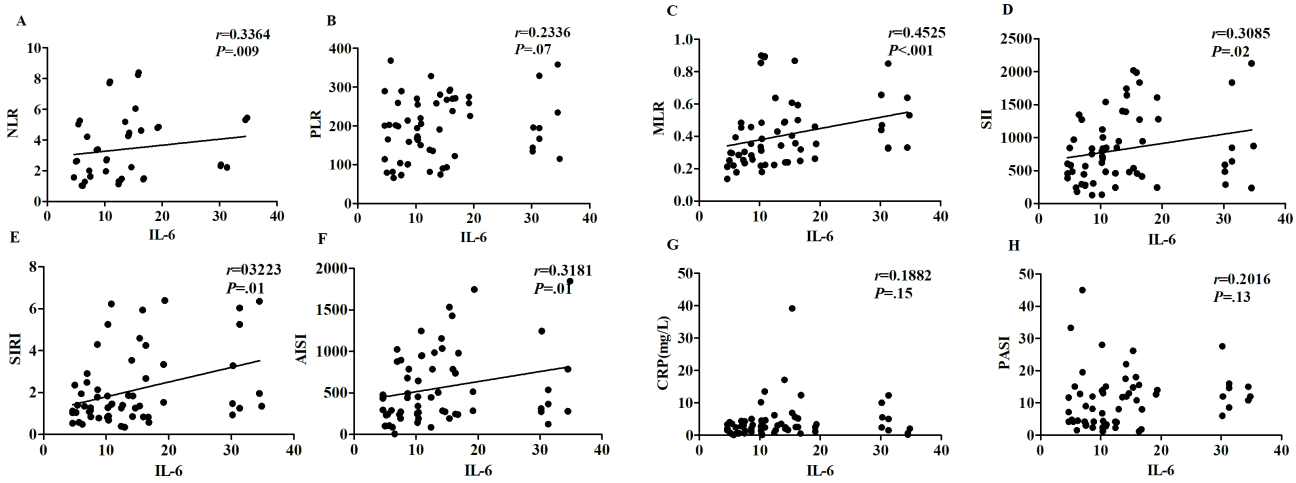
[g]CRP: C-reactive protein.

Subgroup Analysis of Blood Count–Derived Inflammatory Markers

The NLR, PLR, MLR, SII, SIRI, and AISI values in the group with joint involvement were significantly higher than those in the group without joint involvement, and the MLR, SIRI, and AISI values were higher in the groups with scalp and nail involvement. The NLR, PLR, MLR, SII, SIRI, and AISI values did not show significant increases in the groups with calf and genital involvement (Table S8 in Multimedia Appendix 1). The NLR, MLR, SII, SIRI, and AISI values of patients with combined cardiovascular or metabolic diseases were significantly higher and statistically significant (Table S9 in Multimedia Appendix 1).

Combined Analysis of Markers and Cytokines

Immunohistochemical staining of IL-1, IL-6, and IL-17 was performed on patients with psoriasis at the First Affiliated Hospital. Demographic and clinical comparison confirmed that this subcohort was representative of the full cohort (Table S10 in Multimedia Appendix 1). There were positive expressions around keratinocytes and superficial dermal inflammatory cells, as shown in Figure S3 in Multimedia Appendix 2. IL-1 and IL-17 were not expressed in the normal skin around the mole.



XSL•FO
RenderX

However, by calculating the H-score, it was found that IL-17 and IL-1 had no significant correlation with the PASI score, as shown in Figures S4 and S5 in Multimedia Appendix 2.

Moreover, there was no statistically significant correlation between the blood count–derived index and IL-1 and IL-17. The correlations between NLR, MLR, SII, SIRI, and AISI and IL-6 in the skin lesions were statistically significant, with correlation coefficients of 0.3364 (*P*=.009), 0.4525 (*P*<.001), 0.3085 (*P*=.02), 0.3223 (*P*=.01), and 0.3181 (*P*=.01), respectively (Figure 3). There was no correlation between IL-6 and PASI score in the skin lesions (*P*=.13). There was no statistically significant correlation between PLR and CRP (*P*=.07 and .15, respectively).

We conducted an exploratory analysis combining IL-6, IL-1, and IL-17 with the blood count–derived indexes and found that the blood count–derived indexes combined with IL-6 in the skin lesions of patients with psoriasis had a significant correlation with the PASI score, as shown in Table 3. The correlation coefficients of the combination of IL-6 with NLR, PLR, MLR, SII, SIRI, and AISI with PASI scores were 0.66, 0.46, 0.40, 0.64, 0.56, and 0.56, respectively. The combination of IL-1 with NLR and SII and the combination of IL-17 with NLR and SII were significantly correlated with PASI scores. The correlation coefficients were 0.48, 0.50, 0.49, and 0.48, respectively. The combined multivariable model (eg, SIRI+IL-6) showed stronger associations with disease severity (AUC=0.845) and a more favorable clinical net benefit in the decision curve analysis (Figure S6 in Multimedia Appendix 2). To achieve comprehensive visual evaluation of clinical net benefit, the DCA net benefit axis was raised to 1.0 in the present analysis. Calibration analysis and a functional clinical nomogram with an individual case example further confirmed high reliability and facilitated bedside risk assessment. As summarized in the integrated correlation matrix (Figure S7 in Multimedia Appendix 2), the associations remained highly significant after FDR adjustment.

Figure 3. Correlation between blood count–derived indexes and interleukin (IL)-6. AISI: aggregate index of systemic inflammation; CRP: C-reactive protein; MLR: monocyte-to-lymphocyte ratio; NLR: neutrophil-to-lymphocyte ratio; PASI: Psoriasis Area and Severity Index; PLR: platelet-to-lymphocyte ratio; SII: systemic immune-inflammation index; SIRI: systemic inflammation response index.

Discussion

Psoriasis is driven by combined autoimmune and autoinflammatory responses, in which IL-1, IL-17, and IL-6 form an inflammatory cascade by regulating T helper 17 cells, neutrophils, and regulatory T cells [12,13]. Traditional clinical assessments such as PASI and body surface area inadequately reflect systemic inflammation, whereas cytokine-based biomarkers are costly and fail to clearly distinguish current severity from future risk [2,11]. Given the high cost and time consumption associated with specialized cytokine biomarkers, PLR, NLR, MLR, SII, SIRI, and AISI, which could be easily derived as part of a routine complete blood count, have been used in chronic inflammatory diseases, including psoriasis and psoriasis comorbidity [7,14,15]. These indicators of inflammation include neutrophil, platelet, monocyte, or lymphocyte count. Recent reports have indicated that oxidative stress, granular components, and neutrophil extracellular traps are linked to psoriasis initiation and maintenance [16]. The abnormality of the immune system in psoriasis may overactivate platelets, contributing to the disease and its cardiovascular comorbidities, with antiplatelet therapies potentially being effective [17]. A genome-wide study found that a high monocyte and neutrophil count and elevated NLR and PLR increase psoriasis risk [18], whereas patients with psoriasis vulgaris had a lower lymphocyte count than controls [3]. The excessive proinflammatory immune response in psoriasis drives the proliferation of neutrophils, platelets, and monocytes, accompanied by relative lymphocyte depletion.

Previous studies have reported elevated NLR and PLR in patients with psoriasis, although correlations with the PASI score are inconsistent [3,19]. A cohort study linked NLR to baseline PASI score and noncalcified coronary plaque burden [20]. Furthermore, SII was elevated in patients with higher PASI

XSL•FO
RenderX

scores and nail or genital involvement [21]. Population-based National Health and Nutrition Examination Survey data further demonstrated positive associations between NLR, PLR, SII, and SIRI and psoriasis risk [22,23], and higher MLR and SIRI were positively associated with all-cause mortality in adults with psoriasis [23]. PLR and CRP were associated with the diagnosis of PsA, whereas SII and SIRI were not. Patients with higher PLR and SII scores were more resistant to treatment with conventional systemic agents, although no significant differences in these markers were found among psoriasis, PsA, and controls [15]. A recent meta-analysis of 36 studies confirmed significantly higher NLR, PLR, SII, and MLR in patients with psoriasis vs controls, with positive correlations between both NLR and PLR and the PASI score [24]. Inconsistent findings across studies may stem from different cohorts or populations, requiring further large-scale research. In this study, the NLR, PLR, SII, SIRI, and AISI of patients with psoriasis were higher in the group with a PASI score of 10 or higher (Figure 1), with all AUC values exceeding 0.7, supporting their potential role as exploratory severity markers (Figure 2). It was found that there was no statistically significant difference in distribution between the SII, SIRI, PLR, and MLR results and the PASI score in diagnosing moderate to severe psoriasis (Table S4 in Multimedia Appendix 1). Among them, the *P* values of the SII and AISI were .05 in both cases, which might be related to the relatively small number of patients. The higher cutoff values for the NLR, MLR, and SIRI, the higher PASI scores (Figure S1 in Multimedia Appendix 2) and the higher severity level of patients with psoriasis. The independent predictive value of these markers remained robust across different modeling approaches (Table 2). Importantly, sensitivity analysis restricted to patients without comorbidities (n=571) yielded highly consistent odds ratios, confirming that these findings were independent of systemic confounding bias (Table S11 in Multimedia Appendix 1). Comorbidity was modeled as a binary covariate; its detailed classification and modeling framework are provided in Tables S11 and S12 in Multimedia Appendix 1. On the basis of the above analysis, these findings suggest that the SIRI is associated with PASI scores and may help stratify moderate to severe psoriasis, although discriminative accuracy is not sufficiently robust for stand-alone clinical use. The robustness of these markers was further confirmed using log-transformed models, which effectively mitigated the influence of outliers and unit scaling issues. In one study, the SII was higher in patients with PsA than in those without arthritis [25]. Another study mentioned that the SII and SIRI had no significant correlation with the diagnosis of PsA, whereas SII and SIRI values were higher in patients with psoriasis involving the nails [8]. However, subgroup analyses in our study further revealed significantly higher blood count–derived indexes in patients with joint, scalp, or nail involvement, including those with cardiometabolic comorbidities (Tables S3 and S4 in Multimedia Appendix 1). These observations support the notion that blood count–derived inflammatory markers reflect systemic inflammatory burden beyond cutaneous involvement alone. The small sample size of patients with special site involvement and cardiometabolic comorbidities may introduce selection bias; future multicenter studies with larger populations are warranted to verify these findings. The PASI score is the most widely accepted and routinely used clinical index for assessing psoriasis severity. In this study, the PASI score was used as a benchmark outcome for ROC and logistic regression analyses, not as a perfect or gold-standard reflection of overall disease activity.

Currently, standardized objective biomarkers for psoriasis evaluation remain limited, and few studies have explored the combined application of blood count–derived inflammatory markers and proinflammatory cytokines. It was observed that there were positive expressions of IL-6, IL-1, and IL-17 to varying degrees around keratinocytes and superficial dermal inflammatory cells (Figure S2 in Multimedia Appendix 2). Notably, although IL-17 and IL-1 showed no significant correlation with the PASI score in the dataset, the NLR, MLR, SII, SIRI, and AISI were significantly associated with lesional IL-6 expression. This suggests that blood count–derived inflammatory markers may indirectly reflect IL-6–driven myeloid and lymphoid imbalance in psoriasis lesions. In this study, by combining IL-6, IL-1, and IL-17 with the blood count–derived inflammatory markers, it was found that there was a significant correlation with the PASI score, especially in combination with IL-6 (Table 3).

Limitations included the reliance on 2 regional centers, potential residual or unmeasured confounders, limited generalizability due to enrolling only patients requiring systemic therapy, bias from using normal perilesional skin as a control due to local microenvironmental factors, and lack of longitudinal data and external validation. Furthermore, while primary findings were validated using FDR correction, the multidimensional subgroup analyses remain exploratory and require further validation. The cytokine analysis was limited to a small subset as they may be prone to overfitting and lack sufficient generalizability; these exploratory findings should be interpreted cautiously. All these limitations should be addressed in the future.

In conclusion, blood count–derived inflammatory markers were significantly associated with the PASI score in psoriasis and correlated with lesional IL-6 expression. Moreover, the combination of blood count–derived inflammatory markers and proinflammatory factors may serve as a choice for accurately and comprehensively evaluating psoriasis severity and monitoring treatment response in the future, providing new ideas for multidimensional evaluation. As low-cost, accessible alternatives to expensive cytokine profiling, these markers support a shift from reactive to proactive, risk-stratified psoriasis management, aiding early identification of high–inflammatory burden patients. The link between blood inflammatory indexes and lesional IL-6 signaling confirms their biological relevance as surrogates of tissue-level immune dysregulation. The combined application of these markers complements traditional scores, advancing precision dermatology for more objective, individualized disease evaluation and improved long-term outcomes.

Abstract

Background: Postoperative sleep is closely associated with recovery among patients undergoing surgery.

Objective: This study aimed to analyze the research status and developmental trends in postoperative sleep between 2014 and 2024.

Methods: Publications were retrieved from the Web of Science Core Collection. Microsoft Excel and VOSviewer were used to analyze the papers in terms of publication trends, countries, institutions, authors, journals, and keywords.

Results: A total of 964 papers were obtained for the bibliometric analysis. The number of publications on this topic has increased gradually over the last 10 years. Zhu Junchao was the most prolific author in the field, and Chung Frances had the most citations. China had the most publications, followed by the United States. Scientific institutions in China, such as China Medical University and Capital Medical University, have led the way in terms of publication numbers. A total of 40 journals have published at least 5 papers. *BMC Anesthesiology*, with 19 publications, ranked first in publication count. The papers published in the *British Journal of Anaesthesia*, *Journal of Clinical Anesthesia*, *Anesthesia and Analgesia*, *Journal of Pain*, and *Journal of Sleep Medicine* had higher citation counts on average. The high-frequency keywords were “sleep quality,” “postoperative pain,” “quality of life,” and “surgery,” while “lung cancer,” “enhanced recovery after surgery,” “breast cancer,” and “dexamethasone” emerged as new topics in this area.

Conclusions: There has emerged a large body of literature on postoperative sleep over the past 10 years. Authors and organizations from China are leading contributors, followed by those from the United States. Anesthesiology is a critical discipline in this field. Postoperative pain is closely related to postoperative sleep and has become a major research focus. Recent studies have mainly focused on lung cancer and breast cancer surgeries. Enhanced recovery after surgery has become an emerging keyword.

KEYWORDS

bibliometric analysis; postoperative sleep; recovery quality; postoperative pain; enhanced recovery after surgery

Introduction

Postoperative sleep shows a close relationship with the quality of recovery, hormone secretion, metabolism, cognitive function, and autonomic nervous activity [1]. Maintenance of normal sleep after surgery is closely related to postoperative rehabilitation [2]. However, patients undergoing surgery may experience a degree of impact on their sleep quality [3]. Anesthesia has the potential to disrupt the sleep-wake timing system [4,5], as most general anesthetics are either N-methyl-D-aspartate receptor antagonists or γ-aminobutyric acid agonists, and activation of these receptors affects clock gene expression [6]. Glucocorticoids, synthetic analogs of endogenous cortisol, are sometimes administered during surgery and have strong effects on the molecular clock [7]. In addition, the grade and duration of surgery have been demonstrated to determine the degree of postoperative sleep disorders [8,9]. Thus, normal sleep after surgery may be difficult to maintain because of the multifaceted effects of surgery and anesthesia on sleep during the early postoperative period.

Postoperative sleep disorders have received increasing attention from researchers [10]. More than 1900 publications were recorded in the Web of Science (WoS) Core Collection from 2014 to 2023. Despite the increasing number of studies, a comprehensive and systematic overview of the global research status, developmental trends, and research hot spots in postoperative sleep remains lacking. Previous studies have mainly focused on specific clinical issues such as the correlation

XSL•FO
RenderX

between sleep quality and postoperative pain or the effect of a single intervention on sleep improvement. However, there is a lack of macrolevel analyses summarizing the research landscape, identifying collaborative networks, and predicting future research directions in this field.

Bibliometric analysis is a commonly used method for evaluating research trends [11]. To date, no bibliometric study has been conducted to systematically analyze the global literature on postoperative sleep over the past decade. Therefore, this study aimed to fill this gap by performing a bibliometric analysis of publications on postoperative sleep from 2014 to 2024. The specific research goals are as follows: (1) to characterize publication trends and identify key contributing countries, institutions, authors, and journals in this field; (2) to identify the core research hot spots and emerging topics; and (3) to provide a reference for researchers to grasp the global research status and formulate future research directions. The findings of this study will not only help academic researchers identify research gaps but also provide evidence-based insights for clinicians to optimize perioperative management strategies and improve patient recovery outcomes.

Methods

Ethical Considerations

This study did not include human or animal participants; therefore, ethics approval was not required for this study. For this type of study, formal consent was also not required.

Identification of Papers on Postoperative Sleep

This study was a bibliometric analysis based on an accessible database. The WoS Core Collection database was systematically retrieved on May 6, 2025, to search for publications on postoperative sleep. The search terms were as follows: TS= (postoperative sleep disorder) OR TS= (postoperative sleep disturbance) OR TS= (postoperative insomnia) OR TS= (postoperative agrypnia) OR TS= (postoperative sleeplessness) OR TS= (postoperative hyposomnia) OR TS= (postoperative sleep quality). The time span was from 2014 to 2024.

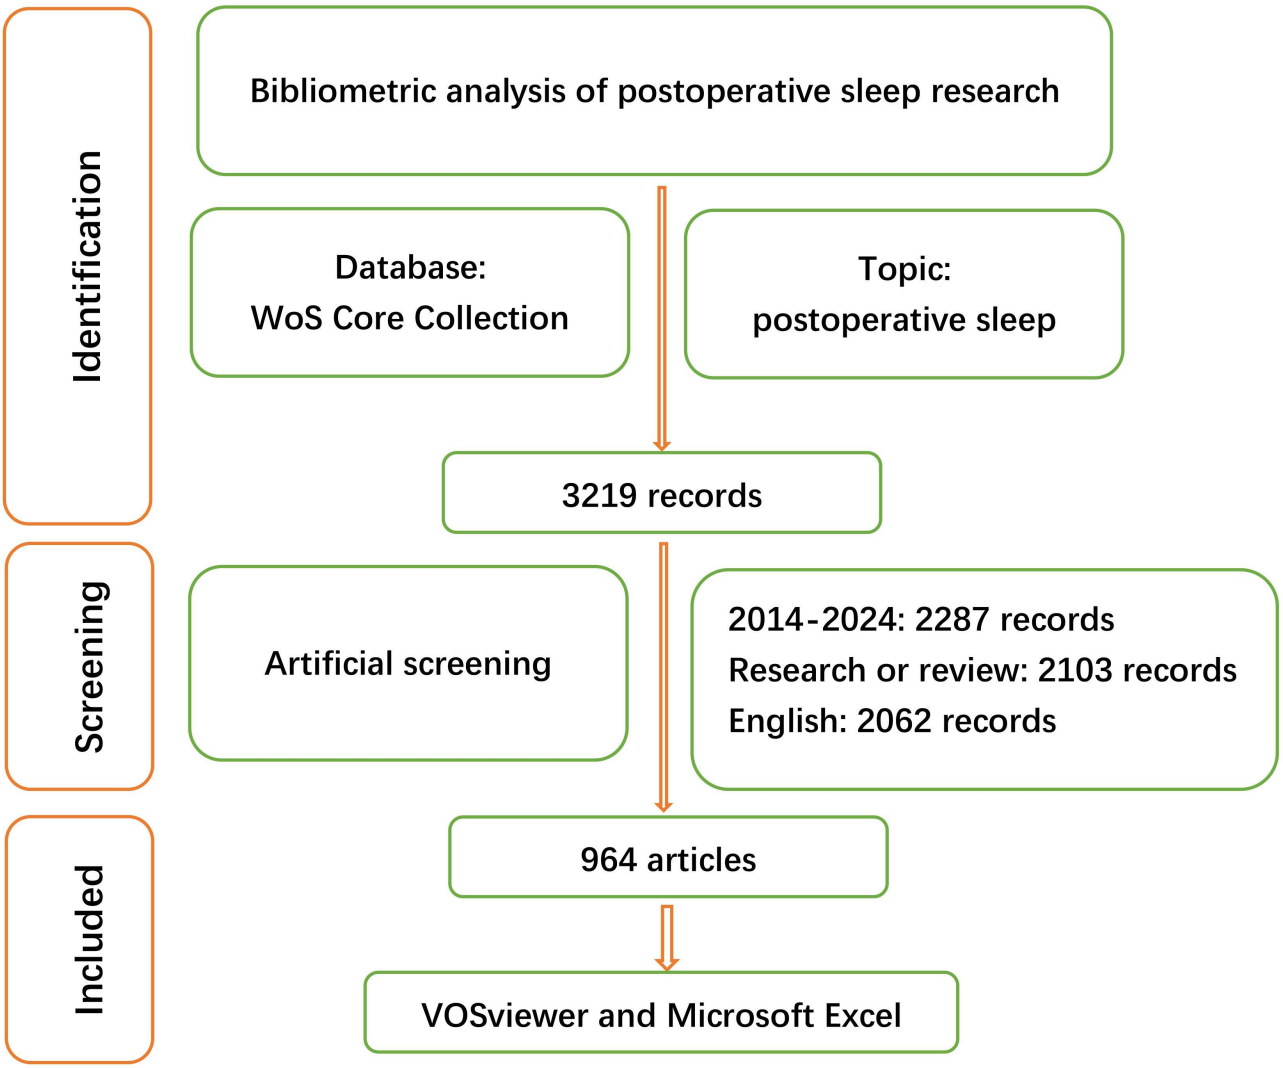
Studies were excluded if they were non-English publications, publications on preoperative sleep disorders, non–surgery-related publications, publication types other than research papers and review papers, retracted publications, or publications on animal experiments. Two investigators independently searched and screened the records. The review process included two parts: (1) title and abstract screening (the 2 investigators independently reviewed the title and abstract of each retrieved publication) and (2) full-text verification (for publications with ambiguous descriptions in the titles and abstracts, the full texts were further retrieved and evaluated). If discrepancies arose, a third reviewer was consulted to resolve them through discussion or arbitration.

Data Collection, Cleaning, and Analysis

Eligible publications were extracted. The extracted items included the title, authors, country or region, journal, affiliation, keywords, and publication year. The files were downloaded in ".txt" and ".xls" formats and then imported into VOSviewer (version 1.6.20) and Microsoft Excel (version 2021). All data extraction procedures were performed on the same day to avoid bias caused by database updates. In addition, the 2 investigators manually collected the specializations of the first authors.

Subsequently, we created thesaurus files to merge synonyms for countries and keywords. For example, "sleep disorders" and "insomnia" were replaced by "sleep disturbance." Thus, VOSviewer could automatically recognize and merge the duplicate terms. Quantitative analyses of the data, such as annual publication numbers and citation counts, were performed by Microsoft Excel.

VOSviewer was used to build a collaborative network of authors, countries, institutions, and journals to study collaborative linkages and the intensity of collaboration among different nodes, as well as to perform a clustering analysis of the frequently cocited keywords. For country, institution, and author collaboration networks, analysis type was coauthorship; the minimum number of papers per country, institution, and author were 5, 5, and 3, respectively; the normalization method was association strength; and the display style (meaning of the color) per country, institution, and author was by average publishing year, by average publishing years, and by cooperation strength, respectively. For the journal collaboration network, the analysis type was cocitation, the minimum number of papers per journal was 5, the normalization method was association strength, and the display style was by average publishing year. For the keyword co-occurrence network, the analysis type was co-occurrence, the minimum number of occurrences of a keyword was 10, the normalization method was association strength, and the display style was by average publishing year.



Results

Overview of the Literature Related to Postoperative Sleep

An initial search indicated that there were 3219 publications that may be eligible in the WoS Core Collection database. Among these publications, 2287 (71.0%) were published between 2014 and 2024. After removing non-English publications and other paper types, 2062 (64.1%) studies were reviewed by reading the titles and abstracts, and 1098 (53.2%) studies were excluded according to the exclusion criteria, with 964 (46.8%) studies finally included in this analysis. The details of this selection process are shown in Figure 1.

Annual Trend of Publication Quantity

Postoperative sleep research has surged over the last decade. Figure 2 shows a substantial increase in annual publications, soaring from just 29 publications in 2014 to 169 publications in 2024. With a mean of 87.6 publications per year and a median of 77 publications per year, the field saw steady growth, punctuated by a significant surge in 2020. Research output has remained consistently high ever since, and these publications have already garnered an impressive 8423 citations.

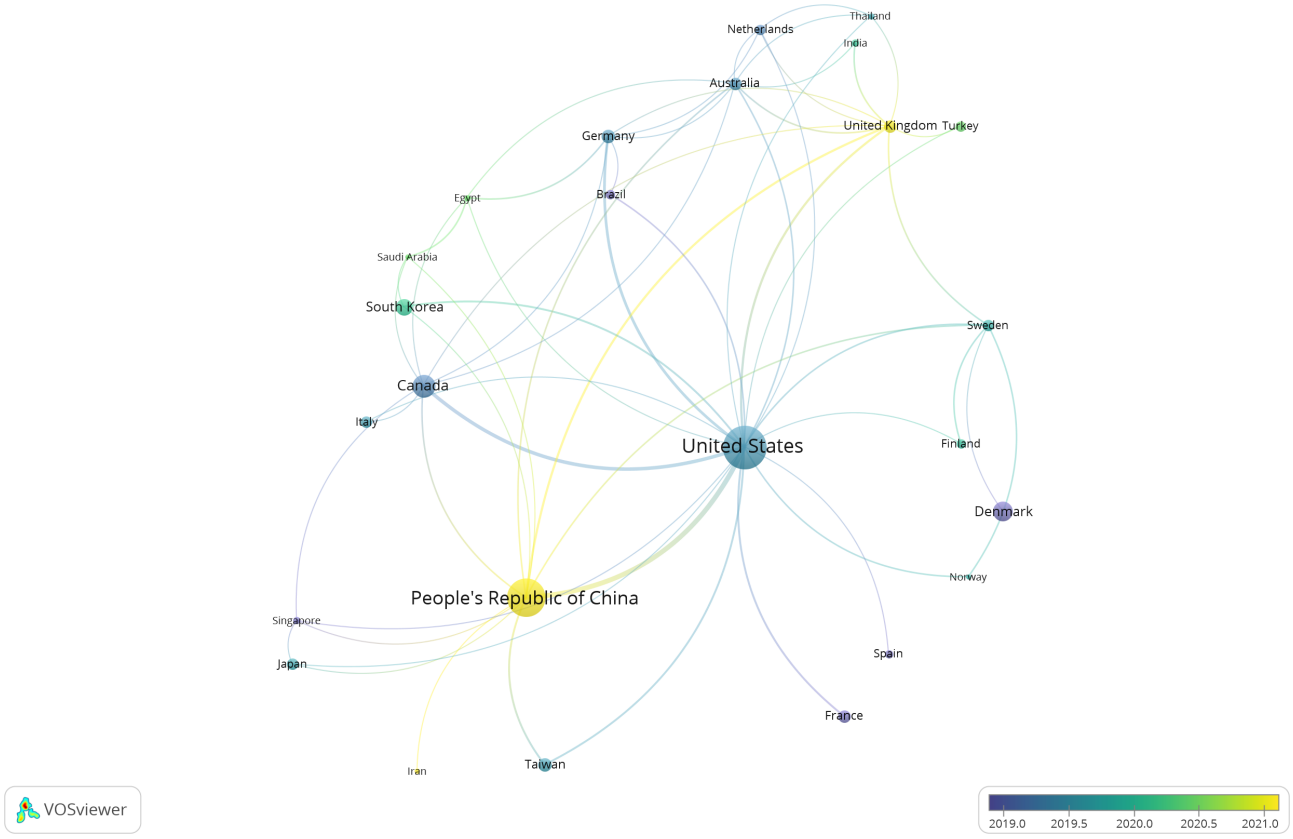
Contributions of Countries or Regions to Global Publications

In the last decade, 54 countries or regions contributed to the research on postoperative sleep. The top 10 countries or regions with the highest number of publications are listed in Table 1. China (n=402, 41.7%) made the highest contribution in terms of the number of publications, followed by the United States (n=201, 20.9%); Turkey (n=50, 5.2%); South Korea (n=48, 5.0%); Japan (n=35, 3.6%); Canada (n=26, 2.7%); Germany (n=25, 2.6%); Taiwan, China (n=23, 2.4%); Denmark (n=23, 2.4%); and Australia (n=19, 2.0%).

The top 10 countries or regions in terms of citation count were the United States (n=2587); China (n=2144); Canada (n=699); Denmark (n=515); South Korea (n=389); Taiwan, China (n=269); Germany (n=257); Australia (n=230); the United Kingdom (n=214); and France (n=210; Table 2). The United States had the most extensive collaboration links with other countries or regions, and the collaboration between the United States and China was strongest (Figure 3). In addition, papers from China, the United Kingdom, and Iran had younger publication ages (Figure 3).

Table . The top 10 countries or regions in terms of publications.



Rank	Countries or regions	Publications, n
1	China	402
2	United States	201

Figure 3. Links among the countries and regions. The nodes in the map have at least 5 papers.

Contributions of the Authors

A total of 4677 authors published papers on postoperative sleep. Figure 4 shows 6 clusters, and the authors in each cluster had close citation relation. The top 10 authors in terms of publication number and citation count are listed in Tables 3 and 4. In terms of publication number, Zhu Junchao ranked first, followed by Song Bijia, Shi Qiuling, and Kehlet Henrik. In terms of citation number, Chung Frances ranked first, followed by Kehlet Henrik, Mace Jess C, and Smith Timothy L. In addition, the first authors mainly specialized in anesthesiology, surgery, internal medicine, and nursing.

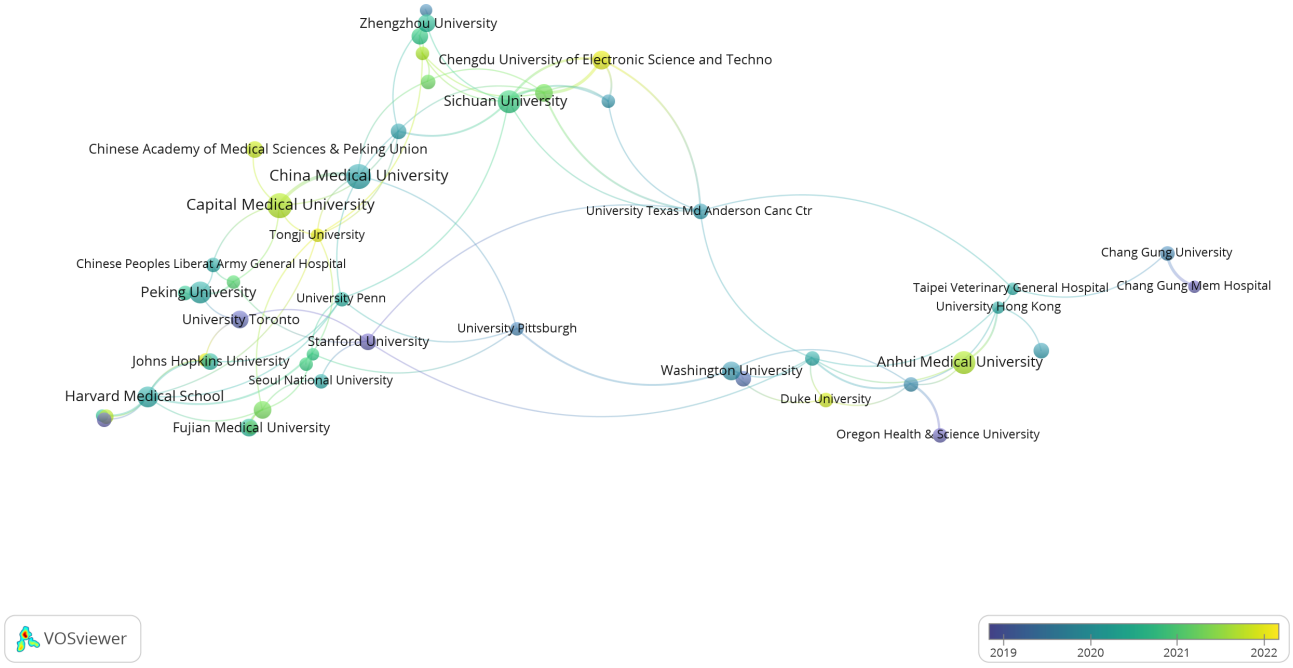
Contributions of the Affiliations



A total of 1153 scientific institutions contributed to these papers. The top 10 affiliations in terms of publication number are listed in Table 5. China Medical University (n=24) ranked first, followed by Capital Medical University (n=23), Sichuan University (n=19), Anhui Medical University (n=18), the University of Copenhagen (n=18), and Peking University (n=18). In terms of citation number, the University of Copenhagen ranked first (n=488), followed by the University of Toronto (n=309), Peking University (n=232), and Oregon Health and Science University (n=224). Universities such as the University of Toronto and Stanford University were active in the 2010s, whereas universities such as Tongji University and Duke University have devoted themselves to this area more recently (Figure 5).

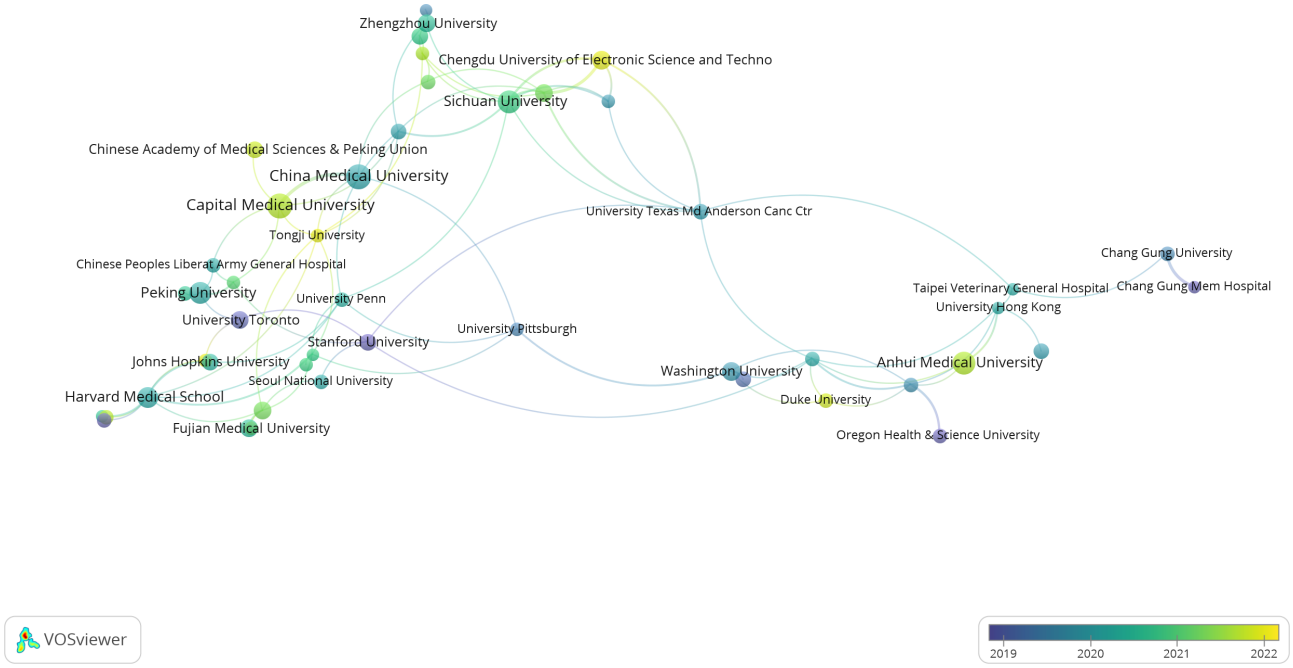

Figure 5. Citation relationships among institutions. The minimum number of papers per institution was set at 5.

