(Interact J Med Res 2026;15:e108273) doi:10.2196/108273

Following the publication of "Periorbital Necrotizing Fasciitis: Case Presentation" [1], concerns were raised regarding a potential conflict of interest between reviewer Karen Wong Riff and the authors. This concern included shared affiliation with members of the author list. This conflict was not disclosed to the JMIR Publications Editorial Office as per journal policy.

This article has been subsequently reassessed by the editor in chief, who determined that the content of this review did not unduly influence the decision to accept the article. The decision to accept the submission was based primarily on the remaining reviewers' comments and the editor in chief's contemporary appraisal of the manuscript.

As such, the JMIR Publications Editorial Office issues this corrigendum to update the Conflicts of Interest statement:

> *Reviewer Karen Wong Riff was found to have an undisclosed conflict of interest with members of the author list under the terms of JMIR Publications policy. The editor in chief determined that the content of the review did not unduly influence the decision to accept the article. The decision to accept the submission was based primarily on the remaining reviewers' comments and the editor in chief's contemporary appraisal of the manuscript.*

The JMIR Publications Editorial Office further issues an additional corrigendum to update the informed consent information, which is included in the "Ethical Considerations" subsection as follows:

Informed consent was obtained, in writing, from the patient for this publication.

We regret that these issues were not identified before publication.

The correction will appear in the online version of the paper on the JMIR Publications website together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Generosity as a Scientific Method: Building Knowledge and Community in a Competitive World

Bruno B Andrade[1,2,3], MD, PhD

Abstract

Generosity can function as a scientific method—a disciplined stance that aligns curiosity with openness, credit-sharing, and stewardship of data, specimens, and ideas. Rather than a soft add-on, generosity structures how questions are framed, teams are built, and results are disseminated, thereby improving rigor, reproducibility, and impact. This viewpoint article advances a conceptual and operational framework for "generosity in science," aimed at researchers, institutions, and funders seeking alternatives to competition-driven models of knowledge production. I examine generosity as practice at the levels of people, collectives, and institutions and argue that persistent global challenges in health demand pro-collaborative architectures. Seen this way, generosity is not mere altruism; it is part of the epistemic engine that turns uncertainty into shared knowledge while distributing opportunity and recognition more fairly. I define core principles of generous research and organize them across three domains: research design, governance, and evaluation. The paper draws on illustrative examples and relevant literature to situate generosity within ongoing debates on open science, team science, and research assessment reform. I outline practical principles for embedding generosity into research design, governance, and evaluation and discuss how these principles can counter vanity metrics and short-term incentives. I conclude that embedding generosity in the infrastructure of science enables better questions, faster learning, and greater public value.

KEYWORDS

generosity; open science; team science; leadership; mentorship

Introduction: A Different Currency of Success

Science has always been sold to us as a race. A race against time, disease, ignorance, and, above all, against other scientists. The metaphors are warlike: we "fight" cancer, we "combat" pandemics, we "outpace" competitors. This narrative has been useful for funding agencies, for politicians, and for institutions that thrive on the drama of competition. Yet, beneath this spectacle, the real progress of science often emerges from something far quieter and less glamorous: the capacity of human beings to share, to collaborate, and to give.

The book *Infectious Generosity* by Chris Anderson argues that generosity is a kind of contagion, spreading rapidly once individuals and institutions embrace it as a central value [1]. It has made me reflect on how my own scientific journey was shaped less by the victories of rivalry and more by the power of generosity. My most meaningful contributions have been born from collaborations that began with trust and flourished through the act of giving, whether data, time, mentorship, or simply space for others to shine. But having collaborative environments, colleagues, and agencies willing to share (space, reagents, time, and data) is practically a privilege. A growing body of research has demonstrated that reward and recognition systems in science are not neutral, but stratified by geographic, linguistic, gender, and racial criteria, shaping who is cited, funded, and visible in the global knowledge economy [2-6]. In this context, generosity cannot be understood solely as an individual virtue; it is also constrained and enabled by structural conditions that distribute opportunities unevenly. Thus, fostering generosity requires interpersonal practices within laboratories, but also systemic changes in how scientific contribution and value are recognized.

The central question is unavoidable: what happens if we take generosity seriously as a scientific method? If we treat it as a core value of our work, not as a footnote to CVs or a soft skill for committees? This viewpoint article explores how generosity operates in contemporary science, the conflicts it faces with the

XSL•FO
RenderX

traditional machinery of academic success, how it may contribute to more inclusive, rigorous, and sustainable forms of knowledge production and why future generations must choose genuine generosity (and not just express it in social media posts) if they are to build a better, more sustainable scientific world.

Generosity in a Scientist's Career

When I look back at my career, the turning points did not come from moments when I "outcompeted" someone, even though an outside observer might initially see it that way. In fact, they came from moments when I decided to share, whether it was reagents, ideas, or time. Early on, I realized that mentorship was not a distraction from science but a way to multiply its reach. I invested time in training students, guiding them through complex questions, and giving them the confidence to pursue independent paths. Some of them are now leading their own groups, writing their own grants, and mentoring the next wave. Their success does not diminish mine; it expands it. Each student mentored is like a small wave meeting the shore: gentle on its own, but when joined with others, they gather momentum until they swell into a tide, a force capable of reshaping coastlines. What begins as individual growth becomes a cascading surge of knowledge, leadership, and impact, where today's student becomes tomorrow's mentor, carrying the motion forward. In this sense, scientific contribution expands through relational networks rather than remaining confined to individual achievement.

A concrete illustration in my career is the Regional Prospective Observational Research in Tuberculosis (RePORT) International consortium. RePORT links national tuberculosis cohorts—initially in India, Brazil, and South Africa, with expansion to additional sites—through a Common Protocol that standardizes clinical definitions, visit schedules, and the collection, quality assurance, and in-country stewardship of data and biospecimens. Each country builds and governs its own repositories while adhering to shared standards, so that specimens and datasets are interoperable and suitable for pooled analyses. This architecture enables capacity building in high-burden settings, supports South-South and South-North collaborations, and shortens the path from discovery to trial readiness for diagnostics, vaccines, and therapies. By design, RePORT operationalizes generosity: local ownership with shared rules for contribution, access, and credit, thereby creating a repeatable template for translational research networks beyond tuberculosis [7].

Importantly, this model also illustrates how generosity can address structural inequities in global science. By prioritizing in-country stewardship, capacity building, and equitable participation, RePORT challenges traditional models in which data and resources are extracted from high-burden settings and concentrated in institutions in the Global North. Instead, it supports a more distributed model of knowledge production, in which scientific leadership, authorship, and infrastructure development are shared across contexts. In this sense, generosity is not only a collaborative practice, but also a mechanism for redistributing visibility, credit, and opportunity within the global scientific ecosystem.

On a smaller scale, generosity often reveals itself in gestures that leave no trace in metrics or bibliometrics, such as sharing an idea over coffee, connecting a young colleague with a senior researcher, or giving space for others to present first. These acts might not count toward impact factors, but they shape scientific communities in profound ways. Science, at its best, is a collective endeavor, and generosity is the glue that keeps the collective from disintegrating into a pile of isolated egos.

The Traditional Model of Academic Success

The dominant model of success in academia thrives on scarcity. It measures individuals through h-indexes, citations, and first- or last-authorships, all of which assume that recognition must be a zero-sum game [8]. In this system, your success is interpreted as someone else's failure, and the currency of prestige is accumulated by exclusion. The system rewards those who guard their data until the moment of publication, who compete for grants as if they were personal trophies, and who see colleagues less as collaborators than as potential rivals.

This model creates an atmosphere of anxiety and mistrust. Young scientists learn quickly that generosity is a liability. Share your idea too soon and someone else might publish it before you. Offer your dataset and you risk losing the first-author paper. Support a colleague's success too enthusiastically and you might find yourself overshadowed. The traditional model frames generosity as weakness and competition as strength, as if science were a gladiatorial contest rather than a collective search for truth.

There are undeniable achievements produced within this model. Competition drives ambition, and ambition produces results. Yet the costs are increasingly evident. Burnout, toxic lab cultures, plagiarism scandals, and inequities in access to funding all stem from the myth that science thrives when individuals fight each other for crumbs of recognition [9]. The model survives because it is convenient to bureaucracies and profitable to publishers, but it suffocates the very creativity it claims to reward. Actually, this is a dangerous trap: it is impossible to do science alone. And seeing rivalry where there should be collaboration is the key to this individual eventually finding themselves alone—and perhaps here, social and collaborative "failure" carries more weight than the journal cover that was published last month.

Generosity as Power

Against this backdrop, generosity may appear as an act of resistance, but it is also an act of strategy. Generosity is not weakness—it is power. It transforms influence from something fragile and temporary into something enduring and expansive. A paper might earn your citations, but a culture of generosity creates networks of trust that outlast any citation count.

History provides striking examples. When Jonas Salk developed the polio vaccine, he refused to patent it, famously asking,

XSL•FO
RenderX

"Could you patent the sun?" [10]. That act of generosity ensured rapid global access and saved millions of lives. Similarly, the Human Genome Project embraced an ethos of open data sharing through the Bermuda Principles, requiring that sequence data be released within 24 hours [11]. This act of generosity neutralized private efforts to monopolize the human genome and revolutionized biomedical research. In addition, this approach operationalized generosity through data governance, enabling global participation and limiting the consolidation of knowledge within proprietary systems.

More recently, the COVID-19 pandemic showed how generosity scales. The unprecedented speed of vaccine development was made possible by rapid, open sharing of viral sequences [12]. The alternative—secrecy, proprietary data, nationalistic hoarding—would have prolonged the catastrophe. Generosity saved lives, while selfishness would have cost them. These examples suggest that, under certain conditions, openness and shared access can function as accelerators of discovery, particularly in contexts requiring coordinated, transnational action.

The examples discussed throughout this viewpoint are illustrative and were selected to clarify how generosity can operate across different scales of scientific practice. They are intended to support conceptual development and practical reflection rather than to constitute a systematic or scoping review of the literature. Across these cases, generosity operates through identifiable mechanisms: open access to data, equitable distribution of credit, and collaborative infrastructure that lowers barriers to participation. These mechanisms transform generosity from an individual disposition into a reproducible feature of scientific systems.

In my own career, I have seen how generosity amplifies influence across continents. When you mentor generously, your students carry your ethos into their own careers, spreading it in places you will never visit. When you share credit generously, collaborators are eager to return with new ideas and resources. When you share knowledge generously, your field grows stronger and your own work finds deeper resonance. Generosity multiplies success, while selfishness isolates it. Furthermore, when mentees are not recognized for their contributions, they may grow disenchanted with science not because of its true potential, but because of failures in mentorship. This neglect can dull the spark of curiosity and drive, pushing away brilliant minds who might have flourished if nurtured. In the end, selfishness not only isolates success; it risks silencing futures that could have expanded the field itself. The "takers" of science may enjoy brief moments of visibility, but their legacies are fragile, sustained only as long as they can monopolize attention.

The Future of Science Through Generosity

Future generations face problems so vast that the old model of academic rivalry will collapse under their weight. Climate change, global pandemics, and the inequities of health cannot be solved by isolated laboratories fighting for primacy. These challenges demand collaborations that cross borders, disciplines, and generations [13]. For such collaborations to thrive, generosity must become the rule, not the exception.

Teaching young scientists to embrace generosity is not sentimentalism, it is survival. Rather than framing success solely in terms of individual achievement, mentorship and education can emphasize collaborative capacity, responsible data sharing, and equitable participation in knowledge production. In this context, generosity is not a form of self-sacrifice, but an investment in collective resilience—and generosity should extend beyond academic walls, whether in health care services, efforts to reduce economic and access inequalities, or general well-being [14-16].

When scientific activity is pursued primarily for individual recognition, concerns about priority and visibility may constrain collaboration and slow the circulation of knowledge. In contrast, when the purpose is to nourish science, empowering others is not a threat but a natural extension of one's mission. By expanding capacity and enabling new voices, the mentor amplifies the very contribution they set out to make, ensuring it reverberates far beyond individual achievements.

Institutions, too, must change. If universities and funding agencies continue to reward individual accumulation above collective impact, they will train generations of scientists ill-prepared for the realities ahead. Instead, we need metrics that value team science [17], platforms that encourage data sharing, and recognition systems that highlight mentorship and collaboration. Generosity must be made visible, measurable, and desirable.

In addition, emerging forms of digital publishing and open science infrastructures create new opportunities to make generosity more visible and traceable. Expanded reference lists, open peer review, data citation practices, and alternative metrics allow for broader recognition of intellectual contributions that extend beyond traditional authorship. These developments suggest that, rather than remaining invisible, many forms of generous scientific practice can be formally acknowledged and integrated into evaluation systems, supporting a more inclusive and representative scholarly ecosystem.

Framework for Incorporating Generosity Into Science

Domains and Principles

To translate generosity from a utopian value into a reproducible characteristic of scientific practice, this article proposes a framework organized into three domains: research planning, governance, and evaluation. Within each domain, generosity should be operationalized through fundamental principles, associated practices, and metrics that can help guide implementation (readjusting whenever necessary). Across all domains and areas of knowledge, four interrelated principles underpin this framework: (1) open science (facilitating the timely and responsible sharing of data, methods, and knowledge), (2) equitable recognition (ensuring fair recognition of contributions across all roles, career stages, and geographic regions), (3) collaborative planning (structuring research

XSL•FO
RenderX

questions and processes to allow for meaningful participation across disciplines, expertise, and contexts), and (4) management (maintaining responsible, long-term care of data, resources, and scientific relationships).

Scientific participation and recognition are shaped by structural inequities related to geography, language, institutional resources, gender, and race. As a result, the implementation of generosity must explicitly account for these asymmetries. Without such consideration, practices intended to promote openness and collaboration may inadvertently reproduce existing disparities rather than mitigate them.

Operational Domains

Research Design

Generosity in research design involves incorporating external collaboration and accessibility into the study. This includes integrating data-sharing plans into study protocols, identifying potential multisite or interdisciplinary collaborating groups, and anticipating the later reuse of data, samples, and materials. Indicative metrics may include a minimum number of prespecified data-sharing plans, the number of collaborating institutions, and the reuse of datasets in secondary analyses.

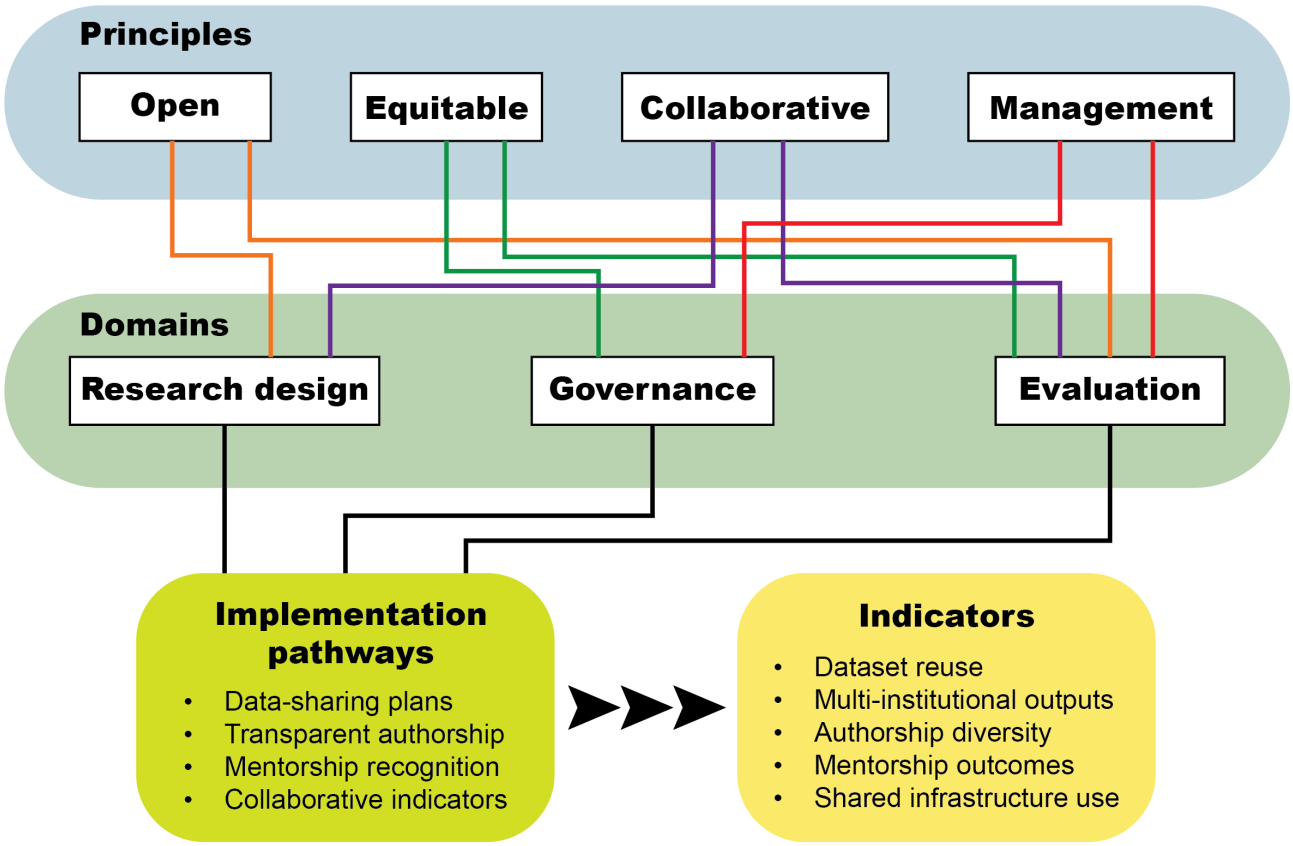
Governance

Governance structures determine how resources, decisions, and recognition are distributed within scientific collaborations. In this domain, generosity also requires actively paying attention to global and structural inequities, including ensuring that researchers from historically underrepresented regions and groups are not limited to roles of data collection but are meaningfully included in leadership, authorship, and decision-making processes.

Generous governance includes transparent authorization and contribution criteria; shared decision-making processes; and equitable access to data and materials. Support for capacity building (infrastructure, resources, analysis, computing power, among others), particularly in resource-limited contexts. Indicative metrics may include the inclusion of early-career researchers in leadership roles and documented policies for data access and recognition attribution.

Evaluation

Evaluation systems shape which behaviors are rewarded in science. Incorporating generosity into evaluation requires recognition of collaborative outcomes (eg, shared datasets, consortium work) and clear inclusion of team contributions to the work, funding, and awards received by the group, among others. Indicative metrics may include citations of shared datasets; participation in multicenter studies; documented contributions beyond first/last authorship; number of students at different levels of knowledge present in each article; and metrics of representation of gender, race/ethnicity, and areas of academic training.



To operationalize generosity, institutions and research groups can adopt practical measures such as (1) incorporating data-sharing plans and timelines into study designs; (2) establishing transparent authorship and credit allocation criteria; (3) recognizing mentorship and collaborative contributions in promotion and funding decisions; and (4) developing indicators that capture collaborative outputs, such as shared datasets, multisite studies, and cross-disciplinary publications.

Integration

Together, these elements position generosity not as an abstract ideal, but as an actionable and evaluable dimension of scientific practice (Figure 1). By integrating principles, domains, and indicators, this framework provides a structured approach for aligning collaborative values with the operational realities of research systems. Importantly, it allows generosity to be recognized, implemented, and assessed across different contexts, from individual projects to large-scale institutional initiatives. In doing so, it lays the groundwork for a shift from competition-centered models toward more collaborative, equitable, and sustainable forms of knowledge production.

XSL•FO
RenderX

Figure 1. Operational framework for embedding generosity in science. This figure illustrates a multilevel framework for embedding generosity in scientific practice. Core principles (top) inform three operational domains (middle), which are translated into actionable implementation pathways (bottom). Indicators provide mechanisms for evaluation and integration into research systems.

Limitations

The framework proposed here is conceptual and intended to guide reflection and implementation rather than prescribe a universal model. Its adoption may face important constraints, including intellectual property considerations, regulatory requirements, time-sensitive research environments, and institutional evaluation systems that continue to privilege individual productivity over collective contribution. In some contexts, data sharing may need to be balanced against privacy, biosafety, sovereignty, or ethical concerns. Moreover, the meaning and feasibility of generosity may vary across disciplines, funding structures, and national settings. These boundary conditions do not diminish the value of the framework, but they do indicate that its implementation must be context-sensitive and institutionally supported.

Conclusion: A Call to Infectious Generosity

This viewpoint has argued that generosity can be understood not only as a scientific virtue, but as a methodological orientation that shapes how research is designed, governed, and evaluated. It guides how we design collaborations, how we mentor, how we share, and how we dream. By aligning practices such as data sharing, equitable credit allocation, and collaborative infrastructure with core scientific goals, it resists the scarcity model and replaces it with abundance, not in the sense of infinite resources, but in the sense of infinite possibilities created through trust.

The framework proposed here highlights how generosity operates across multiple levels (from individual mentorship practices to institutional incentive structures) and identifies actionable pathways for its implementation. At the same time, its adoption is not without challenges, particularly in contexts shaped by competition for funding, intellectual property constraints, and entrenched evaluation systems.

Choosing generosity is not easy in a system that still worships rivalry. It requires courage to give credit when it could have been yours, to share data when secrecy seems safer, to open doors when others are closing them. Yet courage is exactly what science demands of us, and generosity is the most courageous act of all, because it asks us to trust that others will carry forward what we began.

The future of science will be written by those who dare to be generous. If generosity becomes infectious, if it spreads through laboratories and institutions, we may finally build a culture that enables science to deliver on its promises. Not a race, not a war, but a collective journey toward understanding and healing. What kind of research ecosystem do we want to leave for the next generation? One built on rivalry, or one built on generosity? The answer will determine not just the success of our careers, but the fate of our species.

Abstract

Basic sciences remain a cornerstone of medical education, but the terms of the debate about their importance have changed. The central risk is no longer their formal exclusion from medical curricula but their curricular invisibility: the gradual dilution of mechanistic reasoning within integrated, technology-mediated, and institutionally unequal training environments. In this Viewpoint, we revisit the past, present, and future of basic science teaching to argue that reform must protect conceptual progression, curricular visibility, and clinical transfer. Active learning, curricular integration, digital tools, and AI may strengthen scientific literacy, but only when they are anchored in faculty development, institutional support, and explicit commitments to rigor and equity.

(Interact J Med Res 2026;15:e80646) doi:10.2196/80646

KEYWORDS

medical education; medical schools; medical training; basic sciences; technology; pedagogy

Introduction

The teaching of basic sciences has long occupied a central place in medical education, providing the theoretical basis for clinical reasoning and professional practice [1]. Disciplines such as anatomy, biochemistry, and physiology have traditionally supported medical training by helping students understand the structure and function of the human body in health and disease [2,3]. In this article, the term “basic sciences” refers to biomedical disciplines that provide the conceptual and mechanistic basis for understanding normal and pathological processes and for interpreting clinical phenomena. Given their historical role as a core component of medical curricula, revisiting how these disciplines are taught has become increasingly necessary, particularly in light of contemporary educational and health care challenges [2-4]. This discussion is especially important in the current context of curricular reform, in which efforts to improve relevance, integration, and efficiency may also, sometimes unintentionally, weaken the visibility, coherence, or depth of foundational scientific knowledge.

This challenge is particularly evident across many settings in the Global South, where the rapid expansion of medical education has often occurred alongside resource constraints, uneven institutional capacity, and, in some contexts, increasing privatization, raising concerns about training quality and professional preparedness [5-7]. In such settings, the central issue is no longer whether basic sciences remain important but how to preserve their role within increasingly complex, technology-mediated, and unequal educational settings. At the same time, the continuous evolution of medical knowledge and the growing complexity of health care have required substantial changes in how these disciplines are taught [3]. The task is not simply to modernize teaching but to do so without weakening the scientific foundations of medical training. As curricula move toward integration, competency-based education, and digital innovation, basic sciences may either be meaningfully recontextualized or progressively marginalized. This marginalization does not necessarily mean that basic sciences are formally removed from the curriculum. More often, it occurs when they remain present but become fragmented, are

XSL•FO
RenderX

superficially addressed, and are less visible as the conceptual basis for clinical reasoning within integrated curricula. This tension lies at the center of contemporary medical education: how to make the teaching of basic sciences more relevant, practical, and student-centered while preserving the rigor, depth, and conceptual coherence that sustain clinical reasoning and professional judgment.

This Viewpoint is a critical reflection grounded in institutional experience and supported by selected literature. Its purpose is not to review every model of basic science teaching but to clarify the conditions under which reform becomes educationally meaningful. Integration, active learning, and digital innovation matter only when they make the scientific basis of clinical reasoning more visible, more usable, and more durable throughout the curriculum.

The contribution of this article is therefore conceptual. We argue that the main threat to basic science education is not its absence from medical curricula but rather its curricular invisibility. Contemporary debates do not usually call for the formal removal of basic sciences from medical curricula. More often, they question the traditional basic-clinical distinction [3] or advocate the stronger dissolution of the preclinical phase into clinically oriented teaching [8]. The concern lies neither in integration itself nor in efforts to align basic sciences with clinical practice. On the contrary, such initiatives can strengthen medical education when they are well designed. The problem arises when reform weakens the conceptual progression of basic sciences, their curricular visibility, and their interpretive role within integrated curricula. This risk becomes more pronounced when technology is adopted more rapidly than pedagogy, when faculty development is treated as optional, and when educational expansion occurs without commensurate investment in infrastructure and quality assurance. The past-present-future structure is used here to show how this problem emerged, how it currently appears, and what must be preserved if reform is to strengthen rather than weaken the foundational and scientific training of physicians.

The Past: The Historical Legacy of Basic Science Teaching in Medical Education

The modern place of basic sciences was consolidated during the broader transformation that made medical education more scientific, structured, and institutionally grounded [9-11]. The Flexner report [11] and the Dawson report [12] matter here less as historical landmarks than as sources of a tension that is still present: medical education gained scientific legitimacy, but the curricular form used to protect that legitimacy often separated mechanism from clinical use.

The Flexner report [11] strengthened the expectation that clinical practice should rest on foundational scientific knowledge [2,13,14]. Yet the curriculum that followed was commonly lecture-based, discipline-centered, and dependent on memorization and laboratory instruction. The result was productive and limiting at the same time. It gave basic sciences authority, but it also helped place them in a preclinical space that students could experience as distant from patient care. The Dawson report [12], by emphasizing the relation between education, service, and clinical context, pointed to a different possibility, but the compartmentalized model remained dominant.

Throughout much of the 20th century, basic science teaching remained organized around passive transmission, delayed application, and limited clinical contextualization [15,16]. This approach helped consolidate foundational knowledge, but it also encouraged a form of learning in which detail could accumulate without becoming reasoning. The problem became visible across anatomy, biochemistry, and microbiology, where students often encountered scientific content before they understood why it mattered for diagnosis, prognosis, or therapeutic judgment [17-22].

The historical lesson is therefore precise. The basic sciences were protected by a model that also isolated them. Current reforms still carry this inheritance: they must reduce fragmentation and excessive content load without dissolving the conceptual progression that allows foundational knowledge to become clinical reasoning [23]. The task is not to move away from science but to move scientific explanation closer to the work of interpretation, judgment, and care.