Distribution of the Journals

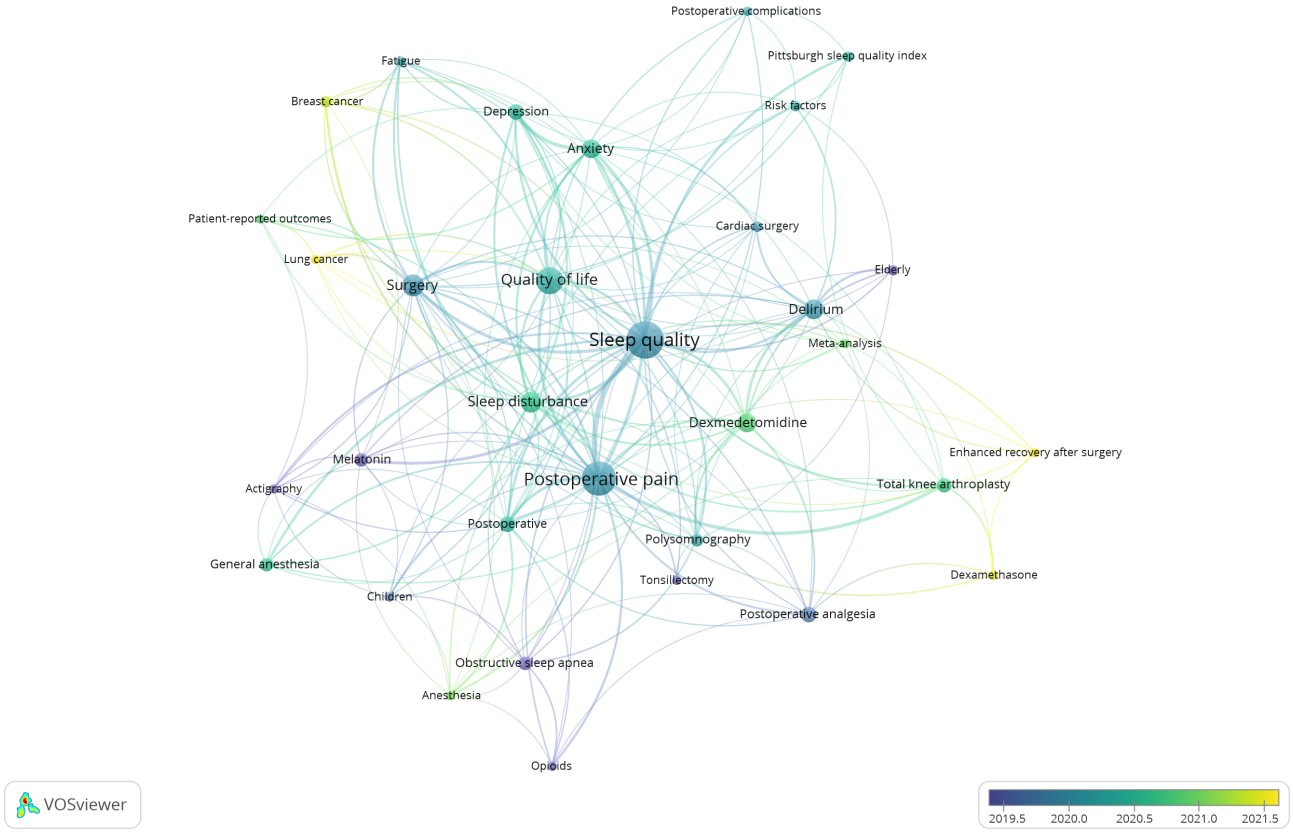
The papers on postoperative sleep in the last 10 years were documented by 392 journals indexed in the Scientific Citation Index. *BMC Anesthesiology*, with 19 publications, ranked first, followed by *Nature and Science of Sleep* (n=16) and *International Journal of Clinical and Experimental Medicine* (n=16). Papers published in the *British Journal of Anaesthesia*, *Journal of Clinical Anesthesia*, *Anesthesia and Analgesia*, *Journal of Pain*, and *Journal of Sleep Medicine* had higher citation counts on average (Figure 6).

Figure 6. Citation relationships among journals. The minimum number of papers per journal was set at 5.

Analysis of Keywords

The keyword co-occurrence analysis (Figure 7) revealed the primary research themes and focal points within the domain of postoperative sleep disturbances. The central and most prominent keywords were postoperative pain, sleep disturbance, and quality of life, indicating that these topics are core concerns driving research. Patient-reported outcomes also feature significantly, highlighting the importance of subjective patient experiences in this field.

Research methodologies are notably represented by specific assessment tools, including actigraphy (objective sleep measurement), polysomnography (the gold standard sleep study), and the Pittsburgh Sleep Quality Index (a common subjective sleep quality questionnaire). Key clinical contexts strongly associated with postoperative sleep issues included



XSL•FO
RenderX

breast cancer, lung cancer, cardiac surgery, total knee arthroplasty, and tonsillectomy.

Pharmacological interventions such as dexmedetomidine and melatonin were also frequently identified. The concept of enhanced recovery after surgery (ERAS) appears frequently, suggesting that its protocols are being examined for their impact on preoperative sleep. Other significant keywords include "fatigue" and "delirium" (a serious postoperative complication potentially linked to sleep disturbance).

The temporal markers (2019.5 to 2021.5) indicate that this topic has received particular attention in recent years. "ERAS," "lung cancer," and "dexamethasone" emerge as more recent keywords in postoperative sleep research.

Figure 7. Co-occurrence analysis of author-provided keywords. The minimum occurrence threshold for inclusion in the map was set at 10.

Discussion

Principal Findings

This bibliometric analysis focused on papers related to postoperative sleep over the past 10 years and provided an overview of publication trends, the distribution of publications, and hot research topics.

On the basis of the data collected in the WoS Core Collection, 964 papers on postoperative sleep were published during the past decade. With an increasing trend, the number of publications remained high. In total, 4677 authors from 1153 institutions across 54 countries or regions worldwide have published their work, and the number of researchers continues to grow. This trend and the distribution of publications suggest that postoperative sleep is an important focus in clinical practice and a prominent topic in the scientific literature, consistent with previous findings that postoperative sleep disorders can affect recovery [10,12,13].

China and the United States contributed the most to postoperative sleep research. They had the highest number of publications and citations and demonstrated the strongest international collaborations. However, fresh institutions in terms of average publication years mainly come from China, which indicates the expanding participation in this field. It is interesting that the top 10 authors and institutions in terms of publication number and citations were all from high-income countries or regions. This finding is not surprising but reasonable. A previous study was conducted to uncover the relationship between the development of anesthesia and gross domestic product from 2009 to 2018, and the results indicated a strong positive correlation [14].

Zhu Junchao is the most productive author in this field. The author has long been devoted to investigating the relationships between organ protection and cognitive impairment in the field of ischemia-reperfusion injury, postoperative outcomes, and sleep quality [15-17]. One of the related studies found that morning operations required a higher dose of anesthetics than evening operations and that the degree of postoperative sleep disorders was greater when the operation was performed in the evening than in the morning [17]. Meanwhile, the results prompted that patients with hyperpathia and somnipathy might benefit from operations performed in the morning [17,18]. Chung Frances, with 248 citations and only 5 publications, is the most cited author in the field of postoperative sleep research from 2014 to 2024. However, he and his research team have

XSL•FO
RenderX

been engaged in postoperative sleep disorders for more than 10 years [13,19,20]. His paper published in *Anesthesiology* in 2014 revealed that the postoperative sleep structure was disturbed in both patients with obstructive sleep apnea and patients with nonobstructive sleep apnea, and they further analyzed disturbances in sleep structure [19]. His systematic review and meta-analysis also revealed the prevalence and risk factors of sleep disturbances in surgical patients [20]. These aforementioned authors are well respected as they greatly contribute to the prevention of postoperative sleep disturbance.

It was reported that the incidence of sleep disturbance was high (54%) during the postoperative period [21]. Determining the prevalence and risk factors related to postoperative sleep disturbance would be beneficial for risk stratification and perioperative care planning. On the basis of the keywords map, sleep quality was closely related to the postoperative quality of life, postoperative pain, delirium, anxiety, depression, dexmedetomidine use, and postoperative complications, while ERAS, lung cancer, breast cancer, and dexamethasone have received much attention recently. Postoperative pain is regarded as a primary risk factor for postoperative sleep disorders, and sleep quality can, in turn, aggravate pain [22-25].

The term “enhanced recovery after surgery” was coined by Henrik Kehlet, one of the most influential researchers in the field of postoperative sleep. Postoperative pain, a key component of ERAS protocols, and postoperative sleep have received considerable attention. Opioids, nonopioids, regional and neuraxial anesthesia, and multimodal analgesia based on the aforementioned techniques have been widely used in ERAS procedures, contributing to improved postoperative pain control [26,27]. Nevertheless, the incidence of postoperative sleep disorders is still high even though postoperative pain is well controlled [28,29]. Future studies are advised to build a systematic strategy for postoperative management.

To our knowledge, this is the first bibliometric analysis based on the WoS Core Collection to assess the studies on postoperative sleep over the past 10 years. This study included a large number of papers (n=964) on postoperative sleep to help identify the research status and hot spots. To improve the quality of the enrolled studies, 2 independent investigators conducted an artificial screening, and disagreements were properly settled. Moreover, duplicate terms were removed as far as possible by creating a thesaurus file.

The findings of this bibliometric analysis provide several practical implications for clinicians engaged in perioperative patient management. First, postoperative pain was identified as a core correlate of sleep disturbance in this study. Practitioners should integrate sleep quality assessment and interventions into ERAS pathways. They can combine multimodal analgesia with sleep-promoting strategies, such as melatonin administration or environmental optimization, to improve both pain control and sleep quality in surgical patients. Second, keyword analysis highlighted lung cancer and breast cancer surgeries as emerging research hot spots. Practitioners should pay special attention to sleep disorders in patients undergoing these procedures.

Third, the analysis shows that anesthesiologists, surgeons, and nurses are the main contributors to this field. Practitioners should establish interdisciplinary teams to address postoperative sleep issues. For example, anesthesiologists can optimize anesthetic regimens to reduce circadian rhythm disruption, while nurses can implement nonpharmacological sleep interventions during inpatient care. In addition, the identification of emerging topics such as ERAS provides direction for future clinical research. Practitioners can design prospective studies to verify the effects of postoperative sleep within ERAS protocols.

However, this study inevitably has some limitations. It was impossible to enroll all publications in this field, and we restricted the paper type to research and review papers. Therefore, the results of this study represent the general situation of postoperative sleep research but cannot precisely reflect all details. We did not use processed parameters such as the Hirsch index to define the top authors and institutions because the primary function of bibliometric analysis is to provide a macrolevel view of a research field. Citation indicators may be influenced by the time of publication, meaning that recently published studies may have been underestimated. The number of citations increased dynamically over time. Thus, bibliometric analyses in this field must be updated in the future.

Conclusions

This study presents the current research status and possible research directions through a visual bibliometric analysis of research on postoperative sleep over the past 10 years. There has been a large amount of literature on postoperative sleep over the past 10 years. Authors and organizations from China are leading contributors, followed by those from the United States. Anesthesiology is a critical discipline in this field. Postoperative pain is closely related to postoperative sleep and has become a hot topic. Recent studies have mainly focused on lung and breast cancer surgeries, and ERAS has become an emerging keyword.

Acknowledgments

The authors thank all individuals who participated in and supported this study. They declare that no generative artificial intelligence was used in any part of the manuscript preparation.

Abstract

Background: In December 2022, in light of the weakened pathogenicity of the new variants and other scientific considerations, China optimized its zero-COVID policy. As the situation evolved, the virus spread more widely across the country.

Objective: This study aims to explore the public's sleep status and its association with purchasing behavior of COVID-19 medicine after the adjustment of zero-COVID policy in China.

Methods: A cross-sectional, internet-based survey among residents aged 18 - 69 years was conducted in Zhejiang province, China, from December 16 to 30, 2022, to collect data on sociodemographic characteristics, COVID-19 drug purchasing behavior, sleep disturbance levels, etc. Chi-square tests, univariate analyses, and multivariate analyses were used to explore the associations among these factors.

Results: Out of 38,480 participants, 20,803 (54.1%) reported sleep disruption after China's COVID-19 response policy adjustment. The degree of impact varied, with 10,964 (52.70%) reporting "slight," 3105 (14.93%) "moderate," 3493 (16.79%) "significant," and 3241 (15.58%) "very significant" impacts. Only 20.90% (782/3742) of those who deemed purchasing unnecessary had sleep disruptions, compared to 45.19% (6214/13,752) of those who acquired medications and 65.79% (13,807/20,986) of those who tried but failed to obtain them. Sleep disturbance levels were significantly associated with sociodemographic factors like age, education levels, occupation, marital status, and presence of family members diagnosed with COVID-19 (P<.05). By age, sleep disturbance proportions differed notably: 36.32% (409/1126) for those under 20 years, 54.81% (19,714/35,970) for the 20 to 60 age group, and 49.13% (680/1384) for individuals over 60 years. For education level, the proportions were 57.44% (517/900, primary school), 54.34% (3928 /7229, junior high school), 54.27% (3808/7017, senior high school), 53.99% (11,974/22,180, junior college/undergraduate), and 49.91% (576/1154, master's degree), showing a clear downward trend as education level increased. By occupation, farmers had the highest rate (855/1447, 59.09%), followed by business/service industry workers and stay-at-home/unemployed individuals (13,925/24,750, 56.26%) and government staff (4161/7712, 53.95%), while 1242 out of 3049 (40.73%) health workers and 620 out of 1522 (40.74%) students had lower rates. Married participants had a 55.21% (17,143/31,053) sleep disturbance rate, and those with COVID-positive family members had the highest rate (2023/2873, 70.41%). Multivariate logistic regression, adjusting for these sociodemographic factors, showed that compared to those who thought purchasing COVID-19 medications was unnecessary, those who acquired medications were 3.11 times (adjusted odds ratio 3.11, 95% CI 2.85 - 3.39) more likely, and those who tried but couldn't get medications were 7.11 times (adjusted odds ratio 7.11, 95% CI 6.53 - 7.74) more likely to experience sleep disturbance.

Conclusions: The adjustment of China's zero-COVID policy affected the sleep health of the public, which was closely linked to drug-purchasing status, especially among the older people, those with lower education levels, and those with family members diagnosed with COVID-19. It highlights the need to develop and deploy interventions aimed at promoting better sleep health in times of crisis.

Introduction

In December 2019, an unprecedented pneumonia outbreak of unknown origin emerged in Wuhan, Hubei province, China [1,2]. Subsequently identified as caused by the novel coronavirus (COVID-19), this highly contagious pathogen rapidly spread beyond China's borders within just 30 days [3-6]. Characterized by potentially severe symptoms such as acute respiratory failure and sepsis [7], COVID-19 posed a significant threat to global public health, prompting the World Health Organization (WHO) to declare it a public health emergency of international concern on January 30, 2020 [8].

To contain the virus, China implemented the dynamic zero-COVID policy, which included strict measures like national lockdowns, school closures, travel restrictions, and the suspension of numerous economic activities [9-13]. However, as the virulence of new virus variants decreased and COVID-19 vaccines became more prevalent, China adjusted its policy on December 7, 2022. The mandatory large-scale nucleic acid testing requirements, the centralized isolation for asymptomatic cases and mild symptomatic patients, and the mobility restrictions were removed [14,15]. This suddenly loosened policy led to a change in the epidemic situation, with a wider spread of the virus across the country.

The COVID-19 pandemic has had a profound impact on people's lives, particularly on their mental health and sleep quality [16-20]. A large-scale global study (combining 250 studies with nearly 500,000 participants from 49 countries) found that about 40% of people had sleep disturbances during the COVID-19 pandemic (95% CI 37.56%-43.48%). Among specific populations, the prevalence of sleep problems varied, with 52.39% (95% CI 41.69%-62.88%) among COVID-19 patients, 45.96% (95% CI 36.90%-55.30%) among children and adolescents, 42.47% (95% CI 37.95%-47.12%) among health care workers, 41.50% (95% CI 32.98%-50.56%) among special populations with health care needs, 41.16% (28.76%-54.79%) among university students, and 36.73% (32.32%-41.38%) among the general population [21]. Research in China shows that the prevalence of insomnia during the early and late stages of the pandemic was 37.0% (95% CI 34.1% - 39.9%) and 41.8% (95% CI 33.6% - 50.0%) respectively. Notably, health care workers, COVID-19 patients, those with chronic diseases, and people with mental disorders are more likely to experience insomnia than the general population [22].

Sleep is a fundamental physiological process that is essential for maintaining physical and mental health [19,23]. It plays a crucial role in various bodily functions, including homeostasis, immune system regulation, cognitive function, neural plasticity, memory consolidation, energy maintenance, macromolecular biosynthesis, and metabolism regulation [24,25]. Conversely, sleep deprivation can lead to a range of adverse health outcomes, such as impaired physical and mental performance, increased risk of depression, stroke, chronic inflammation, cancers, and weakened immune defense, which may be particularly relevant during the COVID-19 pandemic [26,27].

During the pandemic, multiple factors influenced people's sleep quality. The spread of news and rumors through social media, television, and daily interactions about COVID-19's severity and fatality numbers fueled anxiety and fear. Additionally, lack of in-person social connections, changes in eating patterns, less outdoor activities which lead to limited exposure to sunlight, and consequently extended exposure to blue and bright light from screens may lead to disturbed circadian rhythms [21,28-32]. Above all, the suddenly loosened policy and the increased risk of infection may lead some individuals to panic-purchase medical resources—especially COVID-19 medicines (including cough medicine, nasal congestion/snot relievers, fever reducers, pain relievers, and other symptom-alleviating pharmaceuticals for COVID-19)—to ensure timely administration when needed [33,34]. The purchasing behavior towards COVID-19 medicines reflected people's perception of the disease and their self-protection strategies. However, it may also leave those in need unable to obtain them. This behavior was not only driven by the actual need for medications but also by psychological factors, such as the desire for a sense of security in the face of an uncertain health situation. Understanding the relationship between sleep status and these factors after the policy adjustment is of great significance for public health.

However, there is a lack of in-depth research on how the adjustment of China's zero-COVID policy affects the public's sleep status and its connection with the purchasing behavior of COVID-19 medicine. This study aims to fill this gap by conducting a cross-sectional, internet-based survey to assess the public's sleep status and explore its association with the purchasing behavior of COVID-19 medicine after the policy adjustment. The findings of this research can provide valuable insights for public health interventions and future pandemic-related policies.

Methods

Questionnaire

The questionnaire was formulated by the Zhejiang Provincial Center for Disease Control and Prevention based on pandemic-specific context, literature review, and expert consultation. To ensure its reliability, a pilot study was first conducted. Following the feedback from the pilot study and through two rounds of collaboration based on the Delphi method, the questionnaire was revised. During this process, subject matter experts evaluated its face validity, and a literature review was carried out to assess its content validity.

The questionnaire collected sociodemographic data: purchasing behavior of COVID-19 medications; specific types of COVID-19 drugs that respondents had purchased; channels through which they bought these medications; and degrees of their sleep disturbances. Sociodemographic data includes age, gender, education level, occupation, marital status, and diagnosis of COVID-19 among family members. The specific questions regarding the purchasing behavior of COVID-19 medications and the degrees of their sleep disturbances were as follows: (1) "Have you purchased COVID-19 drugs?" (2) "Which of the following COVID-19 drugs have you purchased?" (3) "Through

XSL•FO
RenderX

what channel did you successfully purchase these medicines?" (4) "In the past week, has the adjustment of COVID-19 policies affected your sleep?" No item randomization or adaptive questioning was used, and the 18-item questionnaire was distributed across 3 screens. Participants could review and revise answers via a "Back" button on each screen before submission. IP address tracking was used to prevent multiple entries from the same individual, and no two entries from the same IP address were allowed within 72 hours.

To maintain the quality of the survey data, a quality control question was incorporated into the questionnaire to identify survey respondents who did not answer the questions seriously. The question was, "This is a quality control question, please choose B." All the survey subjects who chose other options were not included in the final data analysis. In addition, server-side completeness checks were implemented upon submission, incomplete responses were rejected, and participants were prompted to fill in missing fields.

The questionnaire was developed and administered entirely in simplified Chinese, consistent with the native language of the target population—see Supplemental File for Chinese (in Multimedia Appendix 1) and translated English version (in Multimedia Appendix 2) of the questionnaire.

Recruitment

The survey was carried out between December 16 and 30, 2022, among residents aged 18-69 years in Zhejiang province, China. Initially, an online open survey questionnaire was dispatched to the 11 municipal Centers for Disease Control and Prevention. These centers then actively promoted and conducted the online investigation by sharing survey links via local official WeChat public accounts, neighborhood WeChat groups, and other regional lifestyle apps. Visitors to the survey link could choose to exit at any time, and no access to other content was restricted to survey completion. The questionnaire was hosted on Wenjuan, a professional web-based platform specialized in questionnaires, tests, assessments, and voting. This platform is dedicated to offering users powerful and user-friendly services such as online questionnaire design, data collection, customized reports, and analysis of survey results.

Measurements Control

Levels of Sleep Disturbance

The Likert scale was used to assess the levels of sleep disturbance related to the COVID-19 epidemic reported by participants. In our research, we used a 5-point Likert scale which consists of 5 answer options: (1) not at all, (2) slight, (3) moderate, (4) significant, and (5) very significant.

Purchasing Behavior of COVID-19 Medicine

Purchasing behavior of COVID-19 medicine was classified as follows: (1) participants who felt it unnecessary to purchase COVID-19 medicine, (2) participants who had tried, but were unable to access any COVID-19 medicine, and (3) participants who had successfully purchased COVID-19 medicine.

Participants were classified as having COVID-19 medication purchasing behavior during the early phase following China's zero-COVID policy adjustment if they had acquired the following drugs at that time: (1) cough medicine, (2) nasal congestion/snot relievers, (3) fever reducers, (4) pain relievers such as ibuprofen (Advil, Motrin IB, and others) or acetaminophen (Tylenol and others), and (5) other pharmaceuticals capable of alleviating COVID-19 infection symptoms.

Family Members Infected With COVID-19

"Family members infected with COVID-19" was defined as "individuals who reside in the same household as the participant and had been diagnosed with COVID-19 (via nucleic acid or antigen testing) at any time prior to the survey."

Statistical Analysis

Data were exported from the Wenjuan website to Excel (Microsoft), and were analyzed using the Statistical Analysis System (SAS), version SAS Viya Long-Term Support 2024.03 (SAS Institute Inc., Cary, NC, USA). Standard descriptive statistics were used for continuous and categorical variables to describe the characteristics of participants in this study. The χ^2 test was used to explore the association between the purchasing behavior of COVID-19 medicines and the levels of sleep disturbance. Univariate logistic regression analysis was conducted to identify the sociodemographic factors associated with sleep disturbance. We used multivariate logistic regression to identify the association between sleep disturbance and purchasing behavior of COVID-19 medicines (categorical variable; reference group was "deemed unnecessary to purchase;" comparison groups was "successfully purchased" and "tried but failed to purchase"). The initial candidate variables included in the model were: age, gender, education level, occupation, marital status, and diagnosis of COVID-19 among family members. A backward stepwise selection approach was used, with a significance level of $P<.10$ for variable retention. Odds ratios (OR) with 95% CI were used to express measures of the associations. P values less than .05 were considered to represent significance (two-sided).

Ethical Considerations

The Zhejiang Provincial Center for Disease Control and Prevention Ethics Board approved the study protocol (2022-027-01). Conducted under strict anonymity, the survey safeguarded the privacy of all participants. No personally identifiable information was collected at any stage of the survey, the dataset was stored by specified staff, and all researchers involved signed a data confidentiality agreement. Informed consent was obtained from all participants prior to their inclusion in the study. By voluntarily clicking an electronic consent box, participants provided their informed consent, thereby indicating their willingness to participate in this research project. As compensation, participants could collect free health education materials at their local Center for Disease Control and Prevention.

Results

Respondents' Characteristics

A total of 40,130 residents took part in the survey, and after implementing quality control procedures, 1650 samples were excluded, with 38,480 samples ultimately included in the study. The sample consisted of 10,431 (27.11%) male participants and 28,049 (72.89%) female participants, with 1129 (2.93%) participants aged 20 years or below, 35,970 (93.48%) participants aged between 20 and 60, and 1384 (3.60%) participants over 60. Regarding occupations, 3049 (7.92%) were health workers, 7712 (20.04%) were government staff, 1522 (3.96%) were students , 1447 (3.76%) were farmers, and 24,750 (64.32%) were business/service industry workers and stay-at-home/unemployed individuals. In terms of education level, 22,180 (57.64%) participants had an education of junior college or undergraduate. Marital status showed that 31,053 (80.70%) people were married and 7427 (19.30%) people were unmarried, while 2873 (7.47%) people resided in households with confirmed COVID-19 cases. The detailed demographic characteristics of the participants are presented in Table 1.

Table . Sociodemographic characteristics of participants completing the online survey in the early stage after the lifting of zero-COVID policy in China (n=38,480).

Characteristic	Count, n (%)
Age (y)[a]	
<20	1126 (2.93)
20 - 60	35,970 (93.48)
>60	1384 (3.60)
Gender	
Male	10,431 (27.11)
Female	28,049 (72.89)
Occupation	
Health workers	3049 (7.92)
Government staff	7712 (20.04)
Students	1522 (3.96)
Farmers	1447 (3.76)
Business/service industry workers and stay-at-home/unemployed individuals	24,750 (64.32)
Education level	
Primary school	900 (2.34)
Junior high school	7229 (18.79)
Senior high school	7017 (18.24)
Junior college/undergraduate	22,180 (57.64)
Postgraduate	1154 (3)
Family members infected with COVID-19	
Yes	2873 (7.47)
No	35,607 (92.53)
Marital status	
Married	31,053 (80.70)
Others (single/divorced/widowed/separated, etc)	7427 (19.30)

[a]In the preliminary analysis, participants were divided into 10-year age groups (<20, 20 - 29, 30 - 39, 40 - 49, 50 - 59, 60 - 69 y). Given similar purchasing behavior in 20 - 29 to 50 - 59 years groups, these 4 groups were merged into 20 - 60 years for concise result presentation, with this data-driven rationale added herein.

The Impact of China's Zero-COVID Policy Adjustment on the Sleep Status of the Public of Zhejiang, China

When the Likert scale was used to assess the degree of impact on participants' sleep, the findings revealed that out of 38,480 participants, 17,677 (45.94%) indicated that the adjustment of China's COVID-19 response policies had no effect on their sleep. In contrast, 20,803 (54.06%) reported experiencing varying levels of sleep disruption. Specifically, 10,964 (52.70%) described the impact as "slight," 3105 (14.93%) as "moderate," 3493 (16.79%) as "significant," and 3241 (15.58%) as "very significant."

XSL•FO
RenderX

Association Between Sleep Status and Purchasing Behavior of COVID-19 Medicine Among the Public in the Early Stage After the Adjustment of China's Zero-COVID Policy

As shown in Table 2, among individuals who had tried, but were unable to access any COVID-19 medicine, 34.21% (7179/20,986) reported no impact on their sleep by the lifting of China's zero-COVID policy in the past week. In contrast, 54.81% (7538/13,752) of those who successfully acquired COVID-19 medications indicated no sleep disturbances. Notably, the proportion of individuals who deemed it unnecessary to buy COVID-19 medications and experienced no sleep disruption was as high as 79.10% (2960/3742).

Table . Impact of purchasing behavior of the COVID-19 medicine on the sleeping status among the participants of an online survey in the early stage after the lifting of zero-COVID policy in China.

Purchasing of the COVID-19 medicine	How has your sleep been affected by the lifting of China's zero-COVID policy in the past week[a]? n (%)					Total
	Very significant	Significant	Moderate	Slight	Not at all	
Participants who felt it unnecessary to purchase COVID-19 medicine	60 (1.60)	62 (1.66)	99 (2.65)	561 (14.99)	2960 (79.10)	3742
Participants who purchased COVID-19 medicine	629 (4.57)	931 (6.77)	917 (6.67)	3737 (27.17)	7538 (54.81)	13,752
Participants who had tried, but were unable to access any COVID-19 medicine	2552 (12.16)	2500 (11.91)	2089 (9.95)	6666 (31.76)	7179 (34.21)	20,986

[a]χ^2=3639.2; *P*<.001.

Among the 3742 respondents who considered purchasing COVID-19 medications unnecessary, the numbers of those experiencing slight, moderate, significant, and very significant impacts on sleep were 561 (14.99%), 99 (2.65%), 62 (1.66%), and 60 (1.60%), respectively. Among the 13,752 participants who had successfully obtained COVID-19 medications, the corresponding figures were 3737 (27.17%), 917 (6.67%), 931 (6.77%), and 629 (4.57%). For the 20,986 individuals who attempted to purchase but failed to obtain COVID-19 medications, the numbers were 6666 (31.76%), 2089 (9.95%), 2500 (11.91%), and 2552 (12.16%). A χ^2 test for comparing multiple sample rates revealed that, overall, there were significant differences among the population rates (*P*<.001).

Factors Associated With Sleep Disturbance Among the Public in the Early Stage After the Adjustment of China's Zero-COVID Policy

As shown in Table 3, there were statistically significant differences in sleep disturbance after the adjustment of China's zero-COVID policy among participants by age, education level, occupation, marital status, and diagnosis of COVID-19 among family members .

XSL•FO
RenderX

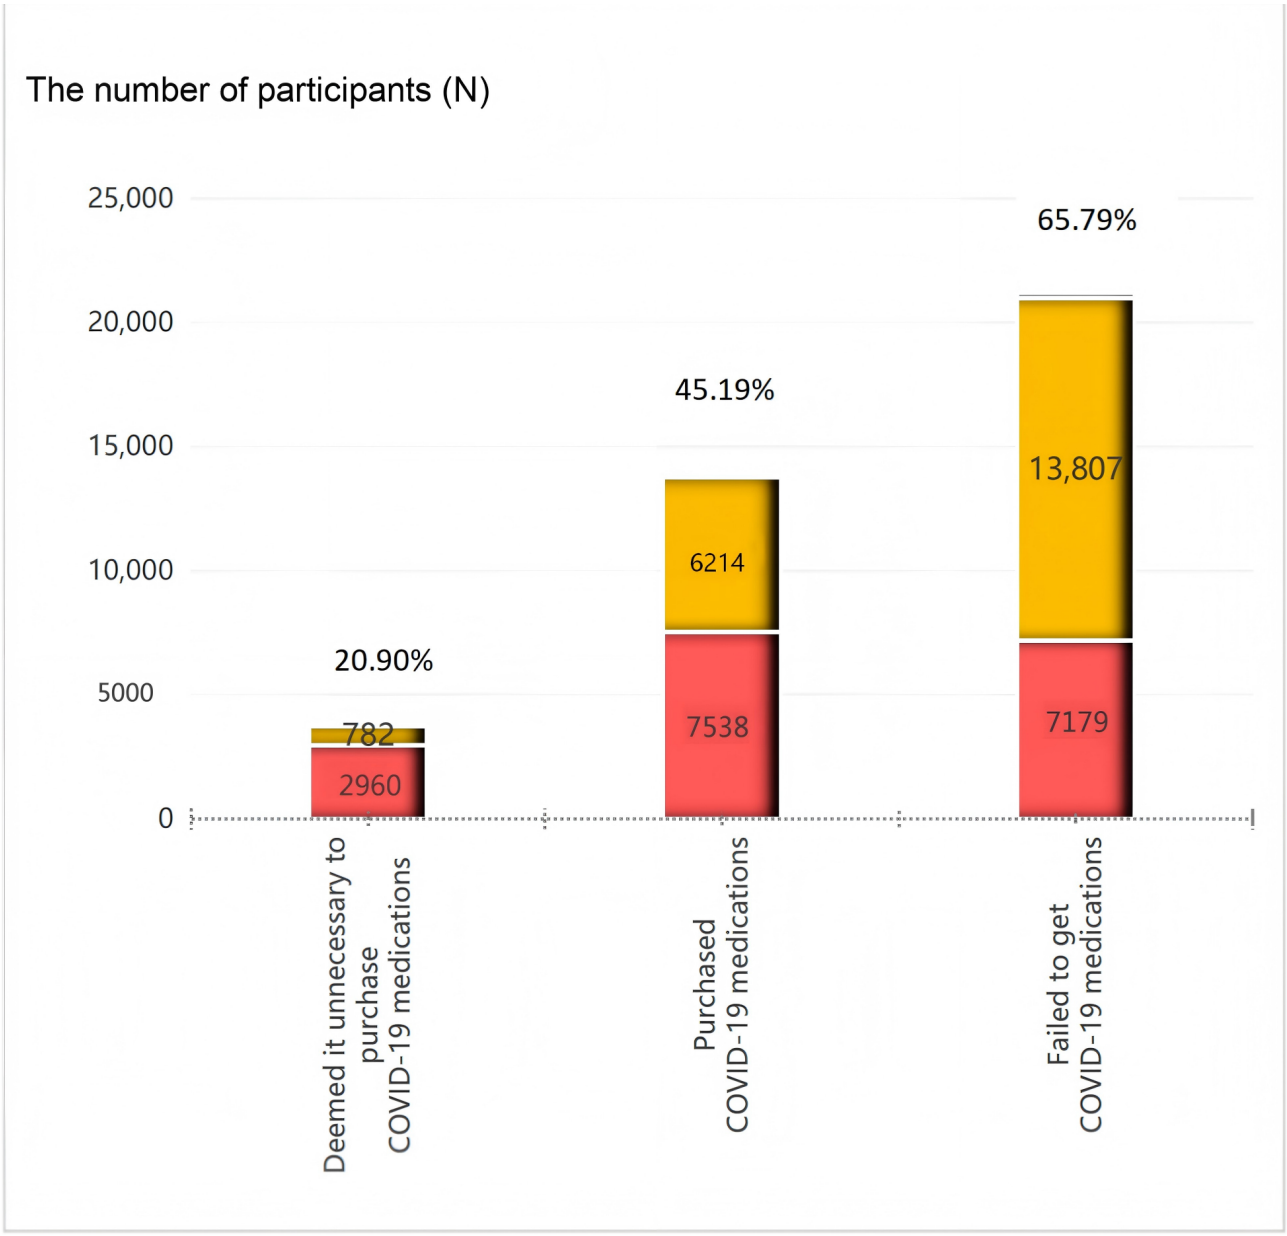
[a]OR: odds ratio.

[b]$P<.001$.



[c]$P<.01$.

Age emerged as a notable predictor: participants aged 20 - 60 years had the highest sleep disturbance rate (19,714/35,970, 54.80%), followed by those over 60 years (680/1384, 49.13%), while 409 out of 1126 participants under 20 years reported sleep disturbance (409/1126, 36.32%). Education level showed a clear inverse relationship with sleep disturbance: the rate was highest among primary school graduates (517/900, 57.44%) and gradually decreased with higher education, reaching 49.91% (576/1154) for master's degree holders. Occupation also played a role. Farmers had the highest rate (855/1447, 59.09%), followed by business/service industry workers and stay-at-home/unemployed individuals (13,925/24,750, 56.26%), government staff (4161/7712, 53.95%), while 1242 out of 3049 health workers (1242/3049, 40.74%) and 620 out of 1522 students (620/1522, 40.74%) had lower rates. Marital status and family COVID-19 diagnosis further contributed to sleep disturbance: married participants had a higher (17,143/31,053, 55.21%) sleep disturbance rate than unmarried/separated individuals (OR 1.27, 95% CI 1.21 - 1.33). Most notably, participants with family members diagnosed with COVID-19 had the highest sleep disturbance rate (2023/2873, 70.41%) across all groups, with odds of disturbance 2.13 times higher than those without infected family members (OR 2.13, 95% CI 1.96 - 2.32) (detailed values in Table 3).

XSL•FO
RenderX

As shown in Figure 1, among individuals who had tried, but were unable to access any COVID-19 medicine, 65.79% (13,807/20,986) reported experiencing sleep disturbance. In contrast, 45.19% (6214/13,752) of those who successfully acquired COVID-19 medications indicated sleep disturbances. Notably, the proportion of individuals who deemed it unnecessary to buy COVID-19 medications and experienced sleep disruption was a mere 20.9% (782/3742).

Figure 1. Stacked bar chart showing individuals affected by sleep disturbance stratified by COVID-19 medication access status among the public in the early stage after the lifting of China's zero-COVID policy. The yellow color represents those who reported experiencing sleep disturbance, and the red color represents those unaffected.

By using multivariate logistic regression analysis and after adjusting for variables including gender, age, education level, occupation, marital status, and presence of family members diagnosed with COVID-19, it was discovered that there was a statistically significant correlation between purchasing behavior of COVID-19 medicine and the sleep status of the participants. Table 4 shows that, compared to those who deemed it unnecessary to buy COVID-19 medications, those who successfully acquired COVID-19 medications were 3.11 times more likely to encounter sleep disturbance (adjusted odds ratio [aOR] 3.11, 95% CI 2.85 - 3.39). Moreover, those who had tried, but were unable to access any COVID-19 medicine were 7.11 times (aOR 7.11, 95% CI 6.53 - 7.74) more likely to experience sleep disturbance.

Discussion

Principal Findings

This study explores the sleep status of the public in Zhejiang province, China, following the adjustment of the zero-COVID policy and explores its relationship with the purchasing behavior towards COVID-19 medicine. The results offer valuable insights into the post-policy-adjustment situation. Given the dearth of similar studies, this research will serve as a foundation for future studies that highlight such crucial issues in the context of future public health emergencies.

After the zero-COVID policy adjustment, news and rumors about infection severity and fatalities—spread via social media, television, and daily interactions—fueled public anxiety and fear. Consequently, people act on their primal instincts and are prone to engage in panic buying to ease this psychological reaction [35]. The results of our study revealed that 35.74% (13,752/38,480) of the participants had successfully purchased COVID-19 medicines, 54.54% (20,986/38,480) had attempted to make a purchase but were unable to obtain any of the drugs, and 9.72% (3742/38,480) felt it was unnecessary to stockpile COVID-19 drugs. Psychologically, those who tried to purchase COVID-19 medicines may be driven by a fear of drug shortages, price increases, the surge in infections, and the availability of medicines and home delivery services during the pandemic [34,36]. Therefore, whether they successfully purchase medications directly affects their psychological state. Those who manage to buy medications will experience a certain degree of anxiety relief, while those who fail to do so may become more anxious [37-40].

Our study revealed that 54.06% (20,803/38,480) of the participants experienced sleep disturbances following the adjustment of the zero-COVID policy. It can be explained as a psychological burden during stressful circumstances. Pandemic-related sleep disturbance was also confirmed by many other studies worldwide. A study carried out in Beijing, China, found that, during the second wave of COVID-19, the overall prevalence of sleep disturbance was 50.8% [41]. Madeleine reported a 33.5% sleep disturbances during the COVID-19 shutdown phase in Germany [42]. It is also documented that there is a negative impact on the quality of sleep among the Spanish population during the lockdown period due to COVID-19 [43]. Studies found that COVID-19 had both negative and positive impacts on adolescent sleep. A study in Canada found that the shutdown of schools due to the COVID-19 pandemic might lead to a 2-hour shift in the sleep of typically developing adolescents, longer sleep duration, improved sleep quality, and less daytime sleepiness compared to those experienced under the regular school-time schedule [44]. Parents of 8th grade students from local schools across Ohio, Kentucky, and Virginia (USA) reported adolescents had more difficulties initiating and maintaining sleep during COVID-19 than before COVID-19, with clinically elevated rates increasing from 24% to 36%. Both bedtimes and wake times shifted later during COVID-19, and adolescents reported more delayed sleep/wake behaviors. Adolescents also reported less daytime sleepiness and longer school night sleep duration during COVID-19 [45].

Our study found that the degree of sleep disturbance varied, with 52.70% (10,964/20,803) reporting “slight,” 14.93% (3105/20,803) “moderate,” 16.79% (3493/20,803) “significant,” and 15.58% (3241/20,803) “very significant.” It suggests a complex and diverse range of effects on individuals, which may be related to various factors. Our study found that sociodemographic factors played a crucial role in sleep disturbances. Older people were more likely to experience sleep disturbances compared to the younger. A systematic review found that studies involving older participants had a higher pooled prevalence of insomnia symptoms during the COVID-19 pandemic [22]. Older individuals may be more sensitive to policy change impacts, due to preexisting health conditions, limited medical access, and greater reliance on stable daily routines—all of which increase their fear of infection [46]. Even though women were found to be more prone to sleep disturbance than men [47-49], the perceived impact of COVID-19 on sleep was not different between sexes in our study, which was also confirmed by research from the United States by Jeremy A Bigalke [50]. Literature reviews also revealed that sex had no bearing on the estimated prevalence of sleep disturbance [21]. Education level was inversely related to sleep disturbances; as the education level increased, the likelihood of experiencing sleep disturbances decreased. This could be because individuals with higher education levels are generally better at accessing and understanding information and medical resources, and thus better able to cope with the stress caused by the pandemic.

XSL•FO
RenderX

Studies found that people with higher socioeconomic status are more likely to attain medical resources during the COVID-19 pandemic [40,51]. While health care workers were documented as the most sleep-vulnerable group early in the COVID-19 pandemic [52,53], our study found the opposite in post-policy-adjustment in China. Different occupations face varying degrees of stress during the pandemic. For example, government staff may be burdened with epidemic-prevention work responsibilities, while business/service industry workers may worry about economic losses, and farmers may be concerned about the impact of the pandemic on agricultural production. However, at the very beginning after the adjustment of zero-COVID policy in China, the anxiety of getting infected without drugs in hand might relate to poor sleep quality. Our previous research found that 56.54% of health workers had successfully purchased COVID-19 medicines, which was the highest among all the occupation groups and might explain the less experience of sleep disturbance in this study [40]. Marital status and family members' COVID-19 diagnosis also had an impact. Married individuals had a higher probability of sleep disturbances, perhaps due to increased family responsibilities during the pandemic. Participants with family members diagnosed with COVID-19 were more prone to sleep disturbances, with a proportion as high as 70.41% (2023/2873), indicating that the direct impact of the disease on the family can cause significant psychological pressure, which was also confirmed by a study carried out in Bangladesh. Participants having relatives or acquaintances infected with COVID-19 were more likely to experience poor sleep quality (68.8% vs 49.0%) [47].

In addition to sociodemographic factors, our study found a strong association between the purchasing behavior of COVID-19 medicine and sleep status. Those who deemed purchasing unnecessary had the lowest proportion of sleep disruptions, while those who tried but failed to obtain medications had the highest. After adjusting for sociodemographic factors, it demonstrated that compared to those who thought purchasing was unnecessary, those who acquired medications were 3.11 times more likely, and those who tried but couldn't get medications were 7.11 times more likely to experience sleep disturbance. This difference highlights the role of medication availability and the psychological stress related to it [35]. For those who manage to buy the medicine, it may bring a sense of security and relieve some anxiety, as they feel prepared for potential infections. However, their higher sleep disturbance rate—compared to those who saw no need to purchase COVID-19 medicines—suggests lingering concerns about the disease and future drug shortages still impact their mental state. For those who fail to purchase it, the situation can exacerbate their anxiety. The fear of not being able to access necessary medications during illness and the uncertainty about their health can heighten stress levels, making them more likely to experience sleep disturbance. Our previous research revealed an inverse correlation between anxiety levels and the behavior of purchasing COVID-19 medications which can further explain the association between purchasing behavior of COVID-19 medicine and sleep status. Compared to those with severe anxiety, those with moderate anxiety were 1.76 times more likely to have purchased COVID-19 medicine (aOR 1.76, 95% CI 1.64 - 1.89); those with mild anxiety were 2.11 times (aOR 2.11, 95% CI 1.98 - 2.24) more likely to have purchased COVID-19 medicine; those with no anxiety were 2.48 times (aOR 2.48, 95% CI 2.31 - 2.67) more likely to have purchased COVID-19 medicine [40]. Individuals who were unable to obtain COVID-19 medications may have experienced heightened anxiety, which in turn could have contributed to increased instances of sleep disturbance. The very strong aOR of 7.11 for those unable to access medications and their likelihood of reporting sleep disturbances is notable. However, this causal inference requires further validation to account for unmeasured confounders (eg, baseline anxiety levels, preexisting sleep disorders).

Limitations

This study has certain limitations. Firstly, to quickly explore the association between sleep disturbance and COVID-19 medicine purchasing behavior, the questionnaire was kept concise, omitting potential confounders (eg, COVID-19 vaccination status, comorbidities). "Participants who had tried, but were unable to access any COVID-19 medicine" was not clearly defined, which may lead to misclassification of participants' purchasing behavior. Sleep disturbance was measured via a single Likert-scale item—practical for large surveys but lacking details on sleep frequency/duration/severity, limiting study depth. These should be explored in future studies. Secondly, the data collection relied on self-reported information, which is subject to recall bias and may distort the study results. Thirdly, among the participants in the online survey, the participation of women and those with a higher education level is significantly higher than that of men and those with a low education level. Thus, applying the survey results directly to the general population could lead to inaccuracies.

Conclusions

The findings reflect 54.1% of participants experiencing varying levels of sleep disturbance after the zero-COVID policy adjustment in Zhejiang, China. The older people, those with lower education levels, those with family members diagnosed with COVID-19, and those who had tried, but were unable to access any COVID-19 medicine were mostly affected. Public health agencies should design tailored communication campaigns for different demographic groups, especially for those high-risk groups, to minimize COVID-19-related fear and anxiety. Additionally, optimizing the supply and distribution of COVID-19 medications might help alleviate the stress of individuals who are unable to access them. A robust, transparent pharmaceutical supply chain monitoring system and dedicated channels (hotlines/online platforms) for reporting shortages would enable timely supply adjustments, ensuring high-risk groups access necessary drugs. Beyond China, our findings hold global relevance to observations in other countries where postpandemic policy shifts linked to anxiety and sleep disruptions [42,43].

Abstract

Background: Insomnia is a common and persistent symptom in major depressive disorder (MDD), associated with poorer outcomes and reduced quality of life (QoL). Despite its prevalence, recent patient-reported data on the burden of insomnia symptoms in MDD remains limited.

Objective: This study aimed to assess the burden of insomnia among individuals with MDD experiencing insomnia symptoms (MDDIS) and its impact on patient-perceived disease burden and QoL.

Methods: A noninterventional, cross-sectional online study was conducted from October 2022 to February 2023 in adults with self-reported MDD and insomnia symptoms, residing in the United States or 1 of 5 European countries (EU5: France, Germany, Italy, Spain, and the United Kingdom). Participants completed validated questionnaires (Patient Health Questionnaire-9 [PHQ-9] for depression severity and Insomnia Severity Index [ISI] for insomnia severity) and provided data on demographics, clinical history, treatment experience, and perceptions. Descriptive statistics were used to summarize results, and subgroup analyses were conducted based on depression status and severity.

Results: Among 1250 participants (United States: 500; EU5: 750), most were cisgender women (United States: 363/500, 72%; EU5: 637/750, 85%), aged ~48 years, and on average 13.4 years in the United States and 11.2 years in EU5 had passed since being diagnosed with MDD. Around 60% (United States: 312/500; EU5: 439/750) reported having moderate to severe insomnia symptoms. Most had used antidepressants (United States: 460/500, 92%; EU5: 646/750, 86%) at least 40% (United States: 198/500; EU5: 343/750) in both regions reported using sleep-related medications (over-the-counter sleep aids, dual-purpose medication, or sleep-specific medication). However, insomnia symptoms persisted, with around half of participants reporting 8 to 15 insomnia nights over 2 weeks. Insomnia symptom severity differed significantly according to depression severity and current depressive episode status. Nearly all participants reported negative consequences for daily functioning, including irritability, cognitive impairment, and reduced productivity, and approximately two-thirds identified sleep disturbances as having a major impact on their daily lives. Satisfaction with current treatments, particularly their effectiveness on sleep, was low, and 65% - 71% (488/750-354/500) of participants expressed a desire for alternative therapies.

Conclusions: Insomnia symptoms are highly prevalent and burdensome among patients with MDD, severely affecting daily life and perceived treatment success. Insomnia remains inadequately controlled despite high medication use. These findings emphasize the need for integrated treatment strategies targeting both mood and sleep symptoms. Given its role in depression relapse, suicidality, and treatment resistance, addressing insomnia symptoms in MDD should be a clinical priority.

Introduction

Background

Major depressive disorder (MDD) or major depression is the most commonly diagnosed form of depression [1] and was ranked by the World Health Organization as the third leading cause of disease burden in 2018, with projections placing it first by 2030 [2]. MDD is defined by a persistently low mood, loss of interest or pleasure (anhedonia), recurrent suicidal thoughts, and a range of physical and cognitive symptoms—including sleep disturbance, changes in appetite and weight, fatigue, psychomotor agitation or retardation, feelings of worthlessness,

XSL•FO
RenderX

and difficulty concentrating [3-5]. According to the *Diagnostic and Statistical Manual of Mental Disorders* (Fifth Edition; *DSM-5*), diagnosis requires at least 5 of these symptoms lasting a minimum of 2 weeks [6].

The global incidence of MDD has steadily increased over the past 3 decades [7], with a sharp 27.6% rise in 2020 linked to the COVID-19 pandemic [8]. The most recent Global Burden of Disease (GBD) study estimated that 229 million people worldwide were affected by MDD in 2021, with the highest prevalence rate in the United States (4527 cases per 100,000 population; 15 million cases) and Europe (3771 cases per 100,000 population; 32 million cases) [7,9]. Globally, MDD is more prevalent in women, with a female-to-male ratio of approximately 1.6, as reported in the most recent GBD study, rising to 1.9 in the United States and Europe [7].

MDD severely impacts quality of life (QoL) not only due to its core symptoms but also because of functional limitations, social disruption, and comorbidities [3,10]. The severity of depressive symptoms directly correlates with greater QoL impairment [11-13]. Among these symptoms, sleep disturbances, especially insomnia, are among the most common, affecting around 60% of people with depression [14,15]. Insomnia symptoms are frequently reported as the main complaint [16], further deteriorating QoL by worsening energy levels and mood, and overall functioning [15,17]. Sleep disturbances in MDD are also linked to more severe symptoms—persistent depression, higher relapse risk, poorer response to traditional depression treatment, and increased risk of suicidality [18-26]. Insomnia symptoms often persist despite antidepressant treatment [27] and after remission of depressive symptoms, making individuals with MDD experiencing insomnia symptoms (MDDIS) particularly difficult to treat [28,29].

Though the literature suggests MDD and sleep disturbances are associated [16,20,30], the persistence and clinical consequences of insomnia symptoms highlight a critical need for interventions to address sleep disorders in MDDIS to improve patients' outcomes. Despite extensive research [31,32], recent data capturing patient-reported outcomes on insomnia symptoms in MDD remain limited, particularly regarding how patients perceive its impact on their lives and how this knowledge can guide the development of more effective care strategies.

Objective

To address the absence of data on patients' perspectives regarding the impact of insomnia symptoms on patients' lives and treatment needs, we collected current patient-reported data on insomnia symptoms among individuals with MDDIS in the United States and Europe. The primary objective of this descriptive study was to assess the burden of insomnia symptoms and patient-reported QoL in this population. We also sought to understand how patients perceive the relationship between their sleep disturbances and depression, how they perceive their current MDDIS treatments, and if they discuss their insomnia symptoms with a clinician or another member of their care team.

In this paper, we present findings from this observational study that provides insights into the lived experience of MDDIS, focusing on how insomnia symptoms shape their daily functioning and well-being.

Methods

Study Design

This was a noninterventional, observational, and cross-sectional web-based study targeting patients who self-reported a diagnosis of depression and symptoms of insomnia.

Study Population

Eligible participants were adults (≥18 years) residing in the United States, or in 1 of 5 European countries (EU5; France, Germany, Italy, Spain, or the United Kingdom), who self-reported a health care professional diagnosis of MDD, self-reported insomnia symptoms, and who provided informed consent. Participants who did not meet the inclusion criteria or who did not fully complete the questionnaire were excluded from the analysis. No medical records, prescriptions, or physician confirmation were requested as part of the study.

The target sample size was 1250 participants: 500 from the United States and 750 from EU5.

Participants were recruited through Carenity (ELSE CARE), an online community launched in 2011, where both patients and caregivers share experiences, access health-related information, and participate in online research studies. Carenity members were invited to participate by email. Recruitment also involved online campaigns (Facebook; Meta Platforms Inc. and Google; Alphabet Inc.). No incentives were provided for participation in the study.

Data were collected between October 2022 and February 2023.

Ethical Considerations

The study protocol was approved by the Western Institutional Review Board–Copernicus Group (WCG IRB; approval number 20223963). All participants provided electronic informed consent prior to completing the study.

Data Collection and Measures

Overview

Participants completed a self-administered online questionnaire. The study included 39 closed-ended questions covering participants' demographic characteristics, clinical profiles, and the impact of MDDIS on daily life. All questions were mandatory, and the study required approximately 15 minutes to complete. Study-specific questions were translated by a certified translation agency in the native language of each targeted country. The translated versions were proofread by native speakers for consistency. The Patient Health Questionnaire (PHQ-9) and the Insomnia Severity Index (ISI) questionnaires were administered using the official translated versions provided by the respective copyright holders.

Sociodemographic Variables

Participants reported their sex, year of birth, and country of residence. Sex was categorized into 5 groups: cisgender male,

XSL•FO
RenderX

cisgender female, transgender male, transgender female, and nonbinary.

Clinical Variables

Participants self-reported a health care professional–confirmed diagnosis of MDD and provided information on the date of diagnosis, the type of health care professional having diagnosed MDD, their comorbidities, MDD characteristics, current and past depression treatments, insomnia symptoms characteristics, and sleep treatment history.

The PHQ-9, a 9-item patient-reported instrument for assessing depression severity, was administered using validated language versions that have demonstrated good psychometric properties [33-37]. The total score ranges from 0 to 27, with higher scores indicating greater depression severity. Severity is categorized as: minimal (0-4), mild (5-9), moderate (10-14), moderately severe (15-19), and severe (20-27).

Outcome Variables

In the questionnaire, participants were informed that "Insomnia, or trouble sleeping, can include falling asleep, staying asleep or waking up early, and being unable to go back to sleep."

To evaluate the burden of insomnia symptoms in MDDIS, participants were asked how many nights they had experienced insomnia symptoms or used treatments for them in the 2 weeks prior to study inclusion (for those with a current depressive episode) or prior to their most recent episode. These are referred to as "insomnia nights" in the patient questionnaire and the paper. Participants also reported the duration of their insomnia symptoms or treatment use. To measure nocturnal and daytime symptoms of insomnia and assess its severity, the ISI, a validated 7-item scale, was also administered [38]. The total score ranges from 0 to 28, with higher scores indicating greater insomnia symptom severity. Insomnia symptoms severity is categorized as: no insomnia symptoms (0-7), subthreshold (8-14), moderate (15-21), and severe (22-28).

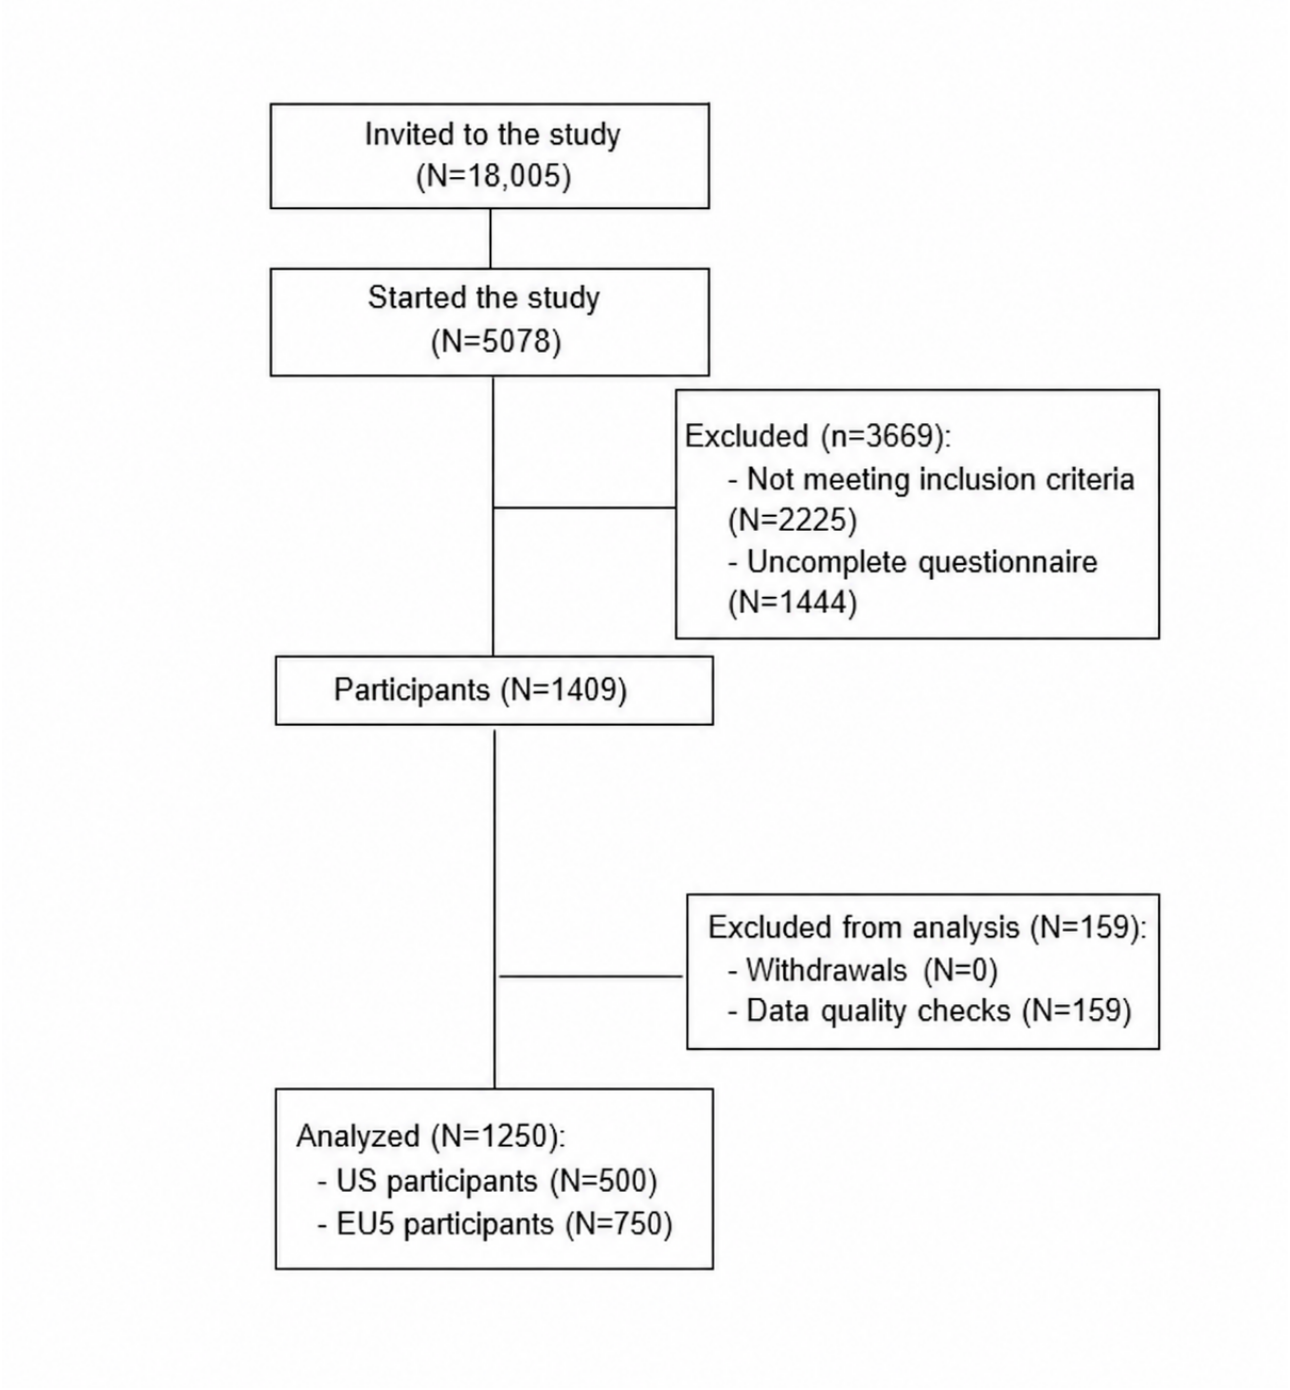
To evaluate the impact of MDDIS on patients' QoL, participants were asked to report, through 2 closed-ended self-designed questions, the MDDIS symptoms that had the greatest impact on their global daily life, and the consequences of sleep disruptions on their daily life during the most recent episode.

Participants were also asked to report their perceptions of the relationship between their MDD and insomnia symptoms, their satisfaction with treatments for MDD and insomnia symptoms, and their unmet needs regarding these treatments.

Statistical Analysis

The study population included all participants who met the study selection criteria and completed the questionnaire. Descriptive statistics were used to characterize the study population and summarize study responses. Quantitative data are reported using mean and its 95% CI and qualitative data are reported as frequencies and percentages. Results are presented separately by region of residence (United States or EU5). Descriptive subgroup analyses were conducted according to current depressive episode status, depression severity, and other relevant clinical characteristics. Differences in the distribution of categorical variables between subgroups were assessed using Pearson chi-square tests or Fisher exact test. All statistical tests were 2-sided, and a P value <.05 was considered statistically significant.

All data management and statistical analysis were performed using R software (version 4.1.2; R Core Team).



Results

Study Population Characteristics

Recruitment targets were met in both regions (United States and EU5), resulting in a total of 1250 participants: 500 in the United States and 750 in EU5. Details of participant disposition are shown in Figure 1. Demographic and clinical characteristics of the study population are detailed in Table 1.

XSL•FO
RenderX

Figure 1. Flowchart of the study population. US: United States; EU5: France, Germany, Italy, Spain, and the United Kingdom.

In both the United States and EU5, the majority of participants were cisgender women (United States: 363/500, 72%, and EU5: 637/750, 85%). A total of 12% (62/500) of US participants identified as transgender or nonbinary, compared to 3% (21/750) in the EU5 sample. Mean age at inclusion was similar across regions (United States: 48.1, 95% CI 46.5 - 49.7 years; EU5: 47.5, 95% CI 46.5 - 48.6 years) and most participants were diagnosed with MDD in their mid-thirties. In both regions, the majority of participants reported receiving their MDD diagnosis from a psychiatrist, with 79% (127/161) in Italy, 72% (111/154) in Germany, 68% (95/140) in Spain, 59% (98/167) in France, and 28% (36/128) in the United Kingdom (Table S1 in Multimedia Appendix 1).

[a]EU5: France, Germany, Italy, Spain, and the United Kingdom.

[b]MDD: major depressive disorder.

[c]HCP: health care practitioner.

[d] "Others" includes psychologist, therapist, mental health service, mental health counselor, nurse practitioner, neurologist, counseling center, not specified.

[e]Time elapsed since the current episode applies to participants with current MDD and those who reported experiencing symptoms of depression.

Comorbid mental health conditions were prevalent. The majority of participants from both regions reported at least one additional condition, most commonly generalized anxiety disorder, chronic anxiety or stress, posttraumatic stress disorder, social anxiety disorder, and panic disorder. At the time of the study, 86% (429/500) of United States and 87% (655/750) of EU5 participants were experiencing depressive symptoms or were in an active depressive episode, which had started less than a year earlier for over half of the participants. Among those not in an active episode, most had experienced one within the past year.

Depression Severity

As measured by the PHQ-9, 34% (170/500) of US participants were classified as having severe depression, 25% (124/500) as moderately severe, and 25% (123/500) as moderate depression (Figure 2). In the EU5 region, 41% (306/750) of participants had severe depression, 27% (203/750) moderately severe, and 19% (146/750) moderate depression. Descriptively, the proportion of participants with severe depression was highest in Spain, the United Kingdom, and Germany, and lower in France and Italy (Table S1 in Multimedia Appendix 1). Across both regions, the distribution of depression severity differed according to age group (both $P<.001$) and the number of insomnia nights reported during the previous 2 weeks (United States $P<.001$; EU5 $P=.04$), with a higher proportion of younger participants (18-30 years) and those who had experienced more insomnia nights reporting severe depression (Tables 2 and 3). Among US participants, a greater proportion of transgender or nonbinary participants had severe depression ($P=.02$).

XSL•FO
RenderX

Figure 2. Severity of depression in US (n=500) and EU5 (n=750) participants as measured by the Patient Health Questionnaire-9. EU5: France, Germany, Italy, Spain, and the United Kingdom; PHQ-9: Patient Health Questionnaire-9.

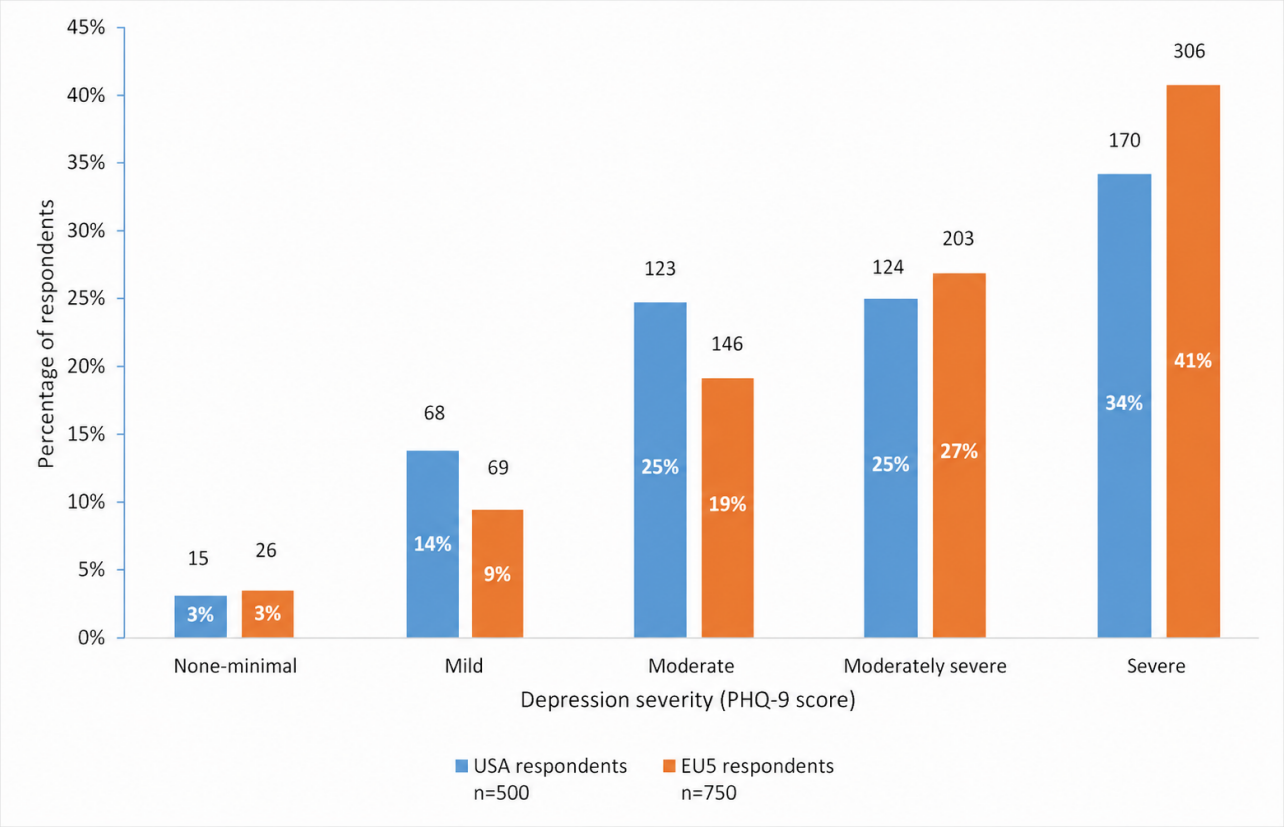

Table . Depression severity by sex, age, and insomnia symptoms frequency in US participants (n=500) as measured by the PHQ-9[a].