The Present: Current Practices and Challenges in Basic Science Education

Basic science teaching in medical education is currently marked by both important advances and persistent tensions. In many schools, disciplines such as anatomy, physiology, biochemistry, pharmacology, and microbiology are being restructured to strengthen the relationship between foundational knowledge and clinical application. This movement reflects broader efforts to move away from fragmented, content-heavy models and toward curricula that are more integrated, interactive, and responsive to contemporary health care needs. However, this transformation remains incomplete, especially in settings where infrastructure is limited, institutional support is weak, or resistance to pedagogical change remains strong.

A central feature of this transition has been the attempt to overcome the longstanding divide between theory and practice. Traditional models, heavily centered on content accumulation and memorization, often produced cognitive overload and limited students' ability to connect foundational concepts with clinical reasoning [8,24]. In response, many medical schools have adopted more integrated approaches, including problem-based learning (PBL), case-based teaching, and spiral curricula, all of which seek to connect basic and clinical sciences more meaningfully [13,25,26]. Recent work in physiology education has also reinforced the value of active learning strategies in basic science teaching [27]. At the same time, curricular reforms have increasingly emphasized the horizontal and vertical integration of the basic sciences across the curriculum, supported by active learning strategies and faculty development efforts aimed at strengthening integration between basic and clinical sciences [28].

Clinically oriented integration may also support retention. Earlier clinical exposure, clerkship-based reinforcement, and

XSL•FO
RenderX

integrated assessment have been associated with stronger preservation of foundational knowledge [28,29]. In a recent single-institution study from Sudan, students performed better on integrated questions than on discipline-specific items, suggesting that basic science knowledge is more durable when students must use it to interpret clinical problems [29]. This evidence supports competency-based education, provided that competence is understood as reasoning with science rather than merely performing clinical tasks [30,31].

Even so, progress remains uneven. Many institutions continue to struggle with insufficient pedagogical support and limited investment in faculty development [32,33]. Educators trained in more traditional systems may find it difficult to adopt active methods, integrate theory with clinical reasoning, or use digital tools effectively [34-36]. Evidence also suggests that even when faculty value active learning more highly, traditional lectures often remain part of their routine, highlighting a possible mismatch between pedagogical beliefs and teaching practices [36]. This gap between curricular intention and classroom reality shows that reform depends not only on curricular redesign but also on preparing teachers to interpret and enact new models consistently. These barriers are especially relevant in contexts where nonphysician educators are responsible for much of the teaching in the basic sciences. Although these faculty members often bring strong disciplinary knowledge and considerable pedagogical potential, they may receive limited institutional recognition or support, which can hinder innovation and interdisciplinarity [37].

These tensions reveal a broader challenge in contemporary medical education: how to modernize teaching without weakening scientific rigor. Making basic science education more relevant does not mean reducing its depth but rather teaching it in ways that are more contextualized, clinically meaningful, and educationally effective. Real clinical cases, cross-disciplinary dialogue, and stronger collaboration between basic and clinical faculty can help students understand how foundational knowledge informs medical judgment and patient care. In this sense, the goal is not to replace the basic sciences but to reposition them more effectively within the curriculum.

Interdisciplinarity has become one of the clearest expressions of this repositioning. Contemporary curricula increasingly incorporate social sciences, public health, and ethics into the teaching of basic disciplines, reflecting the complexity and interconnectedness of modern health care [8,38]. This broader framework supports more patient-centered and socially responsive training while also helping students connect scientific knowledge with the human, ethical, and systemic dimensions of practice. Emerging approaches such as STEAM (science, technology, engineering, arts, and mathematics) may further enrich this process by encouraging interdisciplinary projects, creativity, empathy, and visual reasoning [39]. The approach's emphasis on collaboration, design, and real-world problem-solving can help humanize scientific training while preserving rigor. In medical education, this approach is particularly valuable because it reinforces the idea that science and human experience should not be taught as separate domains.

Technological innovation has also reshaped current teaching practices [40-42]. After the COVID-19 pandemic, digital tools became even more prominent in health professions education [43,44]. In anatomy, cadaveric dissection is now frequently complemented by 3D models, virtual dissections, imaging-based simulations, and, in some contexts, virtual reality [17,18]. These tools can expand access, reduce dependence on costly physical resources, and offer flexible opportunities for visualization and repetition. Although cadaveric dissection retains important symbolic and educational value, newer strategies have broadened the possibilities for anatomy teaching. Of note, technology is most effective when it supports conceptual understanding, guided interpretation, and clinical transfer rather than functioning merely as a substitute for traditional materials or as an isolated innovation.

Similar changes are evident in other disciplines. In histology, pathology, and microbiology, virtual laboratories and digital microscopy have shown educational value while also reducing ethical and logistical concerns related to animals and biological materials [45-49]. In biochemistry, a field often perceived as abstract, gamification, simulation, and clinically oriented cases have made learning more engaging and relevant [50,51]. These innovations make learning more meaningful. Given the direct clinical implications of biochemical knowledge, active and contextualized approaches are particularly important in this area [52,53]. Physiology has also evolved through the use of digital simulations and gamified environments that connect normal and abnormal function while reducing reliance on animal-based teaching in nonclinical settings [54,55]. Across these examples, the underlying issue is not simply the adoption of new tools but the effort to make foundational scientific knowledge more accessible, meaningful, and applicable.

Yet these innovations do not affect all institutions equally. The expansion of online and technology-enhanced education has increased flexibility, autonomy, and opportunities for personalized learning, but it has also deepened inequalities between institutions and regions [7,56]. Many schools, especially in low- and middle-income countries (LMICs), still lack reliable internet access, adequate equipment, or sufficient technical and pedagogical support. This digital divide threatens equity and inclusion and reinforces the idea that innovation without investment may widen rather than reduce disparities [4].

Faculty development is therefore not an accessory to reform; it is the condition that makes reform possible [57]. Teachers need support to design active learning, construct assessments that reward reasoning, connect basic mechanisms to clinical decisions, and use digital tools without allowing the tool to become the lesson [37]. AI literacy now belongs in this preparation, but it should be framed critically: educators must learn where AI can reduce routine work and where human judgment, feedback, and mentorship remain irreplaceable. This support must include physician and nonphysician educators because both carry the responsibility for making science visible within medical training.

Structural problems also remain highly relevant. In many settings in the Global South, medical schools continue to face

XSL•FO
RenderX

curricular fragmentation, inadequate infrastructure, faculty shortages, and uneven regulatory capacity, all of which compromise training quality [5,6,58]. In some contexts, these challenges have been further intensified by the rapid expansion of medical education without proportional investment in educational resources, faculty support, or quality assurance mechanisms. Increasing privatization, weak regulation, and poor coordination between education and health care systems have further widened disparities and left many curricula insufficiently aligned with real health care needs [6,7,58-61].

The present moment is therefore defined by a difficult coexistence. Innovation is real, but so is inertia. Integration, interdisciplinarity, and technology have improved parts of basic science education, while structural weakness still determines how far these gains can extend. Preserving the basic sciences now requires more than new tools or new language. It requires institutional choices that protect scientific depth, make foundational knowledge clinically actionable, and reduce the gap between well-resourced and underresourced schools.

The Future: Emerging Trends and Future Perspectives in Basic Science Education

The future of basic science education will be shaped less by the availability of new technologies than by the judgment used to place them within the curriculum. AI, augmented reality, virtual reality, and high-fidelity simulation can make learning more adaptive and immersive. They can also create another layer of distraction if they are adopted as symbols of modernization rather than as instruments of understanding. Future innovation must therefore be measured by a simple standard: whether it helps students reason more clearly from mechanism to clinical consequence. Concerns about digital fatigue and screen-mediated disconnection make this standard even more important, since medical education still depends on attention, dialogue, mentorship, and relational learning [62,63].

AI offers important possibilities for personalized education, adaptive learning, and scalable instructional support in medical training [64]. Adaptive systems can analyze student performance in real time, provide targeted feedback, and help address knowledge gaps more quickly. These functions may improve learning efficiency. However, the role of AI in replacing teaching competencies remains uncertain. A recent study with educators and technology experts found agreement only in specific areas, particularly those involving low-complexity tasks such as preparing materials or grading [65]. In contrast, linking theory to practice, anticipating student needs, and adjusting strategies were seen as activities that still depend on human judgment. Empathy and critical insight were also identified as irreplaceable aspects of teaching.

These findings suggest that AI can support repetitive tasks but not replace human guidance. Medical education continues to require emotional awareness, empathy, and active listening [66]. At a time when concerns about screen fatigue and digitally mediated disconnection are becoming more visible, preserving human interaction in educational settings becomes even more important [62,63]. In this context, the educator's role is shifting from content delivery to learning facilitation. Teachers are increasingly expected to act as mentors who guide critical thinking and ethical reflection while helping students use technology wisely and maintain human values at the center of education [66]. The educator of the future will therefore need to combine disciplinary expertise, pedagogical judgment, digital literacy, and the ability to sustain reflective and relational forms of learning in increasingly technology-rich environments.

Virtual and augmented reality are also reshaping learning. These technologies create highly interactive environments in which students can explore anatomy and physiology through 3D simulations. Such experiences can improve spatial reasoning and decision-making in clinical scenarios while allowing learners to practice safely before engaging with real patients. However, their expansion should complement, rather than displace, the relational dimensions of medical education, particularly in areas where communication and professional identity depend on interaction with teachers, peers, and patients [67].

Future curricula will likely continue to emphasize collaboration, interdisciplinarity, and competency-based learning. This broader scope can bring ethics, social sciences, and digital health closer to basic sciences, but only if integration preserves the logic of scientific explanation. Memorization should give way to application, reflection, and adaptability, yet application without a foundation becomes fragile. The value of basic sciences lies in their capacity to support reasoning, interpretation, and decision-making across clinical and social contexts rather than in the isolated accumulation of facts.

These changes point to a broader structural transformation. Basic science education is moving from rigid and fragmented models toward curricula that integrate disciplines, technology, and human development. Table 1 summarizes these shifts across pedagogical approaches, curricular structure, teaching tools, engagement, assessment, and clinical integration. The table should be read as a map of pressures rather than a prediction of automatic progress. Equity will decide whether these innovations become shared educational gains or another mechanism of stratification. In low- and middle-income settings, aspirations toward innovation often coexist with unstable connectivity, limited simulation resources, constrained faculty capacity, and uneven regulatory support.

Table . Summary comparison of past, present, and future trends in basic science teaching in medical education.

Aspects	Past trends	Present trends	Future trends
Pedagogical approach	Teacher-centered lectures and passive learning	Student-centered active learning, including problem-based learning and team-based learning	Personalized and adaptive learning used to strengthen reasoning and feedback
Curricular structure	Isolated disciplines with minimal integration across areas	Integrated, system-based, and interdisciplinary curricula	Competency-based curricula with explicit progression of basic science concepts
Teaching tools	Textbooks, cadaveric dissection, and chalkboards	Cadaveric dissections with virtual reality, augmented reality, online platforms, and simulations	Immersive simulation; AI-supported tutoring; and science, technology, engineering, arts, and mathematics–informed resources tied to clear learning goals
Student engagement	Passive learning focused on memorization	Active participation, problem-solving, and collaborative learning	Autonomous learning paths supported by guided feedback and clinically grounded problem-solving
Assessment methods	High-stakes examinations and rote memorization	Formative assessments, objective structured clinical examinations, and competency-based evaluations	Continuous assessment of reasoning, knowledge transfer, and reflective clinical application
Integration with clinical practice	Limited and delayed clinical application	Early clinical exposure and integration of clinical cases	Longitudinal integration of basic and clinical sciences while preserving conceptual visibility

Faculty development will remain critical in this future landscape [68]. Advanced technologies will not improve learning by themselves. Educators must know how to translate complex disciplinary content into clinical meaning, how to design feedback around reasoning, and how to decide when a digital tool adds value and when it distracts from the concept being taught. In basic science education, sustainable reform depends on this pedagogical judgment.

Students will also need to adapt. Active learning and technology-based education require new attitudes toward learning. Students must take greater responsibility for their own progress and develop autonomy, critical thinking, and resilience [69,70]. Success in this context depends on their ability to seek knowledge independently and apply it in dynamic situations. Consequently, the focus shifts from passive absorption to active exploration, supported by strategies that encourage self-regulation and lifelong learning. On the other hand, expectations of autonomy should be balanced with adequate guidance, feedback, and structured support, since students differ considerably in their readiness for self-directed learning and in their ability to navigate complex educational environments.

At the same time, the future of basic science education is threatened by erosion that can be difficult to see. Course hours may shrink, practical experiences may disappear, research requirements may be removed, and student-faculty ratios may grow while the curriculum still appears formally integrated [71]. The consequence is a thinner scientific literacy. Innovation will produce lasting benefit only if it protects the time, faculty, and pedagogical structure required for students to understand mechanisms deeply enough to use them.

A sustainable future for basic science education depends on political will, equitable investment, and cultural change within institutions. Technology can help, but it cannot compensate for weak pedagogy, undervalued faculty, or inadequate infrastructure. The central challenge is to modernize teaching while protecting the scientific and human foundations of physician training across diverse educational realities.

Conclusions

Basic science education is being transformed by integration, active learning, and technology. These changes can improve medical training, but they can also make foundational knowledge less visible if reform is guided by novelty rather than by educational purpose. Across the past, present, and future of medical education, the central question is no longer whether basic sciences matter. It is whether medical schools can preserve the conceptual progression through which anatomy, physiology, biochemistry, microbiology, pharmacology, and pathology become clinical reasoning.

Defending the basic sciences does not mean returning to isolated preclinical courses or resisting curricular integration. It means refusing a weaker bargain in which science remains present in name but loses depth, sequence, and interpretive power. Integration is valuable when it makes mechanisms clinically intelligible. Technology is valuable when it deepens understanding rather than merely replaces attention. Faculty development is valuable when it equips teachers to connect explanation with judgment. The future of medical education will depend on this alignment: innovation that is strong enough to modernize training and scientific literacy that is strong enough to sustain the physicians who will practice in conditions of uncertainty.

Health Care Analytics Challenges: A 3-Pillar Framework Connecting Analytics Maturity, Workforce Agility, and Technical Enablement

Abstract

Health care organizations face a "triple threat" of low analytics maturity, high workforce instability, and semantic technical barriers that together produce a crisis of "institutional amnesia." Leadership turnover, workforce shortages, and widespread intent to leave among informatics specialists systematically erase the tacit knowledge required to navigate complex clinical data schemas, trapping organizations in a cycle where knowledge loss outpaces knowledge capture. Viewed through the socialization, externalization, combination, and internalization model of knowledge creation by Nonaka, the root cause is a "socialization failure": high turnover fractures the social networks required for mentorship, rendering the traditional apprenticeship model of informatics unsustainable. To address this failure, we used a design science research approach synthesizing evidence from health care informatics, knowledge management, and natural language processing to develop a sociotechnical framework: human-in-the-loop knowledge governance (HITL-KG). HITL-KG is designed to shift the locus of organizational knowledge from volatile human memory to durable semantic artifacts called "validated query triples," each comprising a natural language intent, executable SQL, and rationale metadata. By embedding knowledge capture into the daily query workflow, the framework aims to convert ephemeral analytics into permanent institutional assets. The accompanying 3-pillar assessment rubric enables organizations to identify compounding vulnerabilities across analytics maturity, workforce agility, and technical enablement. The "validator paradox" (who validates the AI when experts leave?) is addressed by reframing validation through lean "standard work": each validated query establishes the current known standard rather than eternal truth, functioning as a "knowledge ratchet" that prevents regression. Decoupling analytical capability from individual tenure lets analytics maturity advance even as the workforce evolves. This paper proposes and theoretically motivates the framework; empirical validation is deferred to a companion study.

The Triple Threat: Institutional Amnesia in Health Care Analytics

The health care analytics landscape is currently paralyzed by a "triple threat" of compounding failures: (1) persistently *low analytics maturity*, where despite decades of investment, as of late 2024, only 39 organizations worldwide had reached the top tiers of the Healthcare Information and Management Systems Society (HIMSS) Analytics Maturity Assessment Model (AMAM) [1,2]; (2) a *semantic gap* between clinical intent and technical schema implementation [3,4]; and (3) a profound crisis of *workforce instability* that creates "institutional amnesia" [5].

While technical barriers and maturity models are well documented, the workforce dimension has shifted from a management concern to an existential threat. Modern longitudinal data on analytics staff are fragmented, but the available signals are alarming. As of 2024, a total of 53% of health care chief information officers have held their roles for less than 3 years [6], creating a strategic vacuum at the top. At the operational level, global nurse turnover runs at 16% to 18% annually [7,8], and a 2025 study found that 55% of public health informatics specialists intend to leave their positions [9].

This turnover creates what public administration scholars term "institutional amnesia" [10,11] and organization science studies refer to as "organizational forgetting" [12,13]: the systematic erasure of the tacit knowledge required to interpret complex health data in health care analytics. In health care, "data" are never raw; they are wrapped in layers of institutional context (billing rules, workflow work-arounds, and unwritten exclusions) [14]. When the analyst who knows that "exclusion code 99" actually means "hospice transfer" leaves, that

XSL•FO
RenderX

knowledge evaporates. The organization does not just lose an employee; it loses the ability to accurately measure its own performance.

Current literature approaches these problems in isolation. Analytics maturity models (eg, the HIMSS AMAM) assume a stable workforce capable of linear progression [1]. Technical solutions (eg, natural language to SQL; NL2SQL) assume a stable schema and clear intent [15]. Neither accounts for the reality of the "great resignation," where the rate of knowledge loss often exceeds the rate of knowledge capture [13].

Traditional knowledge management strategies (wikis, data dictionaries, and documentation) have failed because they are *passive* [16]. They require overworked staff to stop working and write down what they know. In a high-burnout environment, this documentation is the first casualty. As a result, health care systems are trapped in a Sisyphus-like cycle: hiring new analysts who spend their limited tenure relearning the same institutional secrets only to leave just as they become productive [17,18]. A foundational 2004 study established that technical IT staff in organizations where IT is a support function, as in health care delivery, had the lowest expected tenure of any organizational category at just 2.9 years [19]. That this 2-decade–old study remains a key benchmark is itself evidence of the crisis: the industry lacks the stability to track its own attrition. Contemporary signals, detailed below, suggest that the situation has worsened.

This viewpoint addresses a critical sociotechnical gap: *how can health systems maintain analytics maturity when workforce turnover exceeds the speed of documentation?*

As a viewpoint, this paper deliberately advances a prescriptive position: that health care organizations should shift from passive knowledge management to active, artifact-based governance. The analysis below is grounded in descriptive evidence of why current approaches fail, but the architectural recommendations are intentionally directive.

We propose that the solution lies not in better documentation but in a fundamental architectural shift: moving from *passive* knowledge management to *human-in-the-loop knowledge governance* (HITL-KG).

Theoretical Grounding: Socialization, Externalization, Combination, and Internalization and the Unstable Workforce

Overview

We ground our analysis in the socialization, externalization, combination, and internalization model of knowledge creation by Nonaka [20], informed by a narrative literature review across health care analytics maturity, workforce turnover, and natural language processing, with gray literature assessed using the authority, accuracy, coverage, objectivity, date, and significance checklist [21]. Gray literature was retained only when no peer-reviewed equivalent existed or when it provided unique industry data. The model describes organizational knowledge as emerging through a continuous cycle of 4 conversion modes:

1. *Socialization* (tacit to tacit)—knowledge transfers through shared experience and co-located practice, as when a senior analyst teaches a junior colleague the unwritten rules of a clinical dataset.
2. *Externalization* (tacit to explicit)—individuals articulate tacit know-how into explicit forms, such as documents or coded artifacts, as when an analyst records why a specific exclusion code maps to hospice transfers.
3. *Combination* (explicit to explicit)—separately documented knowledge is integrated and systematized into broader structures, as when data dictionary entries are consolidated into a governed analytics catalog.
4. *Internalization* (explicit to tacit)—individuals learn from documented knowledge and convert it into personal expertise through practice, as when a new analyst studies validated query libraries.

In a healthy organization, these 4 modes form a self-reinforcing spiral: tacit insights become documented, documentation becomes systematized, and systematized knowledge is internalized by new members who then generate fresh tacit insights [20]. When any mode breaks down, the spiral stalls. In health care analytics, the breakdown is at the very first stage.

The framework's 3 pillars name the organizational capabilities at stake in the "triple threat": analytics maturity, workforce agility, and technical enablement. This structure aligns with established models across health care informatics and knowledge management (Table 1).

Table . Framework alignment with established models.

Pillar	HIMSS[a] AMAM[b] alignment	DIKW[c] hierarchy	Knowledge management
Analytics maturity	Progression from stages 0-7	Data→information	Organizational learning
Workforce agility	Implicit in advanced stages	Knowledge (tacit)→wisdom	Tacit knowledge transfer
Technical enablement	Stages 6-7 requirements	Information→knowledge	Knowledge codification

[a]HIMSS: Healthcare Information and Management Systems Society.

[b]AMAM: Analytics Maturity Assessment Model.

[c]DIKW: data, information, knowledge, and wisdom.

The HIMSS AMAM provides organizational benchmarks but does not address workforce knowledge retention. The data, information, knowledge, and wisdom hierarchy explains progression from raw data to actionable insights but does not

XSL•FO
RenderX

account for institutional memory loss. The 3-pillar framework synthesizes these perspectives, positioning workforce dynamics as the critical enabler connecting data access (analytics maturity) with organizational wisdom (knowledge preservation) [13,20].

The Broken Cycle: Socialization Failure

In the model by Nonaka, *socialization* is the foundational conversion mode: the primary channel through which newcomers absorb tacit context that formal training cannot convey [20]. Socialization depends on 2 preconditions: sustained interaction and sufficient temporal overlap between knowledge holders and receivers [22]. It is, in effect, an apprenticeship model requiring years of shared practice.

In the current health care environment, this mechanism has collapsed. The leadership and operational turnover documented above reveals an "apprenticeship window" shorter than the knowledge transfer cycle it must support: 30% of new employees depart within their first year [23], whereas specialized informatics roles require 18 to 24 months to reach fluency [17]. The arithmetic is unforgiving: by the time a new analyst has absorbed enough tacit context to be productive, their mentor may already be gone, and the new analyst is themselves halfway through an average tenure.

High turnover rates fracture the social networks required for mentorship [7,8]. The resulting knowledge loss is compounding: each departure removes a node from the organization's informal knowledge network, making subsequent socialization attempts less effective because fewer experienced practitioners remain to serve as mentors [24]. Socialization is no longer a viable strategy for resilience.

The Solution: Externalization via Sociotechnical Artifacts

To survive, organizations must shift reliance from socialization to *externalization*: converting tacit knowledge into explicit, durable artifacts [25]. However, traditional externalization (writing wikis, maintaining data dictionaries, and composing runbooks) suffers from 2 critical weaknesses. First, it is passive: it requires overworked staff to interrupt their workflow and perform a separate documentation task [26]. In a high-burnout environment where organizations face persistent attrition and talent shortages [27], this discretionary documentation is the first casualty. Second, it is low fidelity: the act of writing down tacit knowledge inevitably loses nuance, context, and the conditional logic that makes institutional knowledge valuable [22]. The result is documentation that exists but does not adequately capture what the departing expert actually knew.

We propose a form of *active* externalization: one that captures tacit knowledge as a by-product of the daily analytics workflow rather than a separate documentation burden. The mechanism is a new sociotechnical artifact: the *validated query triple* (see Multimedia Appendix 1 for worked examples). This artifact consists of (1) *natural language intent* (the clinical business question, eg, "Hypertension readmissions excluding planned transfers"), (2) *executable SQL* (the technical implementation), and (3) *rationale metadata* (the "why" behind the logic, eg, "Excluding status 02 per Centers for Medicare and Medicaid Services (CMS) 2025 rule").

By capturing these 3 components *during the act of analytics*, we transform the ephemeral work of query generation into a permanent institutional asset [28].

HITL-KG

We propose HITL-KG as the overarching governance framework, extending the knowledge governance approach [29] with the validated query cycle as its core operational process. This framing reflects that the system serves as a governance mechanism, not just a productivity tool.

The HITL-KG Architecture

The HITL-KG architecture (Figure 1) functions as a *governance forcing function*. It inserts a mandatory validation step into the analytics workflow, preventing laundered hallucinations while capturing expert knowledge.

A clinical user's natural language query (step 1) is translated to SQL and run against the data warehouse (steps 2-3); an expert validation gate (step 4) either returns confirmed insights (steps 5-6) or loops back for correction. Confirmed query triples enter organizational memory (step 7; dashed line in Figure 1), which informs future queries and curates the knowledge base (step 8), closing a continuous learning loop in which best practices evolve rather than remain static.

XSL•FO
RenderX

Figure 1. Human-in-the-loop knowledge governance architecture. NLP: natural language processing.