	None-minimal (n=15)	Mild (n=68)	Moderate (n=123)	Moderately severe (n=124)	Severe (n=170)	*P* values
Sex, n (%)						.02[b]
Cisgender female	13 (4)	54 (15)	91 (25)	92 (25)	113 (31)

[a]EU5: France, Germany, Italy, Spain, and the United Kingdom.

[b]PHQ-9: Patient Health Questionnaire-9.

[c]Fisher exact test.

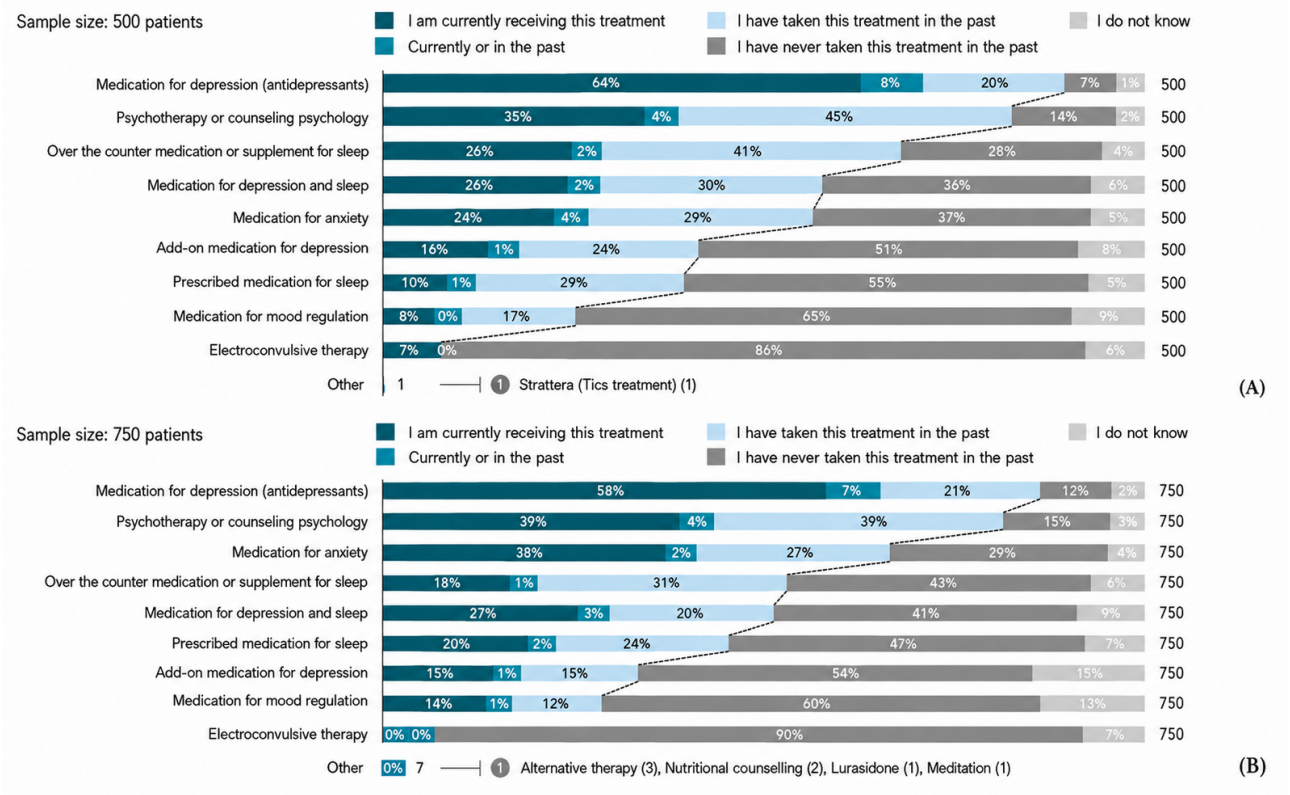
[d]Insomnia nights are defined here as nights with insomnia symptoms or taking treatments for insomnia symptoms (for EU5, n=206 for 0 - 7 insomnia nights and n=276 for 8 - 15 insomnia nights; n=166 for 8 - 15 insomnia nights).

Burden of Depressive Symptoms

At least half of the participants considered each PHQ-9 depressive symptom burdensome. In both regions, the most frequently reported disturbing symptoms, reported by 93% or more of participants, were low energy (United States: 491/500 and EU5: 731/750), depressed mood (United States: 478/500 and EU5: 722/750), sleep issues (United States: 475/500 and EU5: 701/750), and anhedonia (United States: 471/500 and EU5: 714/750; Figures 3A and 3B). Approximately half of the participants in both regions were impacted by sleep disturbances nearly every day.

XSL•FO
RenderX

Figure 3. Burden of depressive symptoms in United States (A, n=500) and EU5 (B, n=750) participants, PHQ-9: Patient Health Questionnaire.



MDDIS Treatment

Most participants had received antidepressant therapy (United States: 460/500, 92% and EU5: 646/750, 86%) and psychological care (United States: 421/500, 84% and EU5: 619/750, 82%) (Figure 4). Sleep-related treatments were also common. In the United States, 68% (341/500) reported using or having used over-the-counter (OTC) sleep aids, 58% (292/500) medications targeting both sleep and depression (dual-purpose medication), and 40% (198/500) prescribed sleep-specific medication. In the EU5, these figures were 51% (382/750), 50% (374/750), and 46% (343/750), respectively. At the time of the study, 28% (138/500 and 140/500) of US participants were taking OTC or dual-purpose medication and 11% (54/500) prescribed sleep-specific treatment. In the EU5, 19% (146/750) were using OTC sleep aids, 30% (222/750) used dual-purpose medication, and 22% (161/750) were receiving prescribed sleep-specific treatment.

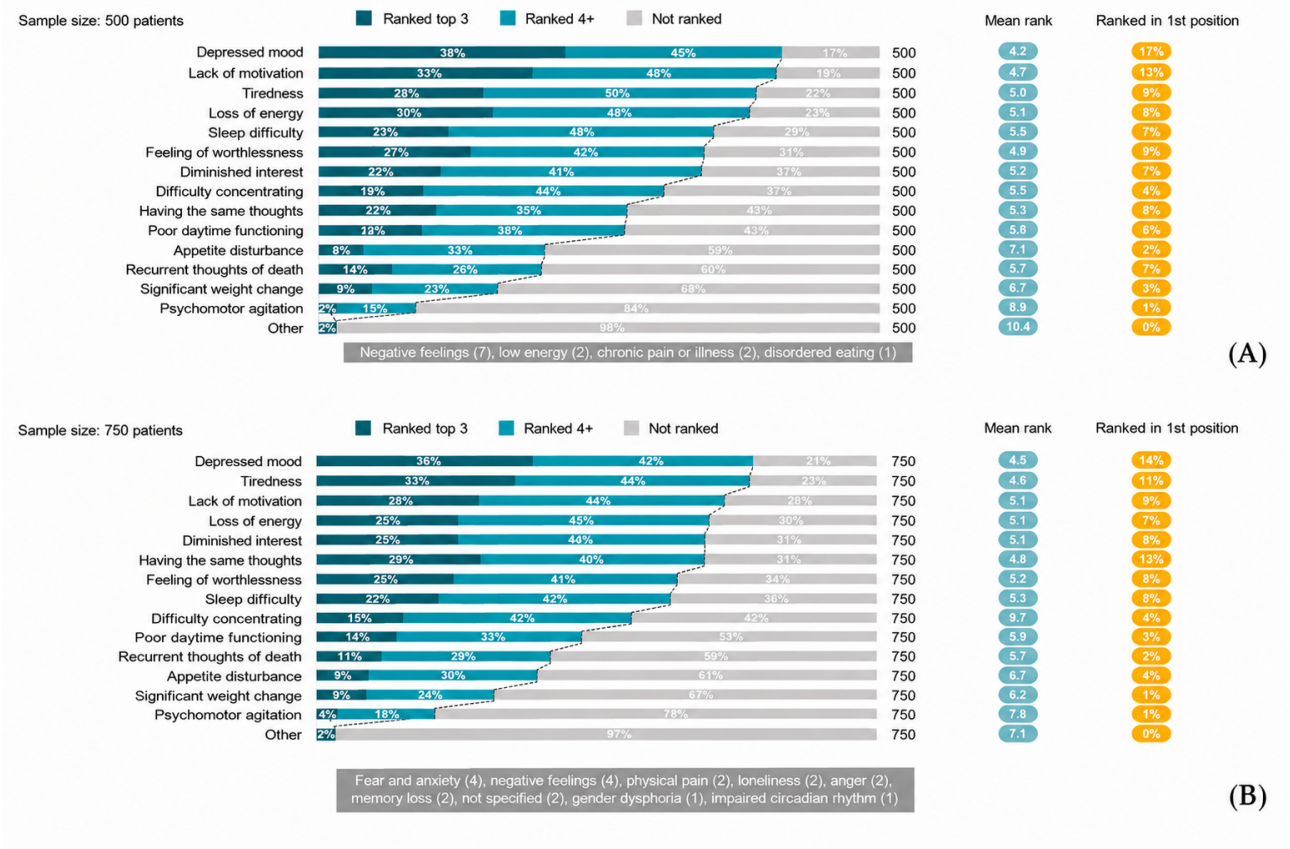
Figure 4. History of treatment for US (N=500) and EU5 (N=750) participants with major depressive disorder (MDD) with insomnia symptoms. EU5: France, Germany, Italy, Spain, and the United Kingdom.

During their current or most recent depressive episode, 36% (160/438) of US participants and 30% (193/643) of EU5 participants reported changing depression treatment 3 times or more.



Burden of Insomnia Symptoms in MDDIS and Its Impact on Patient-Reported Outcomes and QoL

Insomnia Symptoms Frequency

In the US sample, participants reported a mean of 8.1 (95% CI 7.6-8.6) insomnia nights over the 2 previous weeks. Most (354/500, 71%) reported life-impacting sleep difficulties (Figure 5) and had experienced insomnia symptoms for less than 6 months (307/500, 61%; Table 4). The distribution of insomnia-night categories (0-7 vs 8-15 nights) differed according to current depressive episode status (P=.05) and depression severity (P<.001). In particular, the proportion of US participants reporting 8-15 insomnia nights was higher among those with moderately severe (56/88, 64%) or severe depression (68/130, 52%) than among those with lower depression severity categories. The distribution of insomnia-night categories also differed according to sleep medication use (P=.04), with a higher proportion of participants reporting 8-15 insomnia nights among those reporting using OTC or prescribed sleeping medication (153/312, 49% vs 13/42, 31% for nonsleeping medication users).

[b]Insomnia nights are defined as nights with insomnia symptoms or taking treatments for insomnia symptoms.

In the EU5 sample, an average of 9.0 (95% CI 8.6 - 9.4) insomnia nights were reported by 482/750 (64%) participants with sleep disturbances impacting their life, and 63% (474/750) had experienced insomnia symptoms for less than 6 months (Figure 5 and Table 4). The distribution of insomnia-night categories differed across depression severity categories (*P*=.04). However, no statistically significant differences were observed according to current depressive episode status or sleep medication use. The majority of EU5 participants, including those receiving OTC or prescribed sleeping medications, continued to report 8-15 insomnia nights over the previous 2 weeks.

Insomnia Symptoms Severity

Based on ISI scores, 62% (312/500) of the US and 59% (439/750) of the EU5 participants had moderate to severe insomnia symptoms (Figure 6). A total of 26% (37/140) of participants in Spain, 20% (25/128) in the United Kingdom, 18% (27/154) in Germany, 16% (26/167) in France, and 7% (11/161) in Italy reported severe insomnia symptoms (Table S1 in Multimedia Appendix 1). In both regions, the distribution of insomnia severity categories differed significantly across depression severity categories and according to current depressive episode status (all *P*<.001; Tables 5 and 6). A greater proportion of participants in the more severe depression categories were classified as having moderate or severe insomnia symptoms, with 33% (57/170) of US participants and 30% (92/306) of EU5 participants with severe depression reporting severe insomnia symptoms. Additionally, 71% of both United States (185/259) and EU5 (315/448) participants currently experiencing a depressive episode were classified as having moderate or severe insomnia symptoms. In both regions, 40% (United States: 200/500 and EU5: 300/750) of participants considered insomnia symptoms interfered with their daily functioning, and more than half (279/500, 56% of United States and 437/750, 58% of EU5 participants) believed that this impairment was noticeable to others. Dissatisfaction with sleep patterns was reported by 77% (385/500) of US participants and 68% (509/750) of those in the EU5, while 34% (167/500; United States) and 30% (219/750; EU5) expressed important distress or concern about their sleep (Table 7).

Consequences of Insomnia Symptoms on Daily Functioning and QoL

Nearly all participants (489/494, 99% of United States and 692/730, 95% of EU5) reported at least one consequence of insomnia symptoms on their daily lives, with an average of 2.8 (95% CI 2.6 - 2.9) in the United States and 2.5 (95% CI 2.4 - 2.6) in the EU5 region. Approximately 70% (360/494, 73% in United States and 507/730, 69% in EU5) of participants reported more than one consequence, most commonly irritability, concentration difficulties, and reduced productivity (Table 8). The reported consequences of insomnia symptoms differed according to current depressive episode status for certain outcomes (Tables 8 and 9). In the US sample, participants currently experiencing a depressive episode were more likely to report reduced productivity (175/256, 68% vs 19/69, 27%; *P*<.001) and concentration difficulties (160/256, 62% vs 28/69, 40%; *P*=.004) than those not currently experiencing a depressive episode. No significant differences were observed for irritability, increased caffeine consumption, daytime sleep episodes, other consequences, or reporting no consequences. In the EU5 sample, significant differences were only observed for irritability (*P*=.006) and concentration difficulties (*P*=.02). Participants currently experiencing a depressive episode were more likely to report irritability (320/443, 72% vs 48/87, 55%) and concentration difficulties (272/443, 61% vs 40/87, 46%) than those not currently experiencing a depressive episode.

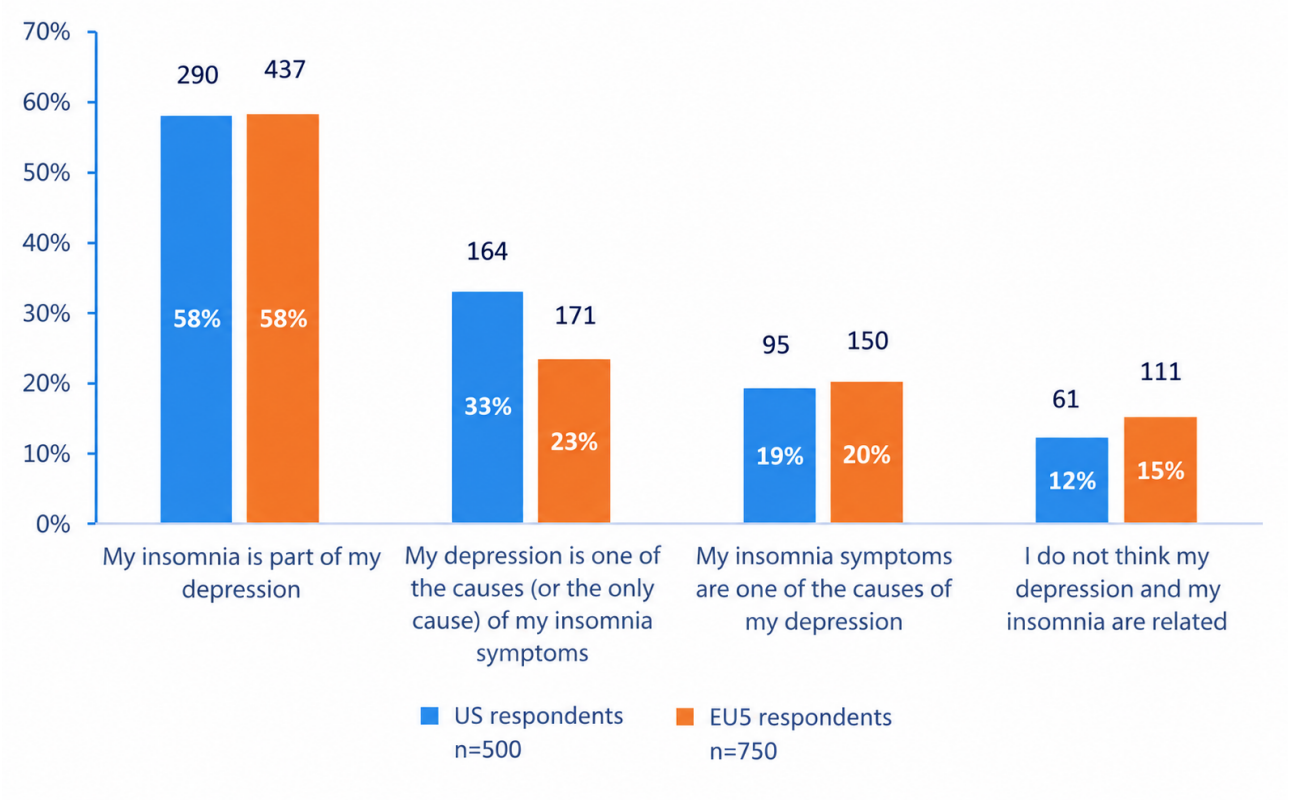
Impact of MDDIS Symptoms on Daily Life



When asked to rank the MDDIS symptoms that had the greatest impact on their lives, most participants in both regions identified depressed mood, lack of motivation, and tiredness as the most disruptive (Figure 5). Among those currently experiencing a depressive episode or symptoms, feelings of worthlessness, loss of energy, and diminished interest were also frequently prioritized.

Perceived Relationship Between Insomnia Symptoms and Depression

When asked how they think insomnia is related to their depression, the majority of participants, 88% (439/500) in the United States and 85% (639/750) in the EU5, believed both conditions are linked. In both regions, 58% (United States: 290/500; EU5: 437/750) considered insomnia symptoms to be part of their depression, while 33% (164/500; United States) and 23% (171/750; EU5) believed their depression was a cause of their insomnia symptoms. Around 20% (United States: 95/500; EU5: 150/750) in each region felt that insomnia symptoms contributed to their depression (Figure 7).

XSL•FO
RenderX

Figure 7. Perceived relationship between insomnia symptoms and depression in the US (n=500) and EU5 participants (n=750). EU5: France, Germany, Italy, Spain, and the United Kingdom.

Satisfaction With Treatment

Patient Satisfaction With Antidepressant Treatment for Depressive Symptoms

Satisfaction with antidepressant effectiveness for depressive symptoms was mixed in both regions. In the United States, 41% (193/472) of participants were dissatisfied, 28% (135/472) were satisfied, and 31% (144/472) reported neutral satisfaction (Table S2 in Multimedia Appendix 2). The distribution of satisfaction ratings differed significantly according to current depressive episode status and depression severity (both $P<.001$) but not according to MDD duration; a greater proportion of patients currently in a depressive episode (121/245, 50%) or experiencing severe depression (93/159, 59%) reported being not satisfied or not satisfied at all. In the EU5 sample, 31% (197/647) of participants reported dissatisfaction, 35% (230/647) reported satisfaction, and 34% (220/647) reported neutral satisfaction. Similarly, satisfaction with antidepressants for depressive symptoms differed significantly according to current depressive episode status and depression severity (both $P<.001$), whereas no significant differences were observed across MDD duration categories. Overall, 40% (157/395) of those currently in a depressive episode and 46% (122/265) of those with severe depression reported being not satisfied or not satisfied at all.

Patient Satisfaction With Antidepressant Treatment for Sleep Symptoms

In the US sample, 57% (269/472) of participants were dissatisfied with the effectiveness of antidepressants for improving sleep, whereas 14% (68/472) reported being satisfied. Satisfaction with antidepressants for sleep symptoms differed significantly according to current depressive episode status ($P=.01$) and depression severity ($P=.006$); 35% (56/159) of participants with severe depression were not satisfied at all (Tables 10 and 11). In the EU5 sample, 41% (264/647) of participants reported being dissatisfied and 26% (168/647) reported being satisfied with the effectiveness of antidepressants for improving sleep. Similarly, satisfaction ratings differed significantly according to current depressive episode status and depression severity (both $P<.001$), with 20% (54/265) of those with severe depression reporting being not satisfied at all. In both regions, no significant differences were observed across MDD duration categories (Tables 10 and 11).

Unmet Needs and Desire for Alternative Treatments

A strong desire for alternative treatments for both depression and sleep difficulties was reported (354/500, 71% in the United States and 488/750, 65% in the EU5), particularly among participants experiencing a current depressive episode or with more severe depression and insomnia symptoms. While most participants had discussed their insomnia symptoms with a clinician or another member of their care team (United States: 390/500 and 78%, EU5: 575/750, 77%), over one-third (United States: 146/390, 37% and EU5: 201/575, 35%) reported receiving no recommendations, especially those with more severe insomnia symptoms (Figure 8).

Discussion

Main Findings

This cross-sectional study provides patient-reported evidence for the burden of insomnia symptoms among individuals with MDD. Overall, insomnia symptoms were commonly reported despite treatment use, with moderate to severe symptoms more commonly reported among participants with more severe depression and those currently experiencing a depressive episode. Participants also described a substantial impact of insomnia symptoms on daily functioning, emotional well-being, cognitive functioning, and productivity, expressing low satisfaction with the perceived effectiveness of current treatments for sleep symptoms and a desire for additional therapeutic options. Collectively, these findings highlight the considerable patient-reported burden associated with insomnia symptoms and suggest that persistent sleep difficulties remain an important aspect of the patient experience.

This study shows that insomnia symptoms remain highly prevalent among patients with MDD, even among individuals receiving treatment. These findings are consistent with previous epidemiological studies showing that sleep disturbance is a common feature of depression and that insomnia symptoms may persist despite improvement in depressive symptoms, increasing the risk of relapse and recurrence [14,15,30,31]. Furthermore, the results suggest a link between insomnia severity and depression severity; participants with more severe depressive symptoms were more likely to report greater insomnia severity, in line with previous literature showing that short sleep and insomnia are independently associated with increased depression severity and symptom frequency [39,40]. These findings support the importance of considering sleep disturbance as a clinically relevant component of the overall burden of MDD, in particular among those with more severe depression.

Beyond their high prevalence, insomnia symptoms were perceived as having a substantial impact on multiple aspects of daily functioning. Participants reported impairments affecting emotional well-being, cognitive functioning, or work productivity, consistent with previous studies demonstrating that people with both depression and sleep problems experience daytime symptoms such as poor concentration and fatigue, and that insomnia symptoms have a strong negative impact on QoL and psychological distress [15,17].

Participants' perceptions further illustrate the complexity of the relationship between insomnia symptoms and depression. Although insomnia is recognized as a core symptom of MDD [14], some participants still do not perceive their sleep difficulties as being part of their depression. This finding may reflect limited awareness of the relationship between these conditions and supports the need to provide patients with information regarding the coexistence of mood and sleep symptoms [14,16,30].

Treatment use was high, despite the prevalence of insomnia symptoms. The majority of participants reported dissatisfaction with the perceived effectiveness of antidepressants for improving sleep symptoms and expressed interest in alternative therapeutic options addressing both depression and sleep. Previous literature

XSL•FO
RenderX

has observed that more than half of patients perceived antidepressants as insufficient for improving sleep and seek additional support [15]. However, this study did not assess treatment adherence, treatment duration, clinical appropriateness, or treatment resistance. Therefore, these findings should be interpreted as reflecting patients' perceptions of persistent sleep difficulties despite treatment rather than evidence of inadequate clinical management.

Despite the well-established literature demonstrating an association between depression and insomnia symptoms [14,16,30-32,41], this association is not adequately reflected in current treatment practices. Although most participants reported discussing their sleep difficulties with a clinician or another member of their care team, over one-third indicated that no treatment suggestions were provided. As the study did not capture the reasons underlying these interactions, alternative explanations, including patient preferences, clinical judgment, or treatment prioritization, cannot be excluded. Nevertheless, these findings suggest a potential communication or care gap that warrants further investigation.

Strengths and Limitations

A major strength of this study is its large multinational sample recruited through an online patient community, allowing the collection of patient-reported experiences from individuals with MDD across 6 countries [42]. The use of validated instruments (PHQ-9 and ISI) ensured standardized assessment of depression and insomnia severity, while the study-specific questionnaire provided valuable insights into patients' treatment experiences, perceptions, and unmet needs. Compared with previous studies that primarily focused on the economic burden and health care resource use associated with insomnia symptoms in MDD [31,32], this study offers a broader understanding of the patient experience and highlights aspects of disease burden that are not routinely captured in clinical practice.

Several limitations should nevertheless be acknowledged. Recruitment through an online platform may have introduced selection bias by excluding individuals without internet access or those less familiar with digital tools, and by preferentially including patients who are more engaged in managing their condition. In addition, the sample was predominantly composed of cisgender women, which may limit the generalizability of the findings to the broader MDD population [7]. The observed differences in the proportion of participants identifying as transgender or nonbinary between the United States and the EU5 may also reflect cultural and societal differences in the willingness to disclose sex identity.

All data were self-reported, introducing the possibility of recall and reporting bias. In particular, the diagnosis of MDD was based on participant self-report and was not independently confirmed through medical records or health care professionals, which may have resulted in diagnostic misclassification. Furthermore, information regarding treatment adherence, treatment duration, treatment optimization, clinician rationale for treatment selection, and treatment resistance was not collected, limiting the interpretation of participants' reported treatment experiences. Sleep duration, a factor known to influence the relationship between insomnia and depression, was also not assessed and may have acted as a confounder. Finally, the cross-sectional design precludes any conclusions regarding temporal or causal relationships between insomnia symptoms and depression severity.

Future longitudinal studies integrating both patient- and clinician-reported outcomes are warranted to better characterize the relationship between insomnia symptoms and the onset, course, and treatment response of MDD. Such studies should also investigate behavioral and educational aspects of insomnia management, including patients' understanding of the relationship between sleep and depression, as well as strategies that promote adaptive coping and improve long-term outcomes.

Implications for Clinical Practice

Given the well-established association between depression and insomnia symptoms reported in the literature [38], our findings further emphasize the importance of considering sleep symptoms during the clinical assessment of patients with MDD. Although this study cannot determine the appropriateness of current treatment strategies, the persistence of patient-reported sleep difficulties and the expressed need for additional therapeutic options suggest that insomnia symptoms remain an important component of patient care deserving continued clinical attention.

Conclusion

This multinational patient study highlights the substantial burden associated with insomnia symptoms among individuals with MDD. Participants reported an impact of insomnia symptoms on daily functioning, emotional well-being, and productivity. More severe depression was accompanied by a greater proportion of participants with moderate or severe insomnia symptoms, and dissatisfaction with current treatment options was widespread. Around two-thirds of participants also expressed a desire for additional treatment options. Although the cross-sectional design and patient-reported nature of the data preclude conclusions regarding causality or the appropriateness of current clinical management, these findings suggest that insomnia symptoms remain an important component of the patient experience in MDD and identify a potential care gap that warrants further investigation.

Abstract

Background: Cognitive behavioral therapy (CBT) is an effective and widely used treatment for major depressive disorder (MDD). However, access is limited by long waiting lists and a shortage of trained therapists. Evidence-based guided and self-guided digital interventions can address these challenges, but their large-scale adoption in routine primary and specialized mental health care has been slow. Blended CBT (bCBT), combining face-to-face therapy with structured, guided digital treatment modules, may increase treatment capacity while maintaining the benefits of therapist support.

Objective: The European Comparative Effectiveness Research on Internet-based Depression Treatment study, conducted across 9 European countries, is the first large-scale comparative bCBT study for MDD. The hypothesis was that bCBT is clinically noninferior and cost-effective when compared with treatment as usual (TAU), which mainly consisted of face-to-face CBT.

Methods: A multisite randomized controlled trial was conducted with a noninferiority margin of *d*=0.20. Main inclusion criteria were age ≥18 years, a diagnosis of MDD based on the Mini International Neuropsychiatric Interview, and a baseline Patient Health Questionnaire-9 (PHQ-9) score of ≥5. The primary outcome was the PHQ-9, with secondary outcomes including MDD remission at 12 months, therapeutic alliance, and costs. Intention-to-treat analyses were performed, and linear mixed modeling was used to assess intervention effects. Cost-effectiveness analyses were conducted from a health care perspective.

Results: A total of 835 patients were included in the study. bCBT was shown to be noninferior to TAU on the primary PHQ-9 outcome during treatment (3 months after the baseline assessment, *d*=−0.26, 95% CI −0.43 to −0.09), at 6 months (posttreatment, *d*=−0.21, 95% CI −0.39 to−0.04), and at 12-month follow-up (*d*=−0.01, 95% CI −0.19 to 0.17). Furthermore, the bCBT group had a significantly lower likelihood of experiencing an MDD episode at 12 months (odds ratio 0.67, 95% CI 0.45 - 0.99). Subgroup analyses indicated that participants with and with no antidepressant use at baseline in both groups benefited equally from their treatment. Deterioration rates (Reliable Change Index) were below 5% in both groups. bCBT appeared acceptable for patients and therapists, with a strong working alliance in both groups. From a health care perspective, bCBT was not cost-effective at 12 months' assessment, as its total costs were not significantly lower than TAU. However, the probability that bCBT is cost-effective is high (0.95) at a willingness to pay (WTP) of €3800 per improvement in the PHQ-9 score, and 0.76 at a WTP of €10,000 per MDD case prevented (average 2017 exchange rate was €1=US $1.13).

Conclusions: bCBT offers an effective and safe digitally supported alternative to face-to-face TAU for patients with MDD and their therapists in routine clinical care. From a health care perspective, its cost-effectiveness depends on policymakers' WTP for the additional clinical benefits achieved.

KEYWORDS

major depression disorder; cognitive behavioral therapy; blended treatment; cost-effectiveness; noninferiority randomized controlled trial; digital mental health

Introduction

Globally, major depressive disorder (MDD) is among the most prevalent mental disorders, affecting approximately 4% of the population each year, corresponding to an estimated 332 million people in 2021 [1]. MDD is a leading cause of disability worldwide and imposes a substantial societal burden through increased health care usage and major productivity losses [2,3]. MDD is frequently accompanied by psychiatric comorbidities, particularly anxiety disorders and alcohol use disorders [4].

XSL•FO
RenderX

Although antidepressants (ADs), psychotherapy, and their combination are all effective treatments for MDD in the short- and long-term [5], patients often prefer psychotherapy over ADs, partly because of concerns about adverse effects and a greater sense of autonomy and self-management [6].

Cognitive behavioral therapy (CBT) is one of the most extensively studied and widely implemented evidence-based psychotherapies for MDD in primary and specialized mental health care [5]. Compared with treatment as usual (TAU) or waiting-list control conditions, CBT demonstrates moderate to large treatment effects, whereas comparisons with other evidence-based psychotherapies generally show only small or nonsignificant differences [5]. Despite this strong evidence base, scaling up face-to-face CBT (ftfCBT) in routine care remains challenging. High treatment costs, long waiting lists, shortages of trained therapists, and limited reimbursement for CBT services—even in high-income countries—continue to restrict access to care [7]. As a result, a substantial global treatment gap persists for people with MDD [8].

Over the past 2 decades, internet-based cognitive behavioral therapy (iCBT) has been developed to address some of these challenges by offering an accessible, cost-effective, and scalable treatment format [9,10]. Numerous meta-analyses have demonstrated that self-guided and therapist-guided iCBT are effective in treating depression. Compared with nonactive controls and participants recruited from the general population, therapist-guided iCBT generally yields moderate to large effect sizes, whereas self-guided iCBT produces smaller, but still significant, effects [11]. Furthermore, a meta-analysis found no significant differences in depression outcomes between iCBT and ftfCBT among patients receiving routine mental health care. However, this meta-analysis by Hedman-Lagerlöf and colleagues [12] included only 5, mostly small-scale, randomized controlled trials (RCTs), highlighting the limited evidence available from routine care settings. Although these findings support the efficacy of iCBT, evidence from routine clinical practice remains limited. Together with the scarcity of implementation studies conducted under real-world conditions, this may partly explain the relatively slow uptake of iCBT for MDD in primary and specialized mental health care (with the exception of dedicated online treatment services).

In addition to the limited routine care evidence base, several barriers have been proposed to explain the slow implementation of iCBT. These include organizational factors (eg, limited managerial support), therapist-related concerns, patient-related barriers, and external factors such as data privacy regulations [13]. For example, therapists question whether findings from existing iCBT studies are generalizable to patients treated in routine clinical practice, who are often perceived to be more clinically complex and socially vulnerable than participants recruited from the general population because of greater symptom severity, higher rates of comorbidity, and greater socioeconomic disadvantage [14]. Therapists with little or no experience using iCBT often worry as well that delivering treatment remotely will hinder the development of a strong therapeutic alliance, despite evidence indicating that therapeutic alliance can be maintained [15,16]. Patients have identified barriers, also including the high level of motivation required to work independently and the reduced amount of face-to-face contact.

These implementation barriers have stimulated interest in blended treatment formats for MDD in routine care. Reviews have shown that blended CBT (bCBT) protocols vary with respect to their treatment composition (integrated or sequential), the role of the digital component (core or supplementary), and the technologies applied (internet, mobile apps, or both) [17,18]. By combining the strengths of face-to-face and digital treatment, bCBT may overcome several perceived limitations of stand-alone iCBT while retaining its advantages in terms of accessibility and efficiency. Recent studies have explored the acceptability and preferences of therapists and patients for bCBT in routine care. These studies indicate that many therapists and patients prefer bCBT over stand-alone iCBT if bCBT maintains the advantage of the clinical flexibility of face-to-face therapy and digitally supports patients' self-management skills [19,20]. Few studies have evaluated the effectiveness of bCBT yet.

Nakao et al (2018) evaluated the effectiveness of bCBT in a small RCT (n=40), comparing bCBT plus standard psychiatric care with standard psychiatric care alone (waitlist) in patients with MDD who had not responded to AD medication. The study reported a large between-group effect in favor of bCBT (d=1.1) [21]. A smaller number of studies have yet clinically evaluated bCBT directly compared with ftfCBT for MDD. Kalde et al [22] (n=82) and Kooistra et al [23] (n=102), for example, reported no significant differences in depressive symptoms between treatment conditions at posttreatment. Although these findings are encouraging, neither study was powered to establish noninferiority. In addition, several bCBT trials have been described in published study protocols, with results awaited [24-26]. Consequently, robust evidence from large, pragmatic, multinational trials evaluating the clinical effectiveness and cost-effectiveness of bCBT in routine clinical practice remains limited.

To address this evidence gap, we conducted the European Comparative Effectiveness Research on Internet-based Depression Treatment (E-COMPARED) study across 9 European countries, evaluating an integrated form of bCBT in which face-to-face sessions were combined with structured internet- and smartphone-based modules within a single treatment protocol [27]. Within this protocol, face-to-face sessions were used for more in-depth therapeutic interactions, assessment of clinical needs, and shared decision-making, whereas the digital modules supported psychoeducation, homework assignments, symptom monitoring, and self-management.

We hypothesized that bCBT would be clinically noninferior to TAU for patients with MDD. In addition, we hypothesized that bCBT would reduce health care costs by requiring less therapist time while maintaining comparable clinical outcomes, thereby improving cost-effectiveness from a health care perspective. Demonstrating that bCBT is clinically noninferior and cost-effective would support its wider implementation, thereby improving access to evidence-based CBT for patients with MDD.

Methods

Study Design and Participants

We conducted a pragmatic 2-arm, open-label, multisite, randomized controlled clinical trial. We applied noninferiority design criteria, including an active comparator (TAU) and a preset noninferiority margin [28]. The E-COMPARED study was conducted across 8 European countries: France, Germany, the Netherlands, Poland, Spain, Sweden, Switzerland, and the United Kingdom, ensuring geographical coverage across Europe. Denmark was subsequently added due to the country's emergent interest in bCBT. We conducted the RCTs in settings where both bCBT and TAU for MDD treatment could be provided. In Denmark, France, the Netherlands, and Switzerland, the study was conducted within specialized mental health services, while in Germany, Poland, Spain, Sweden, and the United Kingdom, it was conducted within primary care. The results were reported in accordance with the CONSORT (Consolidated Standards of Reporting Trials) guidelines for noninferiority trials [29]. We refer to the protocol for a detailed description of the study [27].

Inclusion and Exclusion Criteria

The inclusion criteria were age ≥18 years, meeting *DSM-IV* (*Diagnostic and Statistical Manual of Mental Disorders* [Fourth Edition]) diagnostic criteria for MDD via the Mini International Neuropsychiatric Interview (MINI; excluding sections M [anorexia nervosa], N [bulimia nervosa], and P [antisocial personality disorder]) [30], and depressive symptoms (Patient Health Questionnaire-9 [PHQ-9] score ≥5) [31]. Patients were permitted to receive pharmacotherapy in addition to bCBT at baseline or during treatment, if deemed necessary by a health care professional, in line with routine clinical practice. At the 12-month follow-up, phone-based MINI interviews were conducted by independent, trained interviewers who were masked to the assigned group. The exclusion criteria included currently being at high risk of suicide (MINI section C), psychiatric comorbidity (substance dependence, bipolar disorder, psychosis, and obsessive-compulsive disorder), currently undergoing psychological treatment for depression, language comprehension barriers, lack of a stable internet connection or access to a computer, and either the absence of a compatible smartphone or an unwillingness to loan one for bCBT.

Procedures

Recruitment took place between February 2015 and December 2016; data collection closed on December 31, 2017. Patients were approached by mental health professionals in health care settings, who then referred them to the research team for eligibility assessment. In Germany and Sweden, recruitment leaflets were placed in general practitioner waiting rooms. Sweden also used social media platforms to recruit patients who had contacted primary care services about depressive complaints. Multimedia Appendix 1 provides an overview of the recruitment procedures for each country, along with any additional procedures carried out.

Ethical Considerations

Ethical approval and trial registrations were obtained at the national level. Participants provided written informed consent, authorizing the E-COMPARED partners to share and analyze the anonymized dataset and to report the results in publications. Participants did not receive compensation for study participation. Ethical approval for the trials has been obtained locally in each country: Ethics Committee of the Region of Southern Denmark (S-20150150); France: Comité de protection des personnes, Île de France V (15033-n 2015-A00565-44); Germany: Ethik Kommission DGPsychologie, Universität Trier (MB 102014); The Netherlands: METC VUMC (2015.078); Poland: Komisja ds. Etyki Badań Naukowych (10/2014); Spain: Comisión Deontológica/Comité Ético de Investigación en Humanos (H1414775276823); Sweden: Regionala etikprövningsnämnden (2014/428-31); Switzerland: Kantonale Ethikkommission Bern (001/2015); and United Kingdom: NRES Committee London-Camden and King's Cross (15/LO/0511).

Randomization and Masking

After the baseline assessment, randomization of patients was conducted centrally at VU Amsterdam (Netherlands) by an independent researcher (EK) using automated Random Allocation Software (Department of Anaesthesia, Isfahan University of Medical Sciences). The allocation, stratified by country, was 1:1. Block randomization was used with variable block sizes, ranging from 2 to 14 allocations per block. In the United Kingdom, the process was outsourced to a local independent researcher for logistical reasons, which required the randomization outcome to be available immediately. Furthermore, stratification by recruitment location was applied at the national level for France (11 centers), Switzerland (3 centers), the Netherlands (3 centers), and Sweden (2 cities). Researchers and clinicians were blinded to the randomization scheme, but blinding of treatment allocation was impossible because both groups were evident to the therapists and patients.

Sample Size Calculation

RCTs can determine whether a treatment effect is statistically significant and quantify its magnitude, but they do not necessarily capture the clinical relevance of the findings. Several approaches exist to assess clinical importance. In this study, we adopt the minimal clinically important difference from the patient perspective, as proposed by Cuijpers and colleagues [32], who identified a threshold of Cohen d=0.24. Given our noninferiority design, we applied a more conservative margin of d=0.20 for the primary outcome (PHQ-9). Under this criterion, bCBT is considered noninferior to TAU in clinical terms if the upper bound of the confidence interval does not exceed this predefined margin (1-sided tested). The required sample size was 1052 patients; to allow for dropouts, we aimed to enroll 1200 patients. This calculation was based on 90% power (type II error ≤0.10) and the requirement that the upper bound of the 2-sided 95% CI would not exceed the prespecified noninferiority margin.

bCBT for MDDs

The bCBT protocols used in this study were based on ftfCBT protocols for MDD. The bCBT protocols integrated face-to-face sessions with structured internet-based treatment modules and ecological momentary assessments (EMAs) via smartphone to monitor daily mood, cognition, activity, social interaction, and

XSL•FO
RenderX

sleep. During these face-to-face sessions, the core principles of CBT were applied, alongside mandatory internet modules at all participating sites (Table 1). These mandatory modules focused on psychoeducation, cognitive restructuring, behavioral activation, and relapse prevention, as well as homework assignments. These internet-based modules were discussed in subsequent face-to-face sessions. The mandatory internet modules comprised 75% of the total number of modules. Sites also had the option to add extra modules (25%), such as emotional regulation or coping skills training, to facilitate adaptation to setting-specific practices, while maintaining protocol standardization across sites. At least one-third of the total number of sessions were to be held face-to-face, while another one-third were to be held online to ensure sufficient face-to-face and online modules.

Table . Overview of blended cognitive behavioral therapy applied within each country by platform, setting, duration, number of face-to-face and internet sessions, sequencing and mandatory internet modules (X), and additional modules.

Country	Platform	Setting	Duration	Number of face-to-face and internet modules	Sequencing	Mandatory internet modules (X)[a] and additional modules

[c]PS: problem-solving.

[d]PEX: physical exercise.

[e]SMHC: specialized mental health care.

[f]PE: psychoeducation.

[g]CS: coping skills.

Table 1 summarizes, by country, the setting, duration, intensity, the alternation between face-to-face sessions and online modules, and additional modules for the bCBT group. As we followed routine care procedures, 5 countries used their own bCBT platforms: Denmark, the Netherlands, Spain, Sweden, and Switzerland. Four countries—France, Germany, Poland, and the United Kingdom—implemented a translated version of the Dutch Moodbuster platform for their patients because no bCBT platforms were available in these countries. All these platforms complied with General Data Protection Regulation requirements [33]. bCBT was delivered within primary care in 4 countries, while in Spain, it was provided both within primary care and outpatient specialized mental health care due to constraints within the original specialized mental health care setting. In the other 3 countries, it was delivered within specialized outpatient mental health care settings. bCBT began with a face-to-face session in all the countries. Within primary care, the treatment duration of bCBT ranged from 6 to 13 weeks, comprising 3-7 face-to-face sessions and 5-10 internet modules. Within specialized mental health care services, the treatment duration was longer, typically from 12 to 20 weeks, with 8-12 face-to-face sessions and 7-10 internet modules. All countries alternated face-to-face sessions with online modules, except for Spain (which used 2 face-to-face sessions, 4 internet modules,

XSL•FO
RenderX

and a final face-to-face session). The total number of ftfCBT sessions ranged from 3 to 6 in primary care settings and from 8 to 12 in specialized mental health care settings, and sessions were conducted in accordance with guidelines for treating moderate to severe MDD [34]. These face-to-face sessions lasted between 45 and 60 minutes each. The internet modules required 30-45 minutes of patients' time and needed 3-5 minutes daily to answer the EMA questions. The therapists used the platforms to monitor their patients' progress and to communicate securely with them. They were required to spend approximately 15 minutes each week per patient to review their online homework assignments. CBT therapists comprised licensed professionals and supervised psychology trainees; supervision by a licensed psychologist specializing in CBT applied only in primary care settings.

Treatment as Usual

All participants in the control group received active treatment. TAU comprised routine care for patients with MDD in the treatment settings from which they were recruited (primary care or specialized mental health care). Six countries delivered ftfCBT within routine care (Denmark, France, the Netherlands, Poland, Switzerland, and the United Kingdom). In Sweden, Germany, and partly in Spain, TAU consisted of generic general practitioner care, which might have included watchful waiting, referral to a mental health specialist, psychotherapy (in Sweden and Germany), pharmacological treatment, or a combination of these. In the ftfCBT settings, therapists' professional qualifications were similar to those in the bCBT groups.

Outcomes, Measures, and Time Points

All measures were self-reported and completed online (except for the MINI, which was assessed by independent interviewers blinded to the groups). Primary and secondary outcomes (including costs) were assessed at baseline and at the 3, 6, and 12-month follow-up periods. The MINI was assessed only at baseline and at the 12-month follow-up. We followed routine care RCT protocols in the participating countries, which resulted in primary care studies being shorter in duration and lower in intensity than those conducted in specialized mental health care settings. Posttreatment assessments meant that all participants could have completed their treatment 6 months after baseline. To enable an overall comparison, we therefore defined the 3-month assessment as a during-treatment measurement, the 6-month assessment as a posttreatment measurement, and the 12-month assessment as a follow-up measurement. The outcomes and time points are presented in Table 2. The reliability of the questionnaires is presented in Multimedia Appendix 2. Cronbach α ranged from 0.70 to 0.98, indicating good overall reliability.

Primary Outcome

The PHQ-9 was the primary outcome at posttreatment. It has demonstrated good psychometric properties in both primary and specialized care populations [30,35,36]. The total score ranges from 0 to 27, with 0‐4 indicating no to minimal depression, 5‐9 indicating mild depression, 10‐14 indicating moderate depression, 15‐19 indicating moderately severe depression, and 20‐27 indicating severe depression. Paper-based and online versions of the PHQ-9 yield comparable psychometric properties [37]. The PHQ-9 was also used to assess reliable deterioration. Participants were classified as having reliably deteriorated when the increase in PHQ-9 score exceeded the Reliable Change Index (RCI) threshold (|RCI|>1.96) [38]. See Multimedia Appendix 3 for a detailed description of the deterioration calculation.

Secondary Outcomes

The Quick Inventory of Depressive Symptomatology Self-Report-16 (QIDS-SR 16) was used as a second measure to assess the level of depressive complaints [39]. The MINI [31] was used to evaluate MDD and comorbid anxiety disorders at baseline and at the 12-month follow-up to assess depression-free episodes (remission).

Additional Outcomes

Overview

Patient treatment expectations were measured with the Credibility and Expectancy Questionnaire (maximum score of 27 [40]) at baseline only. The remaining 4 outcomes were assessed during treatment, 3 months after the baseline assessment. Treatment satisfaction was assessed using the Client Satisfaction Questionnaire-8 (CSQ-8; range 8-32 [41]), and satisfaction with the online platforms was evaluated using the System Usability Scale (SUS) [42]. The therapeutic alliance between patients and therapists was measured using the short version of the Working Alliance Inventory, which comprises the Bond, Task, and Goal subscales, and a composite score (Working Alliance Inventory-Short Form [WAI-SF]) for patients [43] and therapists [44]. For descriptive purposes, patients' and

XSL•FO
RenderX

therapists' ratings were transformed into a 0-5 range for each component separately (as well as for the composite score). Patients' alliance with online platforms (experimental group only) was evaluated using the Working Alliance Inventory–Technology (Working Alliance Inventory for Online Interventions-Short Form [WAI-TECH-SF] [45], derived from the WAI-SF). Demographic variables such as age, sex, education, marital status, income, and employment, along with mental health treatment history, were assessed only at baseline. Patients' preference for bCBT or TAU was determined using a simple yes/no/no-preference question.

Cost Measures

Costs were evaluated from the health care perspective, based on health care and patient costs, using the TiC-P (Trimbos/iMTA questionnaire for Costs associated with Psychiatric illness) questionnaire at baseline and at 3, 6, and 12 months [46]. To avoid cost discrepancies due to varying prices across countries, resource usage was assessed using standard Dutch costs [47]. For reference, the average 2017 exchange rate was €1=US $1.1297 (European Central Bank).

Data Collection and Analyses

Each participating country collected data in accordance with a predefined data codebook, which was then uploaded to a centralized database (Research Department of GGZ inGeest Mental Health Care). The encrypted data, free of identifiable patient and therapist information, complied with General Data Protection Regulation regulations [33].

Statistical Analyses

Analyses were based on the intention-to-treat (ITT) principle. We initially considered a per-protocol analysis, as ITT approaches in noninferiority trials may dilute between-group differences by including nonadherent participants, potentially biasing results toward noninferiority [48]. However, we ultimately adopted an ITT analysis because per-protocol can compromise the benefits of randomization and introduce selection bias. In addition, ITT better reflects routine clinical practice, where nonadherence is common, thereby enhancing generalizability to routine care settings. It also captures real-world effectiveness, aligns with health economic evaluation objectives, and accounts for variability in adherence and outcomes.

Descriptive statistics were used to assess baseline characteristics of the participants (Table 3). Multiple imputation was conducted using chained equations with predictive mean matching until the loss of efficiency was less than 5%, resulting in 20 complete datasets [49]. Linear mixed modeling [50] estimated the mean levels of the outcome variable for the TAU group and the intervention effects at 3 time points, using 3 time dummies (3-, 6-, and 12-month measurements) and 3 time dummy-by-group interaction terms; hypothesis tests for these interaction effects were conducted 1-sided, in line with the noninferiority framework. Alongside these fixed effects (for the main estimates), the model included random effects (random intercepts and time slopes for countries) and allowed for correlated residuals (for measurements within individuals). Missing observations for the CSQ and SUS were not imputed, as the answers to these questions were highly subjective. This reduces the risk of bias due to incorrect imputation [51]; AD use at the 3-, 6-, and 12-month assessments was also not imputed. Estimated intervention effects (EE) were presented on the corresponding scales for the 4 outcomes. Cohen *d* and 95% CIs [52] were used to quantify between-group treatment effect sizes for both the PHQ-9 and the QIDS. Effect sizes were classified as very small ($d<0.2$), small (0.2-0.5), medium (0.5-0.8) or large (>0.8). MINI-D (Depression) and MINI-A (Anxiety) were presented as log-odds ratios using the Hasselblad and Hedges logit method [53]. A "leave-one-out" sensitivity analysis assessed the robustness of the overall effect by systematically excluding one country at a time and recalculating the effect size for the primary outcome [54]. To assess the impact of baseline AD use on treatment outcomes during treatment and follow-ups, we extended the linear mixed modeling by adding a third factor (AD use: yes/no). This allowed estimation of marginal mean PHQ-9 scores at different time points for the bCBT and TAU groups within strata of AD use, as well as effect sizes. We calculated a reliable deterioration in the PHQ-9 [38] during treatment (3 months), posttreatment (6 months), and at the 12-month follow-up point. The nonimputed dataset assessed the number of patients who deteriorated, while the log ratios and corresponding effect sizes were estimated using generalized linear (logistic) mixed models. Stata (version 14.2; StataCorp LLC) was used to conduct the analyses.

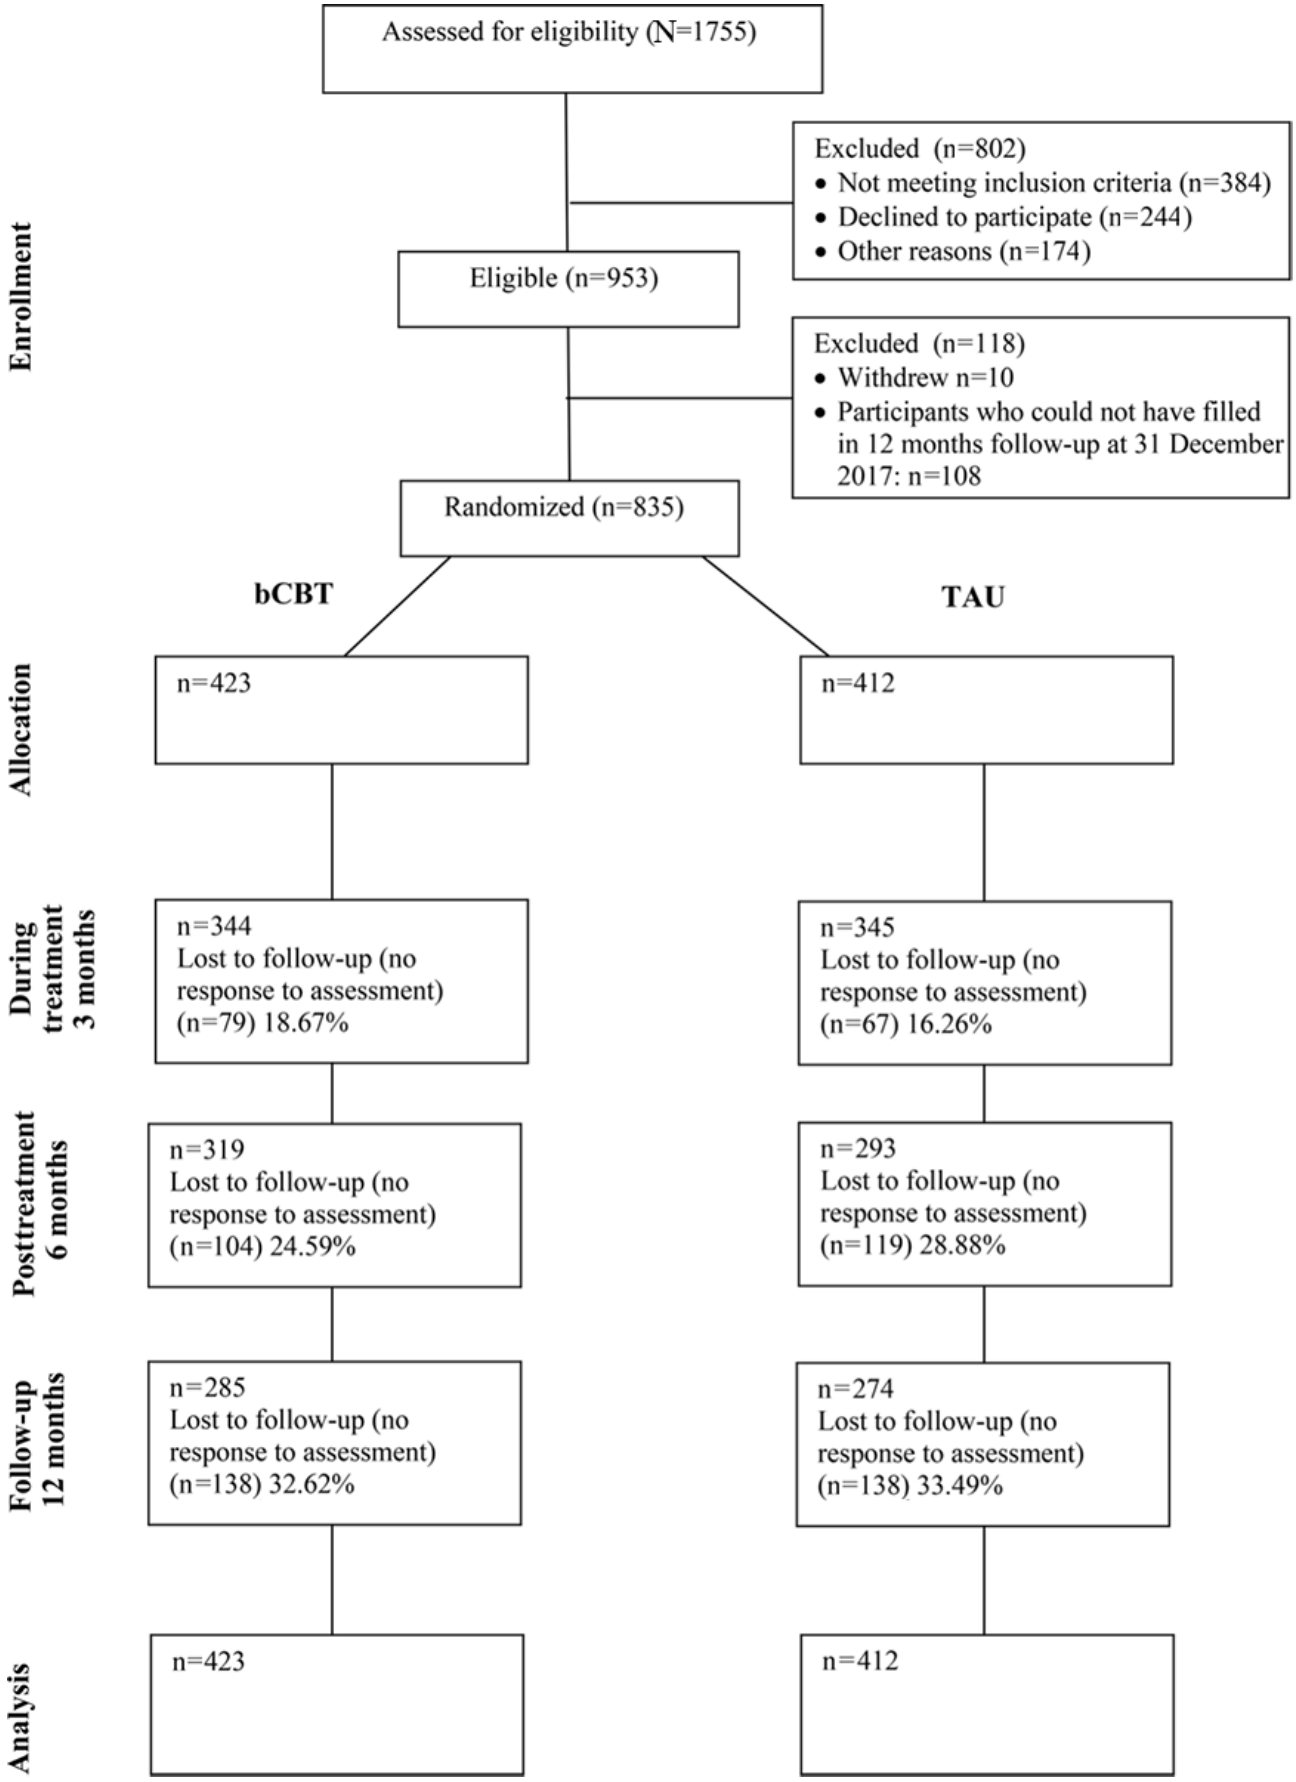
Cost-Effectiveness Analyses

Cost-effectiveness analyses were conducted from the health care perspective, as this perspective best aligned with our hypothesis. This perspective is also recommended by the National Institute for Health and Care Excellence in the United Kingdom [56]. Health-related quality of life for the cost-effectiveness analyses was measured using the EQ-5D-5L [57]. EQ-5D-5L health states were converted into utility scores using the Dutch tariff [58], and quality-adjusted life years (QALYs) were calculated by multiplying utilities by patient time spent in each health state, with linear interpolation applied between transitions.

Within the multiple imputation procedure, predictive mean matching was used to account for the skewed distribution of cost data. Mixed-effects regression models with repeated measurements clustered within participants were used to estimate differences in overall PHQ-9 scores and the number of MDD cases prevented over the 12-month follow-up period. Differences in QALYs and costs were analyzed using linear regression models.

Incremental cost-effectiveness ratios (ICERs) were calculated by dividing the difference in costs between the 2 conditions by the corresponding difference in effects. Statistical uncertainty surrounding the ICERs was assessed using bias-corrected and accelerated bootstrapping with 5000 replications and visualized in cost-effectiveness planes. Cost-effectiveness acceptability curves were constructed to estimate the probability that bCBT was cost-effective compared with TAU across a range of willingness-to-pay (WTP) thresholds. The WTP threshold represents the maximum amount society is willing to pay for 1 additional unit of health gain. No established WTP threshold exists for improvements in PHQ-9 scores. For QALYs, however, a maximum WTP threshold of €50,000 per QALY gained was applied, in accordance with the Dutch Health Care Institute's recommendation for interventions targeting conditions with an estimated disease burden of 0.48. Finally, a sensitivity analysis was conducted in which differences in costs and effects were adjusted for potential confounders, including baseline health care costs, age, sex, and treatment setting (primary vs secondary care) [55,56]. Analyses were conducted in Stata (version 14.2), and reporting adhered to the CHEERS (Consolidated Health Economic Evaluation Reporting Standards) [59].



Results

Overview

Figure 1 illustrates the study's participant flow. Of 1755 participants assessed for eligibility, 953 started treatments, of whom 118 were excluded from our analysis. Ten participants withdrew before randomization, and for 108, the 12-month assessment would be beyond December 31, 2017 (the funder-determined time frame). Thus, the ITT sample included 835 participants, with 423 in bCBT and 412 in TAU. The total study dropout rates for the sample were 17.5% at 3 months after baseline assessment, 26.7% after 6 months, and 33% after 12 months.

RenderX

Figure 1. Flow diagram of participants through the trial based on intention-to-treat (CONSORT [Consolidated Standards of Reporting Trials]). bCBT: blended cognitive behavioral therapy; TAU: treatment as usual.

XSL•FO
RenderX

Table 3 summarizes the participants' baseline sociodemographic, clinical, and cost profiles. Multimedia Appendix 4 presents participant counts and baseline characteristics for each country. The mean age of the total group was 39.17 (SD 13.18) years, with 67% female and half of the sample having a high level of education. The employment rate was 61.80%. The mean PHQ-9 score for the total group was 15.28 (SD 4.7), indicating moderately severe symptoms. Over half (420/835, 50.30%) of the participants had a comorbid anxiety disorder. At baseline, on average, 42.77% (352/823) of the participants used ADs, with no significant differences between the 2 groups. This percentage remained stable over time, averaging 42.65% (351/823) at 3 months, 38.40% (316/823) at 6 months, and 40.70% (335/823) at 12 months, with nonsignificant differences between the groups. At prerandomization, 56.41% (471/835) of the participants preferred bCBT, 16.41% (137/835) preferred TAU, and the remainder reported no preference. The bCBT group scored significantly higher on the credibility and expectancy scales for treatment than the TAU group, indicating moderate to high levels on both measures. Mean health care costs per patient 4 weeks prebaseline were €1172 (SE €185) for the bCBT group and €1338 (SE €183) for the TAU group.

Primary Outcomes

Table 4 and Figure 2 show that, for the primary outcome (PHQ-9), bCBT was noninferior to TAU at 3 (Figure 2A), 6 (Figure 2B), and 12 (Figure 2C) months, as all upper bounds of the confidence intervals lay within the noninferiority margin of ≥0.20. A "leave-one-out" sensitivity analysis also showed noninferiority of the primary outcome at the 3- and 6-month assessments. However, at 12 months, the "leave-one-out" analysis revealed that excluding Germany yields inferior results. This indicates that the overall effect estimate is sensitive to this omission and suggests potential heterogeneity across settings. Together, these findings highlight uncertainty in the 12-month results and suggest that the observed effects may be context-dependent.

Table . Estimated intervention effects and effect sizes on both the primary outcome (PHQ-9)[a] and secondary outcomes (QIDS[b], MINI[c] Depression, and MINI Anxiety), based upon both 1-stage models with random time slopes based upon multiple imputed data (N=835).

Secondary Outcomes

Overview

Noninferiority of bCBT is also shown in Table 4 for the secondary QIDS outcome at 3 months during treatment (d=−0.27, 95% CI −0.48 to −0.06) and at posttreatment (6 months) (d=−0.08, 95% CI −0.25 to 0.10) but not at 12 months' follow-up (95% CI −0.16 to 0.22). The bCBT group also had a lower risk of MDD than the TAU group at the 12-month follow-up (odds ratio [OR] 0.67, 95% CI 0.45-0.99) for anxiety disorders; this difference was not significant (OR 0.78, 95% CI 0.46-1.32).

As shown in Table 4 and Figure 3A, both groups exhibited significant within-group changes in the primary outcome, with a rapid decrease leading up to posttreatment at 6 months. Differences were small but significant for bCBT over TAU during treatment (3 months, d=−0.26, 95% CI −0.43 to −0.09; P=.003) and at 6 months posttreatment (d=−0.21, 95% CI −0.39 to −0.04; P=.016), with a nonsignificant difference between the groups at the 12-month follow-up.

Figure 3. Estimated marginal means PHQ-9 scores at various time points for the bCBT and TAU group (A) and for strata of AD use (B). AD: antidepressant; bCBT: blended cognitive behavioral therapy; CBT: cognitive behavioral therapy; PHQ-9: Patient Health Questionnaire-9; TAU: treatment as usual.

A subgroup analysis (Table 5 and Figure 3B) was conducted to estimate the impact of baseline AD versus non-AD use on the primary outcome (PHQ-9) in bCBT versus TAU. At baseline, the AD groups had a 1.42-point higher PHQ-9 score than the

XSL•FO
RenderX

non-AD user groups, indicating that this group experienced more severe depressive symptoms. AD patients exhibited a greater reduction in depressive symptoms than non-AD users, most likely because their higher baseline scores left more room for improvement (Figure 3). When comparing the impact of AD use and non-AD use on the primary outcome across the 2 groups, no significant differences were found at any of the 3 time points (Table 5, AD vs no AD at baseline, bCBT compared with TAU).

Table . Estimated marginal mean PHQ-9[a] scores at various time points for the bCBT[b] and TAU[c] groups and by strata of AD[d] use.

	Difference in EMM[e] (95% CI)	Difference in Cohen *d* (95% CI)	*P* value
No AD at baseline bCBT-TAU			
3 months	−1.31 (−2.35 to −0.28)	−0.28 (−0.50 to −0.06)	.01
6 months	−1.21 (−2.28 to −0.15)	−0.26 (−0.49 to −0.03)	.02
12 months	−0.32 (−1.41 to 0.77)	−0.07 (−0.30 to 0.16)	.56
AD at baseline bCBT-TAU			
3 months	−1.08 (−2.26 to 0.10)	−0.23 (−0.48 to 0.02)	.07
6 months	−0.71 (−1.95 to 0.52)	−0.15 (−0.42 to 0.11)	.26
12 months	0.27 (−0.97 to 1.52)	0.06 (−0.21 to 0.32)	.66
AD versus no AD at baseline bCBT-TAU			
3 months	0.23 (−1.26 to 1.73)	0.05 (−0.27 to 0.37)	.76
6 months	0.50 (−1.12 to 2.12)	0.11 (−0.24 to 0.45)	.54

[a]PHQ-9: Patient Health Questionnaire-9.

[b]bCBT: blended cognitive behavioral therapy.

[c]TAU: treatment as usual.

[d]AD: antidepressant.

[e]EMM: estimated marginal means.

Using the nonimputed dataset for the entire sample, the overall percentage of patients who deteriorated was low: 4.8% (33/688) at the 3-month assessment, 4.6% (28/609) at the 6-month assessment, and 4.1% (23/561) at the 12-month assessment. There were no significant differences in EE on reliable deterioration between the groups at all 3 time points (OR and Cohen *d*). However, the estimated multilevel logistic model for deterioration yielded unreliable estimates, most likely due to the small number of patients who deteriorated.

Acceptance and Working Alliance

Table 6 presents results for several acceptance and working alliance measures. Patients in the bCBT group scored significantly higher on treatment satisfaction (CSQ-8) than those in the TAU group, with a mean of 25.44 (SD 4.93) at the 3-month assessment. This score falls between “somewhat satisfied” (n=24) and “very satisfied” (n=32), whereas the TAU group scored below the 24 threshold (mean 21.34, SD 5.94). Only the bCBT group (patients) rated the technological platforms’ usability, with a mean SUS score of 40.16 (SD 7.35), below the average of 68. In contrast, the technical alliance (WAI-TECH-SF-C48), also rated only by the bCBT group (patients), was rated more positively, with a mean of 57.12 (SD 16.87) on a scale of 12 - 84. Higher scores indicate a better quality of the technical alliance.

[e]SUS: System Usability Scale.

[f]N/A: not applicable.

[g]WAI-SR-C: Working Alliance Inventory-Short Revised–Client.

[h]WAI-TECH-SF-C: Working Alliance Inventory for Online Interventions-Short Form–Client.

[i]WAI-SR-Therap: Working Alliance Inventory-Short Revised–Therapists.

Patients in bCBT and TAU rated the working alliance as good, with mean overall composite scores of 3.97 (SD 0.77) in the bCBT group and 3.41 (SD 0.99) in the TAU group, out of 5. However, patients in the bCBT group rated the therapeutic alliance (WAI-SR-C) significantly higher (*P*<.001) than those in the TAU group, both for the composite score and for the task, bond, and goal components. The therapists also rated the working alliance as good, but those in the TAU group rated it significantly higher (mean 4.09, SD 0.64; *P*<.001) than those in the bCBT group (mean 3.84, SD 0.70). They also scored significantly higher on the task (*P*<.001) and goal (*P*<.001) components of the WAI-SR-T in TAU compared with bCBT but not on the bond scale.

Costs

Table 7 presents several disaggregated health care cost categories and total health care costs per patient for bCBT and TAU at the 12-month assessment. These costs did not differ significantly between the 2 groups, except for home care costs, which were significantly higher for TAU than for bCBT. However, the average total health care costs per patient were slightly higher for the bCBT group than for the TAU group (estimated mean difference per patient €315, 95% CI −582 to 1163). This difference was primarily driven by the estimated bCBT intervention costs.

XSL•FO
RenderX

Table . Estimated mean (SE) costs (euros) per patient for bCBT[a] and TAU[b], and corresponding differences (95% CI) at 12-month follow-up point (N=835).

Cost category	bCBT (€/SE)	TAU (€/SE)	Difference (95% CI)
Intervention costs	274 (6)	0 (0)	N/A[c]
Primary care costs	440 (31)	525 (49)	−85 (−213 to 7)

[b]TAU: treatment as usual.