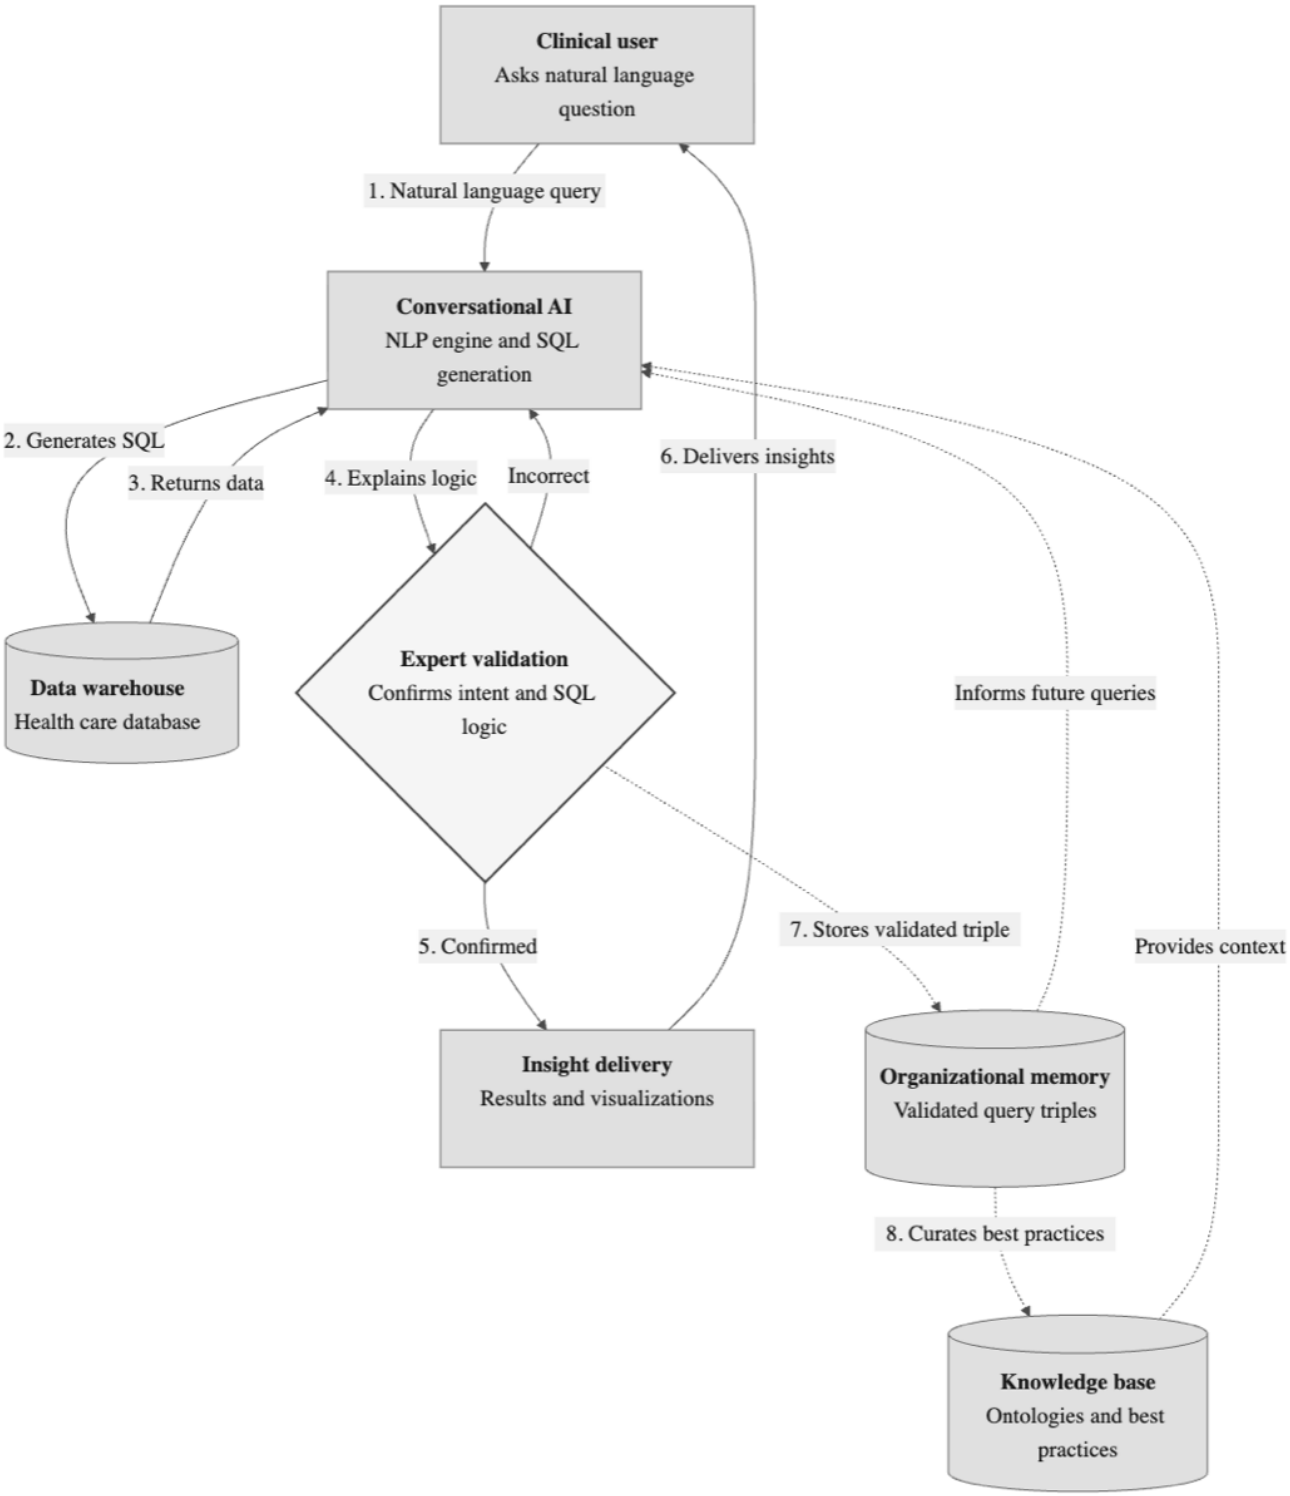

Figure 2 summarizes the corresponding 6-step validated query cycle, tracing queries from clinical intent to expert validation into durable organizational memory.

A natural language question (step 1) yields a candidate SQL (step 2) that the analyst validates against the system's explained logic (step 3), looping back if incorrect. Validated triples are stored in organizational memory (step 4) matched by future queries (step 5) and persist across staff turnover (step 6). The dashed arrows in Figure 2 mark the pillar outcomes: storage advances analytics maturity, persistence stabilizes workforce agility, and retrieval increases technical enablement.

XSL•FO
RenderX

Figure 2. The 6-step validated query cycle and its mapping to the 3 pillars.

XSL•FO
RenderX

The Process of Externalization

The cycle proceeds from query generation, in which a conversational AI system translates the user's natural language question into candidate SQL [30], to *expert validation*, the critical moment of externalization where the domain expert confirms or corrects the AI's interpretation and thereby captures tacit knowledge [31,32]. The validated triple is hashed and stored in organizational memory [33], then retrieved ahead of future probabilistic generation [34]. Multimedia Appendix 1 details each step alongside worked examples.

Comparison With Existing Approaches

Organizations have addressed institutional memory loss through several strategies, each with limitations that HITL-KG overcomes.

Code-based semantic layers (eg, data build tool and LookML) encode business logic in version-controlled repositories but suffer from "schema rot," where electronic medical record (EMR) data models change frequently and maintenance exceeds high-turnover teams' capacity, misaligning the layer and the underlying data [35]. HITL-KG's validated query triples share the version control principle but add the rationale metadata that semantic layers lack: not just *what* a query does but *why*.

Traditional knowledge management (wikis, data dictionaries, and runbooks) relies on passive capture, where users must stop working to document, which reduces participation and produces inaccurate records under cognitive load [16,26]. Such documentation might suffice for a small, stable query set, but real workloads are neither: more than half of analytical queries recur in large production workloads [36], yet even small databases log hundreds to thousands of distinct query strings [37], so a fixed set of documented queries captures neither the large recurring core nor the evolving ad hoc tail. HITL-KG instead implements active capture across both regimes: the query itself is the documentation, validated at the point of use [28].

Unsupervised AI querying removes human oversight entirely; current NL2SQL accuracy makes this unsafe for clinical analytics [38]. HITL-KG occupies the middle ground: AI generates, humans validate.

The Evidence Base: 3 Pillars

Overview

The evidence presented below supports the existence and severity of the problem that HITL-KG addresses and the maturity of the technologies it requires. It does not constitute empirical validation of the framework itself, which remains a theoretically grounded, testable proposition whose empirical evaluation is the subject of future work.

The HITL-KG framework is supported by 3 pillars of empirical evidence synthesized from the literature cited throughout this paper.

Pillar 1: Analytics Maturity Evidence

Analytics maturity describes an organization's progression in using data and quantitative models for fact-based decisions [39], a construct operationalized by staged maturity models that extend beyond the HIMSS AMAM [40,41]. Health care maturity remains chronically low. Assessments reveal that only 26 organizations worldwide achieved AMAM stage 6 and 13 reached stage 7 by late 2024 [1,2]. Because AMAM assessment is voluntary and self-selected, these figures likely overrepresent analytics-committed organizations, so low maturity may be even more widespread than the counts suggest [42,43]. The corollary is that the vast majority of organizations remain at the lower stages, characterized by fragmented data and limited predictive capabilities [44]. However, maturity is not merely an IT metric; it is a clinical safety predictor. In HIMSS's companion, the EMR adoption model, which measures the EMR adoption underlying analytics capability, levels 6 and 7 correlate with 3.25 times higher odds of better Leapfrog Hospital Safety Grades [45]. Low maturity creates a "low maturity trap" where data quality issues (such as the 39%-71% missing data rates in cancer databases [46]) remain uncorrected because the experts who understand the context are leaving.

Critically, low maturity is not simply a status; it is a self-reinforcing trap. Organizations at stages 0 to 3 lack the automated monitoring and data governance infrastructure needed to detect their own deficiencies, so poor data quality goes unrecognized. The clinical consequences are measurable: one Medicare accountable care organization that implemented analytics to overcome electronic health record fragmentation reduced readmission rates from 24% to 17.8% and achieved US $1.6 million in cost savings [47]. However, data interoperability remains a leading obstacle to analytics adoption [3,4]. Barriers including employee resistance to change and lack of organizational readiness further stall data-driven initiatives [48,49]. The trap thus compounds: each year of delayed investment widens the gap between what the organization could know and what it does know.

Pillar 2: Workforce Agility Evidence

Workforce agility is a workforce's capacity for proactivity, adaptability, and resilience under change [50,51]. In health care analytics, the evidence below documents the instability that systematically erodes this capacity. The cost of turnover in informatics is higher than in standard IT. Knowledge loss can cost up to 3 times the annual salary [24,52]. In clinical informatics specifically, replacement costs range from US $50,000 to US $230,000 per departing employee, with a loss of 39 staff members in a single department in 1 year incurring a total cost of up to US $8.97 million [53]. With 30% of new employees leaving within their first year [23], health care IT professionals spend a limited portion of their employment at full productivity as specialized roles require 18 to 24 months to reach fluency [17]. This "revolving door" prevents the accumulation of the "collective knowledge structures" required for complex task performance [13].

The workforce crisis operates at multiple reinforcing levels, as detailed in the Theoretical Grounding: Socialization, Externalization, Combination, and Internalization and the Unstable Workforce section: leadership churn, operational shortages, and foundational attrition collectively prevent the sustained mentorship that socialization requires. This multilevel

XSL•FO
RenderX

instability ensures that the temporal overlap between experienced practitioners and newcomers rarely materializes.

Pillar 3: Technical Enablement Evidence

Technical enablement denotes the technologies and practices that let nonspecialist domain users access and analyze data without heavy reliance on central IT [54,55]. NL2SQL technology has matured along a clear accuracy gradient: general-purpose models achieve approximately 65% execution accuracy on health care–specific benchmarks such as MIMICSQL [56], domain-adapted systems such as MedT5SQL reach 80% accuracy [57], and architecturally specialized approaches combining large language models (LLMs) with structured knowledge representations achieve 94% accuracy on the same benchmarks [58]. While insufficient for unsupervised clinical deployment [38], this gradient demonstrates that the generation engine required for HITL-KG is viable within a human-validated workflow. Notably, high benchmark accuracy does not guarantee real-world generalization: evaluation on more challenging dataset splits reveals accuracy drops from 92% to 28% [59], reinforcing the necessity of the human-in-the-loop architecture. Health care–specific natural language interfaces such as Criteria2Query achieve fully automated cohort query formulation in 1.22 seconds per criterion [60], with over 80% of clinical users indicating willingness to adopt such tools.

However, NL2SQL is an enabler, not a solution in itself. Its deeper significance lies in the organizational prerequisites it demands. For an AI system to translate a natural language question into a correct SQL query, the organization must first establish validated data models, explicit business logic definitions, and codified domain terminology [3,4]. This reframes NL2SQL from a convenience tool into a catalyst for the kind of systematic knowledge externalization that the HITL-KG framework requires. The interface bridges the semantic gap between clinical experts and technical schema, allowing nontechnical domain experts to interact with data alongside broader modernization efforts [61-64]. The very difficulty of making NL2SQL work correctly thus becomes a governance opportunity: it compels organizations to surface and formalize tacit knowledge that would otherwise depart with its experts.

Organizational Self-Assessment

Overview

To operationalize the framework, we propose a *3-pillar assessment rubric* (Table 2) that enables health care organizations to evaluate their current position across each pillar and identify compounding vulnerabilities.

Table . Three-pillar assessment rubric indicators (the full rubric with anchors can be found in Multimedia Appendix 2).

Pillar	Indicators
Analytics maturity	HIMSS[a] AMAM[b] stage, self-service analytics, and AI and NL[c] interface
Workforce agility	First-year analytics staff turnover, leadership tenure, and knowledge concentration
Technical enablement	Data access, interoperability, and schema coupling

[a]HIMSS: Healthcare Information and Management Systems Society.

[b]AMAM: Analytics Maturity Assessment Model.

[c]NL: natural language.

Why Assessment, Not Just Maturity

As noted, the maturity models and knowledge management frameworks in Table 1 assume linear progression by a stable workforce [1]. In practice, an organization that reaches AMAM stage 5 but regresses to stage 3 after the departure of 2 senior analysts has not failed to mature; it has failed to be *resilient*. A recent systematic review of organizational resilience measurement in health care found no consensus on what to measure [65]. Only 4 instruments have been developed specifically for health care, and only 2 have been validated [66]. The 3-pillar assessment rubric addresses this gap by organizing evidence-based indicators around the domains where institutional amnesia operates, measuring not just where an organization stands but also how vulnerable it is.

The 3-Pillar Rubric

Each indicator is scored as being of low, medium, or high strength using evidence-based anchors from the literature reviewed in the The Evidence Base: 3 Pillars section. Organizations scoring predominantly as “low strength” across multiple pillars face the self-reinforcing degradation cycle that the framework identifies as the central threat. Table 2 summarizes the 9 indicators; the full rubric with scoring anchors and evidence can be found in Multimedia Appendix 2.

The “schema coupling” indicator can be operationalized through *continuous analytic integration*: treating validated query triples as software assets within a continuous integration and continuous delivery pipeline that detects data and schema drift [35,67,68]. When a data warehouse schema is updated, the system automatically reruns stored queries and flags failures, transforming institutional memory into a living test suite [69,70].

The rubric complements rather than replaces the AMAM. Where the AMAM measures the sophistication of analytical capabilities at a point in time, the 3-pillar assessment rubric reveals how vulnerable those capabilities are to the compounding effects of turnover, low maturity, and technical barriers. Used together, they provide a 2D view of analytics health.

XSL•FO
RenderX

The Validator Paradox and Standard Work

A critical objection to HITL-KG is circular: if the framework requires domain experts to validate AI-generated queries and the core problem is that domain experts are leaving, then the framework fails precisely when it is most needed. This *validator paradox* represents the strongest counterargument to the approach proposed here, and addressing it requires moving beyond simplistic reassurance.

The resolution draws on lean management's concept of "standard work" [71]. In this framing, validation is not the establishment of *eternal truth* but the documentation of the *current known standard*. Each validated query triple records the best available understanding of how a business question maps to a data operation at that moment; the validation is time-stamped and contextual, not permanent. Critically, as Alukal and Manos [71] establish, standard work is the prerequisite for kaizen (continuous improvement): without a documented baseline, there is no foundation to improve upon. Each validated query, therefore, establishes a floor, not a ceiling. The next expert, veteran or midcareer hire, inherits a baseline to refine rather than reconstructing institutional knowledge from scratch.

This mechanism functions as what we term a *knowledge ratchet*, consistent with findings on collective knowledge structures [13]. Each validated triple prevents regression below the last confirmed state. Even if a subsequent validator is less experienced, the organization cannot slide below the previously validated standard. The ratchet does not guarantee forward progress, but it prevents the catastrophic backsliding that is the central failure mode of institutional amnesia.

Real-world evidence supports this: UC Davis Health moved from AMAM stage 0 to stage 6 by establishing standardized "S.M.A.R.T." definitions for its analytics metrics [72]. Those codified standards survived staff turnover because they existed as organizational artifacts rather than knowledge held solely by their creators. The HITL-KG validated query library serves an analogous function: it encodes analytical decisions into durable, retrievable structures that persist independent of any single analyst's tenure.

The validator paradox is not fully resolved: below a minimum viable expertise threshold, validation becomes meaningless. A junior analyst rubber-stamping AI-generated output without genuine comprehension provides no knowledge ratchet; the validation artifact exists, but its epistemic value is nil. Identifying this threshold remains an open empirical question; future work should measure it via controlled hallucination injection studies in which AI-generated queries containing deliberate errors are presented to validators of varying experience levels.

We propose a provisional 3-tier governance model informed by risk-stratified AI oversight frameworks [73,74] to degrade gracefully when expertise is scarce. The first tier is *full validation*: a domain expert with schema-level knowledge reviews the query triple and confirms semantic alignment (the default). The second tier is *constrained validation*: when no fully qualified validator is available, a less experienced analyst reviews the triple against previously validated queries for the same data domain, flagging deviations for deferred expert review; the triple is stored with "provisional" status. The third tier is *automated matching*: for queries that match an existing validated triple with high semantic similarity, the system accepts the match without human review, logging it for periodic audit.

Organizational governance requirements include who can validate queries (domain expertise thresholds), review workflows for high-stakes queries, query versioning as schemas evolve, and retrieval policies. Drawing on established master data governance practice [75], organizations can designate specific validated triples as "golden queries" certified by a governance committee as the authoritative source of truth for key metrics. Only these certified triples serve as official standards, mitigating shadow IT risks [76] while preserving analytical agility.

Safety as Cognitive Forcing

HITL-KG is fundamentally a *safety mechanism*, not a productivity tool. The central risk of unsupervised AI in clinical analytics is what we term "laundering hallucinations": a plausible-sounding but factually incorrect query result that enters the decision pipeline undetected and influences clinical or operational choices. Because LLMs generate fluent, confident output regardless of correctness, errors arrive dressed in the language of expertise, harder to catch than obviously malformed output.

HITL-KG mitigates this risk through *cognitive forcing functions* [38], a design pattern borrowed from clinical decision-making and safety engineering. Requiring the AI to explain its reasoning *before* presenting results forces the validator into system 2 (analytical and deliberate) thinking rather than system 1 (fast and heuristic) acceptance of superficially plausible outputs. User studies confirm the practical benefit: structured explanation reduces error recovery time by 30 to 40 seconds compared to unstructured output review [77].

Critically, the human validator's value is not merely assumed. Recent studies show that human oversight measurably improves AI-generated analytics: LLM output verified by a reviewer outperformed a human-only workflow (91.0% vs 89.0% accuracy) across 6 systematic reviews [78], and a text-to-SQL validation gate in which experts corrected generated queries improved semantic correctness by 28.4% over end-to-end model output [79]. These gains are conditional on well-designed interaction [80]; the comparative effectiveness of HITL-KG itself remains the subject of the planned empirical validation.

The parallel to aviation safety is instructive: checklists and mandatory callouts made commercial aviation exceptionally safe not by eliminating human error but by surfacing errors before they propagate. HITL-KG applies the same principle: the mandatory validation step is an analytical "callout" that interrupts uncritical acceptance so that the friction of validation is not a cost but the mechanism of safety itself.

Structural Barriers: Why the Problem Persists

Failed standardization approaches (eg, IBM Watson Health [81,82] and Haven [83,84]) demonstrate that centralized models fail clinical reality. Metadata uncertainties and "messy" institution-specific business logic require localized solutions [3,82]. HITL-KG addresses this by capturing *local* logic rather than enforcing *global* standards.

Limitations

This work is a narrative, design science–informed framework rather than a systematic review or multisite empirical evaluation. The literature base is concentrated on English-language sources and recent (2024-2026) workforce and NL2SQL studies, so findings may not capture all regional, specialty-specific, or technological contexts. The HITL-KG architecture and the proposed 3-pillar assessment rubric are conceptual artifacts that require future implementation and validation in diverse health systems before their effectiveness and generalizability can be fully established.

HITL-KG also complements rather than replaces workforce development: it decouples institutional knowledge from individual tenure but still presumes investment in the training and analytics literacy through which staff learn to pose, validate, and interpret queries [17]. This complementarity also bounds the framework. Where data models and business rules change continually, no approach is self-maintaining; precisely because retained expertise cannot manually keep pace with constant change, knowledge must be externalized into curated artifacts, yet the validated query library must itself be actively maintained, a burden that the continuous analytic integration mechanism mitigates but does not remove.

Implications and Future Research

The crisis of institutional amnesia in health care requires a structural shift. As long as analytical maturity is tied to individual tenure, organizations will remain fragile. By implementing HITL-KG, health systems can decouple intelligence from turnover, building a library of validated knowledge that ensures that maturity advances even as the workforce evolves.

Future research should empirically validate and refine the HITL-KG framework and the proposed 3-pillar assessment rubric. Priority questions include how pillar scores correlate with observed continuity of analytics performance during leadership and staff turnover; whether HITL-KG–mediated NL2SQL workflows reduce error rates, recovery time, and rework compared to baseline tooling; and which governance patterns most effectively balance safety, transparency, and equity when human validators operate at scale. Prospective multisite implementation studies, controlled user experiments, and qualitative implementation research will be needed to test these claims across diverse organizational, regulatory, and data environments.

Acknowledgments

STH is the sole author and takes full responsibility for the manuscript's content. Generative AI was used to assist this work, specifically Gemini CLI (Gemini 3; Google) and Claude Code (Claude 5; Anthropic) for manuscript editing, language refinement, and literature search. Generative AI was not used to generate research findings, data, or conclusions; the author conducted the research and verified all claims, citations, and AI-assisted text. Figures were generated using the Mermaid graph language.

Funding

Yuimedi, Inc., provided financial support for the author's time researching and writing this manuscript. The views expressed are the author's own and do not represent the official positions of Indiana University Health or Yuimedi, Inc.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study. All data cited are from publicly available peer-reviewed publications, industry reports, and academic theses referenced in the bibliography. The manuscript source, build pipeline, and literature review code generated for this work are archived on Zenodo [85].

Abstract

Fibromyalgia is a prevalent musculoskeletal pain condition that causes major personal, social, and societal burden. Pharmacological therapies often provide only limited benefit, making multimodal approaches and self-management the cornerstones of care. Such strategies, spanning lifestyle modification, physical activity, psychoeducation, and cognitive-behavioral approaches, target the biopsychosocial complexity of fibromyalgia and promote sustainable coping. In parallel, digital health technologies are transforming how these interventions can be delivered and coordinated in the form of digital therapeutics. This viewpoint draws on a multiphase investigation to appraise the current and future landscape of fibromyalgia self-management in the digital era. Its objective is to present an evidence-based framework and recommendations to guide the development of a mobile health self-management program for patients with fibromyalgia. In phase 1, we conducted a review of international guidelines and randomized controlled trial–based systematic reviews addressing nondigital self-management interventions for fibromyalgia and related nociplastic pain conditions. In phase 2, we analyzed the content and certification status of currently available mobile and virtual health applications for fibromyalgia. In phase 3, we convened a multidisciplinary focus group of rheumatologists, patients, and digital health developers to identify priorities for translating evidence-based self-management content into mobile health formats. Collectively, we suggest that effective digital self-management for fibromyalgia should evolve beyond single-domain interventions toward validated, personalized, and interactive multimodal platforms. Virtual care may increasingly function at the point of care, linking monitoring, education, and behavioral support in one continuum.

Introduction

Fibromyalgia is defined as a syndrome characterized by moderate to severe symptoms, including widespread pain, fatigue, sleep disturbance, cognitive complaints, and an increase in somatic complaints [1]. Despite ongoing efforts to clarify the definition of fibromyalgia, accurately assessing its diagnosis, prevalence, management, and its personal and societal impacts remains challenging [2]. Fibromyalgia can be accompanied by psychiatric, rheumatological, gastrointestinal, or other comorbidities, which further complicate the management and contribute to its overall personal and societal burden [3].

Proposing a clear treatment strategy for fibromyalgia remains challenging. The focus is on nonpharmacological therapies, particularly physical interventions, psychological treatments, and mind-body approaches that aim to promote self-management. Patient education plays a crucial role in enhancing their understanding of the disease and fostering their active participation in its management. Pharmacological treatments have shown limited benefits [4-8]. Multimodal treatment programs are recommended for treatment-resistant

XSL•FO
RenderX

fibromyalgia patients, as they combine different treatment modalities and offer group effects. However, such programs require significant resources that are not necessarily considered cost-effective.

Self-management programs play a crucial role in supporting individuals with chronic conditions [9] and are recommended by management fibromyalgia guidelines [4-7]. The fundamental concept of self-management emphasizes the active involvement of patients [9,10]. Self-management considers the multidimensional nature of the illness and combines multiple interventions such as psychological interventions, exercise, and nutritional aspects. It offers a relevant approach to address the challenges in fibromyalgia management and shows its efficiency to improve fibromyalgia patients' well-being [11,12] and a reduced tendency of patients to seek repeated consultations with health care professionals. A plethora of these programs have shown an improvement in pain intensity, functionality, cognitive behavior, emotions, and quality of life (QoL). However, the quality of these studies is heterogeneous [13-17]. When programs are detailed, their references are often unclear, relying on peer opinions or interviews [18-24], or they may offer only one component, such as psychoeducation or exercises [25-28].

The digital transformation is continuously shaping the health care landscape. It encompasses various digital innovations such as online programs, apps, gaming, virtual reality, or, more recently, generative artificial intelligence (AI) and chatbots [29]. In a clinical context, mobile health (mHealth) apps have demonstrated several key functionalities, including diagnostics and clinical decision support, behavior change interventions, and the delivery of disease-related education and communication support. The latter 3 functionalities are particularly relevant for delivering self-management interventions, empowering patients to monitor and manage their own health conditions, and providing an additional avenue for health care professionals to support their patients' well-being [30]. In 2019, a law was passed in Germany that digital health applications are reimbursable by health insurance companies under certain conditions. Currently, 8 digital health applications for musculoskeletal indications are registered; 2 of those are for chronic pain syndromes, including fibromyalgia [31]. There was a second acceleration of eHealth during the COVID-19 pandemic, notably concerning telemonitoring and video consultations. In the meantime, eHealth interventions have been shown to enhance patients' QoL and treatment experiences [32,33].

Online programs and mobile apps have demonstrated promising benefits for individuals with chronic pain or musculoskeletal conditions [33,34]. The use of mHealth technologies offers an accessible and available 24/7 solution without geographical constraints, empowering patients to become more self-reliant in managing their chronic conditions [35,36]. Notwithstanding, there are several caveats and limitations in existing solutions. A substantial proportion of currently available online fibromyalgia programs are not evidence-based or lack proven, evidence-based content. They are usually not personalized and cannot be updated, as this would alter the certification status of the device. On the other hand, recent digital tools such as large language models (LLMs) and chatbots offer novel approaches that could address some of these limitations.

Aim

The objective of this work is to present an evidence-based framework and recommendations to guide the development of an mHealth self-management program for patients with fibromyalgia. A comprehensive literature review was conducted to evaluate the effectiveness of self-management interventions on symptoms in patients with fibromyalgia (phase 1). Where applicable, relevant practical characteristics of the interventions were also reported. In phase 2, existing therapeutic fibromyalgia apps and online programs were reviewed, and in phase 3, general aspects and user preferences were discussed in focus groups with patients. Finally, we aimed to identify strategies to optimize online self-management interventions and explore their potential for further improvement.

Ethical Considerations

This study is based on previously conducted studies and does not contain any new studies with human participants or animals performed by any of the authors.

Phase 1: Review of Existing Evidence

Overview

MEDLINE and Cochrane databases, encompassing English and French articles from the inception of the databases up until 2023, were searched to identify guidelines and systematic reviews of randomized controlled trials for fibromyalgia self-management. Data from 30 systematic reviews that demonstrated a high or moderate level of confidence based on the AMSTAR 2 evaluation and 8 guidelines with an AGREE II–GRS score higher than 18 were considered to categorize and summarize the evidence on self-management interventions (Figure S1 in Multimedia Appendix 1).

Categorization of Self-Management Interventions

Self-management interventions were categorized into 3 groups: physical exercise, psychoeducative interventions, and mind-body interventions. Additionally, a separate category called multimodal interventions was identified, which encompassed interventions combining 2 or more of the previously mentioned self-management approaches. The European, American, Canadian, and Italian guidelines covered physical exercise, psychoeducative interventions, and mind-body self-management interventions as part of the overall management of patients with fibromyalgia, alongside other treatment modalities [4,6,7,37]. The German guideline divided its recommendations into 4 separate studies: general recommendations [7], recommendations on physical interventions [38], psychological interventions [39], and other interventions such as mind-body therapies [40]. In total, 8 studies focused on physical activities [41-48]; 14 studies on psychoeducative interventions [25,49-60]; 4 studies on mind-body therapies [61-64]; 1 study on multicomponent interventions [11]; 1 study that investigated both psychoeducative and mind-body interventions [65]; and 2

XSL•FO
RenderX

studies that examined physical activities, psychoeducative interventions, mind-body therapies, and multicomponent interventions [66,67]. The studies used various types of control groups, which encompassed the following options: treatment as usual, waiting list or no treatment, alternative pharmacological or nonpharmacological interventions, active or attention control, and placebo or sham interventions. Designing a control group for complex self-management interventions was considered challenging due to the inherent difficulty of blinding participants, which can introduce measurement and interpretation bias [68].

Evidence for Specific Self-Management Interventions

A wide range of variables were assessed both before and after the interventions: pain (both qualitative and quantitative measures), QoL, psychological functions such as depression, anxiety, self-efficacy, acceptance, catastrophizing, and fear-avoidance, physical functions such as strength and disability, sleep quality, fatigue, health care use indicators such as visits, sick leaves, return to work, and care-seeking behavior, as well as trial withdrawal rates and adverse effects. The Fibromyalgia Impact Questionnaire (FIQ) was used as a multidimensional measurement tool.

Physical Interventions

All of the guidelines strongly endorse the inclusion of aerobic exercises and resistance (or strength) exercises in self-management interventions for fibromyalgia [4,6,7,37,38]. On the other hand, flexibility and stretching exercises are either not recommended [6,7] or recommended with weak or insufficient evidence of benefit [37,38]. Exercise interventions were found to be superior to control groups in improving pain, FIQ scores, sleep quality, fatigue, and depression [67]. The characteristics of the exercises were extracted based on the prescription guidelines provided by the American College of Sports Medicine, which include frequency, intensity, time, and type of exercises [69]. Additionally, the duration of the exercises, delivery modalities, whether they were tailored or standardized, and safety considerations were also considered. Aerobic exercises had positive effects on pain, QoL, and depression [42,45,46]. Aerobic exercises demonstrated a high effect on reducing the FIQ [41]. Aerobic exercises probably improve stiffness and slightly improve physical function and cardiovascular function [42]. According to Couto et al [46], resistance exercises yielded positive effects on pain and QoL but did not show a significant effect on depression. On the other hand, Albuquerque et al [41] found that resistance exercise demonstrated a moderate effect in reducing the FIQ scores. Resistance exercise has the potential to improve fatigue and sleep [49]. Although flexibility exercise did not show superiority over control groups (other interventions or no intervention), the quality of evidence is insufficient to draw definitive conclusions regarding the effectiveness of flexibility exercise on fibromyalgia symptoms [41,45,46,48]. However, there is evidence suggesting that physical exercise may help decrease muscle stiffness [48]. Interventions that combine aerobic exercises, resistance exercises, and flexibility exercises have shown greater effectiveness in improving FIQ scores compared to single-type exercise interventions [41]. However, Bidonde et al [43] state that no definitive conclusion can be drawn regarding the optimal proportion, synergy, or specific characteristics of each exercise type [43]. Exergames have demonstrated promising benefits in improving pain, disability, and physical function in both the short and long term [66]. There is a lack of available information regarding other exercises, such as Pilates and motor control exercises. Exercise (aerobic, resistance, and flexibility) characteristics are shown in Table S1 in Multimedia Appendix 1.

Psychoeducative Interventions

Consensus guidelines recommend the inclusion of psychological and educational interventions, such as cognitive behavioral therapy (CBT) and health education [4-7,37]. These interventions can encourage self-management, enhance self-efficacy, and reduce maladaptive thoughts and behaviors [6]. It is particularly important to consider these interventions when patients have comorbid mental disorders [39]. For hypnosis and guided imagery, recommendations are conflicting [4,7,39]. Although other psychological interventions, such as relaxation, therapeutic writing, Roger therapy, family therapy, psychodynamic therapy, and psychoanalytic therapy, are available, they should not be proposed as stand-alone treatments due to the lack of evidence or limited recommendations [39]. CBT incorporates education on the physiopathology of pain, self-management skills, cognitive reappraisal, pacing activities, and problem-solving techniques to help patients modify their behaviors, thoughts, and emotions, ultimately reducing pain, improving functioning, and enhancing mood. Additional components, such as sleep hygiene, may be included. Homework assignments are given to encourage the practice of skills in everyday life [60]. Acceptance and commitment therapy (ACT) and mindfulness-based therapy are extensions of CBT. ACT comprises 2 main core components: mindfulness and acceptance, as well as commitment and behavior change. It involves several processes, including acceptance, cognitive defusion, present-moment awareness, self-as-context, values clarification, and committed action [70]. ACT interventions often incorporate CBT processes, making it difficult to distinguish between CBT and ACT [51]. Evidence suggests that CBT can reduce pain, disability, and negative mood in patients with chronic pain or fibromyalgia, both immediately after treatment and at long-term follow-up (6 and 12 months), although the effect size is small or very small [68,79. Enomoto et al [52] recommend offering CBT for insomnia, or at least CBT for insomnia and pain, to patients with chronic pain who also experience insomnia as a comorbidity. CBT therapy for insomnia has been effective in improving sleep, pain, disability, and depression. ACT has also demonstrated benefits for patients with chronic pain, improving pain acceptance, QoL, pain intensity, functioning, and mood [57,59]. For fibromyalgia, ACT has shown significant improvements in patient functioning in both the short and long term, based on a meta-analysis with moderate-quality evidence [51]. ACT can be considered to enhance patients' psychological flexibility and, subsequently, their functioning in pursuing valued activities [51,59]. Education serves as both an intervention and a CBT tool [58]. Joypaul et al [55] defined education as providing instructions to inform participants, making it applicable to various interventions as an instructional

XSL•FO
RenderX

tool [55]. Therapeutic pain neuroscience education, also referred to as pain neuroscience education by some authors, aims to enhance patients' knowledge and understanding of pain neurophysiology to improve their cognitive and behavioral skills related to pain [56,71]. Therapeutic pain neuroscience education has demonstrated benefits for patients with chronic pain in reducing fear of movement, pain intensity, pain disability, and pain catastrophizing [58]. Therapeutic pain neuroscience education, in the context of chronic musculoskeletal pain, improved pain intensity, pain knowledge, disability, maladaptive thoughts and behaviors, physical function, and health care use, even up to 1 year post treatment [56]. Other educational content has been studied, including lifestyle components focusing on areas such as nutrition, sexuality, social coping strategies, and the regulation and adjustment of everyday life [11]. Education should be an integral part of a multidisciplinary approach to chronic pain, alongside graded physical activities, graded exposure, and pacing, for example, and not offered as a stand-alone treatment [54-56,58,67]. CBT education characteristics were gathered in Table S1 in Multimedia Appendix 1.

Mind-Body Interventions

The classification of mind-body interventions was based on the Medical Subject Headings terms of the National Library of Medicine. They encompass various modalities such as meditative movement therapies (MMTs), respiration exercises, hypnosis and autogenic training, meditation, and relaxation [72]. They focus on exploring the interconnectedness between the brain, body, mind, and behavior, and how emotional, mental, social, spiritual, experiential, and behavioral factors can directly impact health [73]. Guidelines recommend the use of MMTs with confidence [4,7,40]. However, hypnosis, guided imagery, relaxation, or meditation are not recommended, and it is advised not to propose them as stand-alone interventions [7,40]. The Canadian guideline suggests not discontinuing these interventions but informing the patient about their lack of evidence and potential side effects [6]. Therapies such as Qi Gong, Tai Chi, and Yoga, as examples of MMTs, were included [63]. MMTs have shown improvements in outcomes such as physical functioning, pain, and mood for patients with fibromyalgia [65]. Specifically, Tai Chi has been found to significantly reduce FIQ scores, pain intensity, sleep disturbance, fatigue, and depression, while increasing QoL for individuals with fibromyalgia [61]. Tai Chi and Yoga are weakly recommended, whereas the evidence did not allow for a recommendation regarding Qi Gong for chronic pain management [63]. Lee et al [64] did not provide a recommendation for meditation as a treatment for chronic pain due to the limited evidence available. While no specific recommendation was provided in the systematic review, Lee et al [64] suggested that mindfulness-based interventions could potentially offer benefits for chronic pain management.

Multicomponent Interventions

Multicomponent interventions were defined as combinations of at least 2 components, including psychological, physical activity, medical education, and mind-body therapies, based on the self-management program developed by Miles et al [74] and further refined by Geraghty et al [11]. All guidelines recommend not implementing interventions in isolation but rather combining them with other approaches. Multicomponent intervention should include physical and psychoeducational interventions at a minimum [4-7,75]. Multicomponent interventions have demonstrated effectiveness in improving various aspects such as FIQ, pain, sleep, and depression, with greater effects compared to exercise alone, education alone, or psychological interventions alone [61,62]. The positive effects of multicomponent interventions typically last for an average of 14 weeks, and it is recommended to conduct follow-up assessments every 3 months to review and reinforce the treatment strategy [62]. Considering the variations across studies, multicomponent interventions have shown improvements in physical function, pain, FIQ, fatigue, mood, and QoL in both the short and long term [11].

Phase 2: Review of Self-Management Apps

In this part of the work, we investigated which type of self-management is integrated in existing apps for fibromyalgia and chronic pain syndromes (Table 1). Online fibromyalgia applications were identified via PubMed, Google, and the German Digitale Gesundheitsanwendung (DiGA) registry [76], as well as with ChatGPT (OpenAI). Available mobile apps targeting fibromyalgia self-management reveal a strong emphasis on psychoeducational content, particularly CBT, ACT, and pain neuroscience education. Out of the 12 reviewed apps, 10 integrate psychoeducational modules, often presented through structured lessons, interactive exercises, journaling tools, or virtual coaching. Physical activity interventions, such as aerobic or resistance exercise guidance, were integrated in 6 apps, typically via instructional videos, activity logging, or synchronization with wearable devices. Mind-body techniques, including guided meditation, breathing exercises, and mindfulness-based practices, were found in about 5 apps. This distribution highlights a predominant focus on psychological and cognitive strategies in current digital interventions, with fewer apps addressing physical or somatic components in depth.

XSL•FO
RenderX

Table 1. Existing online self-management programs for fibromyalgia.

App name	Therapeutic mechanisms	Regulatory status	Notes
Stanza	ACT[a], CBT[b], mindfulness, journaling, reminders	FDA[c]-cleared in the United States	12-week structured digital therapy, clinical trial support
HelloBetter Chronic Pain	CBT, ACT, mindfulness	DiGA[d]-approved in Germany	Structured 12-week course, reimbursed by German health insurance
Selfapy Chronic Pain	CBT, mindfulness, education	DiGA approval in Germany withdrawn	Evidence-based course, reimbursed via DiGA
Manage My Pain	Pain tracking, journaling, self-monitoring	Available on app stores	Focuses on tracking pain trends for self-awareness and provider communication
Quell Fibromyalgia	Neuromodulation via wearable, symptom tracking	FDA-authorized medical device	App supports wearable neuromodulation therapy for fibromyalgia
FibroMapp	CBT-based tools, symptom tracking, medication management	Available on app stores	Combines tracking and CBT tools; user-driven format
MoreGoodDays	CBT, mindfulness, education	Available on app stores	Structured CBT modules, lifestyle education, mindfulness tools
FibroMinder	Reminders, symptom tracking, task management	Available on app stores	Simple utility app for scheduling and symptom tracking
PainScale	Pain tracking, education, CBT elements, community support	Available on app stores	Community-focused platform with integrated education and logging
FibroTrack	Symptom tracking, lifestyle management	Available on app stores	Focuses on tracking and lifestyle planning features
Curable	Pain neuroscience education, CBT, guided meditation, writing exercises	Available on app stores	Comprehensive app targeting pain beliefs and coping strategies
Fibrowalk	CBT, mindfulness, therapeutic exercise, pain neuroscience education	Not a certified app; delivered via YouTube and email	Multicomponent program with weekly video sessions

[a]ACT: acceptance and commitment therapy.

[b]CBT: cognitive behavioral therapy.

[c]FDA: US Food and Drug Administration.

[d]DiGA: Digitale Gesundheitsanwendung.

Two applications, HelloBetter Chronic Pain and Stanza, are certified digital therapeutics. HelloBetter is DiGA-approved in Germany, meaning they are reimbursable by statutory health insurance and have met criteria for clinical evidence and data security. Stanza, developed in the United States, is US Food and Drug Administration–cleared as a prescription digital therapeutic, offering a 12-week ACT-based program with demonstrated clinical efficacy in reducing fibromyalgia symptoms [77]. The remaining apps, including Curable, MoreGoodDays, Manage My Pain, and FibroMapp, are publicly available but lack medical certification and are typically framed as wellness tools or digital companions rather than regulated treatments. Overall, while several apps offer well-designed psychoeducational modules and basic symptom tracking, fewer integrate evidence-based physical activity interventions or comprehensive mind-body components. Among the 12 fibromyalgia self-management apps analyzed, only 5 (42%) can be considered multicomponent, meaning they integrate at least 2 of the 3 core evidence-based intervention domains: psychoeducational therapies, physical activity, and mind-body techniques. Notably, the certified apps HelloBetter Chronic Pain, Selfapy Chronic Pain, and Stanza fall into this category, offering combinations of CBT or ACT, mindfulness, and, in some cases, activity planning. Noncertified apps such as MoreGoodDays and Curable also include psychoeducation and mind-body interventions, but vary in the depth and clinical rigor of their content. While most of the reviewed apps integrate evidence-based components aligned with current clinical guidelines, such as CBT, ACT, and mindfulness-based techniques, several also include strategies with limited or inconclusive evidence in fibromyalgia. For example, some noncertified apps incorporate generic meditation, unstructured journaling, expressive writing, or broad lifestyle advice without therapeutic framing or individual tailoring.

Phase 3: Patient Preferences and Focus Groups

As previously reported, we investigated patient preferences for mobile app design through 2 online surveys (53 and 33 patients, respectively) and 3 focus groups comprising a rheumatologist, 1-6 fibromyalgia patients, with or without concomitant post-COVID-19 syndrome, as well as an app designer [78]. All patients in focus groups tested a self-developed app designed to assess fibromyalgia symptoms and to deliver an online therapeutic program containing CBT, mind-body techniques, and physical exercise instructions. This program was initially developed during the pandemic for fibromyalgia associated with postviral syndrome and was subsequently adapted as an

XSL•FO
RenderX

experimental chronic pain companion (Pain Organiser and Companion System). The design and content of this app are described in detail elsewhere [78,79]. In the final focus group (n=1), the online program was connected to an LLM-based chatbot and tested by the patient (see Future Directions section).

Participants emphasized that simplicity, clarity, and accessibility are crucial for adherence, given common cognitive fatigue ("fibrofog") and limited digital literacy. Users preferred short, well-structured modules, clear navigation, and scientifically validated content in plain, nontechnical language. Autonomy and empowerment emerged as central themes. Patients valued tools that visualize progress, such as symptom tracking and diaries, helping them recognize links between behavior and symptoms. Personalization was highly desired; users wanted adaptable exercises, favorite lists, and an interactive virtual coach or chatbot that responds to individual needs and previous activity. An empathic, motivating tone was considered essential. Participants appreciated friendly communication and multimedia content, particularly physiotherapy videos and mindfulness modules. Emotional design elements, positive wording, supportive colors, and encouraging feedback were viewed as vital for engagement and adherence. Reliability and trustworthiness were further priorities: users expected apps to be evidence-based, transparent, and secure, with clear data protection and professional validation. Barriers such as poor navigation, cognitive overload, or lack of emotional connection can significantly reduce adherence. The focus group highlighted that fibromyalgia mHealth apps offer the potential to serve as multicomponent platforms, covering the 3 key therapeutic domains discussed above: psychoeducation, mind-body techniques, and physical exercise guidance. Of note, instructions for physical exercises were appreciated by participants in the focus groups, ideally with more individualization (eg, for individuals with obesity).

Key Findings and Lessons Learned

There is proven evidence for psychoeducational interventions, mind-body therapies, and physical activities in fibromyalgia. All 3 are included in most of the current fibromyalgia mHealth applications on the market, several of those with proven efficacy in randomized controlled trials, although the underlying therapeutic content is not openly accessible [75]. CBT remained strongly recommended to assist patients with fibromyalgia in managing their pain, comorbidities, and lifestyle [49] and is the main approach used in existing fibromyalgia apps. Apart from CBT interventions, psychoeducation focuses on pain coping skills, mindfulness, lifestyle modification, and pain neuroscience education. The recommendations regarding mind-body therapies such as MMT, meditation, relaxation, or hypnosis are conflicting but safe and therefore might be integrated in apps as an adjunct. Certain interventions, such as stress reduction, breathing, and relaxation exercises, are notably suitable for integrating into apps as animation can be positive, such as a balloon for breathing exercises.

Half of the existing fibromyalgia apps integrate physical exercises into their program, but mostly only to a lower degree compared to CBT. The content of existing apps contrasts with technically more sophisticated physiotherapy or online rehabilitation apps; for example, integrating computer vision to instruct and monitor a wide range of exercises. In general, it can be postulated that true multicomponent apps integrating all 3 validated pillars of fibromyalgia self-management, psychoeducation, physical activity, and mind-body techniques, guided by clinical standards and codeveloped with patient input, would improve the effect.

From a technical side, both web and native apps are viable platforms for integrating self-management tools and tracking disease activity in fibromyalgia. Native apps are particularly effective at incorporating wearable data directly from mobile devices, enabling continuous monitoring and data capture. Symptom tracking is typically based on patient-reported outcomes or symptom scores, including measures of pain, QoL, depression, anxiety, self-efficacy, acceptance, catastrophizing, fear-avoidance, physical function (eg, strength and disability), sleep quality, fatigue, and health care use indicators such as clinic visits, sick leave, and return-to-work patterns.

These apps often incorporate validated instruments such as the FIQ, the Symptom Severity Score, or the Widespread Pain Index to assess disease activity. Therapeutic content is typically delivered through text, animated videos, or voice formats, providing education, instructions, and exercises. In some cases, apps are integrated with connected devices, such as wearables that deliver millimeter wave stimulation [80]. Animation can be used to enhance certain exercises, such as balloons being used to synchronize breathing frequency and intensity.

Stand-alone apps, particularly those certified as digital therapeutics, often include a structured program guide to track patient progress. This is important for potential reimbursement by health insurers. Increasingly, mHealth apps also integrate chatbots that guide users through the program, enhance flexibility, and potentially improve adherence, one of the main challenges of these interventions. Successful therapeutic apps for this population require a balance between scientific rigor, user-friendly design, and emotionally intelligent interaction. A clinical and evidence-based framework for fibromyalgia interventions in apps can be found in Table 2. Textbox 1 presents practical recommendations for the corresponding app design and implementation roadmap.

Table 2. Evidence-based framework for fibromyalgia online interventions.

Intervention domain	Evidence level and rationale	Implementation in mobile health app	Digital enablement features	Evaluation metrics
Psychoeducational therapies (CBT[a], ACT[b], and PNE[c])	Strong evidence from RCTs[d] and guidelines for reducing pain, distress, and maladaptive thoughts	Modular courses; microlearning sessions; quizzes; journaling; goal setting; and self-efficacy tracking	Chatbots or avatars for guidance; adaptive progression based on symptom and mood data; empathy-based conversational tone; and voice message transcription	Pain, FIQ[e], self-efficacy, catastrophizing, engagement rate, and module completion
Physical activity and graded exercise	Strong evidence for aerobic and resistance training improving function and mood	Video demonstrations; personalized exercise plans; daily movement reminders; wearable integration (steps, HR[f], and HRV[g])	AI[h]-driven motion feedback (computer vision); adaptive load progression; safety alerts; and gamification	Physical function (FIQ physical domain), fatigue, adherence (logged sessions), and HR and HRV trends
Mind-body techniques (mindfulness, Tai Chi, breathing, and relaxation)	Moderate evidence for improving sleep, mood, and QoL[i]	Audio-guided meditations, breathing animations, mindfulness timers, and relaxation music	Adaptive session lengths; stress biofeedback using HRV; sleep tracking linkage; and integration with smartwatches	Sleep quality, stress index, anxiety, HRV, and app usage continuity
Symptom tracking and patient-reported outcomes	Essential for personalization and clinical insight for HCP[j]	In-app FIQ, pain diaries, and fatigue and sleep trackers	Voice or video symptom entry; AI-based summary visualization; and adaptive dashboard	Data completeness, trend accuracy, and correlation with clinical outcomes
Personalization and adaptive design	Increasingly essential for engagement and relevance	Custom goal setting; phenotype-based pathways (eg, obesity-, menopause-, and PTSD[k]-related FM[l])	Machine learning–based tailoring; predictive suggestions for pacing and exercise. Adapted avatars, eg, older people with obesity	User satisfaction, engagement over time, and adaptive accuracy
Behavior change and motivation	Crucial for long-term adherence	SMART[m] goal planning, feedback loops, and progress visualization	Gamification, motivational messaging, positive reinforcement, and social comparison (optional)	Retention rate, adherence index, and self-efficacy gain
Communication and support	Improves adherence and patient safety	Chatbot or professional chat; asynchronous therapist feedback	Hybrid care integration (eg, AI triage + human follow-up); crisis escalation paths	Message frequency, satisfaction, and safety events
Data integration and clinical workflow	Enables clinical supervision and research	Clinician dashboard, FHIR[n]-based interoperability, and data export to EHR[o]	Sidecar EMR integration; secure teleconsultation channel	Clinical uptake, data completeness, and clinician feedback
Accessibility, UX[p], and emotional design	Critical for usability and adherence in cognitive fatigue	Clean interface, large icons, voice navigation, and light and dark modes	Emotionally supportive design (colors, feedback tone), simplified onboarding, and language localization	SUS[q] score, accessibility compliance, and dropout rate
Privacy, certification, and ethics	Required for trust and scalability	CE[r], FDA[s], or DiGA[t] conformity, and transparent data policies	Privacy-by-design architecture; on-device data processing	Certification status, GDPR[u] or HIPAA[v] compliance, and user trust rating

[a]CBT: cognitive behavioral therapy.

[b]ACT: acceptance and commitment therapy.

[c]PNE: pain neuroscience education.

[d]RCT: randomized controlled trial.

[e]FIQ: Fibromyalgia Impact Questionnaire.

[f]HR: heart rate.

[g]HRV: heart rate variability.

[h]AI: artificial intelligence.

[i]QoL: quality of life.

[j]HCP: health care professional.

[k]PTSD: posttraumatic stress disorder.

[l]FM: fibromyalgia.

[m]SMART: specific, measurable, achievable, relevant, time-bound.

[n]FHIR: Fast Healthcare Interoperability Resources.

XSL•FO
RenderX

[o]EHR: electronic health record.

[p]UX: user experience.

[q]SUS: System Usability Scale.

[r]CE: Conformité Européenne.

[s]FDA: US Food and Drug Administration.

[t]DiGA: Digitale Gesundheitsanwendung.

[u]GDPR: General Data Protection Regulation.

[v]HIPAA: Health Insurance Portability and Accountability Act.

Textbox 1. Recommendations for the fibromyalgia mobile health self-management program development.

Recommendation

- Involve key stakeholders (fibromyalgia patients, multidisciplinary professionals, and digital experts) through surveys, interviews, and co-design workshops.
- Conduct a structured needs assessment, addressing core fibromyalgia symptoms and patient priorities (eg, fatigue, pain, and cognitive dysfunction).
- Provide a transparent overview of the content for users, health care providers, and regulators, eg, using knowledge graphs or content maps.
- Tailor content to user characteristics such as socioeconomic background, gender, age, culture, and health literacy.
- Base all interventions on clinical evidence, including physical activity, cognitive behavioral therapy, psychoeducation, and mind-body strategies.
- Include personalized modules for subtypes and comorbidity (eg, perimenopausal symptoms, obesity, anxiety, posttraumatic stress disorder–associated hypermobility, migraine, etc).
- Adhere to established standards and guidelines, such as Xcertia, National Institute for Health and Care Excellence, Haute Autorité de Santé, and World Health Organization, covering content, privacy, usability, and operability.
- Design the app as a complementary tool, not a substitute for face-to-face care.
- Use interoperable data formats, such as Fast Healthcare Interoperability Resources, to enable secure integration with health care systems and devices.
- Connect to wearable data, allowing tracking of physical activity, sleep, or heart rate variability to enrich outcome measures.
- Include a clinician-facing dashboard to enable remote monitoring, triage, and decision support.
- Ensure robust data security and privacy compliance, including user consent, encryption, and data governance.
- Provide a structured and simple onboarding process, guiding users through initial setup and goals.
- Ensure user-friendliness with intuitive design, a responsive user interface, customizable settings, reminders, and accessible language.
- Include motivational features, such as gamification, progress tracking, and positive reinforcement.
- Incorporate core functional modules, including symptom tracking, educational content, communication, and self-assessment tools.
- Implement adaptive, guided interventions rather than static or generic content to boost engagement and outcomes.
- Define and track recognized fibromyalgia end points to support evidence generation and reimbursement (eg, Fibromyalgia Impact Questionnaire, pain scales).
- Follow an iterative development cycle, including continuous evaluation of effectiveness, usability, and safety.
- Plan for scalability, dissemination, and regulatory approval, including Conformité Européenne marking, Digitale Gesundheitsanwendungen eligibility (Germany), or US Food and Drug Administration listing.

Areas of Uncertainty

The literature search was limited to PubMed and Cochrane databases, potentially introducing selection bias, and the cutoff at 2023 excluded recent studies or emerging interventions. Another limitation of this viewpoint concerns the transferability of conventional evidence-based therapies to digital formats. The effectiveness of individual therapeutic elements within apps remains largely untested, and user experience likely plays a decisive role. Adherence is particularly critical, as unguided online interventions often show low engagement. Psychiatric comorbidities, such as depression, trauma, and cognitive fatigue, further affect adherence and suggest that some users may benefit from guided or coach-assisted programs rather than fully automated ones. The human and group-based components of multimodal therapy are difficult to replicate digitally, raising questions about the optimal degree of human involvement in digital therapeutics. Device-based or biofeedback interventions were not included, as they require additional hardware not universally accessible; however, future versions may integrate smartwatch-based or wearable data.