[c]Not applicable.

Cost-Effectiveness Analyses

Table 8 presents the cost-effectiveness analysis results at the 12-month follow-up from a health care perspective. The mean overall change in PHQ-9 score over the 12-month period was small but significantly higher for bCBT than for TAU. Within the main analysis, the ICER for the PHQ-9 score was €643 per point of improvement, meaning that to gain a single point of improvement in the PHQ-9 score, an investment of €643 is required for bCBT compared with TAU.

XSL•FO
RenderX

Table . Multiple imputed, pooled cost-effectiveness outcomes for bCBT[a] compared with TAU[b] (euros) at the 12-month follow-up point[c].

Outcome	ΔC[d] (95% CI) (€)	ΔE[e] (95% CI)	ICER[f] (€)	CE[g] plane			
				NE[h]	SE[i]	SW[j]	NW[k]

[a]bCBT: blended cognitive behavioral therapy.

[b]TAU: treatment as usual.

[c]Differences in PHQ-9 score and MINI were multiplied by −1 in order to ensure that the CE planes and cost-effectiveness acceptability curves were interpretable. Thus, differences in PHQ-9 score should be interpreted as additional points of improvement in bCBT compared with TAU and differences in MINI as cases of MDD prevented within bCBT compared with TAU.

[d]ΔC: The difference in costs between blended care and usual care.

[e]ΔE: difference in effects between bCBT and TAU.

[f]CER: incremental cost-effectiveness ratio.

[g]CE: cost-effectiveness.

[h]NE: northeast.

[i]SE: southeast.

[j]SW: southwest.

[k]NW: northwest.

[l]PHQ-9: Patient Health Questionnaire-9.

[m]MINI: Mini International Neuropsychiatric Interview.

[n]QALY: quality-adjusted life-years (based on EQ-5D-5L).

The cost-effectiveness plane shows that in 73% of the bootstrapped simulations, bCBT was both more effective and more expensive (Table 7: northeast quadrant of the cost-effectiveness plane). Figure 4 present the cost-effectiveness planes, plotting differences in costs against differences in effects (PHQ-9 (Figure 4A), presence of MDD (Figure 5A), and QALYs (Figure 6A) between the 2 conditions combined with the cost-effectiveness acceptability curves (Figure 4B, Figure 5B, and Figure 6B) representing the probability that bCBT is cost-effective compared with TAU across a range of WTP thresholds (WTP for PHQ-9, presence of MDD, and QALYs). As no universally accepted thresholds exist for these outcomes (except for QALYs), WTP values were varied from €0 to €50,000 to reflect a broad range of decision-making scenarios.

XSL•FO
RenderX

Figure 4. Cost-effectiveness plane of incremental costs versus change in PHQ-9 score over 12 months (A) across willingness-to-pay thresholds (B). bCBT: blended cognitive behavioral therapy; PHQ-9: Patient Health Questionnaire-9; TAU: treatment as usual.

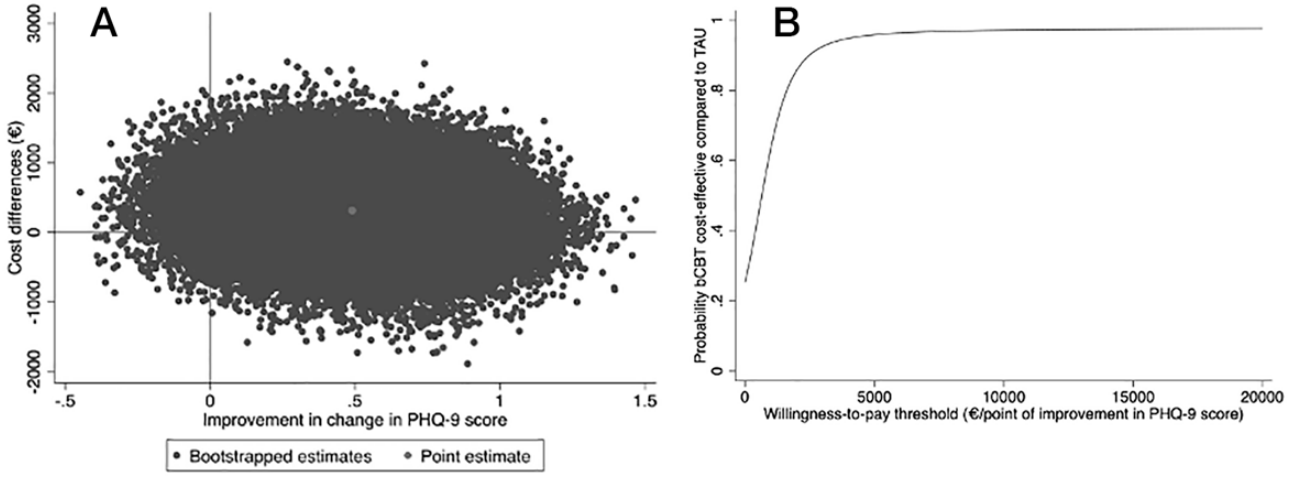

Figure 5. Cost-effectiveness plane of incremental costs versus change in presence of MDD (A) (MINI, 51) and across willingness-to-pay thresholds over 12 months (B). bCBT: blended cognitive behavioral therapy; MDD: major depressive disorder; MINI Mini International Neuropsychiatric Interview; TAU: treatment as usual.

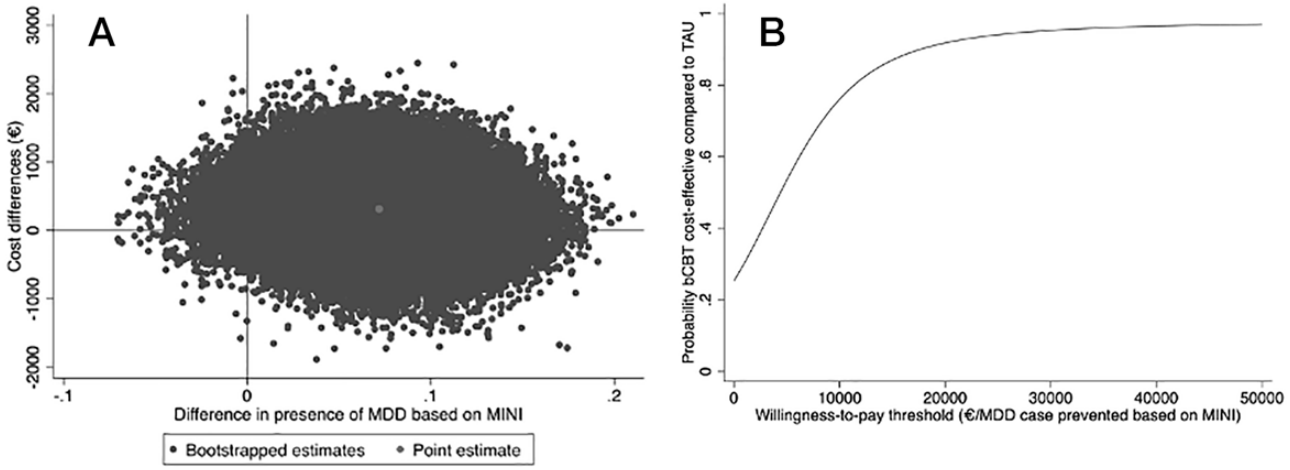

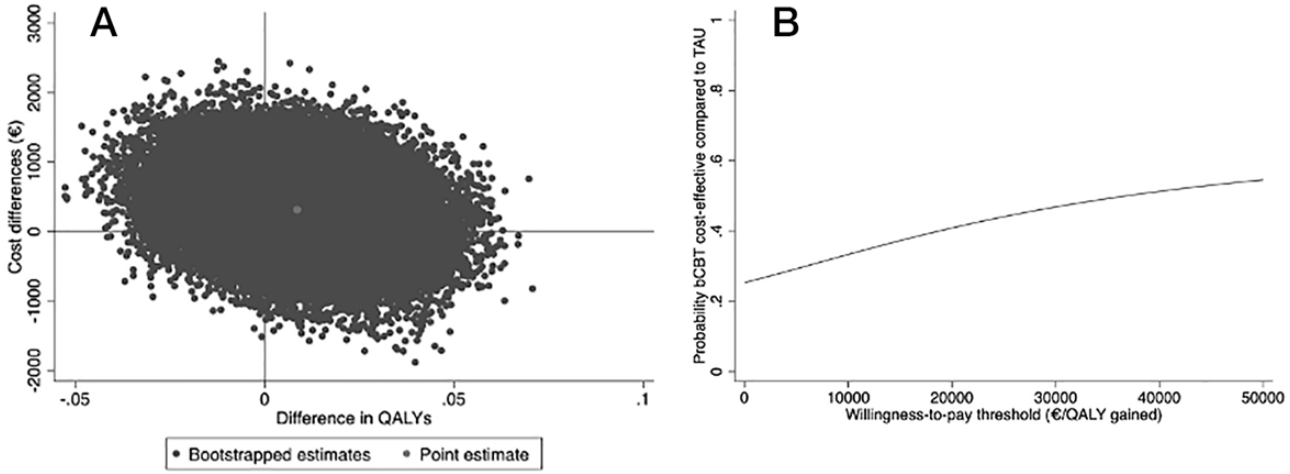

Figure 6. Cost-effectiveness plane of incremental costs versus change in QALYs (A) and acceptability curve across 12 months (B). bCBT: blended cognitive behavioral therapy; QALYs: quality-adjusted life-years; TAU: treatment as usual.

Cost-effectiveness planes illustrate the uncertainty around the ICER across the 4 quadrants. In Figure 4, 73% of bootstrap replications fall in the northeast quadrant, indicating that bCBT is not only more effective than TAU but also more costly (PHQ-9). It also shows that, for a 1-point improvement on the PHQ-9 and a WTP of €0, the probability of cost-effectiveness was low (0.25), rising to 0.95 at a WTP of €3,800.

A similar pattern was observed for preventing an MDD diagnosis at follow-up (12 months; Table 7). The ICER for preventing 1 MDD case was €4381, indicating that this amount

XSL•FO
RenderX

would need to be invested in bCBT rather than TAU to prevent an MDD diagnosis. As shown in Figure 5, 74% of the cost-effectiveness pairs fall within the northeast quadrant (more effective and more expensive), while the remaining 26% are in the southeast quadrant (more effective and less expensive). Figure 5 also shows that the probability of cost-effectiveness ranges from 0.25 at a WTP of €0 to 0.76 at a WTP of €10,000 for every MDD episode prevented.

For QALYs, the difference between bCBT and TAU was small and not statistically significant (Table 7), with considerable uncertainty indicated by the spread of bootstrap replications across all quadrants. The ICER indicates a cost of €36,729 per QALY gained. At a €50,000 threshold, the probability that bCBT is cost-effective is 0.55 (Figure 6). In the adjusted analysis, the cost difference between bCBT and TAU increased to €421 (Table 7), but this difference was not statistically significant, and the overall results were consistent with the main analysis.

Discussion

Principal Findings

Our hypotheses were that bCBT for patients with MDD would be clinically noninferior to TAU and more cost-effective from a health care perspective. The results showed that while bCBT was noninferior to TAU, it was not cost-effective. The first part of our hypothesis was confirmed, as all the differential effects observed for the primary outcome (PHQ-9) in the comparison between bCBT and TAU fell within the conservative noninferiority margin (Cohen *d*=0.20). Depressive symptoms showed a significant decline up to the posttreatment assessment, and this improvement was maintained at the 12-month follow-up. The posttreatment effects for both groups also aligned well with the benchmark (*d*=1.19 [60]) for the treatment of depression with CBT in routine care settings. Additionally, the long-term effects observed in both groups are comparable with those found in meta-analyses of CBT for depression [61,62]. The bCBT group also had a lower risk of experiencing an MDD episode than the TAU group at the 12-month follow-up (OR 0.67, 95% CI 0.45-0.99). AD use was evenly distributed between the 2 groups (approximately 40%) from baseline to the 12-month follow-up, with no significant differences in proportions. Subgroup analyses indicate that participants with and without baseline AD use benefited equally from treatment. These findings are comparable with those of a meta-analysis by Cuijpers and colleagues [63], which reported a similar percentage of AD use in psychotherapeutic RCTs and found that the effects of psychotherapy for adult depression were not concurrently mediated by pharmacotherapy use. Adverse treatment effects were limited, as indicated by the reliable deterioration rates (less than 5%) for the overall group up to the 12-month follow-up. These rates compare favorably with those found in a meta-analysis of deterioration rates within psychotherapies for depression [64].

Patients' acceptance of treatment, in terms of both the credibility and expectancy of therapy, was significantly higher for bCBT than for TAU, as was patients' satisfaction with treatment. This may be partly explained by the higher baseline preference for the bCBT group, which, in turn, was influenced by patients' willingness to participate in the study. An additional explanation for these higher satisfaction ratings may be that the internet-based components of bCBT better support patients' self-management than traditional face-to-face psychotherapy, as patients are less reliant on therapists only during their treatment. This may also partly explain why, although patients and therapists valued the working alliance as strong in both conditions, patients in the bCBT group gave higher ratings than those in the TAU group. Conversely, therapists rated the therapeutic alliance significantly higher in TAU than in bCBT, except on the bond subscale. This difference may reflect therapists' preference for face-to-face contact, including access to nonverbal cues, as well as established professional norms [65]. Nevertheless, the observed difference was relatively small, and other studies have not found such disparities [16]. Overall, these findings suggest that a strong working alliance—encompassing both human and technological components—can be established between patients and therapists in bCBT, although many participants in our study were relatively new to this mode of treatment delivery. The high alliance ratings reported by patients in both conditions are consistent with findings from the meta-analytic review by Flückiger et al [66]. For a more detailed analysis of the association between working alliance and treatment outcomes for E-COMPARED, see the study by Doukani et al [67].

Only a few RCTs have directly evaluated the clinical effectiveness of bCBT for MDD compared with active face-to-face treatment controls, limiting direct comparisons with our study. These trials recruited outpatients with MDD, compared bCBT with ftfCBT or face-to-face psychotherapy, and had broadly comparable treatment durations and intensities (12 - 20 weeks). Their findings are generally consistent with ours. For example, Berger et al [68] reported that CBT supplemented with internet-based modules was superior to ftfCBT at 12 weeks posttreatment (moderate effect) [68]. Similarly, Thase et al [69] demonstrated the noninferiority of integrated bCBT compared with ftfCBT 4 months after baseline assessment, whereas Kooistra et al [23] found no significant differences in depressive symptoms between the 2 treatment conditions. Berger et al [68] and Kooistra et al [23] also reported similarly low deterioration rates, good therapeutic alliance, and high treatment acceptability, with no significant between-group differences. These findings should, however, be interpreted cautiously because the available trials were relatively small and therefore provided limited certainty regarding treatment effects.

Since completion of our study, Schaeuffele et al [70] reported the results of the large pragmatic PsyTOM trial conducted in Germany, which compared a transdiagnostic blended psychotherapy intervention with routine face-to-face psychotherapy for patients with a broad range of mental health disorders. Based on a superiority design, the authors found no evidence that blended treatment resulted in greater clinical improvement or fewer face-to-face sessions up to 6 months after randomization [70]. Although these findings differ from ours, direct comparisons should be made cautiously because the interventions and study designs differed substantially. Whereas E-COMPARED evaluated a structured, integrated bCBT

XSL•FO
RenderX

protocol specifically designed for patients with MDD, PsyTOM evaluated a highly flexible transdiagnostic blended intervention delivered across multiple therapeutic orientations. In addition, PsyTOM included patients with a wide range of mental health disorders, did not restrict inclusion to formally diagnosed disorders, and allowed therapists considerable flexibility in determining both treatment duration and the use of digital components. The PsyTOM authors therefore suggested that the absence of superiority may reflect the flexibility and heterogeneity of the intervention rather than the ineffectiveness of blended treatment itself.

From a health care perspective, bCBT was associated with nonsignificantly higher health care costs than TAU over the 12-month follow-up period. Although differences in clinical outcomes were modest, they consistently favored bCBT, with slightly greater improvements in PHQ-9 scores and fewer MDD episodes. Consequently, whether bCBT can be considered cost-effective depends on how much policymakers are willing to pay for these additional health gains. Evidence on the cost-effectiveness of bCBT compared with active face-to-face treatment remains scarce. This is not unexpected, as relatively few pragmatic trials have evaluated blended care under routine clinical conditions, and economic evaluations have only occasionally been conducted alongside these trials. The few available studies have also reported inconsistent findings, with some reporting lower health care costs primarily because blended care reduced therapist time, whereas others found no significant cost differences. These inconsistencies likely reflect differences in study design, intervention characteristics, health care settings, cost perspectives, and economic evaluation methods rather than true differences in the cost-effectiveness of bCBT [23,69].

Strengths and Limitations

This study is the first large-scale noninferiority trial to date, examining the clinical effectiveness and cost-effectiveness of bCBT compared with face-to-face TAU, predominantly ftfCBT. Noninferiority trials within routine mental health care remain scarce because of the large sample sizes required (small noninferiority margins necessitate high precision), the need for evidence-based treatment comparators, and evaluations under real-world conditions [71]. We addressed this gap by achieving a substantial sample size, using active comparators, setting a clear noninferiority margin, and conducting our RCT within routine care practices. Dropout rates in the total sample ranged from 17.5% at 3 months to 33% at the 12-month follow-up. The proportion of participants lost at 3 months (17.5%) was comparable with the average dropout reported in randomized trials of individual psychotherapy for depression in routine care [72], whereas the higher attrition at 12 months is consistent with the challenges of maintaining participant engagement during long-term follow-up. Despite this, dropout warrants careful consideration in future studies, as it may affect the validity of the findings and may indicate challenges with treatment adherence. The multifaceted nature of our study, which comprised diverse settings and technical platforms, enhances the generalizability of our results to routine care settings. Generalizability is further strengthened by including patients with and without AD use at baseline, reflecting the characteristics of patients with MDD in routine clinical practice.

Our study is not without its limitations, however. The sample size was smaller than planned due to time and budgetary constraints. However, our ability to detect noninferiority based on the predefined margin for the primary outcome during and after treatment and follow-up suggests that the sample size was sufficient to assess noninferiority [73]. This noninferiority of bCBT compared with TAU was also supported by the secondary QIDS-16 outcome at the 3- and 6-month assessments, consistent with the findings for the primary outcome (PHQ-9). However, the 2 depression measures no longer yielded consistent findings at the 12-month assessment, suggesting that the longer-term treatment effects should be interpreted with some caution. Next, all participants met the diagnostic criteria for MDD (MINI) and had a PHQ-9 score above 5 at baseline. However, because treatment was delivered within routine health care settings, participants received bCBT or TAU in either primary or specialized mental health care services. Consequently, the duration and intensity of treatment varied across settings; for example, specialized mental health care generally provided more frequent and longer treatment sessions than primary care. This between-setting heterogeneity represents a potential source of confounding that is inherent to pragmatic trials. Nevertheless, leave-one-out sensitivity analyses indicated that the overall findings were robust and were not driven by any single study site. Only the noninferiority analysis of the 12-month primary outcome showed some uncertainty after exclusion of 1 site, suggesting that the longer-term findings should be interpreted with some caution. Although this heterogeneity may have influenced the observed treatment effects, it also reflects routine clinical practice and therefore enhances the external validity of the findings.

The inability to blind patients and therapists, a common feature of psychotherapeutic studies, may also have influenced our results [74]. However, the assessors of the MINI interview were blinded, and other assessments were based on self-report. It was not possible to assess the therapists' treatment fidelity, which may also have influenced the treatment outcomes. Additionally, some therapists delivered both treatments, which was necessary because the RCT was conducted within routine care. This may also have influenced treatment outcomes due to a preference for, or greater familiarity with, one treatment over the other [75]. Given that bCBT was still relatively new for most therapists, this could indeed have been an issue. Our cost-effectiveness analyses may also have been hampered by the sample size calculation, which was based on a noninferiority clinical margin rather than on economic outcomes. Thus, the sample size may have been underpowered to detect real effects in the cost differences between the 2 groups.

Conclusions

To the best of our knowledge, this is the first large-scale RCT evaluating the clinical effectiveness, cost-effectiveness, and safety of bCBT for MDD in routine care, compared with TAU. The demonstration of clinical noninferiority positions bCBT as an additional acceptable treatment option for patients and therapists in routine mental health care. However, large-scale

XSL•FO
RenderX

implementation will also depend on more robust evidence of its cost-effectiveness. This may improve as blended care becomes more established in practice, with increasing familiarity among patients and therapists and further optimization and standardization of delivery processes. Future studies are advised to support our outcomes. Studies are also recommended to investigate in greater depth the facilitators and contextual characteristics of bCBT for successful implementation in routine care. Future studies are also needed to explore alternative modalities of "blending," such as face-to-face psychotherapy combined with videoconferencing, virtual reality, or AI-supported interaction between therapists and patients based on natural language models, alongside active and passive EMAs.

Acknowledgments

The authors would also like to acknowledge the contributions of the patients, therapists, and general practitioners from the participating countries, as well as GAMIAN for keeping the patients' perspective at the forefront. A special tribute is reserved for Dr Jeroen Ruwaard and Professor Dr Jan Smit, who both played a pivotal role in the European Comparative Effectiveness Research on Internet-based Depression Treatment (E-COMPARED) study. Dr Jeroen Ruwaard passed away unexpectedly in 2019. Unfortunately, Professor Dr Jan Smit had to withdraw as coauthor due to personal circumstances. Finally, the authors would like to thank all other contributors to the E-COMPARED project, particularly Dr Christiaan Vis and Dr Stasja Draisma and the External Advisory Board for their reflection upon the scope and outcomes of the E-COMPARED project study. Machine tools were used to suggest language improvements within the manuscript.

Funding

The European Comparative Effectiveness Research on Internet-based Depression Treatment (E-COMPARED) study was funded by the European Union's Seventh Framework (FP7), grant agreement HEALTH-F3-2013-603098. Denmark received funding from the Innovation Fund Denmark to support the Danish trial in the ENTER project, which provided data for the E-COMPARED project. The funding bodies did not influence the study design.

Data Availability

Data are available on request from the authors.

Authors' Contributions

HR, AK, JB, RA, and MH designed this study. HR and AK managed the project. AvS, KM, GA, DDE, TB, KC, RB, CB, RA, and RC led the national study sites as principal investigators. IT, LK, KM, TK, JBH, AC-P, AG-P, NT, and ES managed and conducted the national trials. The analyses were carried out by AH, JB, HR, AK, and MS, while HR, AK, AH, and JB wrote the manuscript. All authors reviewed, provided input, and approved the final manuscript.

Conflicts of Interest

DDE reports having received consultancy fees from, and served on the scientific advisory boards of, several companies such as Sanofi, Minddistrict, Lantern, Schoen Kliniken, and German health insurance companies (Techniker Krankenkasse, BARMER). He is a shareholder of the Institute for health training online GmbH (GET.ON/HelloBetter), a provider of digital therapeutics for mental disorders in routine mental health care (unrelated to the present work). DDE report having received consultancy fees and fees for lectures/workshops from chambers of psychotherapists and training institutes for psychotherapists in the e-mental-health context. All other authors declared no conflicts of interest.

Abstract

Choroidal metastases (CM) represent a rare but clinically significant manifestation of systemic malignancy, most frequently from lung cancer. The choroid's vascular anatomy allows hematogenous tumor seeding. Although CM may be the first clinical sign of an underlying malignancy, evidence guiding its management in the modern immunotherapy era remains limited, as most published cases predate the widespread use of immune checkpoint-inhibitors. We describe a 33-year-old male patient presenting with ocular pain and visual disturbance, who was found to have an amelanotic choroidal lesion. Systemic workup revealed small pulmonary nodules and an iliac crest lesion. Sequential biopsies suggested that this was metastatic adenocarcinoma of unknown primary origin, but most likely of lung origin, without actionable mutations or PD-L1 (programmed death-ligand 1) expression. Management required multidisciplinary coordination and included carboplatin, paclitaxel, and pembrolizumab, followed by radiation to the orbit, iliac crest, and mediastinal sites of disease. Unfortunately, he experienced progression while on maintenance immunotherapy with new rib and brain lesions, for which he underwent treatment with platinum, pemetrexed, and bevacizumab with additional radiotherapy. Despite loss of vision in the affected eye, he achieved durable disease control and remains free of radiographic recurrent disease>4 years after diagnosis. This case illustrates that multimodality salvage strategies—integrating systemic therapy with aggressive local radiation—can provide unexpectedly prolonged survival even after immunotherapy failure. Importantly, current guidelines offer minimal direction on managing CM in this context, and prior case reports do not reflect present-day treatment realities. The key message for clinicians is that CM should not automatically be approached with palliative intent; carefully selected patients may benefit from an oligometastatic strategy that actively targets limited metastatic sites to prolong survival. Our findings underscore the need for ophthalmology, radiation oncology, and medical oncology collaboration when vision-threatening or occult metastatic lesions arise. For readers, the takeaway is that choroidal metastasis—particularly in the era of immunotherapy—warrants individualized, multidisciplinary evaluation rather than default palliation. Our case demonstrates that coordinated multimodality management can achieve long-term disease control, highlighting a treatment paradigm worth considering for selected patients and calling for updated guidelines that reflect modern therapeutic capabilities.

(Interact J Med Res 2026;15:e77895) doi:10.2196/77895

KEYWORDS

choroidal; metastasis; non-small cell lung cancer; cancer of unknown primary origin; multi-modal therapy

Introduction

Rare presentations of cancer can include metastases to the orbit through hematogenous dissemination. The uveal tract is a highly vascular complex made from the choroid, ciliary body, and iris. Importantly, the eye contains the blood-retinal barrier, analogous to the blood-brain barrier. However, the choroid layer lies outside retinal pigment epithelial tight junctions and is therefore exposed to unimpeded drug delivery from the vasculature [1]. One of the most common sources of choroidal metastases is primary lung cancer, with 88% of lung metastases to the eye involving the choroid, with an associated overall survival at one-year of 54% [2]. Consequently, choroidal metastases (CM) of unknown origin are often treated similarly to lung cancer as

XSL•FO
RenderX

the clinical, imaging, and histopathologic features of choroidal lesions frequently resemble those seen in lung cancer patients [3,4]. The prognosis for carcinoma of unknown primary (CUP) with CM is generally poor, with median overall survival ranging from 3 to 12 months, as patients tend to present with advanced and disseminated disease [5,6].

Case Presentation

Patient Information

The patient was a 33-year-old male at the time of initial presentation with no significant past medical history. He presented with right ophthalmalgia, blurry vision, and sinus congestion. Clinical course was as follows (Table 1).

Table . Timeline of key events in the described patient presentation

Day	Description of key events.
Day 0-2	Initial presentation: chief complaint of right ophthalmalgia and blurry vision. Ophthalmology observed an amelanotic right choroidal lesion. MRI[a] Orbit showed enhancing plaque of the posterior-lateral wall of right globe. CT[b] chest showed RML and RUL nodules
Day 44-113	Pathological workup: right intraophthalmic choroidal biopsy with scant atypical cells. PET (Positron Emission Tomography) revealed non-avid RML[c] and RUL[d] nodules and mildly avid L iliac crest. R choroidal FNA[e] read as metastatic carcinoma, compatible with pulmonary adenocarcinoma. L iliac biopsy with further suggestion of lung origin (CK7, TTF1+)
Day 125-313	Initial chemoimmunotherapy: started on carboplatin, paclitaxel and pembrolizumab for 4 cycles followed by pembrolizumab maintenance. Completed stereotactic radiation to R orbit
Day 293-324	Disease progression: clinical and radiographic progression at ribs and lungs as well as intracranial site
Day 313-743	Oligometastatic salvage therapy: given radiation to chest wall and left frontal operculum. Started on carboplatin, pemetrexed, and bevacizumab for 4 cycles followed by pemetrexed and bevacizumab maintenance. Bevacizumab was continued as maintenance for 14 cycles
Day 743-Present	Surveillance: no clinical or radiographic evidence of disease progression as of day 1563.

[a]MRI: magnetic resonance imaging.

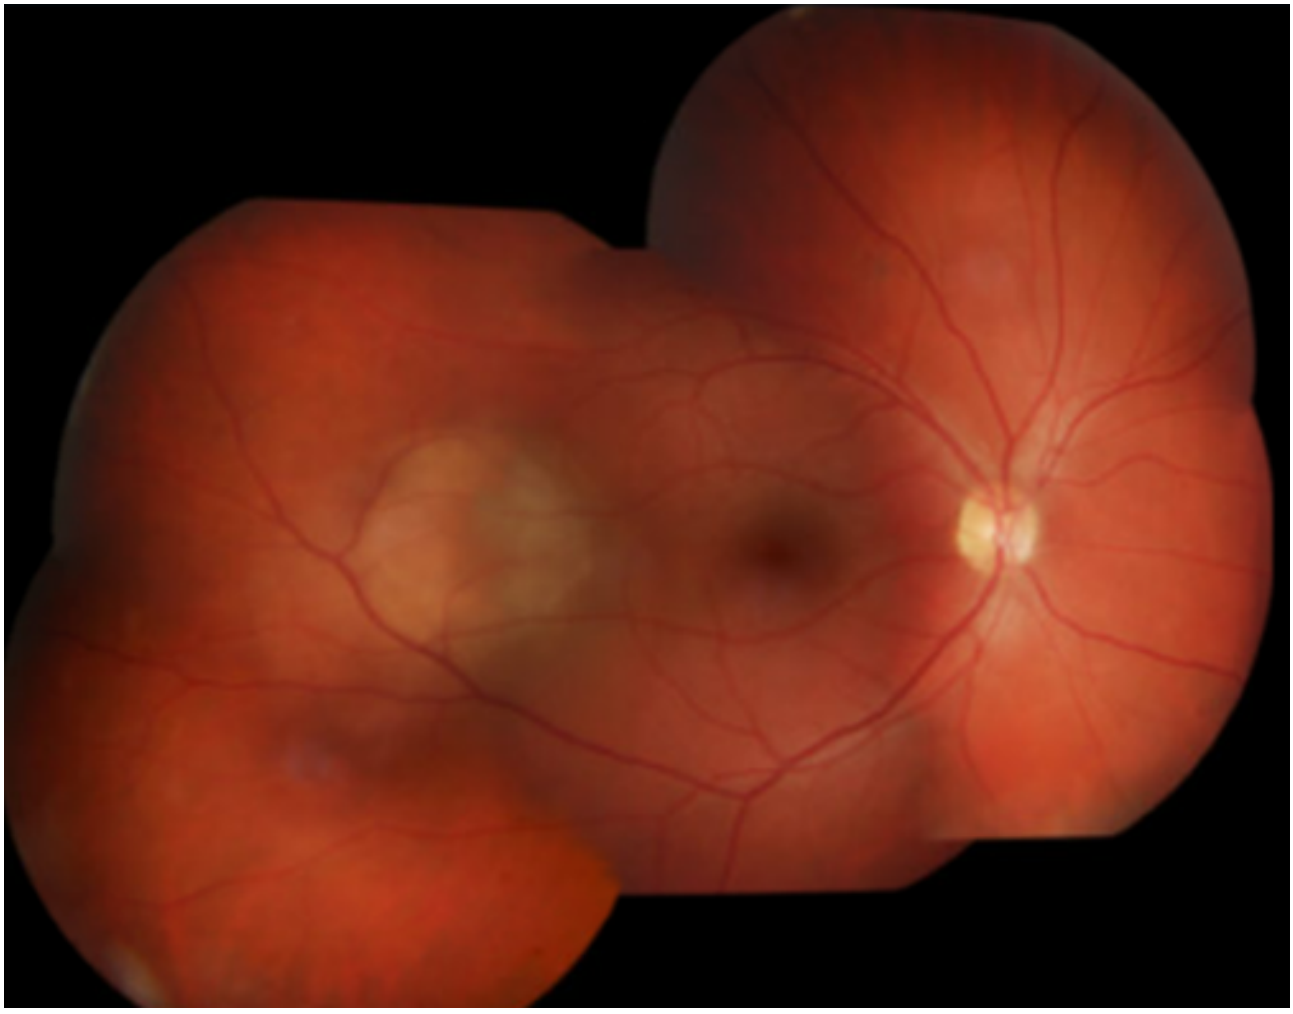
[b]CT: computed tomography.

[c]RML: right middle lobe.

[d]RUL: right upper lobe.

[e]FNA: fine-needle aspiration.

Ethical Considerations



The patient involved in this case report has given his informed consent authorizing the use and disclosure of his health information.

Clinical Findings

Evaluation by ophthalmology revealed an amelanotic right choroidal lesion (1.04 × 1.15×.31 cm, Figure 1). The patient had 20/20 - 1 vision bilaterally with full visual fields.

XSL•FO
RenderX

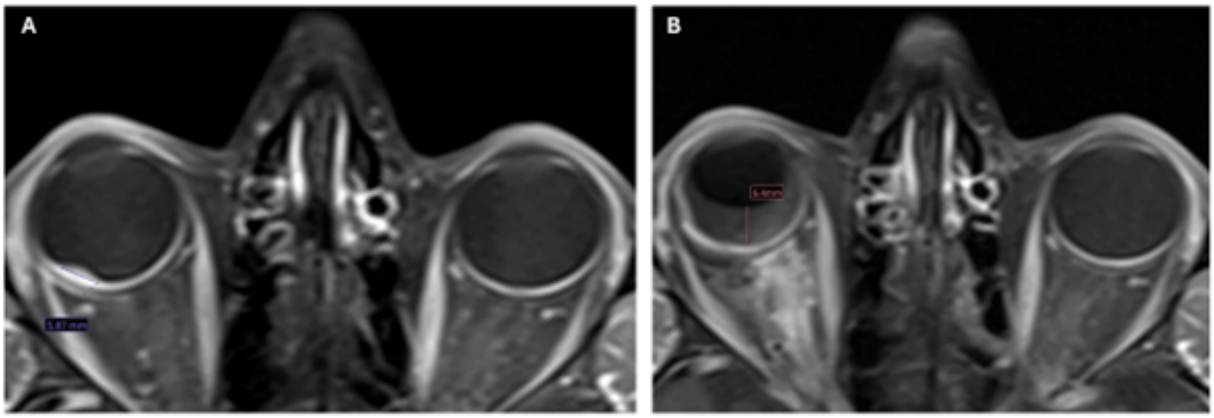
Figure 1. Ophthalmologic evaluation showed an amelanotic right choroidal lesion.