Finally, personalization remains a key challenge. As fibromyalgia is heterogeneous, tailored approaches—whether based on symptom profiles or machine learning–derived phenotypes—are needed. Future studies should also account for contextual factors such as age, culture, digital literacy, and

XSL•FO
RenderX

socioeconomic status, as well as identify which behavior change techniques drive engagement and outcomes. Guided and adaptive interventions appear more effective than static content, highlighting the importance of iterative, patient-centered design in future mHealth development.

Future Directions

As seen in other digital interventions, such as for depression, the inclusion of a channel for direct interaction with a health care professional or, potentially, a bot can increase effectiveness. Voice message transcription features can facilitate semiautomated, asynchronous communication. In this context, agentic AI trained on such interactions may provide supplementary or alternative support. Dashboards play a critical role in integrating fibromyalgia mHealth applications into the clinical workflow, enabling health care professionals to monitor their patients and app activity. Ideally, these dashboards should interface with electronic medical records through sidecar applications [81]. Personalization of content according to fibromyalgia subtypes should be encouraged. However, this increased individualization may make the creation of robust evidence or standardized certification more challenging. As a future perspective, new content formats could be developed and evaluated, such as therapeutic stories or short interventions. For example, therapeutic stories could resemble YouTube Shorts, with AI algorithms applied to tailor and deliver these formats accordingly. Other future digital directions for fibromyalgia apps will move beyond psychoeducation toward multimodal, personalized therapy ecosystems. Integration of exercise modules, CBT, and mindfulness into cohesive platforms is expected, with adaptive interfaces that adjust content to each user's symptom patterns, motivation, and cognitive load. LLMs and AI-powered chatbots will evolve from static text-based assistants to emotionally intelligent digital companions that guide users through daily self-management, provide empathetic feedback, and interface with sensor data from wearables for sleep, mobility, or stress tracking. These systems could enhance adherence, detect flares early, and personalize pacing and exercise recommendations. Meanwhile, interoperability, data privacy, and regulatory validation will remain crucial to ensure clinical reliability and ethical use. Ultimately, the future of fibromyalgia apps lies in hybrid digital care, combining automated AI-driven support with human coaching and clinical oversight. By blending evidence-based therapy, personalization, and human empathy, next-generation digital therapeutics may finally bridge the gap between self-management and sustained symptom improvement.

Conclusion

Evidence-based foundations are needed to inform the development of effective digital therapeutic applications for fibromyalgia. To build impactful digital therapeutics, it is essential to integrate validated self-management strategies, engage key stakeholders, and consider social and cultural determinants. An iterative development process, guided by ongoing assessment of usability, effectiveness, equity, and safety, will ensure that mHealth tools align with both clinical goals and patient needs.

Acknowledgments

We thank Physio Homecare for providing physical exercise videos for the Pain Organiser and Companion System app. Generative artificial intelligence was used for editing the manuscript. Support for content creation is provided in Table 2.

Data Availability

All data generated or analyzed during this study are included in this published article. Quantitative and qualitative data of focus groups can be found in [78].

Authors' Contributions

All authors have contributed to the conception of this article and approved the final version to be published. TLF and TH wrote the manuscript. TLF performed the literature review and was involved in a focus group. MB and IL facilitated the focus groups. MB created the app and led focus groups. TH was involved in app development and led focus groups.

Conflicts of Interest

MB and TH are the board members of Atreon.

Abstract

Background: With the ongoing digitalization of health care, digital health literacy (DHL) is becoming increasingly important, requiring appropriate measurement instruments (DHLMIs). However, the wide range of available DHLMIs makes selection difficult and raises questions about their suitability and comparability.

Objective: This review aimed to provide an overview of available DHLMIs for adult populations and to compare their dimensions, identifying overlaps and differences to determine which (key) dimensions are most commonly studied and thus define DHL.

Methods: A narrative overview of reviews was conducted. The database search was conducted in November 2024, with an updated search in March 2026, in PubMed and Google Scholar using specific search terms and predefined inclusion and exclusion criteria. This was complemented by a forward citation search in Web of Science. All identified records were screened in a multistage process. At the review level, systematic and scoping reviews published since January 1, 2020, were included that analyzed DHLMIs in adult populations. At the primary study level, studies were included in which DHLMIs were used for self-assessment, performance-based evaluation, or a combination of both. Data extraction was performed by one reviewer and verified by a second reviewer. Data on underlying theories, methods of data collection (performance-based or self-reported), and target groups were extracted. DHL dimensions, their definitions, and the associated items were categorized by 2 researchers using qualitative content analysis according to Kuckartz.

Results: A total of 12 reviews were included. Of the 170 measurement instruments examined in these reviews, 33 (19%) were selected for detailed analysis after applying the inclusion and exclusion criteria. The majority of the included measurement instruments (n=20, 61%) were not based on a theory, 20 (61%) measured DHL exclusively via self-report, and 21 (64%) addressed specific target groups. The measurement instruments encompassed a total of 209 original dimensions of DHL. The number of dimensions measured per instrument varied between 2 and 22. The qualitative content analysis identified a total of 30 assigned dimensions. Key dimensions captured in almost all instruments, although under different names, include evaluating health information, using health information, researching health information, and the ability to use technology.

Conclusions: The large number of measurement instruments and original dimensions makes it difficult to select suitable instruments for measuring DHL and to compare and synthesize study results. Nevertheless, we were able to identify key dimensions as relevant regardless of target groups and types of digital applications, which could be used to develop a core outcome set for DHL. Our findings offer a foundation for refining existing instruments and developing new ones. They provide practical guidance for researchers and health care professionals in selecting suitable DHLMIs. Additionally, our review underlines the importance of theory to ensure content validity and comparability of DHLMIs.

Introduction

Background

Health literacy is a key resource for achieving and maintaining good health [1,2]. It is defined as the knowledge, motivation, and ability of individuals to access, understand, evaluate, and apply health information to make informed decisions that support or improve health and quality of life [3]. While health information was traditionally accessed through print media, (audio-)visual broadcasts, or direct interaction with health care professionals, due to increasing digitalization, the internet has become the dominant source of health-related information [4,5].

To enable effective use of this information, individuals need to have digital health literacy (DHL). Understanding how this concept has developed over time is essential for contextualizing the diversity of available measurement instruments and the dimensions they cover. The concept of eHealth literacy, on which DHL is based, was first defined by Norman and Skinner in 2006 as the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to address or solve a health problem [6,7]. Their Lily Model described eHealth literacy as a set of 6 core literacies: traditional literacy, health literacy, information literacy, scientific literacy, media literacy, and computer literacy [7]. As digital health technologies evolved beyond static web resources to include interactive, mobile, and social media platforms, the concept of "digital health literacy" was introduced to capture the broader and more complex skill set required to effectively engage with these new environments [8]. Norman [9] himself acknowledged these limitations in his 2011 update, and subsequent scholars have proposed revised or entirely new definitions and models (eg, [10,11]). This progress has prompted the development of broader conceptual frameworks. The conceptual heterogeneity of the field is illustrated by a concept analysis by Ban et al [8], which identified multiple competing definitions and traced how the concept has continued to evolve in response to technological and contextual change.

The diversity of available theoretical models, coupled with the absence of a universally accepted definition, is reflected in the large number of measurement instruments available [10-12]. These differ in their underlying theoretical frameworks, target populations, assessment methods—ranging from performance-based to self-reported approaches—and the dimensions they cover. The wide range of instruments available makes selection difficult and raises questions about the suitability and comparability of study results. This challenge is not limited to DHL but is also present in clinical settings, for example, in the assessment of disease severity using instruments for atopic dermatitis [13].

Previous reviews have analyzed the psychometric properties of available digital health measurement instruments (DHLMIs) using the COSMIN methodology [12,14] or conducted content analyses restricted to instrument development studies for the general population [15] or focused exclusively on either self-reported [12] or performance-based instruments [16]. However, no review has yet applied a structured qualitative content analysis to systematically examine and synthesize the dimensional landscape across the full breadth of DHLMIs in active research use, including instruments for both the general population and specific target groups, such as older adults or individuals with chronic conditions. This review aimed to address this gap.

Study Objectives

The objective of our study was to provide a comprehensive overview of existing DHLMIs, both self-reported and performance-based, to systematically analyze and synthesize the dimensions across instruments, including those developed for the general population and those targeting specific populations, such as older adults or individuals with chronic conditions. We focused on the underlying theory, assessed dimensions, assessment methods (ie, performance-based, self-report, or mixed method approaches), and target populations. Rather than aiming to identify a single universal instrument, our goal was to identify overlaps and differences between instruments and to determine which key dimensions are most commonly operationalized across DHLMIs, thereby contributing to a more systematic understanding of how digital health literacy is currently conceptualized and measured in research practice. This analysis is intended to support researchers in making more informed decisions about which instrument to use, to provide instrument developers with an evidence-based starting point, and to contribute to the development of a core outcome set for DHL.

Methods

Overview

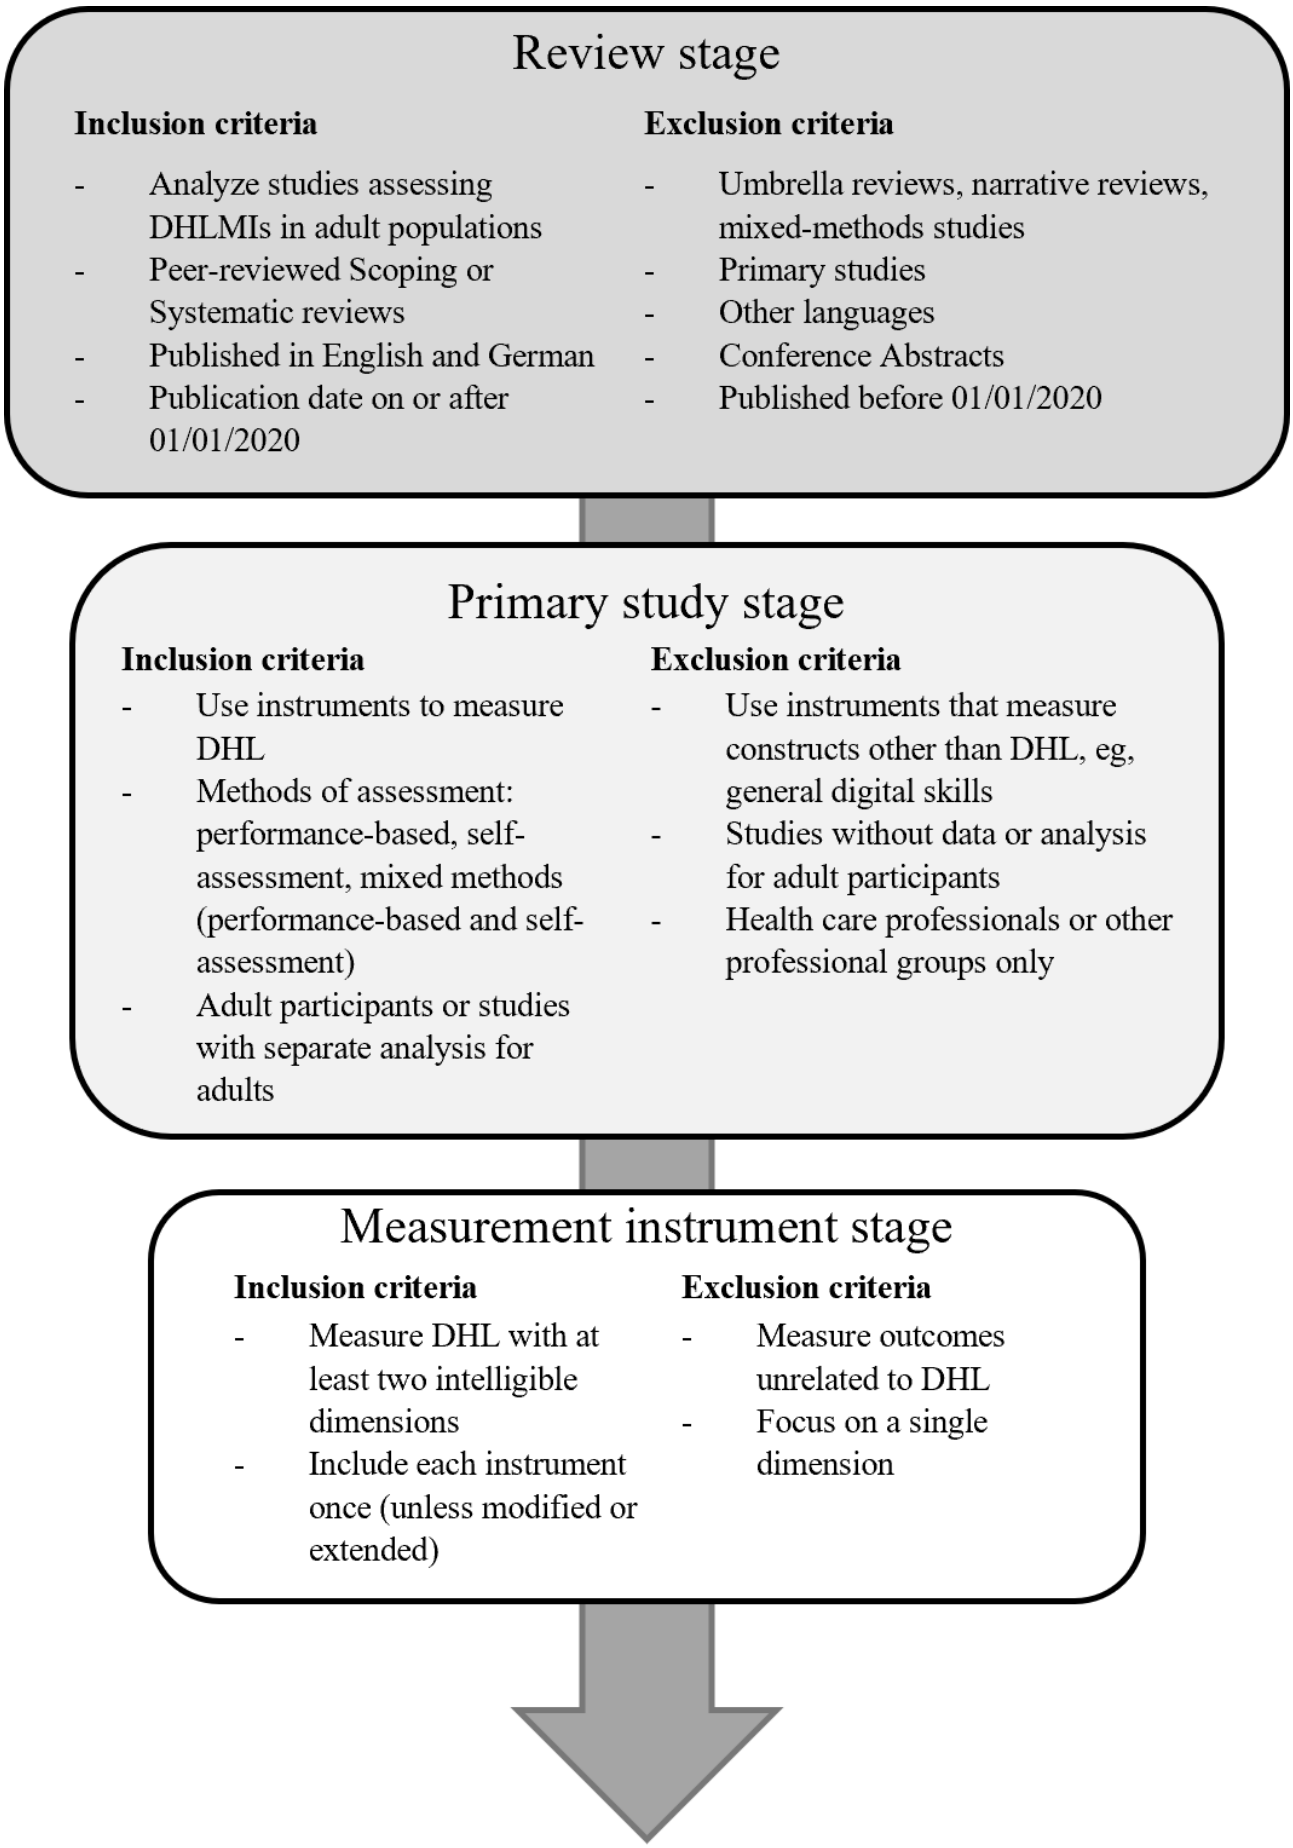
We conducted a narrative overview of reviews, including their primary studies, to provide a meta-level synthesis concerning the aforementioned research aim. We opted for a narrative review because it offers a more flexible structure and is not as strictly bound to a search and evaluation protocol. This allows us to more easily integrate different perspectives, theories, and study types into this study and provide a broader overview of the research field [17]. This approach is particularly suitable for heterogeneous topics where existing research is diverse, making it easier to present and discuss the variety of approaches and findings [18].

Another reason for choosing a narrative review is that it supports our primary objective. Our primary objective was to analyze the dimensions represented in the measurement instruments. This question is inherently qualitative in nature and is best addressed through an interpretive synthesis. Despite our narrative approach, we have applied several systematic principles in key areas of our work, which are described in more detail below.

Search Strategy

We conducted an electronic database search on November 4, 2024, with an additional update search on March 26, 2026. Searches were performed in PubMed and Google Scholar to capture relevant interdisciplinary sources. Furthermore, a forward citation search in Web of Science was conducted as part of the update search to enhance the comprehensiveness of the literature search.

XSL•FO
RenderX



Our search terms included the free text terms: “Digital Health Literacy,” “eHealth Literacy,” “Digital Literacy,” “Digital Health Competence,” “Health Information Literacy,” “Digital Health Skills,” “Digital Health Knowledge,” “Online Health Literacy,” and “Electronic Health Literacy,” in various combinations with the terms “tool” or “instrument” via the Boolean operator “AND.”

Study Selection

A 3-stage inclusion process at the review, primary study, and measurement instrument level was used to arrive at the number of instruments relevant to our analysis (Figure 1).

XSL•FO
RenderX

Figure 1. Inclusion and exclusion criteria. DHL: digital health literacy; DHLMI: digital health measurement instruments.

XSL•FO
RenderX

At the review stage, we included reviews that analyzed studies assessing DHLMIs in adult populations. Specifically, we considered systematic and scoping reviews published in English or German since January 1, 2020, to present the current evidence. In addition, the search periods of the reviews also cover primary studies from earlier years, which, in turn, examine measurement instruments developed at that time. We excluded umbrella reviews, mixed methods studies, narrative reviews, primary studies, and research published in languages other than English or German. Conference abstracts and studies published before January 1, 2020, were also excluded. To focus on the most recent evidence on the topic, we also excluded conference abstracts and studies published before January 1, 2020. At the primary study stage, we included studies that used instruments to measure DHL through self-report methods, performance-based assessments, or a combination of both. We restricted inclusion to studies conducted with adult participants or studies that included mixed age groups if a separate analysis for adult participants was available. Studies conducted exclusively with health care professionals or other professional groups were excluded, as this review focuses on DHLMIs designed to assess personal DHL in the context of individual health management, rather than professional digital health competence applied in clinical practice.

At the instrument stage, we included instruments published in English or German that measured DHL by considering at least two intelligible dimensions. DHL is conceptualized as an inherently multidimensional construct across established theoretical frameworks, including the Lily Model [7], the eHealth Literacy Framework [19], and the Transactional Model of eHealth Literacy [20]. Instruments capturing only a single dimension fail to adequately operationalize this complexity. Therefore, we restricted inclusion to instruments measuring at least two distinct dimensions of DHL. Additionally, we excluded instruments that measured only health literacy without digital attributes or digital literacy without health-related components.

If one measurement instrument was used in more than one study, we only included the instrument once in our analyses, unless the original measurement instrument was supplemented or modified in another study. If a measurement instrument was used in multiple studies, we selected the most recent primary study to ensure that all previous developments and refinements of the instrument were taken into account.

Data Extraction

We developed a standardized data extraction sheet within the research team. All relevant information on the included reviews, primary studies, and measurement instruments—including dimensions, theory, methods of assessment (performance-based or self-assessment), target groups, contexts of use, and purpose—was extracted and recorded in said extraction sheet. Data extraction was carried out by one reviewer (PK) and verified for accuracy and completeness by a second reviewer (LH).

Data Synthesis

To determine which conceptual dimensions (*original dimensions*) were covered by the included measurement instruments, we conducted a structured qualitative content analysis following the approach by Kuckartz [21]. Therefore, we reviewed the dimension definitions and items from each instrument and grouped them into broader categories, which we called *assigned dimensions*. Where dimensions were not explicitly described, the assignment to our categories was based directly on the items. These categories were developed and refined through joint coding by 2 researchers (PK and LH). Differences in coding were discussed and resolved by consensus within the entire research team (PK, LH, and MS). Dimensions for which no clear definitions or corresponding items were available or accessible were excluded from this analysis. Subsequently, the assigned dimensions were systematically grouped into overarching domains.

To assess the prevalence of each assigned dimension, we applied two counts of frequency: (1) frequency across instruments, where a dimension was counted once per instrument regardless of how often it appeared within it; and (2) frequency per original dimension, where each occurrence of the assigned dimension across different original dimensions within the same instrument was counted separately. The latter step was necessary as we found different definitions for the measurement instruments for the assigned dimensions. This dual approach enabled us to capture both the overall representation and the specific distribution of each assigned dimension.

Results

Overview of Included Studies Focusing on DHLMIs

We identified 12 reviews [4,11,12,14-16,22-27] that met the inclusion criteria and were included in our analysis (Table 1).

These reviews were published between 2021 and 2026 and included a total of 589 primary studies. Five (42%) of the included reviews were systematic reviews [4,12,14,24,27], and the remaining reviews were scoping reviews. Seven (58%) reviews examined DHLMIs for specific target groups or settings such as adults living in community environments [4], people in hospital settings [23], older adults [22,24,26,27], or patients of health and social care professionals [25], while the other reviews studied DHL as a generic construct [11,12,14-16]. Four (33%) reviews [4,11,12,14] considered only self-reported measurements, and one (8%) review [16] examined only performance-based measurements. Six (50%) of the 12 reviews investigated both self-report and performance-based measurements [15,23-27]. The median number of primary studies included was 40 (range 2-251). The median number of included instruments was 10, with a range of 2 to 44. The primary studies included in the reviews comprised a total of 170 instruments. After removing the duplicates, a total of 94 instruments remained. Of these 94 instruments, 51 measured DHL, of which 33 met our inclusion and exclusion criteria.

[a]DHL: digital health literacy.

[b]NR: not reported in the reviews.

[c]S: self-reported.

[d]P: performance based.

Overview of DHLMIs

In total, 33 different DHLMIs were identified that met our inclusion criteria (Table 2). These were used 234 times in the primary studies (Table 3). The measurement instruments reviewed by Délétroz et al [14] and Wang et al [15,26] are not included in this count, as none of these reviews reported information on the frequency of use of instruments in primary studies. The most frequently used instruments used in the primary studies included in the reviews were the 8-item eHealth Literacy Scale [6] (n=163, 72%), the eHealth Literacy Questionnaire [28] (n=13, 6%), the Digital Health Literacy Instrument Screening Tool [29] (n=12, 5%), the eHealth Literacy Assessment toolkit [30] (n=8, 3%), the Transactional eHealth Literacy Instrument [20] (n=5, 2%), the Electronic-Health Literacy Scale [31] (n=3, 1%), and the Extended eHealth

XSL•FO
RenderX

Literacy Scale [32] (n=3, 1%). Three instruments (Digital Health Technology Literacy Assessment Questionnaire [33], eHEALS+not specified [34], and Readiness and Enablement Index for Health Technology [35]) were used twice. All other 23 instruments were used in only one primary study [29,36-57].

These were developed between 2006 and 2023. Thirteen (40%) of these were developed in North America [6,20,30,31,37,38,40-42,44,50,53,56], 10 (30%) were developed in Asia [33,34,36,39,43,45-47,51,57], and 10 (30%) were developed in Europe [28,29,32,35,48,49,52,54,55,58]. For most instruments (n=20, 61%), no theoretical basis for the development of the instruments was reported (Table 2) [29,31,35,37,39-41,43,45-48,50,52-58]. The Lily Model served as the theoretical basis for 8 (24%) instruments [6,30,32,34,36,42,44,49]. The remaining instruments not developed from scratch without any theoretical foundation were based on other theories, such as the Transactional Model of eHealth Literacy (TMeHL) [20].

Across all instruments, a total of 209 original dimensions of DHL were identified (Multimedia Appendix 1).

The number of original dimensions per instrument ranged from 2 [33,43] to 22 [53]. The sample size of the studies on instrument development ranged from 15 [29] to 1914 participants [34]. Of these instruments, 12 (36%) were designed for the general population [6,28,30,31,37,47,48,51,54,55,57,58], and 21 (64%) targeted specific population groups [20,29,32-36,38-46,49,50,52,53,56], such as students or older people with chronic diseases. The average age of participants in these studies ranged from 12.9 (SD 0.9) [42] to 71.27 (SD 10.82) years [45]. In terms of gender, 14 (43%) studies had an almost equal proportion of male and female participants [20,30-34,36,44-46,51,54,55,57,58]. In the remaining studies, the study population was predominantly women (n=12, 36%) [29,35,37,40-42,47,49,50,53,56] and men (n=4, 12%) [6,43,52,54]. Three (9%) studies [28,39,48] did not report on the gender distribution in the analyzed population.

The DHLMIs varied in their design: 7 (21%) of the instruments measured DHL on a performance basis [29,37,38,40,47,53,55], 20 (61%) applied self-reported measurements [6,20,28,30-33,35,39,42-46,48-52,57], and 6 (18%) combined both approaches [29,34,36,41,54,56].

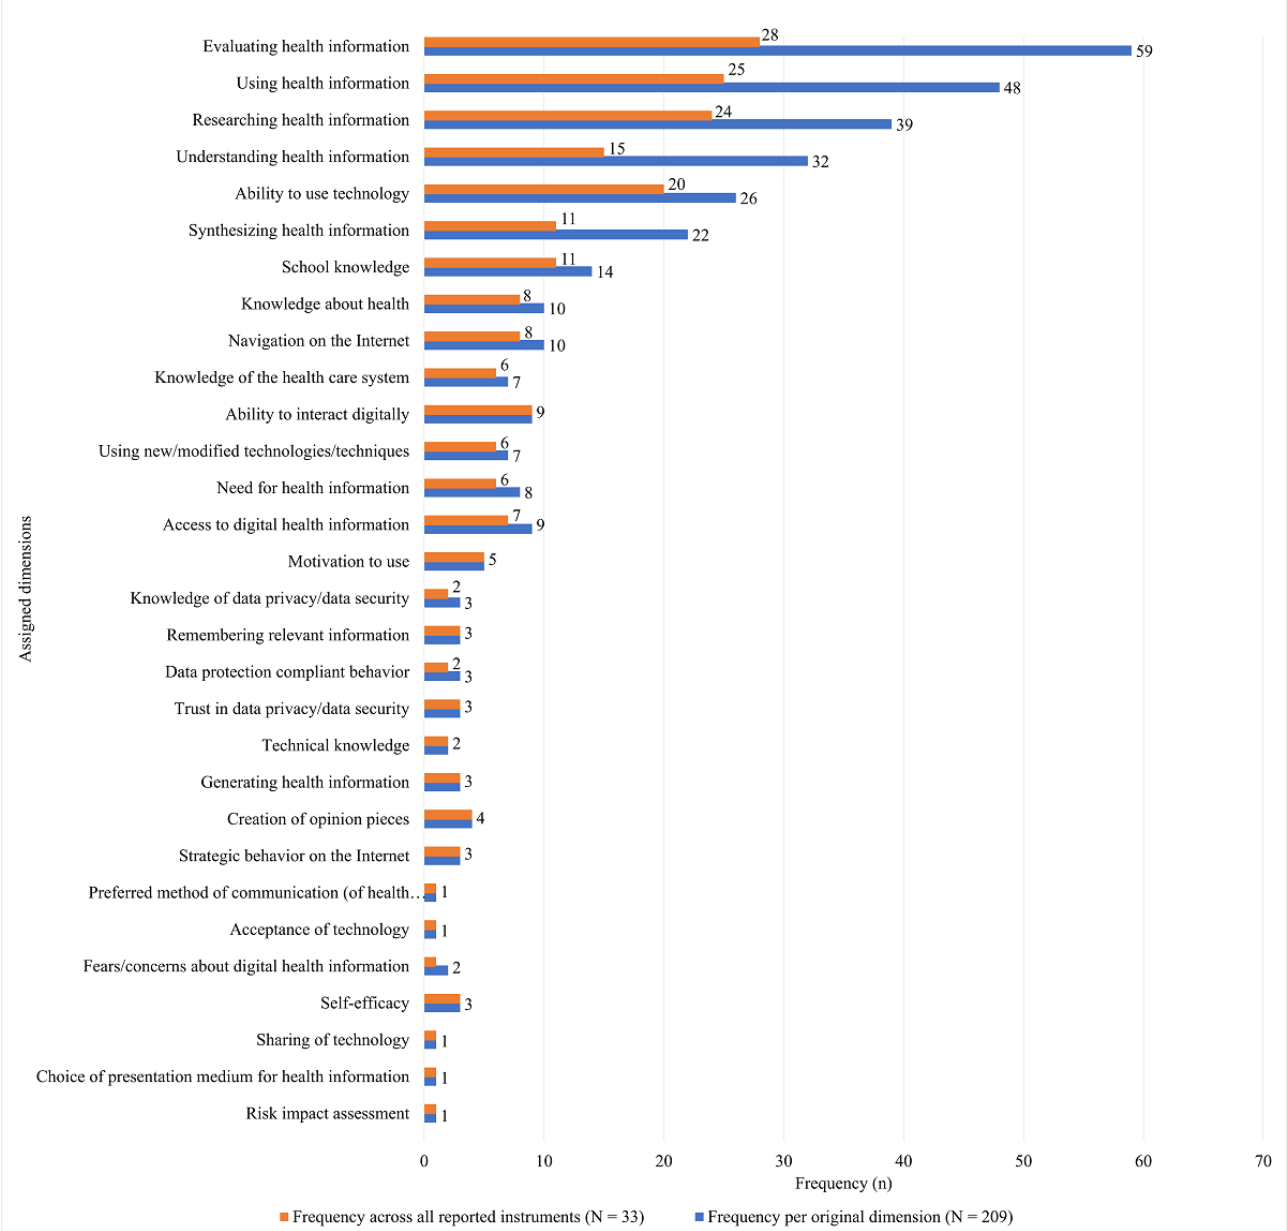
Overview of Assigned Dimensions



The number of assigned dimensions per instrument and per original dimension is shown in Figure 2.

A total of 30 dimensions were assigned during the qualitative content analysis. For some dimensions, a clear categorization was not possible; this occurred in 17 cases for the frequency per original dimension and in 7 cases across all reported instruments. The most frequently assigned dimension was "evaluating health information." This dimension was measured in 28 (84%) of the 33 instruments. This was followed by "using health information" (n=25, 76%), "researching health information" (n=24, 73%), "ability to use technology" (n=20, 61%), and "understanding health information" (n=15, 45%). A very similar order emerged when counting the assigned dimensions according to the original dimensions of the measurement instruments: the dimension "evaluation of health information" was measured most frequently, accounting for 59 of the 209 original dimensions. Consequently, this dimension was operationalized in 59 different ways ("approaches"). The other most commonly reported dimensions were "using health information" (n=48, 23%), "researching health information" (n=39, 19%), "understanding health information" (n=32, 15%), and "ability to use technology" (n=26, 12%).

The assigned dimensions derived from the original dimensions could be sorted into 6 domains (Figure 3): "Action," "Knowledge," "Technology & Privacy," "Preferences/Needs & Motivation," "Risks From Health Information," and "Other." Four of the 5 most used categories (see above) belong to the "Action" domain. The dimensions from the domain "Risks from Health Information" were used least frequently. The domains covered by each instrument are presented in Table 4. A codebook containing the domains, their assigned dimensions, and descriptions is provided in Multimedia Appendix 2.

RenderX

Figure 2. Frequency of use of the assigned dimensions.

XSL•FO
RenderX

Figure 3. Frequency of use of the assigned dimensions by domains. Action includes skills like understanding, using, and evaluating health information, as well as digital interaction and navigation. Knowledge refers to factual knowledge such as understanding the healthcare system, school-taught content, and general health knowledge. Preferences/needs & motivation encompasses preferred formats, need for health information, and motivation to engage with it. Risks from health information involves concerns and perceived risks related to digital health information. Technology & Privacy covers data protection, trust in digital security, technology use and sharing, and technical knowledge.

Discussion

Principal Findings

Our analysis identified 33 DHLMIs from 12 reviews. Almost two-thirds (n=20, 61%) of these instruments were not based on a theory. The majority of the instruments (21/33, 64%) were developed for a specific target group. Most of them (20/33, 61%) assessed DHL via self-report, while only 21% (7/33) relied exclusively on performance-based assessment.

The analysis of the measured dimensions revealed a wide variety of DHL dimensions across the instruments. However, the qualitative content analysis revealed that there are key dimensions of DHL that are captured in almost all instruments, but often under different names. These key dimensions include evaluating health information, using health information, researching health information, and the ability to use technology. Such key dimensions covered by a majority of instruments were defined and operationalized differently throughout the included studies and instruments, severely limiting the comparability of results [59]. This problem could be due to a low discriminant validity of health literacy subconstructs [60], of which DHL is one, with navigational health literacy being another, which partly covers similar constructs [61].

The lack of any theory as a basis for several of the measurement instruments analyzed is especially noteworthy because existing models are based on existing evidence and definitions themselves [7]. Thus, the use of acknowledged models for instrument development ensures content validity [62]. Furthermore, comparability of results of different instruments is more feasible when they are based on the same theoretically sound dimensions [63]. That being said, the wide number of assigned dimensions within our content analysis that applied to more than one original dimension, and, likewise, the number of original dimensions that fit into more than one assigned dimension hint at a limited comparability of the results the measurement instruments we studied will likely gain [59].

Comparability of results, however, is the basis for the generalization of study results and distinguishing between target groups is only possible based on a unified set of dimensions on which said groups might differ [64]. It is because of considerations such as this that researchers call for core outcome sets in the measurement of key dimensions to be measured in evaluation studies [65], not only, but also concerning digital health applications.

We acknowledge that DHL, such as health literacy, is a context-dependent, dynamic construct, with the required competencies varying substantially across societies, health care systems, and target populations [66-68]. This contextual dependency, combined with the diversity of target populations (eg, older adults vs students), application contexts (eg, clinical vs community settings), and assessment methods (eg, self-reported vs performance-based measures), makes developing a single, universal DHLMI a significant challenge. Nevertheless, this does not preclude identifying a common conceptual core. A Core Outcome Set of key DHL dimensions would not prescribe a fixed, universal instrument; rather, it would provide a shared dimensional framework that can be adapted to specific cultural contexts, health care systems, and target populations. This approach would enable researchers to use contextually appropriate instruments while ensuring that a common set of dimensions is covered. This would increase the comparability of findings across studies that use different DHLMIs.

Our qualitative content analysis of DHL dimensions builds on and extends the work of Wang et al [15], who also conducted a content analysis of eHL instrument dimensions. However, the 2 analyses differ in scope due to differences in inclusion criteria, which likely explain differences in the resulting dimension landscape.

Wang et al restricted inclusion to studies whose primary focus was the development of a new DHL instrument, explicitly excluding studies in which instrument development was not the main objective. Furthermore, they included only instruments developed for the general population, excluding instruments designed for specific target groups. Our review, in contrast, included both instrument development studies and application studies—for example, studies evaluating digital health interventions or examining DHL as an outcome in clinical or community settings—as well as instruments developed for specific populations, such as older adults or patients with chronic conditions. This broader inclusion allows our analysis to reflect more closely which instruments and dimensions are actually used in research practice, rather than being limited to the subset of instruments and dimensions prominent in the instrument development literature.

As a result, our analysis captures a broader and more heterogeneous range of dimensions, which may partly be explained by the varying constructs and comparison measures used during instrument development and validation. Instruments were often validated against different related concepts, including health literacy, digital literacy, self-efficacy, or technology use, reflecting divergent assumptions regarding the conceptual boundaries of DHL. This may contribute to the considerable heterogeneity observed across existing measurement tools.

Both our analysis and that of Wang et al confirmed the observation that discrepancies in the conceptualization of DHL across instruments limit comparability—a challenge that becomes even more apparent when the full breadth of instruments in active research use is considered. Comparability and synthesis of research findings are essential to provide informed and comprehensive insights into the current state of DHL. Such insights form the foundation for the development of targeted policies and interventions aimed at strengthening DHL at national and international levels. To date, assessments of DHL have relied primarily on separate primary data collections, such as the national survey conducted in Germany [69]. A more efficient and systematic approach would involve aggregating findings from existing studies through meta-analyses, which allow for a structured integration and comparison of results across contexts and populations, or even across regions and countries. Standardizing measurement instruments would also improve comparability and enable earlier identification of trends, gaps in health care, and emerging needs,

XSL•FO
RenderX

which are critical elements for evidence-based policy-making [70].

For the effective implementation of digital health care solutions, it would be both desirable and necessary—although still rarely practiced—for health care providers to assess patients' DHL before suggesting or prescribing the use of such solutions [71]. This consideration motivated our initial intention to provide a short-form measurement instrument suitable for daily health care practice and its time restraints [23]. Systematic assessment would help ensure that digital solutions reach those who can benefit most, thereby improving both individual health outcomes and quality of care while at the same time reducing health disparities due to a digital divide [23].

The large number of measurement instruments available also poses a challenge for developers of digital health solutions, making it difficult to identify and select appropriate tools for assessing the impact of such interventions on DHL [72]. This issue is particularly relevant in the context of effectiveness assessments, such as those required for approval of the German digital health application. The selection of the most appropriate and meaningful instrument to demonstrate effectiveness remains an open question in this process [73]. Furthermore, the development of digital interventions specifically designed to improve, rather than merely assess, DHL requires a solid theory and validated measurement tools that capture the core dimensions of DHL [74].

Strengths and Limitations

To the best of our knowledge, this is the first review to synthesize both self-reported and performance-based instruments for measuring DHL with a structured qualitative content analysis to systematically analyze and synthesize the dimensions covered by DHLMIs across both instruments developed for the general population and those targeting specific populations. We also provide an overview of available instruments, categorized by target group and a theory. This overview offers a foundation for the refinement of existing or the development of new instruments and serves as practical guidance for researchers, practitioners, and policymakers when selecting suitable tools.

A particular strength of this review is its inclusive conceptual scope. Reflecting the conceptual heterogeneity of DHL, our review systematically mapped all available instruments, not restricting inclusion to those operationalizing health information competencies alone. The resulting dimensional framework therefore extends beyond information-seeking and appraisal to encompass competencies such as technology use, interactive engagement, and the ability to actively generate and share health-related content. These dimensions are directly relevant to the use of digital health services. This broad coverage means that the findings of this review are relevant not only to health information contexts but also to the growing landscape of digital health service use.

However, our review also has limitations. It is neither a full-scale systematic nor an umbrella review [75]. Despite our narrative approach, we have applied several systematic principles in key areas of our work. These include defining a clear research question, applying explicit inclusion and exclusion criteria, describing the selection process for reviews and instruments, conducting structured data extraction, and transparently presenting and discussing the results. Given the systematic nature of our approach in many respects, we considered using the term "review of reviews" but decided against it because our work does not meet all the associated criteria and we did not want to misrepresent our methodology. The chosen narrative format nevertheless seems appropriate, as the research field is conceptually heterogeneous and the included studies vary considerably in methodology and research focus. It is precisely this heterogeneity that precluded a quantitative synthesis of the findings. It should also be noted that the theoretical framework of DHL remains incomplete. Existing theoretical frameworks, including those underlying the 8-item eHealth Literacy Scale and related eHealth competency models, do not yet provide a sufficient basis for the creation of a comprehensive model that covers the many dimensions of this field. When theory is insufficient to capture the complexity of a phenomenon, qualitative and interpretive methods can support concept development. Another limitation is that only measurement instruments that have already been analyzed in a review were taken into account. Therefore, very new measurement instruments, for example, were not included in our analysis. As our study focused on the dimensions of DHL rather than the quality of the measurement instruments, it cannot make any statements about their validity or other quality characteristics. Furthermore, future studies should examine the measuring instruments' test quality criteria to establish a solid basis for further research.

Furthermore, we did not extract data on translated, cross-culturally adapted, or validated versions of the included instruments, as this was not one of the objectives specified in advance for our review. Future reviews of instruments for measuring DHL could systematically document the available language versions and cross-cultural validation studies. This would enable a more comprehensive assessment of the international applicability and dissemination of the instruments and the dimensions of DHL they measure.

Qualitative content analysis was not done independently; however, category formation was done by 2 researchers in open discussion and checked by a third.

When considering the "key dimensions" identified through qualitative content analysis, it is important to acknowledge that they are based on measurement instruments whose validity should be critically examined—particularly those relying solely on self-report [12]. Therefore, while these key dimensions should be interpreted with caution, they still form part of the current evidence base.

Our qualitative approach to analyze the existing instruments allowed us to uncover underlying dimensions of DHL that should be covered by a consolidated instrument in the future. From a purely scientific standpoint, our work underlines the need for instruments that are based on theory as well. Future work on a Core Outcome Set for the evaluation of digital health applications will therefore profit from our work as well.

RenderX

Conclusions

Our review has 3 direct implications for research and practice. First, researchers can use the resulting dimension profiles to make more informed and transparent decisions when selecting an instrument suited to their research question and target population. Second, instrument developers gain an evidence-based starting point for the conceptual grounding of new or revised instruments. Third, the identified dimensional core across instruments provides a foundation for the development of a core outcome set for DHL, which could support greater comparability across studies in the future.

Given the contextual dependency of DHL across different societies and health care systems, the goal is not to develop a single universal instrument but to establish a shared conceptual core of key dimensions that can serve as a basis for culturally and population-specific adapted instruments, ultimately supporting greater comparability of findings across diverse research contexts.

Acknowledgments

We would like to thank Franz Kappert for proofreading the manuscript in terms of understandability and Jesus Escalona for helpful input regarding the qualitative content analysis.

The authors declare the use of generative AI (GenAI) in the research and writing process. According to the Generative AI Delegation Taxonomy [76], the following tasks were delegated to GenAI tools under full human supervision: editing, summarizing text, translation, reformatting, and recommendations. AI tools were not used for any of the following: conceptualization, literature review, methodology, software development and automation, data management, or ethics review. Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Funding

The authors would like to thank the Else Kröner Fresenius Center (EKFZ) for Digital Health for funding the research group “Evidence-based Implementation of Digital Health Solutions” in the context of which this review was conducted.

Authors' Contributions

MS, LH, and JS developed the project proposal together and obtained funding for the project. MS is responsible for the overall project leadership. PK, LH, and MS were responsible for the study design of the review. PK conducted the literature search. PK conducted the data extraction, which was verified for accuracy and completeness by LH and MS. PK and LH performed the qualitative content analysis with input from MS. PK, LH, JS, and MS derived points for discussion and implications. PK drafted the manuscript. All authors critically revised the manuscript for intellectual important content. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

PK declares that she has no conflicting interests. Unrelated to this study, MS received a personal honorarium for speaking engagements from the Saxony Medical Service, the Association of Substitute Health Insurance Funds (Verband der Ersatzkassen e. V.), and the Saxony State Medical Association. Unrelated to this study, LH has received personal grants from Thieme for participation in a discussion board on digital health application in occupational therapy, from the Volkswagenstiftung for participation in a scoping workshop on organizational healthcare research, from the Saxony State Medical Association for a speaking engagement and from Springer Publishing for a first authorship in Das Gesundheitswesen. Unrelated to this study, JS reports institutional grants for investigator-initiated research from the German Federal Joint Committee (G-BA), the Federal Ministry of Health (BMG), the Federal Ministry of Education and Research (BMFTR), the Federal State of Saxony, Novartis, Sanofi, ALK, and Pfizer. He also participated in advisory board meetings as a paid consultant for Sanofi, Lilly, and ALK.

Abstract

Background: Mental health conditions, including depression, anxiety, and psychological distress, are prevalent among the aging population and affect their health, functioning, and quality of life. Access to proper and high-quality mental health treatment is necessary; however, mental health treatment and care remain underused due to stigma, workforce shortages, cost, and mobility limitations. Digital mental health interventions (DMHIs) are emerging as a promising strategy to improve the accessibility and effectiveness of mental health services for older adults, but older adults have historically been underrepresented in DMHI development and evaluation. Additionally, the effectiveness of different types of DMHIs and how age-centered design approaches influence outcomes remain underexplored.

Objective: This scoping review mapped and synthesized evidence on DMHIs focused on adults aged 50 years and older and identified gaps in the evidence base related to study design, age-related adaptations, and clinical outcomes. Specifically, we examined (1) the technologies and therapeutic approaches used, (2) the outcomes and effectiveness of DMHIs, and (3) age-centered adaptations and their outcomes.

Methods: This scoping review searched for studies focusing on DMHIs for older adults across PubMed, PsycINFO, Scopus, Ageline, and Web of Science that were published from 2000 to February 2025. Eligible studies evaluated or described the design of DMHIs targeting mental health conditions among adults aged 50 years or older. Two rounds of independent screening and data extraction were conducted by multiple reviewers. Extracted data included study design, sample characteristics, intervention features, technologies used, age-related adaptations, and clinical outcomes.

Results: Seventy-two studies met the inclusion criteria, of which 36 were randomized controlled trials and 54 reported clinical outcomes. Web-based cognitive behavioral therapy was the most commonly used approach, followed by games, virtual reality, mobile apps, chatbots, and robots. Fifty-four studies reported positive clinical outcomes, most commonly reductions in depression, anxiety, or psychological distress. However, only one-third of the studies incorporated age-centered design adaptations or co-design approaches, such as simplified interfaces, larger fonts, age-relevant content, or participatory development with older adults.

Conclusions: Among studies reporting positive clinical outcomes, DMHIs can reduce depression, anxiety, and psychological distress. However, with only half of the included studies using randomized controlled trial designs, the overall evidence base remains moderate. In addition, age-adaptive design remains underdeveloped. Future research should strengthen trial designs and systematically examine how usability and age-centered adaptations influence DMHI effectiveness.

KEYWORDS

digital mental health interventions; gerontechnology; scoping review; age-adaptation design; cognitive behavioral therapy

Introduction

Mental health conditions, such as depression and anxiety, are prevalent among older adults and can significantly impact their health and quality of life [1]. Although many evidence-based mental health treatments exist, they are persistently underused among older adults [1]. Factors such as stigma [2], transportation barriers [3], a shortage of mental health professionals [4], financial constraints [5], and insufficient insurance coverage [6] are common access barriers faced by many vulnerable populations needing mental health treatments. These access barriers are compounded in older adults due to misconceptions

XSL•FO
RenderX

about mental health conditions, such as the belief that depression is a normal part of aging [7], challenges in identifying and diagnosing certain medical health conditions in later life [1], and more pervasive mental health stigma [8], as well as reluctance to seek help [9].

Digital mental health interventions (DMHIs) are a promising solution to address the growing unmet mental health needs among older adults. Various technologies have been used to deliver mental health treatments, such as smartphone apps, telecommunication tools (eg, SMS text messaging, emailing, and video conferencing), online platforms, computer-based programs, remote monitoring devices, wearable technologies, and virtual reality (VR) [10-13]. DMHIs have been hailed for their scalability, accessibility, efficiency, and potential cost-effectiveness [10,14]. Many DMHIs can be used repeatedly with different patients without losing their therapeutic power and at a reduced marginal cost, making them especially helpful in underresourced settings [15]. Many DMHIs are self-guided, which may provide more privacy for those with internalized stigma toward mental illness and make them more receptive to treatment [16]. In addition, many DMHIs can be accessed anywhere with an internet connection, thus eliminating the need for attending office-based treatments, a significant barrier for those with transportation barriers due to mobility difficulties or driving cessation [17]. Some DMHI modalities, such as internet-based cognitive behavioral therapy (CBT), have a robust body of evidence supporting their effectiveness in mixed-age samples and diverse settings [18-20].

Although the potential of DMHIs is increasingly recognized, older adults have traditionally been underrepresented and sometimes excluded from DMHI development and testing. Despite the age-related digital divide, older adults have increasingly used technologies for health promotion and maintenance, particularly since the COVID-19 pandemic [21]. The increased adoption and acceptance of technology have paved the way for a wider uptake of DMHIs among older adults. Indeed, we have observed an uptick in DMHI studies focused on older adults, including those from socioeconomically disadvantaged backgrounds [22-24]. Given the fast pace of technological advancement and continued interest in DMHIs, a comprehensive and up-to-date review is essential to pinpoint existing gaps and suggest future directions.

The purpose of this scoping review was to systematically scope and map existing evidence on DMHIs focused on older adults. Previous review papers have focused on DMHI trials to evaluate whether they are clinically effective in reducing depression, anxiety, or other mental health symptoms among older adults [25,26]. Different from reviews that primarily provide evidence on intervention effectiveness, this review emphasizes that the success of DMHIs for older adults depends not only on clinical efficacy but also on usability, age-relevant content, and fit with older adults' needs. This review provides more insight into how DMHIs are designed, how age-centered adaptations are incorporated, and how these adaptations may contribute to positive clinical outcomes. Our goal is to move beyond simply asking whether DMHIs benefit older adults. Instead, we aim to stimulate discussions around which program features are most likely to induce behavioral change, identify opportunities for treatment innovation, and provide insights for designing future DMHIs that better meet the needs of older adults.

To this end, this scoping review aimed to (1) describe the types of technologies and program features used in DMHIs for treating and preventing mental health conditions in older adults, (2) assess the range and nature of procedural, content, and technological adaptations made in DMHIs specifically for older adults, and (3) qualitatively explore and summarize the clinical outcomes of DMHIs across various technologies and program features.

Methods

Study Design

A scoping review fits our study aim well, as it allows for a comprehensive mapping of existing studies, identification of gaps in the current literature, summarization of research activities, and dissemination of findings to inform future research, policy, and practice [27,28]. We carried out the review process following the framework developed by Arksey and O'Malley [27] and later refined by Levac et al [28].

Search Strategy

Electronic searches for this study were initially conducted in June 2022 across 5 databases: PubMed, PsycINFO, Scopus, Ageline, and Web of Science. An updated literature search was performed in February 2025 to capture new studies published since the initial search. Multimedia Appendix 1 shows the search terms, which were developed based on the PICO (population, intervention, comparator, and outcome) framework: (1) population: studies involving participants aged 50 years or older; (2) intervention: DMHIs providing treatment and support for mental health conditions; (3) comparator: any comparator or no comparator; (4) outcome: types of technologies used, adaptations made for older adults, and the effects of DMHIs.

Our search was limited to publication years from January 2000 to February 2025, as studies on telepsychiatry began to emerge around 2000 [29]. Only studies reported in English were included. The references of the included studies and relevant review papers were checked for additional relevant studies. If full-text studies were not available, the corresponding authors were contacted. The initial search process was carried out by the first author, and duplicates were removed prior to screening. The inclusion and exclusion criteria, as well as data extraction forms, were drafted by the first author and the corresponding author.

Inclusion and Exclusion Criteria

Table 1 presents the inclusion and exclusion criteria for study selection. Studies were included if they: (1) were empirical studies (qualitative or quantitative) evaluating the outcomes of DMHIs or describing the design process of DMHIs; (2) focused on older adults, defined as studies in which all participants were aged 50 years or older, or where analyses were stratified to isolate treatment effects for this age group; (3) involved interventions targeting mental health conditions commonly experienced by older adults; (4) focused on DMHIs, including web-based interventions, software applications, artificial

XSL•FO
RenderX

intelligence (AI) tools, video game consoles, or wearable technology aimed at addressing mental health conditions; and (5) were written in English.

XSL•FO
RenderX

Table . Inclusion and exclusion criteria.

Element	Inclusion criteria	Exclusion criteria
Population	• At least any kind of mental health conditions (eg, depression, general psychological distress, psychological distress with physical condition, anxiety, posttraumatic stress disorder, and grief) • Aged ≥50 years	• Aged <50 years
Intervention	• DMHI[a] (eg, web-based interventions, software apps, artificial intelligence, video game consoles, and wearable technology)	• N/A[b]
Comparison	• Different interventions (eg, delayed-treatment waitlist control group, waitlist control group, standardized institutional rehabilitation, support from voluntary caregiver associations, placebo control exercise, and conventional care)	• N/A
Outcomes	• Types of technologies being applied, adaptations to older adults, and effects of DMHIs	• N/A
Study design	• Empirical studies (qualitative or quantitative) (eg, RCT[c], single-group studies, observational studies, quasi-experimental studies, and mixed methods studies)	• Review articles • Protocols • Perspective pieces
Language	• English papers	• Non-English papers
Types of mental health problems	• Depression • General psychological distress • Psychological distress with physical condition • Anxiety • Posttraumatic stress disorder • Grief	• Loneliness • Isolation • Sleep disorder
Type of technology	• DMHIs (eg, web-based interventions, software apps, artificial intelligence, video game consoles, and wearable technology for any mental health condition)	• Technologies for monitoring mental health symptoms • Focused on cognitive training or cognitive rehabilitation with the primary goal of improving cognition or managing symptoms of dementia • Chronic disease self-management tools with the primary purpose of improving self-management behaviors among persons with chronic physical health conditions • Primarily aimed to improve health and physical functioning, even if they reported improved mental health outcomes • Telepsychiatry or tele–mental health studies, where services were provided by phone or teleconferencing tools by a human therapist • Focused on electronic health or medical records, decision support tools for clinicians, analytic services, services that primarily provided support and education to health professionals, clinical practice management software, and clinical workflow and communication software

[a]DMHI: digital mental health interventions.

[b]N/A: not applicable.

[c]RCT: randomized controlled trial.