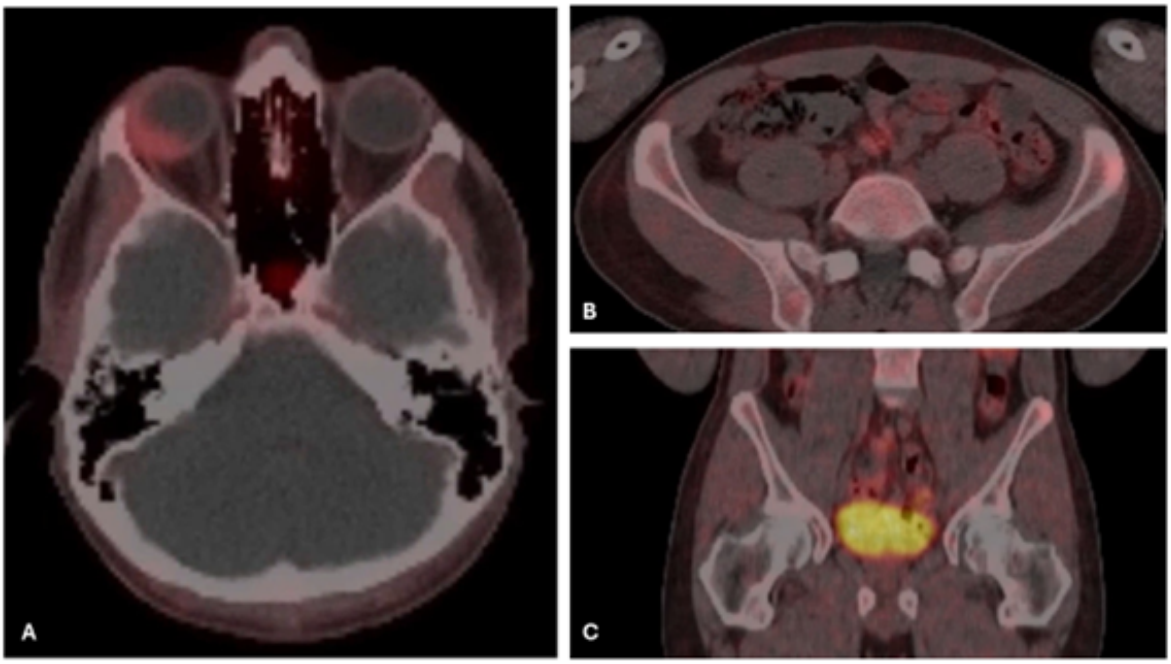
Diagnostic Assessment

MRI Orbit on Day 0 (Figure 2A) confirmed an enhancing plaque along the posterior-lateral wall of his right globe. A CT Chest (Day 2) demonstrated a right middle lobe (RML) (0.5cm) and right upper lobe (RUL) nodule (0.2cm). The patient underwent intraophthalmic choroidal biopsy (Day 44). Pathology read as scant atypical cells, with few cells showing 'neuroendocrine-like nuclear features.' A DOTATATE PET (Positron Emission Tomography) on Day 64 was performed, which showed mild avidity in the right globe mass (SUV 2.6, Krenning 1) (Figure 3A), a nonavid RML nodule (0.5cm, below PET resolution) and RUL nodule (0.2cm), and a mildly avid left iliac crest lesion (1cm) (Figure 3B, C). The patient subsequently underwent a right choroidal fine-needle aspiration (FNA) on Day 69, with pathology read as metastatic carcinoma, compatible with pulmonary adenocarcinoma. Notably, the histology did not resemble a retinal pigment epithelium tumor and was positive for CK7 and TTF1 but negative for PD-L1, thyroglobulin, PAX8, CD20, GATA3, CD3, and Melan-A. CK20 was only weakly focally positive. Synaptophysin highlighted pieces of retina but not the tumor. Molecular testing showed no actionable mutation in EGFR, KRAS, BRAF, or HER2. Unfortunately, testing for ALK, RET, ROS1, NTRK1/3 and MET was inconclusive due to insufficient sample. A left iliac biopsy (Day 113, Figure 4) and mediastinal lymph node (4R) FNA biopsy (Day 114) were also read as carcinoma showing CK7 and TTF1 positivity. An insufficient sample of tumor was procured for sequencing; however, immunohistochemical (IHC) analysis was negative for EGFR, ALK, ROS, and BRAF driver mutations. No PD-L1 expression (0%) was observed. The patient was discussed in a multidisciplinary tumor board with the ultimate determination that this was metastatic adenocarcinoma of unknown primary, but most likely of pulmonary origin and to treat as non-small cell lung cancer (NSCLC).

XSL•FO
RenderX

Figure 2. (A) MRI orbit (Day 0) showed enhancing plaque along the posterior-lateral wall of his right globe. (B) MRI orbit (Day 1,123) showed new right optic nerve enhancement.





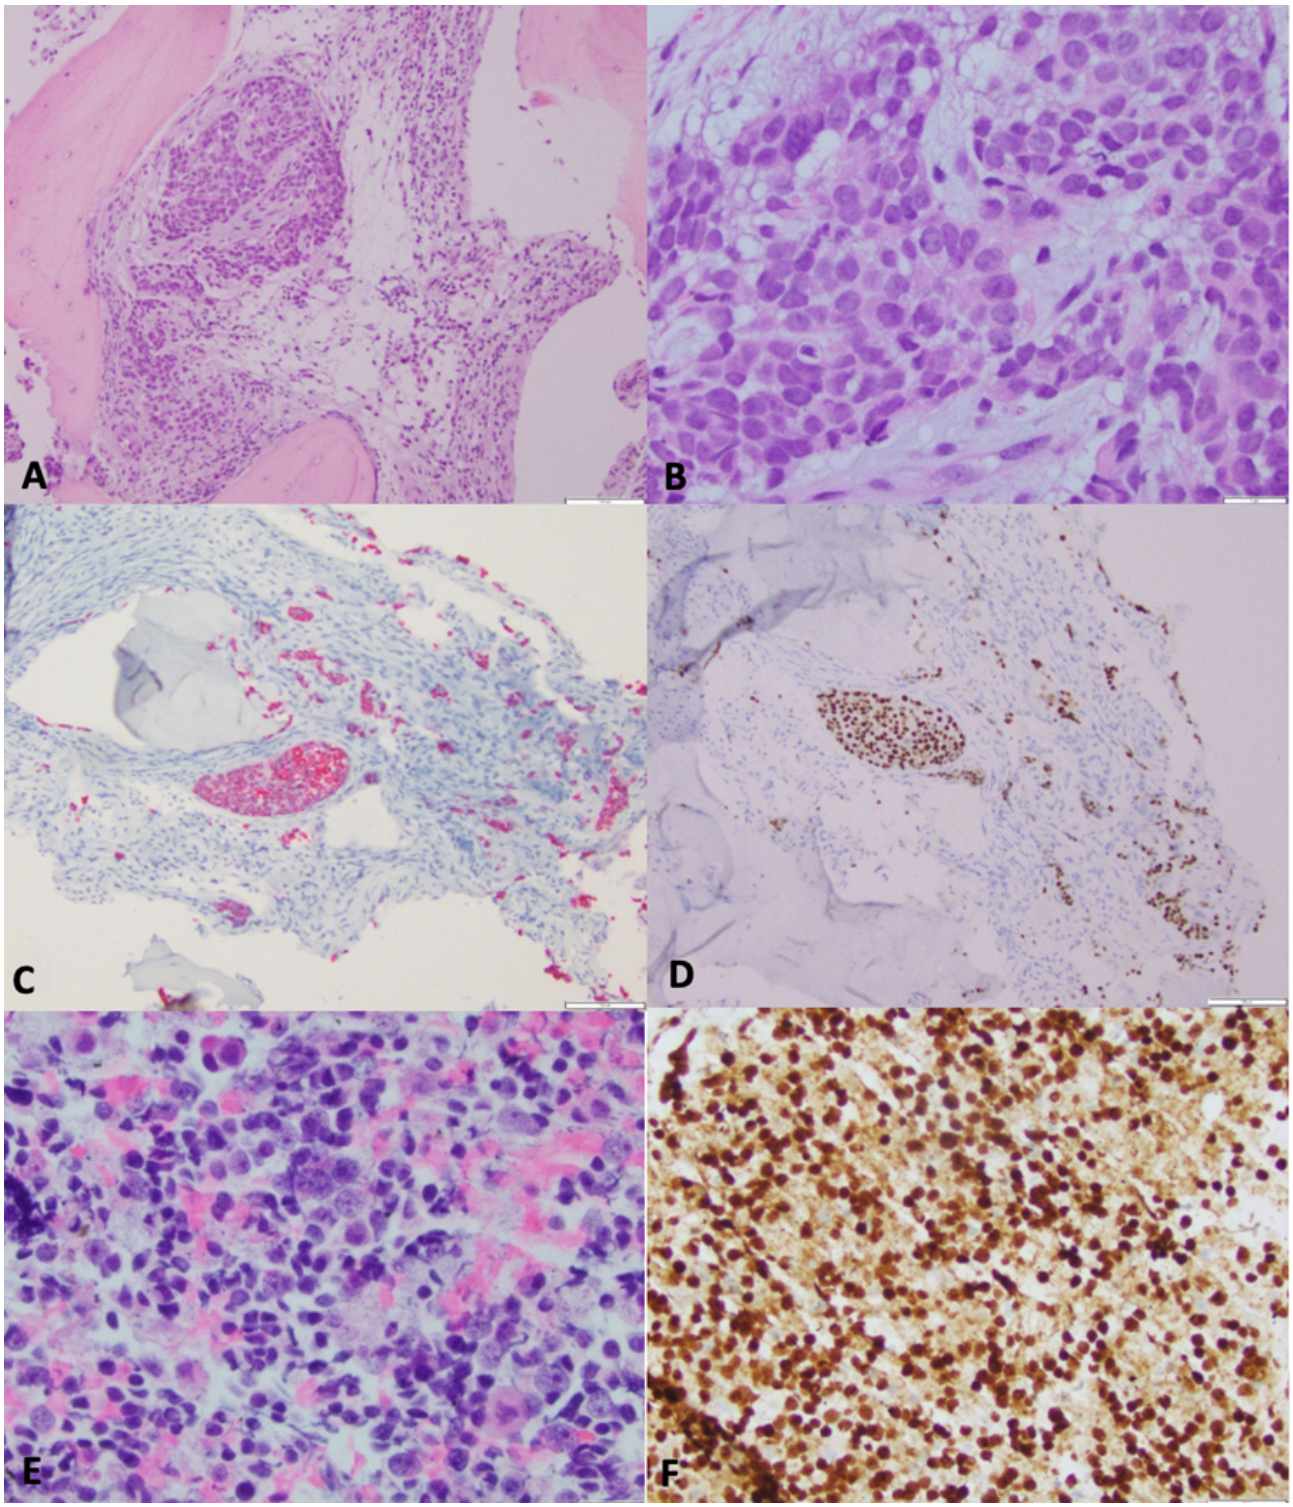


Figure 3. DOTATATE PET Imaging on d 64 demonstrating sites of metastatic involvement(A) Axial DOTATATE PET of the orbits showing mild radiotracer avidity within the right choroidal lesion (SUV 2.6; Krenning score 1), corresponding to the enhancing plaque previously identified on MRI; (B) Axial PET of the pelvis showing a mildly avid lytic lesion in the left iliac crest (approximately 1 cm), consistent with metastatic involvement; (C) Coronal PET confirming the left iliac crest lesion with focal uptake.

XSL•FO
RenderX

Figure 4. Iliac crest biopsy (Day 113) and pulmonary lymph node biopsy (Day 114). (A, B) Iliac crest bone lesion, H&E, 10 x and 40 x: tumor cells with bone; (C) Iliac crest bone lesion, Cytokeratin AE1/3 immunostaining, 10 x: cytokeratin stain confirming the tumor cells are carcinoma; (D) Iliac crest bone lesion, TTF-1 immunostaining, 10 x: TTF-1 stain supports lung origin; (E) Pulmonary lymph node: H&E, 40 x; tumor cells are morphologically comptabile with those in bone; (F) pulmonary lymph node: TTF-1 immunostaining, 20 x: TTF-1 stain supports lung origin. TTF: thyroid transcription factor.

Therapeutic Intervention

Following tumor board discussion, treatment was initiated with carboplatin (AUC 6), paclitaxel (200mg/m^2), and pembrolizumab (200mg) every 21 days (C1D1 on Day 125) for 4 cycles, with pembrolizumab continued as maintenance after cycle 4. Alternative therapies considered included a palliative approach with chemotherapy alone, but age, functional status, limited extent of disease, and the patient's wishes to pursue an aggressive therapeutic approach led to the chosen treatment protocol. Paclitaxel was chosen over pemetrexed as the taxane used because it was deemed to cover more histologies in the event that the cancer was not actually of bronchopulmonary origin. Patient completed stereotactic radiosurgery (SRS) (Day

XSL•FO
RenderX

173) with 36 Gray (Gy) in 4 fractions (fx) to the right orbit lesion. Following cycle 4, he was placed on pembrolizumab maintenance. PET (Day 211) showed an interval increase in L iliac crest lesion and increased conspicuity of R lung base grouped nodularity, but otherwise stable R paratracheal (0.7cm) and mediastinal (0.4cm) lymph nodes and a decreased RML (0.3cm) pulmonary nodule. He also completed radiation to the left iliac (Day 252, 50Gy in 5 fx), RML (Day 252, 50Gy in 5 fx), and mediastinal nodes (Day 273, 40Gy in 10 fx). However, he began having rib pain and PET/CT (Day 293) showed a new lesion in the left 4th rib and RLL, as well as an increase in additional right pulmonary nodules, concerning for progression. Concurrently, MRI Brain (Day 324) had also shown a new left frontal gyrus lesion. Given his age and continued limited disease involvement, an oligometastatic approach was used, and the patient completed radiation to the left chest wall (Day 313, 50Gy in 5 fx) and left frontal operculum (Day 337, 1 fx). Pembrolizumab was stopped (last dose on Day 315) due to radiographic progression, and he was started (C1D1 on Day 344) on carboplatin (AUC 5), pemetrexed (500mg/m^2), and bevacizumab (15mg/kg) every 21 days for 4 cycles, with pemetrexed and bevacizumab continued as maintenance after cycle 4. Pemetrexed and bevacizumab were held after 14 cycles (last dose on Day 743) in preparation for cataract removal of the right eye, and he was subsequently placed on surveillance with MRI Brain and PET imaging every 3 months.

Follow-Up and Outcomes

He developed eye pain, and MRI orbit (Day 1123, Figure 2B) showed right optic nerve enhancement, which was new from previous imaging and felt secondary to prior radiotherapy. He received one dose of intraocular bevacizumab injection, which completely resolved the pain. The patient had developed blindness in his right eye after initial treatment, but remained with 20/20 vision on the left. He maintained his employment and continues with regular follow-up and surveillance imaging every 3 months. His scans as of Day 1563 show no evidence of recurrence.

Discussion

Given CUP with CM tends to present with late, advanced, and disseminated disease, the general treatment protocol is palliative, focusing on symptom control and vision preservation. For most patients, external beam radiotherapy is the standard local treatment for symptomatic choroidal metastases, with systemic therapy including platinum- or taxane-based chemotherapy used for widespread disease [7]. Systemic therapy for CM of CUP often mirrors lung cancer regimens because empirical chemotherapy and targeted therapies have demonstrated efficacy in controlling both systemic and ocular disease in lung cancer patients [8-10]. For metastatic non-small cell lung cancer, platinum-based chemotherapy with PD-1 blockade is the standard first-line treatment; however, data regarding CM in the age of immunotherapy are limited. Recently, Li et al presented a case of a 65-year-old male patient with NSCLC and CM who demonstrated ultrasonic regression, improved visual acuity, and symptomatic relief after treatment with pemetrexed and capecitabine plus pembrolizumab [11]. A second case report by Matsuyama et al describes treatment with nivolumab plus ipilimumab plus chemotherapy, which resulted in symptomatic improvement and no relapse at 18 months follow-up [12]. These isolated cases underscore both the rarity of CM and the need for evidence-guided management strategies.

Bevacizumab, an extracellular VEGF-A inhibitor, has strong anti-angiogenic properties and has been used to treat CM from pulmonary, breast, and colorectal metastases. For instance, Riess JW et al described a case series of 3 patients with NSCLC and CM who were treated with a backbone of platinum-based chemotherapy plus bevacizumab [13]. The first patient received SRS to the symptomatic CM with improved vision and 12 months of progression-free survival. The second patient was found to have CM after right eye vision loss. This vision normalized following whole-brain radiotherapy that included the choroidal regions. Thereafter, the patient received 14 cycles of chemotherapy followed by erlotinib for a discovered EGFR mutation and progression. The third patient tolerated 16 months of chemotherapy followed by a recurrence of CM, which was treated with an ALK inhibitor for a found translocation. Furthermore, George et al reported on a 42-year-old female patient diagnosed with NSCLC with CM who achieved complete response of her 1.2cm CM following 3 cycles of carboplatin, gemcitabine, and bevacizumab, and was still alive with reported normal vision following her 7th maintenance dose of bevacizumab [14].

In the case of our patient, timely referral to ophthalmology led to recognition of a uveal lesion within three weeks of symptom onset. PET imaging can be helpful in defining dominant lesions and disease burden but histologic evaluation is necessary to guide diagnosis. In situations such as ours, where the primary site cannot be readily identified from imaging, judicious use of immunohistochemistry and molecular profiling is called for. In the era of immunotherapeutics, the median survival of newly diagnosed NSCLC without targetable mutation ranges from 14 to 22 months [15,16]. At the time of writing, our patient has survived 4 years with no radiographic or clinical signs of recurrence. While we must be careful not to read too much into an isolated case, it is the authors' belief that an aggressive oligometastatic approach with multimodality salvage options may be best for all NSCLC patients or patients with suspected primary lung malignancy who initially present with choroid disease and limited disease elsewhere.

As presented, this case illustrates an innovative management strategy for choroidal metastasis in the era of immunotherapy. While prior reports describe short-term responses to chemotherapy, anti-VEGF therapy, or immune checkpoint inhibitors, none have documented long-term survival following an oligometastatic approach that was applied both at diagnosis and after systemic progression. Our patient's survival of more than 4 years exceeds historical expectations for metastatic NSCLC without targetable alterations or PD-1 expression and highlights the potential benefits of aggressive local therapy even at the cost of vision.

The substantial collaboration required to execute this treatment approach is equally important. Coordination between imaging,

XSL•FO
RenderX

multiple ophthalmologic biopsies, and subspecialty pathologic review was essential for diagnosis. Treatment required communication between medical and radiation oncology to prioritize systemic control while delivering targeted radiation to multiple metastatic sites. This approach reflects the real-world practice and serves as a model for clinicians managing similarly rare and complex presentations.

Conclusion

CM remains an uncommon presentation of systemic malignancy, and contemporary management is challenged by the absence of evidence-based guidelines that reflect the current era of immunotherapy. Our case demonstrates that even after progression on checkpoint inhibitors, carefully selected patients may achieve prolonged survival through a coordinated multimodality approach that integrates systemic therapy with site-directed radiation. This experience suggests that CM should not automatically be considered a purely palliative entity, particularly when disease burden is low and lesions are anatomically accessible for local therapy.

More broadly, this report emphasizes the importance of early ophthalmologic evaluation for unexplained visual symptoms, the value of thorough systemic staging when CM is suspected, and the critical role of multidisciplinary collaboration involving medical oncology, radiation oncology, and ophthalmology. As prior published cases predate modern immunotherapy, this case highlights an unmet need for updated clinical guidance on managing CM in patients who have progressed on or failed to respond to immune checkpoint inhibitors.

Abstract

This multifacility retrospective analysis of 25 hospitals using BioVigil Technologies' electronic hand hygiene monitoring system demonstrated a mean of 46.95% (95% CI 35.5% - 58.4%) sustained reductions in health care–associated infections in 2024 compared to pre-implementation baselines, highlighting the clinical and operational value of automated hand hygiene monitoring at scale.

(Interact J Med Res 2026;15:e101905) doi:10.2196/101905

KEYWORDS

electronic hand hygiene monitoring; infection reduction; clinical outcomes; patient safety; hand hygiene compliance; CMS quality reporting; health care–associated infections; Centers for Medicare & Medicaid Services

Introduction

Health care–associated infections (HAIs) remain a challenge for health care facilities worldwide, contributing to patient morbidity, mortality, and substantial economic burden. In the United States, approximately 1 in 31 hospitalized patients acquires at least 1 HAI, at a cost of billions annually [1]. Despite longstanding evidence-based guidance, sustained improvements in infection rates have proven difficult across diverse health care settings.

Electronic hand hygiene monitoring (EHHM) systems offer a promising approach to enhancing adherence to infection prevention protocols while providing robust data for operational decision-making. By delivering real-time feedback to health care workers and tracking performance at the unit and facility level, these systems can identify and correct lapses in hand hygiene behavior, a primary contributor to HAIs [2]. Prior studies demonstrated that automated monitoring improves compliance and reduces infection rates, though reported effects vary by system design. A recent meta-analysis found EHHM increased compliance approximately 1.6-fold and was associated with markedly lower HAI rates, while trials of group-level dispenser-counting and proximity-based badge systems have shown more modest or inconsistent gains; long-term, multifacility analyses remain limited [3].

This analysis evaluates HAI performance among 25 BioVigil client facilities using publicly reported Centers for Medicare & Medicaid Services (CMS) data. Differing from group-level dispenser counters or proximity-based badges, BioVigil's EHHM technology chemically verifies hand sanitization; confirms soap-and-water wash duration; and its color-coded badge provides real-time feedback through visual, vibrational, and audible cues, supporting cross-contamination prevention and individual-level accountability. By comparing pre- and post-implementation periods, we aim to quantify the clinical and economic impact of EHHM across diverse hospital types and sizes, providing insight into strategies for infection prevention improvement.

Methods

Study Design

Facilities were included if BioVigil's EHHM was implemented in 2023 or earlier, CMS HAI data were complete for 2024 and the year preceding implementation, and CMS reporting was available at the individual facility level. These criteria yielded 25 facilities.

The facilities included 16 short-term acute care hospitals, 1 long-term acute care hospital, seven critical access hospitals, and one Veterans Affairs hospital, collectively comprising 4198 beds and 284 clinical units. CMS-reported HAIs for short-term acute care hospitals included catheter-associated urinary tract infections, central line-associated bloodstream infections, methicillin-resistant *Staphylococcus aureus*, surgical site infections, and *Clostridioides difficile* infections; long-term acute care, critical access, and Veterans Affairs hospitals reported catheter-associated urinary tract infections, central line-associated bloodstream infections, and *Clostridioides difficile* infections. Earliest full EHHM implementation occurred in 2016 (2 facilities) and most recently in 2023 (3 facilities).

This retrospective, observational analysis evaluated HAI outcomes aggregated at the hospital level. Percent change from

XSL•FO
RenderX

baseline to 2024 was calculated for each facility and across the study population. Descriptive statistics, including mean, median, and 95% CIs, characterized sustained changes in infection counts. EHHM operational data from 2024 were also analyzed to quantify hand hygiene opportunities, real-time corrective reminders, and overall compliance rates. All data were publicly available CMS reports or deidentified operational records; no patient-level data were used.

Ethical Considerations

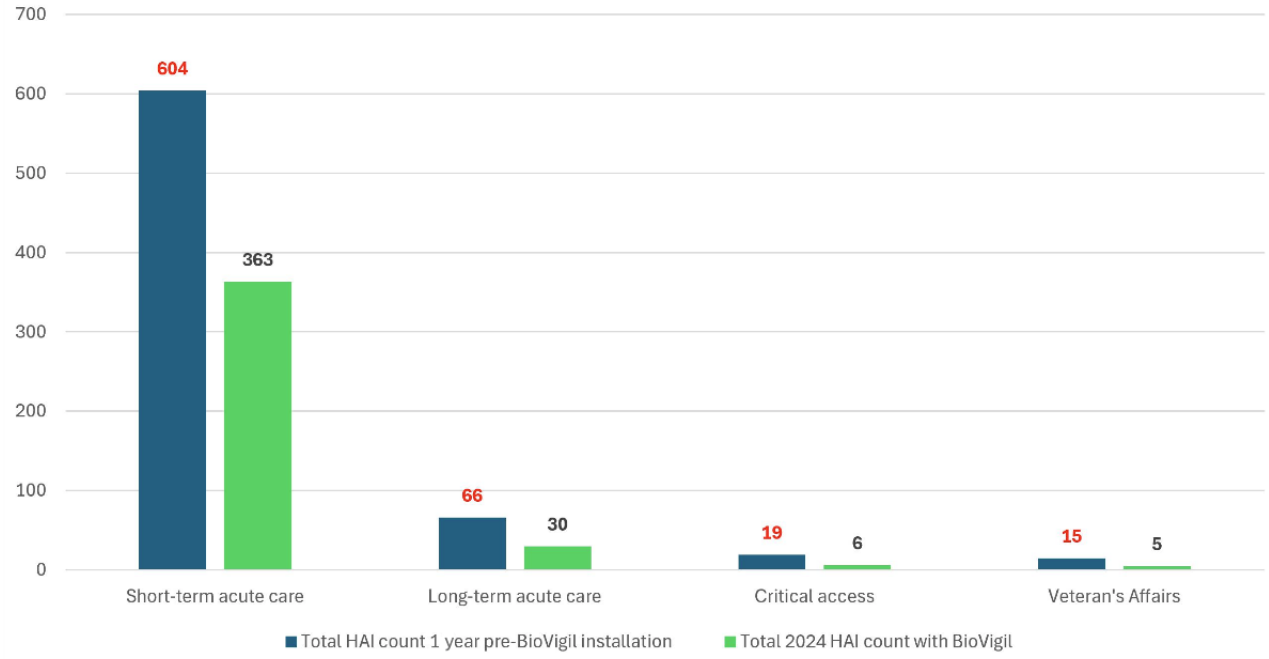
This study utilized only deidentified, publicly available datasets from the CMS and summarized medical device usage counts. Because no individual-level or identifiable patient information was accessed or analyzed, this research did not constitute human subjects research, and institutional review board review was not required.

Results

In 2024, BioVigil's EHHM system captured 67,663,570 hand hygiene opportunities across all 25 facilities. During this period, 1,112,148 potential cross-contamination events were corrected in real time through badge-based reminders. This contributed to an average hand hygiene compliance rate of 91.25% across the study population.

Of the 25 facilities, 22 demonstrated reductions in total HAI counts compared to their pre-implementation baseline. Four facilities achieved net-zero HAIs in 2024, representing a 100% reduction. One facility exhibited no change, and 2 experienced minimal increases of 2 and 4 cases, respectively—both from unusually low baseline years that likely underrepresent each facility's true pre-EHHM infection burden (Table 1).

Table . Facility characteristics and health care–associated infection (HAI) reductions in 2024.



Faculty name	Facility type	Approximate bed count (rounded to nearest 25)	BioVigil contract start year	HAI percent decrease in 2024
Hospital 1	Critical access	25	2023	100
Hospital 3	Critical access	25	2018	100
Hospital 10	Short-term acute care	50	2021	100
Hospital 15	Critical access	25	2021	100
Hospital 19	Short-term acute care	150	2023	82.35
Hospital 16	Short-term acute care	50	2021	75
Hospital 21	Short-term acute care	375	2021	71.43
Hospital 24	Veteran's Affairs	350	2023	66.67
Hospital 22	Short-term acute care	125	2022	64.71
Hospital 25	Short-term acute care	300	2014	64.06
Hospital 23	Short-term acute care	300	2018	55.71
Hospital 18	Long-term acute care	275	2020	54.55
Hospital 7	Critical access	25	2021	50
Hospital 20	Short-term acute care	75	2016	46.15
Hospital 8	Critical access	25	2021	44.44
Hospital 2	Short-term acute care	150	2021	39.13
Hospital 4	Short-term acute care	750	2020	37.33
Hospital 5	Short-term acute care	175	2017	24.32
Hospital 11	Short-term acute care	100	2021	20
Hospital 6	Short-term acute care	300	2020	17.46
Hospital 9	Short-term acute care	200	2021	13.04
Hospital 13	Short-term acute care	150	2021	11.11
Hospital 12	Critical access	25	2021	0
Hospital 17	Short-term acute care	460	2019	–13.79
Hospital 14	Critical access	25	2021	–50

Across all 25 facilities, the mean sustained HAI reduction was 46.95% (95% CI 35.5% - 58.4%), closely aligning with the median of 50% (IQR 30.83%-73.22%) (Figure 1). Among the 22 improving facilities, the mean reduction was 56.25% (95% CI 43.2% - 69.3%) with a median of 55.13% (IQR 37.78%-74.11%), collectively representing 300 fewer CMS-reported HAI cases in 2024. For context, national National Healthcare Safety Network data from over 38,000 US health

XSL•FO
RenderX

care facilities showed year-over-year declines of only 2% - 11% across the 6 CMS-reportable HAI categories during the same period [4].

Figure 1. Health care–associated infection (HAI) annual counts pre–BioVigil electronic hand hygiene monitoring (EHHMS) installation versus the 2024 performance with EHHMS (by hospital type; 22 facilities).

Financial and operational efficiencies were also observed, estimated using external benchmark averages. At a mean cost of $29,412 per HAI case [5], the observed reduction corresponds to approximately $8.82 million in avoided costs, excluding extended length of stay, readmissions, and CMS value-based purchasing penalties. Additionally, 16 of 25 facilities reported hand hygiene data to the Leapfrog Group; benchmark labor estimates suggest exclusive reliance on manual observation would have required approximately 136,620 staff hours and $5.74 million in labor costs in 2024 [6].

Discussion

This analysis demonstrates that the large majority of BioVigil Technologies' client facilities achieved meaningful, sustained reductions in HAIs in 2024. These findings extend prior evidence of EHHM's effectiveness by documenting outcomes across a geographically and structurally diverse portfolio of 25 facilities over extended post-implementation periods. This is an analytical scope not well represented in existing literature, which has largely focused on single-site studies or short-term compliance metrics [3].

While prior work has established that automated monitoring improves adherence, this analysis suggests that sustained, high-level compliance translates into durable reductions in reported infection counts. This suggests EHHM may promote lasting behavioral change beyond attributable observation effects. From clinical and policy perspectives, these results reinforce the case for broader institutional investment in scalable, automated monitoring as a complement to existing infection prevention infrastructure.

This analysis has a few limitations to consider. First, as a retrospective, observational study without a randomized control group, causal attribution between EHHM implementation and HAI reductions cannot be definitively established, as additional infection prevention initiatives may have contributed. Second, baseline comparisons relied on a single pre-implementation year, which may not fully capture natural year-to-year variability, particularly in smaller facilities with low baseline counts. Third, the study population was limited to BioVigil clients that met the inclusion criteria, which may introduce selection bias and limit generalizability.

In conclusion, the majority of BioVigil client facilities experienced substantial HAI reductions in 2024 relative to pre-implementation baselines. This is regardless of system use duration. These outcomes suggest EHHM is an effective, sustainable, data-driven strategy to strengthen infection prevention performance, improve patient safety, and enhance health care efficiency.

Acknowledgments

The author wishes to acknowledge the Centers for Medicare & Medicaid Services (CMS) for making hospital-acquired infections data publicly available, which served as the foundation for this work. The author also states that generative AI (Claude) was used solely to review the structure of this Research Letter for conformity with journal requirements.

Abstract

Our study uses the latest Transparency in Coverage data to show that there is wide variation in health care prices for some of the most commonly utilized services in the United States. The findings demonstrate that there is an opportunity for employers, policymakers, and other stakeholders to curb health care spending by choosing cost-efficient health care networks and providers.

(Interact J Med Res 2026;15:e96883) doi:10.2196/96883

KEYWORDS

healthcare prices; price transparency; cost of care; transparency in coverage; healthcare price variation

Introduction

Health care prices in the United States have historically been hidden from the public hindering meaningful analysis of health care markets and prices. This matters because prices impact access to care and are a major driver of high health care spending [1,2].

The information landscape began to change with first price transparency rule, Hospital Price Transparency (HPT) in 2021 which required hospitals to disclose prices of a select set of services. Then, in 2022, the Transparency in Coverage (TiC) rule began to require insurers to release negotiated rates for all covered services.

These datasets have proven valuable in shedding light on variation in health care prices. HPT data has been used to demonstrate large variation in prices for urological procedures [3], and radiology services [4], among others. Recent studies have begun to exploit more comprehensive TiC data and show wide variation in prices for inpatient and outpatient services [5], within hospitals for commonly provided services [6], among others.

We assess the within-provider variation in prices for the top 20 most commonly services in an office setting and find that the average difference between the minimum and maximum rates is 40% of the national Medicare rate. Our results complement Wang et al (2024) study which examines within-hospital price variation for inpatient and outpatient services and finds that difference between minimum and maximum prices negotiated by hospitals to be 86% and 222% of Medicare rates, respectively [6].

Methods

We downloaded the machine-readable files for the largest national payers (Cigna, Aetna, United Healthcare, various Blue Cross and Blue Shield plans) for the third quarter of 2025.

These files contain information on negotiated rates for all covered services along with identifying information on provider tax identification number (TIN), payer name and plan type.

We removed duplicates and ‘ghost rates’—negotiated rates corresponding to a provider for a service they are unlikely to ever bill for,—which are common in TiC data following the established methodology from published literature [7].

This analysis focuses on the top twenty most commonly utilized HCPCS ((Healthcare Common Procedure Coding System) codes in an office setting (determined based on national Medicare data and Colorado and New Hampshire’s All-Payer Claims databases). To limit the influence of outliers, we exclude rates below the 1st percentile and above the 99th percentile for each billing code and restrict the sample to billing code–TIN combinations with at least two negotiated rates.

The analysis data consists of approximately 5.6 million negotiated rates for 20 HCPCS codes in an office place of service. Table 1 shows the distribution of negotiated rates by billing codes.

XSL•FO
RenderX

Table . Percentiles and counts of negotiated rates by billing codes.

Billing code	Billing code description	Percentiles ($)					Standard deviation	Skewness	No. of negotiated rates
		10th	25th	50th	75th	90th

We first calculate the mean, median, minimum, and maximum rates at the provider TINs and billing code level. These represent the calculated measures of prices a provider is willing to accept across insurers for a billing code.

We then take the average of these estimates across provider TINs at the billing code level to calculate the mean, median, minimum, and maximum rate a provider is willing to accept for a billing code on average.

We define the range of rates as the difference between the average minimum and average maximum rates divided by the national Medicare rate for each billing code.

Ethical Considerations

This study is exempt from ethics review, as all data used is publicly available. The study uses data on health care prices released by insurers and does not involve any human subjects. It is thus exempt from institutional review board.

Results

Table 2 shows the average mean, median, minimum, and maximum –negotiated rates for the top 20 billing codes. All four summary statistics are unweighted averages and represent the average of the respective summary statistics across all provider TINs at the billing code level. Out of the 20 billing codes, difference between the maximum and minimum rate is greater than or equal to 50% of the national Medicare rate for four billing codes - 80048 (Basic Metabolic Panel), 80061 (Lipid Panel), 85610 (Prothrombin Time), and 88305 (Surgical Pathology).