XSL•FO
RenderX

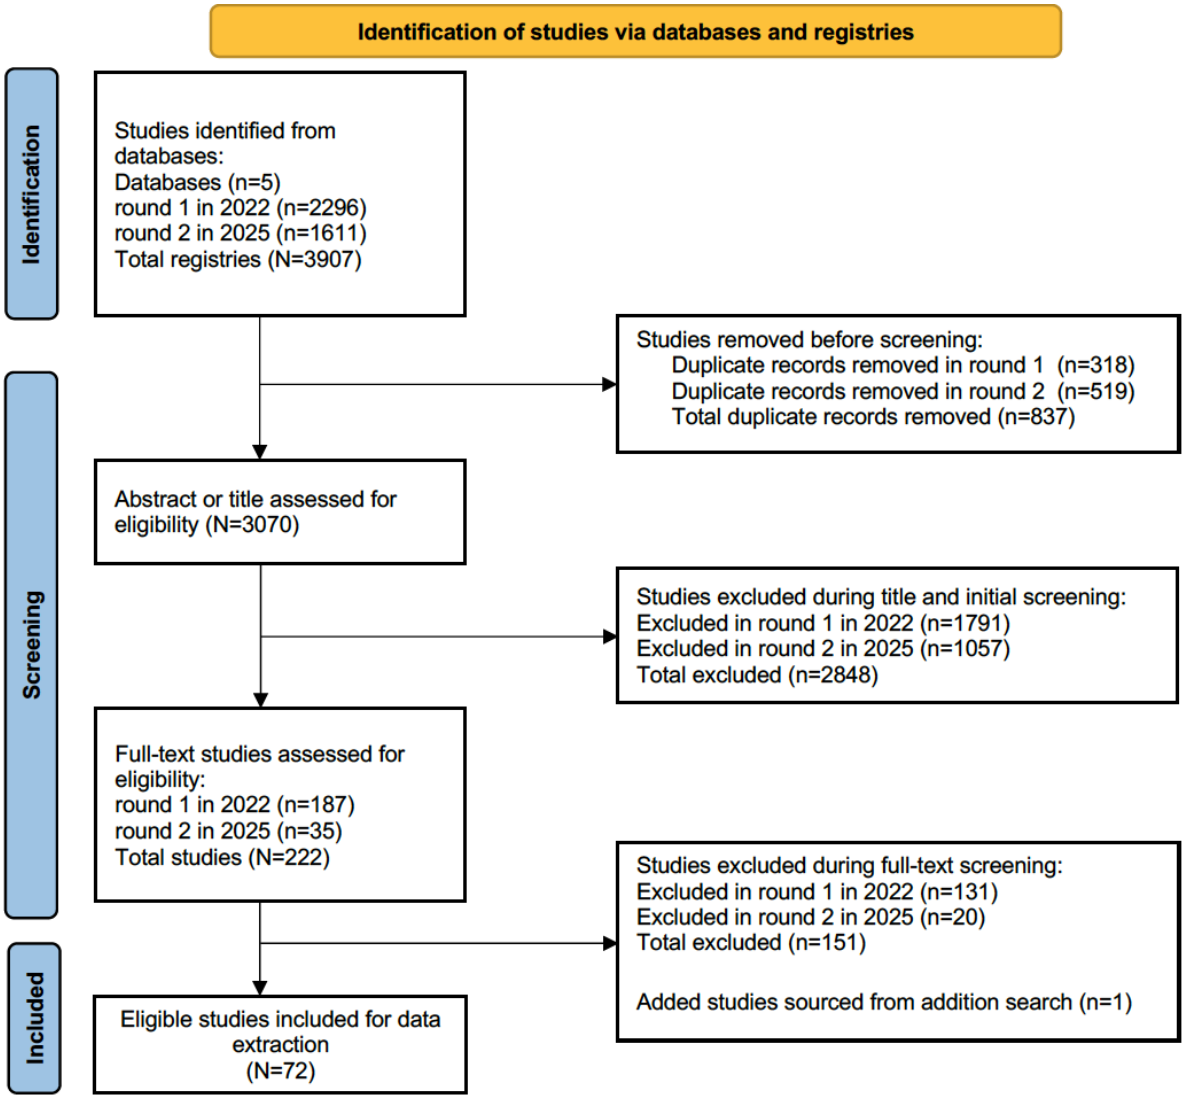
Studies were excluded if they met any of the following criteria: (1) the study sample included individuals under the age of 50 years, and the treatment effects for older adults (≥50 y) were not isolated through stratified analysis; (2) they were review articles, study protocols, or perspective or commentary pieces; (3) the focus was solely on technologies used for monitoring mental health symptoms without a therapeutic component; (4) the primary aim was cognitive training or rehabilitation focused on improving cognition or managing symptoms of dementia; (5) the intervention centered on chronic disease self-management tools with the primary goal of improving self-management behaviors or physical health outcomes, even if mental health outcomes were reported as secondary outcomes; (6) the study focused exclusively on telepsychiatry or tele–mental health interventions delivered by a human therapist through phone or video conferencing; or (7) the study focused on tools such as electronic health or medical records, decision support tools for clinicians, analytic services, educational or support services for health professionals, clinical practice management software, or clinical workflow and communication tools not intended for direct mental health interventions.

In the first round of screening conducted in 2022, 2 reviewers (LZ and JC) independently screened titles and abstracts using the inclusion and exclusion criteria outlined above. A second round was carried out by 2 coauthors (LZ and SJ) in 2025, following the same procedure. Studies meeting all inclusion criteria were retained, and those meeting any exclusion criteria were removed. Disagreements between reviewers were resolved after consultation with the corresponding author.

Data Extraction and Synthesis

Three reviewers (LZ, JC, and CZ) independently extracted data, with discrepancies resolved by the corresponding author. Data were entered and managed in an electronic database. Extracted data included the country of study, recruitment settings, study design, sample characteristics (eg, sample size, mean age, gender composition, and education level), mental health condition of focus, types of technologies, intervention features (eg, mode of delivery, type of device required, theoretical underpinnings, and treatment duration), clinical outcomes, and a narrative summary of key findings.

We summarized study characteristics and created cross-tabulations of key characteristics to conduct a qualitative synthesis and identify common themes. Specifically, we examined the distinctive features of different types of DMHIs, the mental health conditions they targeted, and the extent to which these technologies improved participants' experiences and outcomes.



Results

Study Selection

Figure 1 presents the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of the screening process. This scoping review was conducted and reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines (Checklist 1). A total of 3907 potentially relevant studies were identified across rounds 1 and 2, with 3070 remaining after duplicates were removed. Title and abstract screening yielded 222 studies for full-text review. After the full-text review, 72 studies were included in this scoping review. The screening process was managed using the Rayyan platform (Rayyan Systems Inc).

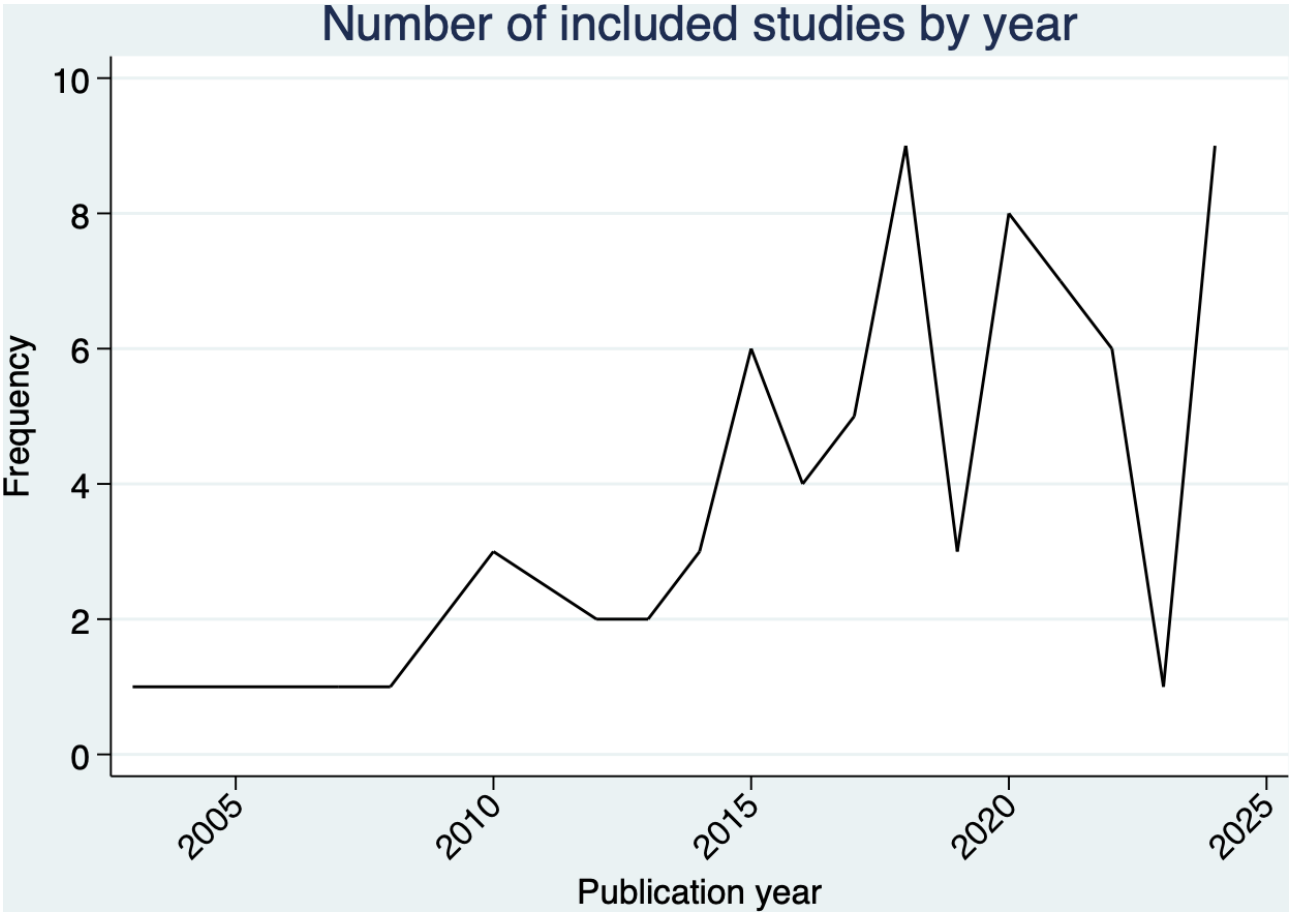
XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

Note on detailed reasons for study exclusion during full-text screening:

- Included participants aged <50 years (Round 1: 73; Round 2: 4; total: n=77)
- Intervention not focused on mental health (eg, focused on physical health, cognitive training, sleep, loneliness or social isolation, or self-management; round 1: 38; round 2: 9; total: n=47)
- Wrong study types (eg, protocol, review, perspective, correspondence, or conference poster; round 1: 8; round 2: 1; total: n=9)
- Not an empirical intervention study (eg, theoretical or conceptual therapeutic paper; round 1: 4; round 2: 0; total: n=4)
- Not a digital mental health intervention (eg, telehealth or SMS text messaging provided by a human therapist; round 1: 5; round 2: 4; total: n=9)
- Study not found (Round 1: 1; Round 2: 2; total: n=3)

Main Characteristics of the Included Studies



Among the 72 included studies, the majority were published after 2015. Table 2 and Figure 2 illustrate an increasing trend in publications since 2020, reflecting the significant expansion and adoption of digital mental health solutions since the COVID-19 pandemic [30].

XSL•FO
RenderX

Table . Number of included studies per year (N=72).

Year group	Value, n (%)
Before and in 2004	1 (1.39)
2005 - 2009	3 (4.17)
2010 - 2014	10 (13.89)
2015 - 2019	27 (37.50)
2020 - 2025	31 (43.06)

Figure 2. Number of included studies published each year.

More detailed study characteristics are presented in Multimedia Appendix 2. The intervention took place across 18 countries, with the largest number of studies conducted in the United States (n=31), followed by Australia (n=10). Other top countries included China, Sweden, Italy, and Finland. This indicates that while the United States and Australia have a strong presence, interest in DMHIs is growing globally. That said, most of these countries represent the Global North. The sample sizes of the included studies ranged from as few as 3 participants to over 900. Most studies targeted older adults aged 60 years and above, with mean sample ages ranging from 55 to 88.2 years. Of the 72 studies that reported gender composition, 65 included more than 50% female participants. Most studies recruited participants through a variety of channels, including long-term care agencies, clinical settings, community centers, and online platforms or websites. Completion rates were generally high, with 47 studies reporting adherence rates of 80% or higher.

Regarding study design, nearly half of the studies (36/72) used randomized controlled trials (RCTs), followed by 14 single-group studies, 10 observational studies, 9 quasi-experimental studies, 2 case studies, and 1 mixed methods study. Among the 36 RCTs, 12 used a waitlist control (WLC), 10 used treatment as usual (TAU), 8 used an active comparator (AC), 2 used delayed treatment, 2 used a placebo control, and 2 combined WLC with AC. Of the 9 quasi-experimental studies, 2 used WLC, 2 used TAU, 4 used AC, and 1 used a combination of TAU and AC. RCTs are generally considered the strongest design for establishing causal effects [31]. Within this group, studies using an AC provide the most rigorous evidence, as they control for nonspecific factors and reduce biases associated with treatment, whereas those using WLC, TAU, or delayed treatment provide more moderate levels of causal inference [32,33]. In this review, 10 of the 36 RCTs used AC as a comparator (or included AC in combination), and 5 of the 9 quasi-experimental studies also incorporated ACs. Overall, these findings suggest

XSL•FO
RenderX

that the evidence base for DMHIs targeting older adults is developing unevenly. Although a substantial proportion of studies used RCT designs, the overall quality of evidence is only moderately strong, as many studies used WLC or TAU designs, which limits the strength of causal inference and interpretation.

Characteristics of the Interventions and Their Clinical Outcomes

More detailed intervention characteristics are provided in Multimedia Appendix 3. CBT was the most commonly used therapeutic approach (n=32), delivered predominantly via websites (26/32) and frequently tailored to meet the needs of older adults. Other therapeutic modalities included mindfulness (n=2), psychoeducation (n=4), and problem-solving therapy (n=2). Less common approaches included life review therapy (n=1), positive psychology (n=1), acceptance and commitment therapy (n=1), cognitive behavioral stress management (n=1), stress inoculation training (n=1), and cognitive restructuring (n=1).

Regarding the targeted mental health conditions, most interventions focused on depression (n=30), followed by general psychological distress (n=11), psychological distress associated with specific physical health conditions (n=12), anxiety (n=8), and comorbid anxiety and depression (n=8). A small number of studies focused on posttraumatic stress disorder (PTSD; n=2) and grief (n=1).

Regarding technology requirements, 16 of the 72 studies required older adults to own a device, 32 provided devices for participants, and 24 did not report this information. This suggests that at least some studies considered technology access and tried to be digitally inclusive. In terms of technology type, the most frequently used was web-based platforms (n=38), followed by games or exergames (n=7), VR (n=6), mobile apps (n=6), and chatbots (n=4). Less commonly used technologies included robots (n=3), video-only programs (n=3), audio-only programs (n=2), voice assistants (n=1), offline platforms (n=1), and wearable devices (n=1).

Regarding the intervention period, 11 studies lasted fewer than 8 weeks, 31 lasted 8 to 12 weeks, 2 extended beyond 12 weeks, and 28 did not clearly report the program duration. In terms of the number of sessions, 52 studies included fewer than 4 sessions, 11 involved 4 to 8 sessions, and 9 had more than 8 sessions. Overall, most interventions were relatively short in duration, clustering within the under-8-week and 8‐to 12-week ranges, while only a few extended into longer-term formats. Interventions with fewer sessions also predominated compared with those involving more intensive or extended session series.

Out of 72 papers reviewed, 54 reported positive clinical outcomes. Among these 54 interventions, the majority—33 (61.11%)—used web-based platforms. Other interventions with positive clinical outcomes included 6 games (11.11%), 5 VR (9.26%), 2 mobile apps (3.70%), 3 chatbots (5.56%), 1 robot (1.85%), 1 offline-platform program (1.85%), 1 video-only program (1.85%), 1 audio-only program (1.85%), and 1 voice assistant (1.85%). These findings show that current DMHIs generally demonstrate benefits to users and that positive outcomes are not limited to a single technology type but are instead distributed across multiple technologies.

Among the 54 interventions that reported positive clinical outcomes, 23 targeted depression as a primary or secondary outcome (42.59%), 8 focused on general psychological distress (14.81%), 8 were designed for psychological distress associated with physical health conditions (14.81%), 6 addressed anxiety (11.11%), 6 targeted both anxiety and depression simultaneously (11.11%), 2 focused on PTSD (3.70%), and 1 on grief (1.85%). These findings highlight that DMHIs have demonstrated effectiveness across a wide spectrum of mental health conditions.

Therapeutic Approaches, Technological Platforms, and Adaptations for Older Adults

Table 3 presents the distribution of DMHIs across different mental health conditions. Web-based platforms were the most commonly used technology across nearly all conditions (total n=38), particularly for depression (n=17), psychological distress with comorbid physical illness (n=7), and comorbid anxiety and depression (n=6). Game-based interventions were the second-most frequently used (total n=7), targeting depression (n=4), and general psychological distress (n=2). These were followed by VR interventions (total n=6), applied across a more diverse set of mental health issues, including depression (n=2), general psychological distress (n=1), psychological distress with comorbid physical illness (n=1), PTSD (n=1), and grief (n=1). Mobile apps (total n=6) were also distributed across multiple conditions, including depression (n=2), general psychological distress (n=1), psychological distress with comorbid physical illness (n=2), and comorbid anxiety and depression (n=1). Other technologies, such as chatbots, voice assistants, audio-only programs, video-only programs, and robots, appeared in smaller numbers.

[a]VR: virtual reality.

Across intervention types, web-based programs, particularly those using CBT, were the most developed and commonly used. These interventions were often applied to depression, anxiety, and psychological distress and were most frequently associated with positive clinical outcomes. However, the larger number of web-based CBT studies does not necessarily mean that this modality is superior to other technologies. Mobile apps, VR, chatbots, robots, and voice assistants appeared less frequently, but they suggest a growing diversification of DMHIs for older adults and may offer opportunities for more interactive, creative, and engaging forms of intervention delivery. However, studies and evidence on these technologies remain relatively limited.

In reviewing the designed features of DMHIs, this study also found that older adults, as users, often faced difficulties with navigating online platforms, limited internet skills, and technical issues. Common issues reported by users included poor web interface usability, accessibility barriers, and content perceived as nonengaging [34]. Low digital literacy further complicated the use of mobile apps and web-based interventions, as many older adults struggled with smartphone navigation, small screen sizes, and technical problems, which limited sustained engagement [35]. Some participants also struggled to see the personal relevance of the interventions, resulting in low sustained engagement. They expressed a desire for greater customization and improved mobile functionality to enhance relevance [36].

In response, adjustments were made to better tailor interventions to older adults' needs. Adaptations to enhance accessibility, usability, and engagement were reported in 23 of the 72 studies, indicating that adaptations tailored to older adults remain relatively uncommon and present substantial opportunities for future development. Among these 23 studies, usability-related design improvements included larger buttons, high-contrast visuals, simplified language, reduced text, and larger fonts in printed training materials [37]. In addition, several interventions used age-specific cases, scenarios, or narratives in educational materials. For instance, the treatment protocol for depression and anxiety was modified by incorporating age-appropriate strategies [38] such as case examples and skill demonstrations tailored specifically for older adults. Similarly, studies also incorporated assistive devices—including sensor pens, tablet holders, and touchscreen tools—to accommodate physical limitations and enhance the accessibility of information and communications technology—communication interventions and information and communications technology—entertainment interventions [39]. Game-based interventions commonly included features such as slower pace, low stimulation, minimal competition, and calming visuals and sounds to match older adults' physical capacities and processing speeds. For example, 1 study [40] designed cognitive control interventions with these features to reduce anxiety and improve engagement. Moreover, participatory design approaches were commonly used to guide product development to better fit the needs of older adults. For example, 1 study [36] used a "blue-sky" approach—a creative, open-ended design process—to create prototypes focused on meeting the unique needs of older adults.

Specific tailoring strategies varied by technology type (Table 4). Web-based interventions (n=13) most frequently incorporated age-friendly design features, such as large fonts, simplified navigation, and age-relevant case examples. Game-based

XSL•FO
RenderX

interventions (n=4), often used in physical exercise programs, reduced difficulty levels and incorporated calming visuals and gentle physical movements, sometimes supported by physical aids. Mobile apps (n=3) offered simplified interfaces and peer support features, with some specifically developed for long-term care settings to address both cognitive and physical health needs. Audio-only and offline platforms (n=2), along with chatbots and robots (n=1 each), incorporated button-based interfaces and multimodal input options (eg, voice and text) to facilitate ease of use and social interaction.

Table . Tailoring of digital mental health interventions for older adults.

Technology type and target mental health conditions (studies)	Tailoring to the needs of older adults
Web-based (n=13)	
Depression (n=7)	• Used age-specific cases or scenarios in educational materials. • Applied age-friendly design features to improve usability, such as larger buttons, high-contrast visuals, simplified language, less text, and larger fonts in printed training materials
Anxiety and depression (n=2)	• Adjusted content using older adults' narratives and experiences
General psychological distress (n=2)	• Incorporated assistive devices, such as sensor pens, tablet holders, and touchscreen tools, to accommodate physical limitations • Used participatory design approaches to tailor product features
Psychological distress with physical conditions (n=1)	• Adapted content from interventions previously proven effective for older adults • Modified materials to align with older adults' mental health needs
Anxiety (n=1)	• Used age-relevant, real-life scenarios and illustrations • Designed therapeutic modules at a slower pace and with less stress to align with users' processing speed
Game (n=4)	
Depression (n=2)	• Adjusted game difficulty to match older adults' physical capacities • Incorporated safety-focused designs considering energy and mobility limitations
Anxiety (n=1)	• Included game features such as slower pace, low stimulation, minimal competition, and calming visuals and sounds
General psychological distress (n=1)	• Incorporated gentle physical activities and encouraged social interaction through gameplay
Mobile app (n=3)	
Depression (n=2)	• Considered care settings (eg, clinical, community, long-term care) in design • Simplified interfaces to support older adults with cognitive and communicative limitations
Psychological distress with physical conditions (n=1)	• Included peer support features targeting both mental and physical health needs of older adults
Audio only or offline platform (n=2)	
Depression (n=2)	• Based on CBT[a] therapist manuals tailored for older adults • Incorporated age-specific examples, larger font sizes, and simplified navigation to improve accessibility
Chatbot (n=1)	
Anxiety and depression (n=1)	• Built on a popular platform already familiar to older adults • Used button-based interfaces and age-appropriate exercise videos to improve usability and relevance

[a]CBT: cognitive behavioral therapy.

In Table 4, there are 4 main types of tailoring strategies synthesized from the included studies: interface adaptations, content adaptations, delivery support, and participatory design. Interface adaptations included larger fonts, simplified

XSL•FO
RenderX

navigation, high-contrast visuals, button-based interfaces, and reduced text. Content adaptations included age-relevant examples, older adult narratives, slower pacing, and scenarios reflecting later-life experiences. Delivery support included technical assistance, coaching, device provision, and assistive tools to reduce barriers related to digital literacy and physical limitations. Finally, there are also a few interventions that incorporated participatory approaches, in which older adults contributed to intervention development, prototype testing, or usability refinement. All 4 types are important, but they have been developed to different degrees. In existing DMHIs, age-centered design is most often implemented through usability modifications, while deeper forms of participatory development and systematic testing of adaptation strategies remain limited.

Although the reviewed studies did not directly test whether age-related adaptations and specific features themselves contributed to clinical improvements, several features appeared to frequently co-occur with positive engagement with the intervention or clinical outcomes. For example, interventions that provided personalized support, such as coaching or technical assistance, often reported higher engagement and adherence. One example is the Empower@Home program, an intervention whose intellectual property is owned by the Regents of the University of Michigan and which was developed by the author XX and her team [37]. Similarly, programs incorporating social interaction components, such as peer support or group activities, were found to reduce loneliness and improve psychiatric self-management [10]. Age-appropriate content, scenarios, and illustrations were also present in several effective interventions [37,38], while interactive, feedback, and motivational elements appeared in programs with both psychosocial and physical benefits [41].

Taken together, these patterns suggest that age-friendly and age-centered design features may enhance the acceptability and potential benefits of DMHIs for older adults. However, because previous studies did not explicitly test the effects of individual design elements—aside from a few qualitative and mixed methods studies that explored these issues [37,42]—future research should examine these features systematically to clarify their specific contributions to engagement and outcomes.

Discussion

Summary of Study Findings

This scoping review provides an overview of the current development of DMHIs targeting older adults. These DMHI programs have used a range of technologies, such as web-based platforms, mobile apps, VR, and chatbots. In recent years, the rapid development of AI has offered new possibilities for personalizing and adapting DMHIs even further. However, we identified few studies that used AI. This may partly reflect the limitations of not including specific AI-related terms in the literature search and our general focus on digital interventions, as well as the typical lag between recent technological innovation—such as the large language model boom in industry—its adoption in real-world products, and subsequent academic work [43]. As emerging technologies like AI continue to advance, future research on DMHIs for older adults should incorporate the evolution and upgrading of technology and examine how these exciting changes shape intervention design, delivery, and evaluation, as well as how emerging technologies can be integrated ethically and effectively into DMHIs targeting older adults in real-world practice [44].

This review also informs us that, beyond technological innovation, tailoring products to older adult users' needs and making products aging-appropriate are also important. The active participation of older adults in both the design and evaluation stages can help make products accessible, usable, and age-friendly. Evidence suggests that involving older adults throughout the design process helps ensure that interventions align with users' needs and preferences, which can improve both engagement and effectiveness [45,46]. However, this review found that only a few studies applied a co-design approach to developing or evaluating DMHIs for older adults—for example, a co-design workshop to test a chatbot prototype [47] and a brainstorming session on mobile app design [36]. Future DMHI design or adaptation should consider actively engaging older adults across all stages to help ensure that interventions are culturally and contextually relevant.

Regarding age-adaptation design, in this review, 31.94% (n=23/72) of the included studies developed or tested interventions that incorporated older adult–centered features to enhance usability and engagement, which shows that current DMHIs with older adult–centered design are underdeveloped to some extent. One possible reason is that many interventions are originally designed for the general population and then adapted for older adults during the launch or usability testing stage to expand the user market [48,49]. This indicates an existing gap between the growing realization of the importance of older adults as target users and the development of underlying design principles for age-centered tailoring in intervention development or improvement.

Also, prior research has highlighted the unique challenges that older adults face when using DMHIs, including usability barriers, accessibility issues, and difficulties integrating technology into daily routines [50]. Many of the interventions in these 23 studies incorporated age-friendly design features, such as larger buttons, high-contrast visuals, simplified language, and larger fonts to accommodate physical and cognitive limitations, which aligns with the aim of overcoming the challenges mentioned above. These 23 studies also inform us that most age-related adaptations are simple and focus on improving ease of use and accessibility tailored to older adults, which also echoes previous studies that caution that complex or visually "fancy" interfaces do not necessarily improve outcomes; rather, simple and accessible designs tend to be more usable and acceptable [14,50].