[a]TIN: tax identification number.

Across the 20 billing codes, we find the average variation between the minimum and maximum rates to be 40 % of the Medicare rate (unweighted).

Discussion

Our assessment shows that providers negotiate a wide range of prices for the same service across insurers. Thus, the same provider can be low cost for one network but high cost for another network. Our findings that prices for commonly utilized services can vary by up to 40% of the Medicare rate in an Office setting compliments existing literature that documents substantial variation in prices across and within hospitals. This highlights the importance of the choice of network and benefit design in reducing health care spending. For employers, health plans, and policymakers, our findings demonstrate that choice of networks and providers can have a substantial impact on health care spending. Future work should aim to understand how navigating patients to lower cost providers can generate potential savings.

Abstract

Natural health product (NHP) regulations have shifted in Canada, with the aim of reducing "red tape" and enabling market entry. This study assessed how many "stem cell" supplements for sale on Amazon.ca had Health Canada–required natural product number (NPN) licenses compared with vitamin D and "longevity" supplements. It also conducted a marketing overview analysis comparing the Amazon.ca discourse across the 3 product types. Findings show a gap in regulatory licensing compliance between "stem cell" supplements and vitamin D or "longevity" supplements. Marketing discourse also presented potential conflict with regulatory parameters. We discuss the impacts of loosening NHP regulations and the potential for products with weak evidentiary bases to enhance validation through NPN licensing.

(Interact J Med Res 2026;15:e86747) doi:10.2196/86747

KEYWORDS

stem cells; regenerative medicine; Amazon; e-commerce; supplements; natural health products; regulation

Introduction

Scientifically unsupported commercial activity has long accompanied exciting regenerative medicine research [1]. "Stem cell" supplements are now emerging in online marketplaces, including Amazon. In 2024, our research team assessed "stem cell" supplement marketing on Amazon.com, finding inconsistent adherence to Canadian and American regulations [2]. In Canada, supplements that are natural health products (NHPs) require a licensed good manufacturing practices site and product license (natural product number [NPN]) from Health Canada for marketplace entry [3]. Internal analysis on our 2024 study data found that many "stem cell" supplements lacked traceable NPNs in Health Canada's NHP database. In 2025, Health Canada implemented NHP regulatory changes to reduce regulatory "red tape" and facilitate market access [4]. This project's goal was to reassess whether, in July 2026, stem cell supplements on Amazon.ca aligned with NPN license—and broader NHP—regulations.

Methods

Overview

In July 2026, we deployed the Apify Amazon Scraper (Apify), a data scraper, to build a dataset of "stem cell supplement" advertisement data for 100 relevant products on Amazon.ca. We also downloaded advertising data from 100 vitamin D and 100 longevity supplements (search: "vitamin D supplement" and "longevity supplement") to act as control and comparison product types. Vitamin D is popular and typically unrelated to stem cells/regenerative medicine, whereas "longevity" supplements may be associated with aging-related health claims similar to stem cell supplement marketing [2]. Downloaded data, held and analyzed on Google Sheets, included over 400 data columns for each product (including labels, product and use descriptions, and details).

Analysis consisted of describing the central advertising themes across the 3 product types (vitamin D, longevity, and stem cell supplements) and determining whether each product had a legitimate NPN (traceable and active) on Health Canada's NHP database [5]. To discern central themes, we deployed a straightforward keyword analysis, modeled on our previous research [2], establishing 6 overarching categories: cell activity, health topic, serious health topic, general effect, general qualifier, and science (Table 1). This analysis provided a general marketing overview and potential distinctions between the 3 product types. To identify NPNs, we searched product advertising data, including images (eg, product labels), and, if found, verified NPN legitimacy. If no product NPN was found in the advertisement data, we searched the NHP database for product or brand name(s). Products marketed for animals or exclusively for skin care were excluded, as were duplicates. The data from products with broken Amazon URLs or products listed as "not currently available" were analyzed but excluded from the results.

Ethical Considerations

Ethics approval and informed consent were not required as all Amazon ads are publicly visible. No product, brand, or company names appear in this manuscript.

Results

Nearly all supplements had legitimate NPNs. All 78 vitamin D products and all 90 longevity products had legitimate NPNs. Of the 80 stem cell supplements (56 unique brands), 73 (91%) had NPNs. The 7 (9%) products lacking NPNs came from 3 unique brands and explicitly mentioned “stem cell” in their Amazon.ca marketing. Of these 7 products, 2 were available for purchase but showed a discontinued NPN in Health Canada’s database. An additional 2 stem cell products and 1 longevity product did not produce a legitimate NPN but were excluded for having broken URLs or being unavailable for purchase.

NHP companies selling vitamin D, longevity, and stem cell supplements presented different themes in the advertising discourse (Table 1). Compared to vitamin D products, stem cell and longevity supplements presented greater focus on cell activity and covered a much greater range of health topics (eg, energy, aging, immunity, stress, oxidative, and brain related). Vitamin D products focused almost exclusively on immunity and bone health. Stem cell products presented cell activity with greater frequency than longevity supplements. None of the

XSL•FO
RenderX

product types mentioned serious health topics with frequency. The effect descriptors “heal,” “support,” and “boost” were common across all product types, but “cure” and “treat” were scant. The general qualifiers “pure,” “wellness,” and “natural” had a similarly prominent presence across the 3 product types. Stem cell products had the highest presence of science-related discourse (n=28, 35%) compared to longevity (n=20, 22%) and vitamin D (n=8, 10%) (Table 1).

Discussion

The overwhelming majority of vitamin D, longevity, and stem cell supplements on Amazon.ca in this cross-sectional sample analysis had traceable NPNs in Health Canada’s NHP database. Only stem cell products presented cases of regulatory NPN noncompliance (7/80, 9%). Demonstrating overall regulatory compliance, the marketing for these products scarcely mentioned serious health topics (eg, cancer, dementia) and causal modes of action (eg, cure, treat), which could constitute NHP regulatory breaches [6]. Issues persist, however, about the validation of questionable NHPs by Health Canada’s current regulations and whether obtaining a Health Canada–certified NPN may bolster product credibility.

NHPs certified by Health Canada should not have free rein for deceptive marketing. Both the stem cell and longevity supplements’ marketing in this study frequently mentioned cell activity and a range of health topics. For example, nicotinamide, which is mentioned in approximately 30% of stem cell supplement marketing and 30% of longevity supplement marketing, remains therapeutically speculative despite preclinical development [7]. Vitamin D supplementation also has inconclusive health benefits for nondeficient patients [8]. Canadian NHP regulations restrict marketing that distorts the evidentiary base related to health claims [2]. This project’s broad marketing analysis found science-related discourse in 35% of the stem cell supplement ads and 22% of the longevity supplement ads. Scientific discourse typically works toward promoting evidence around product reliability or efficacy [2]. Notably, stem cell and longevity supplements have a more speculative evidentiary base but more frequently presented appeals to science.

Health Canada’s recent loosening of NHP regulations may be increasing the e-commerce market availability of NHPs, including on Amazon.ca. Correspondingly, the nature of effective surveillance (eg, automated, licensing, risk-based targeting) and enforcement may be fluctuating significantly. The relatively high levels of regulatory compliance shown in this research suggest an opportunity for increasing regulatory pressure around deceptive or overexaggerated product promotion, especially given recent industry-favorable measures to facilitate market access. Ongoing and diligent NHP marketplace surveillance is needed to track the emergence of new products (where compliance may be low) and the corresponding marketing used to promote products with limited, circumstantial, or nonexistent health value for Canadian consumers.

Acknowledgments

The authors thank Tuvini de Silva for her coding contributions and Robyn Hyde-Law for project management and administrative assistance.

Funding

This research was funded by the Stem Cell Network under the projects Law, Public Policy and Social License for Next-Generation Regenerative Medicine (grant number 917390), and Regenerative Medicine, Wellness Influencers, and Scienceploitation (grant number IE-C5R1-1). The funder had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; or decision to submit the manuscript for publication.

Data Availability

Data have been uploaded to a publicly accessible OSF repository [9].

Authors' Contributions

ARM and TC conceived the study. MJ collected the data. ARM and MJ performed the analysis. ARM and MJ wrote the manuscript. ARM, MJ, and TC approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: Dengue fever can lead to significant hepatic involvement and marked aminotransferase elevation and is associated with increased morbidity and prolonged hospitalization. N-acetylcysteine (NAC) has been proposed as a supportive therapy for dengue-induced liver injury. However, prospective comparative evidence from endemic regions such as Vietnam remains limited.

Objective: This study aimed to evaluate the association between intravenous NAC administration and clinical outcomes (primarily length of hospital stay), as well as the secondary effects of NAC on liver transaminase levels (posttreatment aspartate aminotransferase [AST] and alanine aminotransferase [ALT] and their changes from baseline) and platelet recovery in patients with dengue fever with marked aminotransferase elevation (AST or ALT ≥400 U/L).

Methods: A prospective, nonrandomized comparative study was conducted at the Department of Tropical Diseases, Viet Tiep Hospital, Hai Phong, Vietnam, from June to December 2024. A total of 128 adult patients with laboratory-confirmed dengue fever and marked aminotransferase elevation (AST and/or ALT ≥400 U/L) were enrolled. Treatment allocation was not randomized and was determined by the treating physicians based on aminotransferase elevation and overall clinical condition. Patients received either intravenous NAC (100 mg per kilogram per day) plus standard supportive care (NAC group; n=68) or standard care alone (non-NAC group; n=60). The primary outcome was length of hospital stay. Secondary outcomes included liver transaminase levels and platelet recovery at discharge.

Results: Baseline AST, ALT, bilirubin, and international normalized ratio values were broadly comparable between groups, although several clinical and hematological characteristics differed at baseline. The NAC group had a significantly shorter hospital stay (mean 5.01, SD 1.28 vs 6.12, SD 1.25 days; *P*<.001). The AST and ALT levels were significantly lower in the NAC group (AST: mean 154.83, SD 67.22 vs 184.62, SD 79.88 U/L and *P*=.02; ALT: mean 113.09, SD 33.31 vs 156.35, SD 73.66 U/L and *P*=.004). The posttreatment platelet count was significantly higher in the NAC group (median 31.50, IQR 19.00-50.15 G/L vs 17.00, IQR 8.75-36.23 G/L; *P*=.001). The median increase in platelet count was also greater in the NAC group (15.05, IQR 7.05-26.10 G/L vs 6.95, IQR 4.22-15.43 G/L; *P*=.001). No severe infusion-related adverse events were documented during the study period.

Conclusions: In this prospective, nonrandomized comparative study, intravenous NAC administration was associated with shorter hospitalization and lower posttreatment aminotransferase levels in adult patients with dengue fever and marked aminotransferase elevation. No severe infusion-related adverse events were documented during the study period. However, the nonrandomized design and potential for confounding limit causal inference. Larger, multicenter randomized controlled trials are warranted to clarify the therapeutic role of NAC in dengue-related hepatic complications.

Introduction

Dengue fever is a vector-borne viral infectious disease caused by dengue virus (DENV) and transmitted primarily by the *Aedes aegypti* and *Aedes albopictus* mosquitoes [1]. It represents a major global public health challenge, particularly in tropical and subtropical regions.

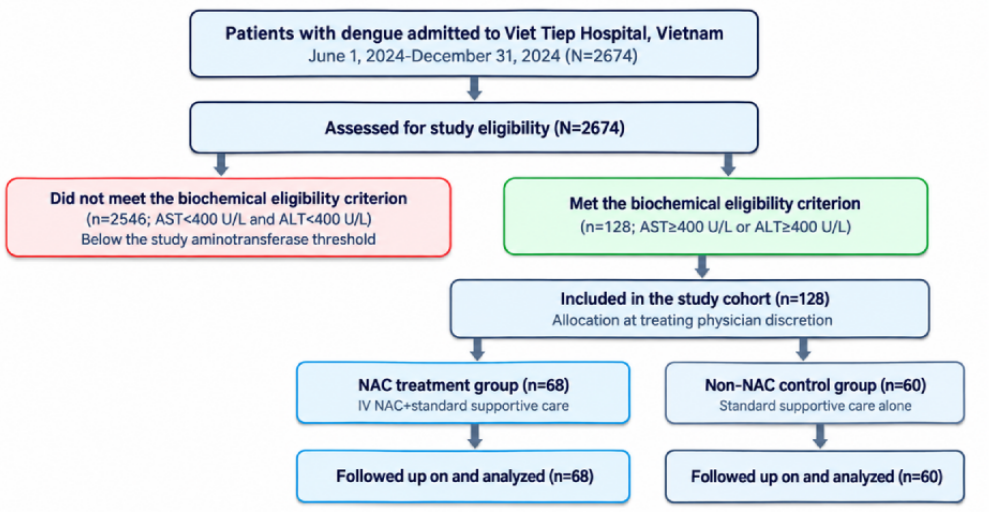
According to the World Health Organization, dengue cases have increased dramatically in recent decades. In 2023, over 5 million cases and more than 5000 deaths were reported across more than 80 countries and territories. Vietnam alone reported 149,557 cases, including 36 fatalities in that period [2].

Hepatic involvement is one of the most clinically significant complications of dengue fever. DENV-induced liver injury ranges from mild transaminase elevations to fulminant acute liver failure and is associated with higher mortality risk and prolonged hospitalization. Clinical manifestations of hepatic damage include nausea, vomiting, anorexia, abdominal pain, elevated transaminases, and hyperbilirubinemia [3,4].

The pathogenesis of DENV-induced liver damage remains incompletely understood. Proposed mechanisms include direct viral cytopathic effects, hypoxia-mediated injury, and immune-mediated hepatocyte apoptosis [3]. During acute infection, antioxidant enzyme levels, including glutathione peroxidase and glutathione reductase, decline, whereas aspartate aminotransferase (AST) and alanine aminotransferase (ALT) rise [5]. Experimental murine studies have demonstrated that DENV-induced acute liver failure involves proinflammatory cytokines (interleukin [IL]-2, IL-6, IL-8, and IL-22) and that N-acetylcysteine (NAC) attenuates liver damage, reduces hepatocyte apoptosis, and inhibits viral replication in HepG2 cells via interferon-mediated antiviral pathways [6]. NAC also preserved antioxidant enzyme levels and redox balance in DENV-infected mouse livers [7,8].

Supportive care and close clinical monitoring are central to dengue management [9]. NAC is an established antioxidant and glutathione precursor with well-characterized hepatoprotective properties [10,11]. It is recommended by the European Association for the Study of the Liver for acute liver failure from any cause [12] and has been used in dengue-associated acute liver injury in several Asian countries, with consistently positive outcomes reported [13-15]. However, robust randomized controlled trial evidence specifically on DENV-induced hepatic injury is lacking [16]. The 2023 Vietnamese Ministry of Health guidelines recommend NAC for patients with dengue fever with AST or ALT of 1000 U/L or higher [17]. The threshold of AST or ALT of at least 400 U/L was selected for this study to evaluate NAC at an earlier stage of marked aminotransferase elevation. This threshold should be regarded as an exploratory study criterion rather than an established indication for routine NAC treatment. The nonrandomized findings are intended to generate hypotheses and do not support changing clinical guidelines without confirmation in randomized controlled trials.

Methods



Study Design and Setting

This was a prospective, nonrandomized observational comparative study conducted at the Department of Tropical Diseases, Viet Tiep Hospital, Hai Phong, Vietnam, from June 1, 2024, to December 31, 2024. This study aimed to evaluate the association between NAC administration and clinical outcomes and the safety of intravenous NAC as an adjunctive therapy in adult patients with dengue fever complicated by marked aminotransferase elevation. No a priori sample size calculation was performed. This study used a prospective consecutive convenience sample comprising all eligible adult patients with dengue fever with marked aminotransferase elevation (AST or ALT ≥400 U/L) recruited during the predefined study period from June 2024 to December 2024 (N=128; n=68 in the NAC group and n=60 in the non-NAC group).

The detailed patient flow is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Flow diagram of patient screening, inclusion, and analysis. ALT: alanine aminotransferase; AST: aspartate aminotransferase; IV: intravenous; NAC: N-acetylcysteine.

Participants

A total of 2674 patients with dengue fever were initially screened during the study period (June 1, 2024 to December 31, 2024). Of these, 2546 (95.2%) patients did not meet the biochemical threshold for marked aminotransferase elevation (AST or ALT<400 U/L). Among the 128 (4.8%) patients who met the inclusion criterion, no additional patients were excluded based on predefined exclusion criteria.

Ultimately, 128 patients were allocated to either the NAC group (n=68, 53.1%) or the non-NAC group (n=60, 46.9%) based on physician discretion. All 128 enrolled patients completed follow-up and were included in the final analysis.

Patients were eligible for inclusion if they met all the following criteria: (1) age of 18 years or above; (2) laboratory-confirmed dengue fever, defined as a positive dengue NS1 antigen and/or positive dengue immunoglobulin M antibody; and (3) marked aminotransferase elevation, defined as AST of 400 U/L or higher and/or ALT of 400 U/L or higher (the entry threshold of AST or ALT ≥400 U/L was selected as an exploratory study criterion to evaluate potential benefits of NAC at an earlier stage of marked aminotransferase elevation. This cutoff does not represent an established routine indication for NAC or a definition of acute liver failure, and its exploratory nature is recognized).

Patients were excluded if they met any of the following criteria: preexisting chronic liver disease (chronic hepatitis B or C, alcoholic liver disease, or cirrhosis), history of hepatotoxic drug use prior to admission (excluding standard therapeutic-dose paracetamol for symptomatic fever management), pregnancy or lactation, known hypersensitivity to NAC, or age under 18 years.

Treatment Protocol

Treatment allocation was not randomized. Eligible patients were allocated to 2 groups based on clinical judgment in routine practice, reflecting real-world clinical decision-making. Intravenous NAC was initiated at the discretion of the treating physician after consideration of aminotransferase elevation and the patient's overall clinical condition [17].

All included patients presented with marked aminotransferase elevation (AST or ALT ≥400 U/L) an exploratory threshold selected for this study. Clinicians tended to initiate intravenous NAC in patients presenting with overt hepatic involvement (eg, hepatomegaly and right upper quadrant tenderness) or rapidly progressive transaminitis accompanied by severe systemic symptoms (eg, persistent vomiting), reflecting a targeted pragmatic approach. Patients with stable transaminitis and milder clinical features were managed through standard supportive care alone [17].

In the NAC group, patients received intravenous NAC (BFS-Depara; Ha Noi CPC1 Pharmaceutical JSC) at 100 mg per kilogram per day diluted in 5% glucose solution and administered via slow intravenous infusion. NAC therapy was initiated at the discretion of the treating physician. Treatment was continued for 3 days, with earlier discontinuation at the discretion of the treating physician based on the patient's clinical and biochemical response.

In the non-NAC (control) group, patients received standard supportive care for dengue fever, including fluid management, antipyretics, and close clinical monitoring, without NAC administration.

Standard supportive care was provided according to the Vietnamese national dengue management guideline and institutional practice [17]. It included clinically guided fluid management; symptomatic treatment where appropriate; serial assessment of vital signs and warning signs; complete blood count monitoring; liver biochemical testing; and clinical surveillance for bleeding, plasma leakage, hemodynamic deterioration, and other dengue-related complications. The supportive treatment was individualized; the intensity and components of supportive care were not identical between groups.

Clinical and Laboratory Monitoring

Overview

All patients underwent daily monitoring of clinical symptoms and signs; hematological parameters (complete blood count); and biochemical parameters, including AST, ALT, total bilirubin, and international normalized ratio (when indicated). Liver function tests were recorded at baseline (at NAC initiation or hospital admission for the non-NAC group) and at day 3 of treatment or at hospital discharge, whichever occurred first. Patients were closely observed for adverse reactions to NAC infusion, including hypersensitivity reactions, nausea, vomiting, and anaphylaxis.

Safety Assessment

Safety outcomes and infusion-related reactions were actively monitored through continuous clinical surveillance during intravenous NAC administration. Monitoring focused on hypersensitivity and anaphylactoid symptoms, including rash, pruritus, respiratory distress, hemodynamic changes, and gastrointestinal intolerance.

Outcomes

The primary outcome was length of hospital stay (days). Secondary outcomes were changes in serum AST and ALT levels after treatment; platelet count recovery, assessed using the minimum platelet count at the end of the treatment assessment period (day 3 or hospital discharge, whichever occurred first); and change from baseline to this posttreatment measurement. In addition, the change in AST and ALT levels (Δ) was calculated.

Statistical Analysis

Statistical analysis was performed using the SPSS software (IBM Corp). Continuous variables are expressed as means and SDs or medians and IQRs as appropriate. Categorical variables are presented as frequencies and percentages. Continuous variables were compared using the Student 2-tailed *t* test for normally distributed data or the Mann-Whitney *U* test for nonnormally distributed data. Categorical variables were compared using the chi-square or Fisher exact test.

Ethical Considerations

The study protocol was approved by the scientific council and ethics committee of Viet Tiep Hospital, Hai Phong, Vietnam. Written informed consent was obtained from all participants or their legal guardians prior to enrollment. All procedures were conducted in accordance with the principles of the Declaration of Helsinki.

Results

Patient Characteristics

During the study period, 128 patients with laboratory-confirmed dengue fever and marked aminotransferase elevation (AST and/or ALT ≥400 U/L) met the inclusion criteria. Of these, 68 received intravenous NAC, and 60 received standard supportive care alone.

Baseline demographic characteristics are summarized in Table 1. The mean age was 47.79 (SD 17.43) years in the NAC group and 52.81 (SD 14.11) years in the non-NAC group. Although the mean age was numerically lower in the NAC group, the between-group difference was not statistically significant (*P*=.07). Sex distribution was comparable between groups, with no statistically significant differences.

Table 1. Demographic characteristics of study patients (N=128).

Characteristics	NAC[a] (n=68)	Non-NAC (n=60)	Total
Sex, n (%)			
Male	25 (36.8)	28 (46.7)	53 (41.4)
Female	43 (63.2)	32 (53.3)	75 (58.6)
Age (y), mean (SD)	47.79 (17.43)	52.81 (14.11)	50.14 (16.10)

[a]NAC: N-acetylcysteine.

Baseline Clinical and Laboratory Features

Baseline clinical and paraclinical characteristics are shown in Table 2. All 128 included patients had concurrent elevations in both AST and ALT, and no patient had isolated AST elevation. The NAC group had a longer duration of fever prior to admission (mean 4.57, SD 1.31 vs 3.92, SD 1.41 days; *P*=.007) and higher rates of vomiting (37/68, 54.4% vs 19/60, 31.7%; *P*=.01) and hepatomegaly (37/68, 54.4% vs 12/60, 20%; *P*<.001). The higher prevalence of mucosal bleeding in the non-NAC group represented a baseline imbalance. Its cause could not be determined from the available data, and residual confounding related to bleeding severity may remain. Baseline laboratory parameters, including AST, ALT, total bilirubin, hemoglobin, hematocrit, platelet nadir, white blood cell count, and international normalized ratio, were not significantly different between groups (*P*>.05 for all comparisons), indicating comparable baseline biochemical severity despite more pronounced clinical manifestations in the NAC group.

Treatment Outcomes

Overview

Posttreatment outcomes are summarized in Table 3.

Table 3. Treatment outcomes at discharge.

Outcomes	NAC[a] (n=68)	Non-NAC (n=60)	*P* value
Hospital stay (d), mean (SD)	5.01 (1.28)	6.12 (1.25)	<.001
Posttreatment AST[b] (U/L), mean (SD)	154.83 (67.22)	184.62 (79.88)	.02
Posttreatment ALT[c] (U/L), mean (SD)	113.09 (33.31)	156.35 (73.66)	.004
ΔAST (U/L), mean (SD)	454.85 (261.85)	326.91 (170.44)	.002
ΔALT (U/L), mean (SD)	312.03 (154.21)	263.62 (153.99)	.08
Posttreatment platelet count (G/L), median (IQR)	31.50 (19.00-50.15)	17.00 (8.75-36.23)	.001
Change in platelet count (G/L), median (IQR)	15.05 (7.05-26.10)	6.95 (4.22-15.43)	.001

[a]NAC: N-acetylcysteine.
[b]AST: aspartate aminotransferase.
[c]ALT: alanine aminotransferase.

XSL•FO
RenderX

Length of Hospital Stay

The mean duration of hospitalization was significantly shorter in the NAC group than in the non-NAC group (5.01, SD 1.28 vs 6.12, SD 1.25 days; *P*<.001).

Liver Enzyme Recovery

Mean posttreatment AST levels were significantly lower in the NAC group (154.83, SD 67.22 vs 184.62, SD 79.88 U/L; *P*=.02), as were posttreatment mean ALT levels (113.09, SD 33.31 vs 156.35, SD 73.66 U/L; *P*=.004). The mean change in AST was 454.85 (SD 261.85) U/L in the NAC group vs 326.91 (SD 170.44) U/L in the non-NAC group (*P*=.002). The mean change in ALT was 312.03 (SD 154.21) vs 263.62 (SD 153.99), respectively (*P*=.08).

Platelet Recovery

The posttreatment platelet count was significantly higher in the NAC group (median 31.50, IQR 19.00-50.15 G/L vs 17.00, IQR 8.75-36.23 G/L; *P*=.001). The median increase in platelet count was also greater in the NAC group (15.05, IQR 7.05-26.10 G/L vs 6.95, IQR 4.22-15.43 G/L; *P*=.001). However, because platelet counts were not assessed at uniform predefined time points for all participants, the study could not determine whether NAC accelerated the rate of platelet recovery.

Safety

All patients recovered and were discharged in stable condition. No patients required intensive care unit admission, and no severe infusion-related adverse events were recorded during the study period.

Discussion

Principal Findings

In this prospective, nonrandomized comparative study of 128 adult patients with dengue fever and marked aminotransferase elevation, intravenous NAC administration was associated with a shorter duration of hospitalization and lower posttreatment AST and ALT levels compared with standard supportive care alone [17]. The mean hospital stay was approximately 1 day shorter in the NAC group (5.01, SD 1.28 vs 6.12, SD 1.25 days; *P*<.001). Posttreatment AST and ALT levels were also significantly lower in the NAC group. These associations were observed despite the NAC group presenting with more pronounced clinical manifestations at baseline, including longer fever duration and higher rates of vomiting and hepatomegaly. NAC was well tolerated, with no infusion-related adverse events documented.

Detailed Discussion

The observed association between NAC administration and shorter hospital stay is consistent with prior reports, including the case series by Dissanayake et al [15], that have demonstrated shorter hospitalization among patients with dengue fever with severe hepatitis treated with NAC. A reduction of approximately 1 hospital day may be operationally relevant during dengue outbreaks, particularly in resource-constrained settings. However, the clinical and economic importance of this difference was not directly evaluated and should be confirmed in prospective randomized and health economic studies.

The more pronounced reduction in AST and ALT levels in NAC-treated patients aligns with the known antioxidant and hepatoprotective mechanisms of NAC. DENV infection is associated with oxidative stress, mitochondrial dysfunction, and immune-mediated hepatocyte injury [5,6]. As a glutathione precursor, NAC may mitigate oxidative damage and promote hepatocellular recovery, thereby accelerating the normalization of liver enzymes. Experimental data have also suggested that NAC may exert direct antiviral effects by inhibiting DENV replication via interferon-mediated pathways [6], although viral load was not assessed in the present study.

Alternative explanations for the observed findings must be considered. The NAC group had a longer duration of fever prior to admission (mean 4.57, SD 1.31 vs 3.92, SD 1.41 days; *P*=.007). Patients presenting later in the course of dengue may have been closer to the spontaneous recovery phase; therefore, part of the observed biochemical improvement may reflect the natural disease course rather than NAC administration alone. The higher prevalence of vomiting and hepatomegaly in the NAC group may reflect physician selection of patients with more prominent hepatic manifestations. However, the present study cannot determine whether hepatomegaly modifies the association between NAC and clinical outcomes. This question requires a prespecified subgroup analysis within a randomized trial.

Furthermore, the coexistence of hepatomegaly and marked aminotransferase elevation may represent a more clinically pronounced pattern of dengue-associated hepatic involvement. The potential biological effects of NAC, including restoration of glutathione availability and attenuation of oxidative stress, provide a rationale for further evaluating whether patients with this combined clinical and biochemical phenotype might derive greater benefit from NAC. However, the present observational study was not designed to determine whether hepatomegaly modifies the association between NAC treatment and clinical outcomes. This observation should therefore be regarded as hypothesis generating. Future prospective studies with prespecified subgroup and interaction analyses are warranted to determine whether this phenotype identifies patients who may derive greater benefit from NAC.

Although both groups received care according to the same institutional dengue management framework, the intensity and components of supportive treatment were not quantified in sufficient detail. Differences in fluid management, antiemetic treatment, oral intake, or other supportive interventions may have contributed to the observed outcomes.

Mucosal bleeding was assessed at baseline (upon admission), before treatment initiation. Therefore, the higher prevalence in the non-NAC group (30/60, 50% vs 17/68, 25%) represents a baseline imbalance rather than a treatment effect. As this was a nonrandomized study, the specific reason for this imbalance could not be determined from the available data, and residual confounding related to differences in disease or bleeding severity cannot be excluded.

XSL•FO
RenderX

An interesting finding was the difference in platelet counts between groups. While NAC is not conventionally regarded as a thrombopoietic agent, this effect may be indirect, reflecting reduced systemic inflammation and oxidative stress rather than a direct pharmacological action on platelet production. Hepatic recovery could theoretically influence platelet production through restoration of thrombopoietin synthesis; however, dengue-related thrombocytopenia is multifactorial and may also involve bone marrow suppression, immune-mediated platelet destruction, peripheral consumption, and systemic inflammation. Because thrombopoietin was not measured and platelet counts were not assessed at fully standardized time points, this study cannot establish a mechanistic link between NAC, hepatic recovery, thrombopoietin production, and platelet changes. Given the observational nature of this study, this association warrants cautious interpretation.

NAC was well tolerated in all patients, with no infusion-related adverse events documented, consistent with its established safety profile in paracetamol-induced and non–paracetamol-related acute liver failure [12,18].

The findings may be most relevant to adult patients treated in comparable dengue-endemic hospital settings with access to serial aminotransferase testing and safe intravenous infusion monitoring. However, generalizability is limited by the single-center design, local treatment practices, physician-directed treatment allocation, and selected study population. The results should not yet be interpreted as supporting the routine use of NAC at an aminotransferase threshold of 400 U/L in other health care systems.

To our knowledge, this is among the first prospective comparative studies evaluating intravenous NAC specifically for dengue-associated marked aminotransferase elevation in Hai Phong, Vietnam, contributing to the limited evidence base in this field.

Limitations

This study has several important limitations.

First, the single-center, nonrandomized design with physician-directed treatment allocation may have introduced selection bias and confounding by indication. No formal randomization sequence or allocation concealment procedure was used, and blinding was not possible.

Second, the sample size was modest, and no a priori sample size calculation was performed; the study used a prospective convenience sample of eligible patients during the predefined study period, which may limit the precision and generalizability of the findings.

Third, several baseline clinical characteristics differed between groups, including fever duration, vomiting, hepatomegaly, and mucosal bleeding. These imbalances, together with differences in supportive treatment and incompletely measured prehospital paracetamol exposure, may have contributed to the observed outcomes, and residual or unmeasured confounding cannot be excluded.

Fourth, supportive treatment was individualized according to clinical condition, and its intensity and specific components were not quantified in sufficient detail. Differences in fluid management, antiemetic treatment, oral intake, or other supportive interventions may therefore have influenced length of hospital stay and biochemical outcomes.

Fifth, platelet counts were not assessed at uniform predefined time points for all participants; consequently, this study could not adequately compare platelet trajectories or determine whether NAC accelerated platelet recovery.

Sixth, secondary biochemical markers, including alkaline phosphatase, gamma-glutamyl transferase, serum albumin, and creatinine, were not systematically measured at uniform time points, limiting a more comprehensive longitudinal assessment of hepatic and renal involvement.

Seventh, viral load and dengue serotype were not measured, precluding assessment of their potential influence on treatment response and clinical outcomes.

Eighth, safety monitoring relied on routine inpatient clinical surveillance rather than a standardized prospective adverse event grading system. Although no severe infusion-related adverse events were documented, mild or transient reactions may have been underrecorded.

Finally, follow-up was limited to the hospitalization period, and longer-term outcomes were not assessed.

Conclusions

In this prospective, nonrandomized comparative study, intravenous NAC administration was associated with shorter hospitalization and lower posttreatment aminotransferase levels in adult patients with dengue fever and marked aminotransferase elevation. No severe infusion-related adverse events were documented during the study period, although routine clinical surveillance may have underestimated mild or transient reactions. However, the nonrandomized design, potential for physician treatment bias, baseline clinical imbalances, and unmeasured confounding limit causal inference. These findings suggest that NAC may have potential as an adjunctive therapy in this clinical setting. Larger, multicenter randomized controlled trials with standardized supportive care protocols and prespecified end points are warranted to clarify the therapeutic role of NAC in dengue-related hepatic complications and determine whether the observed associations reflect a true treatment effect.

Acknowledgments

The authors thank the patients, their families, and the clinical teams at Viet Tiep Hospital for their contributions to this study. During the preparation of this work, the authors used an AI-assisted writing tool (ChatGPT 5.5; OpenAI) to check grammar and

improve the readability of the manuscript. No AI tool was used to generate scientific content. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the accuracy and integrity of the publication.

Funding

This study was funded by the Department of Science and Technology of Hai Phong City. The funder had no role in the study design; data collection, analysis, and interpretation; manuscript preparation; or decision to submit the manuscript for publication.

Data Availability

The datasets supporting the conclusions of this study are available from the corresponding author (HN) on reasonable request.

Authors' Contributions

HTTN and TAN designed the study and drafted the manuscript. LTT, HTN, and TTHP oversaw patient recruitment and data collection. TAN and LTT performed the statistical analysis. All authors contributed to interpretation of the data, critically revised the manuscript for important intellectual content, and approved the final version for submission.

Conflicts of Interest

None declared.

The JMIR Publications Editorial Office is retracting the article "Antibiotic Prescribing Behavior of Physicians in Outpatient Departments in Hospitals in Northwest Ethiopia: Structural Equation Modeling Approach" [1] due to concerns regarding the integrity of the peer review process.

Author Asrat Agalu Abejew responded, stating that there were no conflicts of interest with the reviewers. However, the Editorial Office has determined that there is sufficient evidence indicating that the peer review process was compromised to proceed with a retraction.

Author Asrat Agalu Abejew disagreed with the decision to retract the article. The other authors did not respond to communications.