Regarding future research and practice, the review establishes multiple essential research paths that will help scientists and practitioners enhance their understanding of DMHIs for older adults. First, this study revealed that while nearly half of the evaluation studies used RCT designs, most studies used waitlist or TAU control groups as their comparison conditions. These research designs may limit the ability to establish clear cause-and-effect relationships and may also produce exaggerated

XSL•FO
RenderX

treatment outcomes [31]. Future research should strengthen methodological rigor by using RCTs with active comparison groups and longer follow-up periods. In addition, future evaluations should not only assess clinical effectiveness but also examine whether interventions are usable, accessible, and appropriate for older adults in real-world settings.

Second, the studies presented in Tables 2 and 3 demonstrate that most investigations took place in high-income countries, particularly Australia and the United States, while minority groups and people from low- and middle-income countries remained underrepresented. This limited representation restricts the generalizability of the findings and may contribute to digital health disparities, as interventions developed in resource-rich settings may not reflect the needs, preferences, language backgrounds, cultural contexts, or technology access barriers of diverse older adult populations. From a participatory design perspective, the development of inclusive DMHIs requires researchers to actively involve diverse older adults and community stakeholders throughout the design, adaptation, and evaluation process [48]. Future research should, therefore, expand studies in low- and middle-income countries and among diverse older adult populations to better address mental health disparities [51].

Third, this review found that only about one-third of studies incorporated usability adaptations or age-centered design strategies, while most did not sufficiently address digital literacy, technology accessibility, or user interface challenges faced by older adults. From a universal design perspective, DMHIs should aim to reduce barriers related to accessibility, usability, health literacy, sensory changes, and technology confidence, while avoiding the assumption that older adults are a homogeneous user group [52]. Gerontechnology frameworks similarly emphasize the importance of aligning technological design with the physical, cognitive, emotional, and social dimensions of aging [53]. Therefore, future interventions should move beyond simply adapting existing digital tools for older adults and instead use more theory-informed and participatory approaches to age-centered design.

Limitations

This scoping review has several methodological limitations that should be considered when interpreting the findings. First, our search strategy was intentionally broad to capture the wide range of DMHIs. While this approach allowed us to map the landscape of existing interventions, it may have missed studies in niche areas that use more specialized terminology. For example, we did not include more specific terms such as machine learning, deep learning, natural language processing, large language model, and generative AI. Therefore, our review may have limited the inclusion of AI-powered interventions. As AI-enabled DMHIs may differ from traditional DMHIs in terms of user interaction, data use, data safety, and ethical risks, the lack of inclusion of AI-enabled DMHIs may limit our ability to capture important trends in this rapidly emerging area of DMHI research. Second, as a scoping review, our goal was to describe and categorize the types of technologies, intervention designs, and adaptations rather than to evaluate intervention efficacy quantitatively. Because we included a wide variety of study designs, intervention types, and outcomes, our ability to compare or quantitatively synthesize the study findings was limited. Another limitation is that we did not conduct a formal quality appraisal or risk-of-bias assessment in this study. While formal quality appraisal is not always required for scoping reviews, the absence of such an assessment limits our ability to evaluate the methodological rigor of each study. Because studies with different designs, samples, comparison conditions, and follow-up periods were synthesized together, this study provides a descriptive overview that scopes and maps the current evidence rather than offering evidence of intervention effectiveness or study quality across all included studies. Future reviews with a narrower scope could conduct formal quality appraisal and quantitative synthesis to better assess intervention effectiveness. Third, the quality of individual studies was not systematically assessed. Judging by the range of study designs included, many interventions would benefit from more rigorous evaluation methods, such as RCTs with adequate sample sizes and follow-up periods. In addition, we only included studies published in English, which likely explains why most included studies were conducted in Western or Global North countries. Finally, we primarily included peer-reviewed journal studies and may have missed gray literature, potentially leading to publication bias.

Conclusions

This review examined the increasing yet unequal growth of DMHIs, which provide services to adults who are 50 years or older. The 72 studies demonstrated that DMHIs using web-based interventions and other digital tools, including games, VR, mobile apps, chatbots, and robots, produced positive results for the treatment of depression, anxiety, and psychological distress in older adults. The current evidence supporting DMHIs for older adults remains moderate because most studies lack active comparison groups and fail to demonstrate real-world implementation. The research found that age-related adaptations and co-design methods to address age-specific design requirements and usage remained limited throughout the study. Future research needs to establish trials with active comparison groups and extended observation periods, as well as conduct studies on DMHI implementation in regular health care services and community-based environments while including diverse older adult groups and testing user-friendly features with technology training and access support to develop better DMHIs for older adults.

Abstract

Background: Aging populations worldwide face increasing health care demands, particularly for chronic disease management. While telemedicine offers a viable solution to enhance health care access, significant trust-related barriers hinder its adoption among older adults, warranting a scoping synthesis of available evidence.

Objective: This scoping review aims to map the available evidence on trust barriers experienced by older adults in telemedicine, identify underlying vulnerability domains, and chart the evidence base for design and policy recommendations.

Methods: We conducted a scoping review in accordance with PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines, analyzing literature from PubMed, Web of Science, and Scopus. Thematic analysis was applied to synthesize findings from 30 included studies.

Results: Four primary trust barriers were identified: technophobia and technical difficulties, privacy and data security concerns, negative emotional and social impacts, and a strong preference for in-person care. These barriers mapped onto 4 vulnerability domains: limited telemedicine literacy (particularly low eHealth self-efficacy), declining health status (including sensory and cognitive impairments), psychological and cognitive factors (such as anxiety about losing autonomy), and inadequate social support systems. The review also underscored how rapid technological change amplifies these challenges for older adults.

Conclusions: Effective telemedicine implementation for older adults requires multipronged interventions, including age-appropriate interface design, targeted digital literacy training, robust privacy protections, and personalized support systems. These approaches address both technological and psychosocial barriers, potentially increasing engagement while mitigating vulnerabilities. Future research should assess the effectiveness of these interventions across diverse older populations.

KEYWORDS

trust; vulnerability; telemedicine; older adults; digital health; health equity

Introduction

Background

As demographic transitions advance, characterized by declining fertility and increasing mortality in most countries, along with increased life expectancy due to the decline in deadly infectious diseases, there has been a remarkable increase in global population aging. It is estimated that by 2050, the worldwide aging rate will rise to 15.9%, with projections indicating it could reach 22.4% by the year 2100 [1,2]. Aging populations present a growing health care challenge, as older adults often require care for chronic diseases such as heart conditions, diabetes, or respiratory issues. Traditional in-person health care, hindered by mobility limitations, transportation difficulties, and frequent appointments, is often inaccessible, while telemedicine offers a promising alternative to enhance convenience [3-5].

Telemedicine can be broadly defined as the use of telecommunication technologies to provide medical information and services [6-9]. In practice, it encompasses a suite of resources designed to facilitate communication between patients and health care providers, including online consultations, remote monitoring, and virtual rehabilitation. Nevertheless, addressing trust-related challenges is essential for the widespread adoption of telemedicine, particularly among older adult populations [7,10-12].

Trust is commonly defined as the willingness of trustors to accept vulnerability, and the level of vulnerability at the individual level is key to understanding trust [13-15]. Perceived trust issues have been documented in existing research among

XSL•FO
RenderX

older adults, including the use of digital health technologies [9,16,17], concerns about information privacy [18,19], and doctor-patient interaction [14-16]. Trust deficits among older adults have been identified as substantive obstacles to telemedicine uptake, limiting service acceptance and access to health care [20,21].

While prior studies have highlighted the trust issues that older adults encounter in telemedicine, a critical knowledge gap remains. Although trust is commonly defined as an acceptance of vulnerability [13-15], more research has emphasized surface-level factors underlying trust concerns. The deeper dimensions of vulnerability that directly shape trust perceptions remain underexplored. Because vulnerability is not simply an outcome but an intrinsic element of trust dynamics, it cannot be overlooked. In this review, we conceptually distinguish trust barriers as the observable manifestations of distrust or resistance in the context of telemedicine, and vulnerabilities as the underlying predisposing states or conditions that create susceptibility to these barriers. This distinction follows Hamm et al [13], who define vulnerability as an intrinsic antecedent of trust dynamics rather than an outcome. Without clarifying how specific vulnerabilities manifest and interact among older adults, strategies to enhance trust in telemedicine risk lacking the precision necessary to dismantle entrenched barriers and improve health care access for this population.

Objective

This scoping review aims to map the available evidence on trust barriers in older adults' telemedicine use; chart how these barriers link to underlying vulnerability dimensions, and as an exploratory extension; and identify practice-informed design recommendations. At present, in the field of gerontechnology and digital health, it remains unclear how trust-eroding factors in telemedicine are interrelated with the vulnerabilities of older adults at the individual, interpersonal, and system levels.

To achieve this, the study focuses on 4 interconnected research questions (RQs), informed by established digital health frameworks (eg, the Technology Acceptance Model for Mobile Health) [22,23] and extended to center on dimensions of vulnerability:

- RQ1: What evidence exists regarding the adoption of telemedicine among older adults in existing research?
- RQ2: What trust-eroding factors in telemedicine are documented among older adults, and how do they vary across individual, interpersonal, and systemic levels?
- RQ3: How do these trust-eroding factors correlate with specific dimensions of vulnerability at the individual, interpersonal, and systematic levels?
- RQ4: What intervention strategies can address these vulnerabilities and enhance trust in telemedicine?

These questions operationalize a multilevel analytical lens, encompassing the individual level (eg, declining health status, sensory impairments, and limited digital literacy) [24,25]; the interpersonal level (eg, patient-provider communication patterns [26,27], caregiver support, and peer influences on technology perceptions); the systemic level (eg, data privacy regulations, platform design standards, and the availability of technical support infrastructure) [24,25,28-30]; and the cumulative interactions across levels [31,32].

By synthesizing the current state of knowledge, this study aims to advance theoretical understanding of how vulnerability shapes trust dynamics in aging populations. It moves beyond surface-level trust factors to examine their root causes within layered vulnerabilities. Practically, it seeks to inform scalable, evidence-based interventions that enhance telemedicine acceptance and effectiveness, bridging empirical insights with real-world solutions.

Methods

Overview

A scoping review, combined with thematic analysis, was conducted to examine trust barriers experienced by older adults in telemedicine and their associated vulnerabilities. Scoping reviews are valuable for rapidly mapping key concepts, primary sources, and evidence types within a research area, particularly in complex or underexplored fields [33,34]. This approach is especially effective for (1) identifying the scope of available literature on a specific topic, (2) providing an overview of key concepts, and (3) identifying gaps in the research landscape [35-39]. In contrast, systematic reviews primarily synthesize quantitative outcomes to assess intervention effectiveness [38-40].

Given the fragmented and limited research on the determinants of trust and associated vulnerabilities in telemedicine adoption among older adults, a scoping review with thematic analysis was selected as the methodological approach. Existing studies have largely emphasized surface-level trust issues without systematically exploring the underlying dimensions of vulnerability that shape these perceptions. This omission has left a significant gap in understanding how technological, informational, and relational vulnerabilities interact to influence trust in telemedicine. To address this gap, the combined scoping review and thematic analysis was deemed most appropriate.

Thematic analysis was employed to analyze the qualitative data extracted from the included studies. This approach offers a flexible yet rigorous method for analyzing textual data, enabling the identification, analysis, and reporting of patterns (themes) within the data [40,41]. Thematic analysis was chosen to provide a rich, nuanced understanding of the factors influencing older adults' trust in telemedicine. Examples of studies employing a combined scoping review and thematic analysis approach exist in diverse fields such as medicine, education, and sociology [42-45]. Thematic analysis followed an inductive approach [46], proceeding in 6 stages: familiarization with data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and producing the report. Initial coding was performed by the lead author. To establish interrater reliability, the second author independently coded approximately 30% of the extracted excerpts. Interrater agreement was substantial (Cohen κ=0.78) [47]. Discrepancies were resolved through consensus discussion with all of the coauthors. Thematic saturation was considered achieved when the final 5 studies reviewed yielded no new codes.

XSL•FO
RenderX

The study was conducted and reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines (Checklist 1), an evidence-based framework consisting of a 4-phase flow diagram and a 27-item checklist to ensure methodological rigor and transparency in scoping reviews [48-50].

Searching and Screening Process

Electronic searches for this scoping review were conducted in May 2025, timed with the World Health Organization (WHO) Global Strategy on Digital Health 2020 to 2025, post its mid-2025 progress review to capture up-to-date evidence on older adults' digital health. Three significant databases were considered as primary sources, namely PubMed, Web of Science, and Scopus, as they include subjects such as health, aging, medicine, digital technology, communication, and psychology.

Before finalizing the search strategy, we explored the 3 databases using key concepts such as "telehealth," "trust," and "vulnerability." Keywords were expanded based on the initial search results. Next, a unified search term incorporating Boolean operators was utilized across all databases:

((((trust AND (vulnerability OR vulnerable)) AND (telemedicine OR telehealth OR eHealth OR mHealth)) AND (elderly OR older adults OR old people)) AND patient).

In PubMed, searches were conducted using both free-text keywords and MeSH terms (eg, "Telemedicine" [MeSH], "Aged" [MeSH], and "Trust" [MeSH]) to ensure comprehensive coverage. The search covered all publication years and was limited to English-language sources. To ensure methodological rigor, only peer-reviewed journal papers and review papers were included.

Inclusion criteria were as follows: (1) studies must directly address trust issues or the vulnerability of old patients in telemedicine; (2) study participants must be aged 55 years or older, or include a dedicated analysis of a group over 55 years old. Reviews with unreported demographics were included only if 75% or more of their synthesized studies explicitly focused on older adults (eg, through keywords such as "geriatric" or "aging"); and (3) studies must be patient-centered and conducted from the patients' perspective.

Exclusion criteria included (1) non–peer-reviewed and nonscholarly materials, such as conference papers, book chapters, reports, design work, personal interview reports, newspaper articles, and other nonacademic publications; (2) studies with missing data or requiring paid access beyond institutional subscriptions, due to practical accessibility limitations; and (3) on PubMed, papers not based on human subjects were specifically excluded. These criteria ensure that the review's findings directly inform its research questions regarding enhancing trust in telemedicine among older adults.

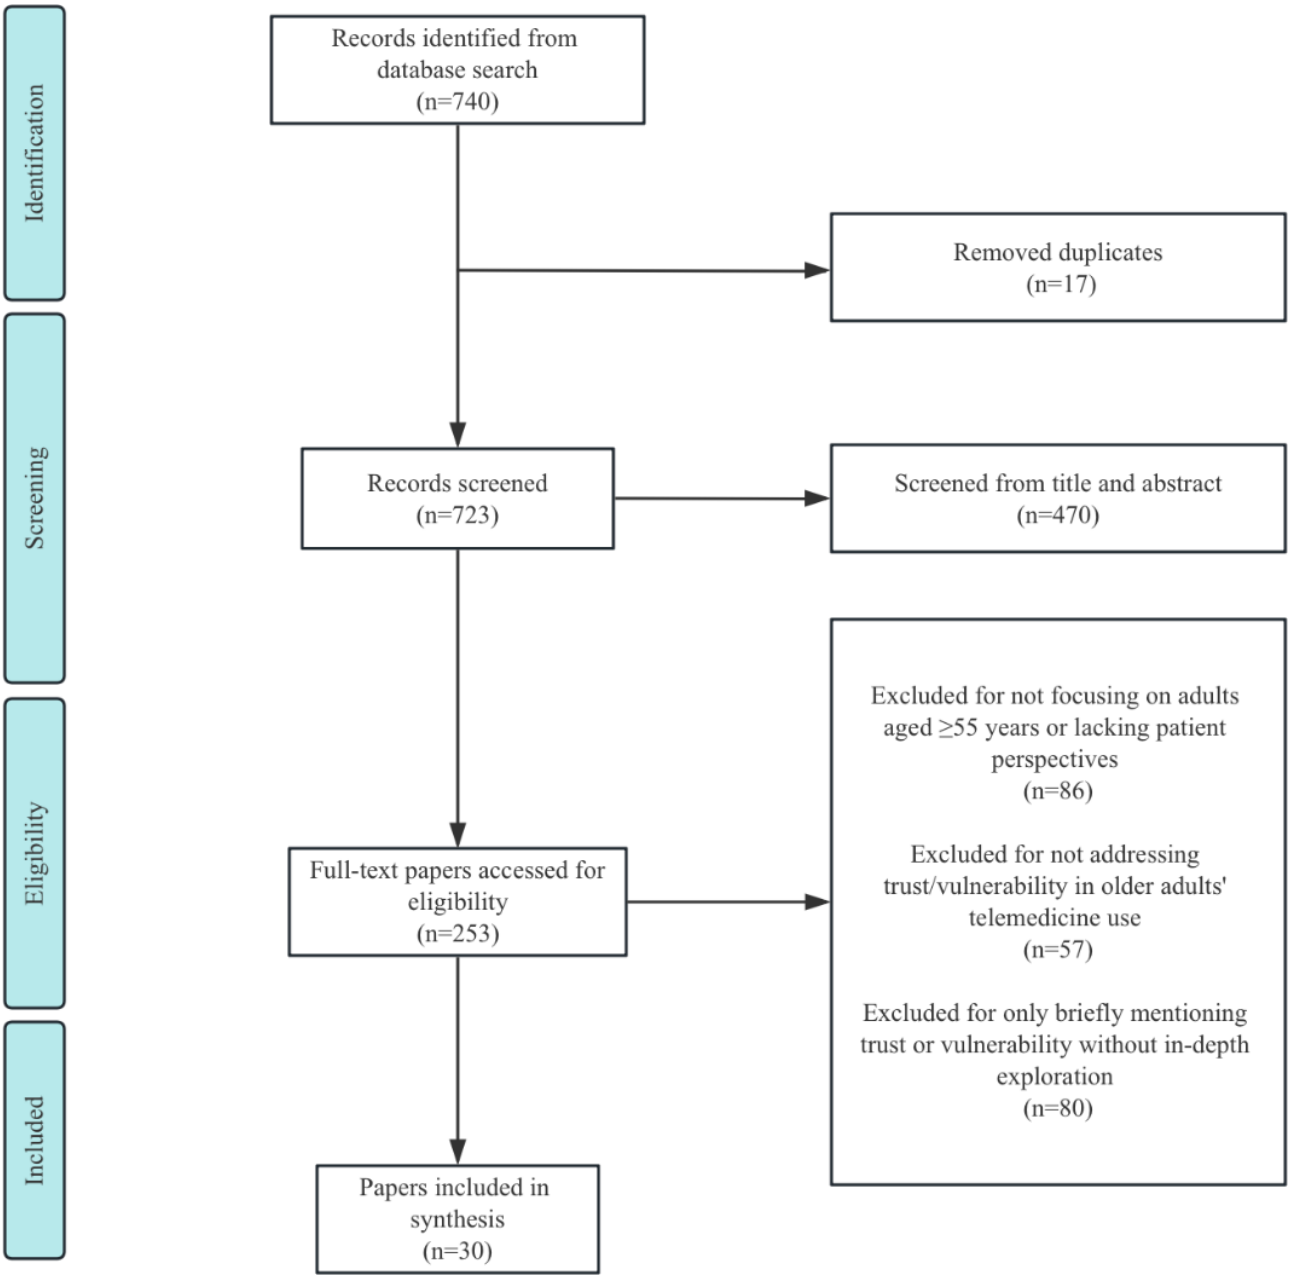
Overall, the search yielded 740 publications across 3 databases, which was reduced to 723 after duplicates were removed using EndNote 21.4 (Clarivate Analytics). The first author independently screened titles and abstracts for relevance, followed by a second round of eligibility assessment. Of these, 253 studies met the inclusion criteria and proceeded to full-text review.

Papers that did not focus on older patients aged 55 years or older or did not discuss issues from the patients' perspective were excluded (86/723, 11.9%), as were papers that did not capture trust issues or the vulnerability of older patients in telemedicine (57/723, 7.9%). In addition, we discarded papers that only briefly mentioned trust and vulnerability without exploring these concepts in depth (80/723, 11.1%). Specifically, studies that referenced trust and vulnerability in passing—such as in the introduction or discussion—without providing a focused analysis, dedicated sections, or empirical evidence directly addressing these concepts were excluded. This decision was made by assessing the relevance of trust and vulnerability to the study objectives, methodologies, and findings.

Data extraction was performed using a standardized charting form developed iteratively. The form was piloted on 5 randomly selected included studies and refined by the research team to ensure completeness and consistency. The final charting form captured the following variables for each included study: (1) author(s) and year of publication, (2) journal and study design, (3) participant age range and sample size, (4) geographic focus and country, (5) telemedicine modality, (6) specific trust barriers identified, and (7) vulnerability dimensions reported. Two independent reviewers performed data extraction, and discrepancies were resolved through discussion or consultation with a third reviewer. Extracted data were cross-verified by both reviewers.

Findings were synthesized using inductive thematic analysis, following the six-phase framework described by Braun and Clarke [46]: (1) familiarization with the data through repeated reading of the extracted text, (2) generating initial codes applied to trust-barrier and vulnerability-related content, (3) searching for themes by grouping related codes, (4) reviewing themes for coherence and distinctiveness, (5) defining and naming final themes, and (6) producing the synthesis report. Codes and emerging themes were discussed among coauthors to enhance interpretive rigor.

Results



Characteristics of Included Studies

The final sample comprised 30 studies, of which 28 (93.3%) were published between 2020 and 2025 and only 2 (6.7%) prior to 2020. This dominance of post-2020 publications reflects the rapid expansion of telemedicine research during the COVID-19 pandemic, as the public health crisis heightened the need for remote health care solutions. The included studies consisted of quantitative research (11/30, 36.7%), qualitative research (8/30, 26.7%), mixed-methods research (1/30, 3.3%), and reviews (10/30, 33.3%). The 11 quantitative studies (typically large cross-sectional surveys using validated scales) provide the strongest evidence for the relative prevalence of specific barriers. The 8 qualitative studies offer contextually rich descriptions of lived trust experiences, capturing mechanisms that quantitative measures may not fully detect. The 10 review papers

XSL•FO
RenderX

(comprising 5 scoping reviews, 2 systematic reviews, 1 rapid review, 1 realist review, and 1 narrative review) synthesize broader evidence but introduce additional heterogeneity across populations and contexts. The descriptive characteristics of all included studies are presented in Multimedia Appendix 1. A total of 30 papers were included in the review, and the extraction procedures are presented in Figure 1.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram of the study selection process for the scoping review.

Geographic and Economic Distribution of Studies

The included studies were conducted across 12 countries, with China contributing the largest number (7/30, 23.3%), followed by the United Kingdom (3/30, 10%) and the United States (2/30, 6.7%). Other contributing countries included Germany, Sweden, the Philippines, Malaysia, India, Australia, New Zealand, and Finland (each with 1/30, 3.3%). Geographic coverage revealed a stark imbalance: most studies (28/30, 93.3%) focused on high-income regions (Europe, North America, and parts of Asia), with very few addressing low- and middle-income countries, underscoring a global equity gap.

Population size varied by study design. Quantitative studies had larger samples (111 - 1852 participants), whereas qualitative studies (including mixed-methods research) had smaller samples (6 - 98 participants). For review papers, the number of included studies ranged from 10 to 193, except for 1 narrative review that did not report a specific sample size.

Although the general threshold for older adults is often 65 years or more (WHO standard: ≥60), more than a quarter of the included studies (8/30, 26.7%) expanded this range. Specifically, 18 (60.0%) papers reported an age range of 60 years old and above, whereas 8 (26.7%) papers broadened the range to 55 years old and above; 2 (6.7%) papers did not report precise age

XSL•FO
RenderX

ranges (one reported an average age of 66.94 years, and the other reported the majority were over 65 years). Another 2 (6.7%) reviews did not report the age range but were also retained after verifying that over 75% (22/30) of their original studies focused on the older adult population. Researchers cited several reasons for the expansion: (1) 50 or more is a common threshold in technology-use literature, reflecting demographic trends; (2) widening the range avoided excluding high-quality studies and supported inclusive evidence; (3) in some populations (eg, the homeless), 50 or more is recognized as older due to “accelerated aging;” and (4) alignment with the global minimum retirement age of 50 years, which accounts for socioeconomic dimensions of aging.

Across the 30 included studies, telemedicine modalities varied, with 5 common types identified: telemedicine apps (11 papers), wearable devices (10 papers), video consultations (5 papers), electronic surveillance (4 papers), and government services (4 papers). Other modalities included social media services, family therapy, virtual diagnostics, monitoring sensors, SMS text messaging, and online counseling (each reported in 1‐2 papers). Six papers did not specify the modality. Table 1 provides the detailed evidence on older adults’ telemedicine adoption.

[b]Not applicable.

Dimensions of Trust Barriers

Analysis of the included studies identified 4 thematic categories of trust barriers: technophobia and difficulties, preference for in-person care, privacy and data concerns, and emotional and social impacts.

Technophobia and Difficulties

Technical issues were the most prevalent barrier, reported in 28 (93.3%) papers. Subthemes included low technical skills (eg, inability to navigate interfaces and limited understanding of monitoring mechanisms; 19/30, 63.3%), lack of technical support (eg, absence of family assistance and inadequate troubleshooting services; 14/30, 46.7%), age-related sensory or cognitive decline (eg, impaired vision or hearing and reduced attention span; 12/30, 40.0%), and technical anxiety or fear of using electronic devices (9/30, 30.0%). Less common but notable factors included physical coordination limitations (eg, motor impairments affecting device use; 4/30, 13.3%) and inconsistent user interfaces across platforms (2/30, 6.7%). Modality-specific patterns were evident: studies involving telemedicine applications (11/30, 36.7%) most frequently identified barriers related to interface complexity and low self-efficacy, with participants reporting difficulty navigating functions, performing self-monitoring tasks, or evaluating information reliability. Studies involving wearable devices (10/30, 33.3%) emphasized physical operation difficulties and doubts about data accuracy, reflecting the additional dexterity

XSL•FO
RenderX

and technical comprehension demands of sensor-based technologies.

Preference for In-Person Care

A strong preference for in-person care was another significant barrier, identified in 26 (86.7%) papers. Specifically, 18 (60.0%) papers directly reported a preference for in-person care; 15 (50.0%) noted concerns about the accuracy of telehealth diagnostics or equipment; and 11 (36.7%) indicated reliance on manual verification processes. Low health literacy, contributing to skepticism toward telemedicine, was reported in 5 (16.7%) papers. Cultural influences were highlighted in 3 papers, pointing to disparities in the acceptance of innovative medical approaches across Eastern and Western contexts or between ethnic groups. Studies (4/30, 13.3%) examining government digital health services additionally identified complex digital pathways, inadequate multilingual support, and structural access inequities as barriers reinforcing this preference, suggesting that system-level design failures can compound individual reluctance toward remote care.

Privacy and Data Concern

Privacy and data issues were identified in 23 (76.7%) papers. Concerns included fear of data leakage or breaches (16/30, 53.3%), perceived intrusiveness of continuous monitoring (10/30, 33.3%), and lack of ownership or control over data, including uncertainty about sharing practices (5/30, 16.7%). In a few cases, lack of personal devices or internet access contributed to privacy-related distrust (3/30, 10.0%). Studies involving electronic surveillance technologies (4/30, 13.3%) generated the most acute privacy concerns, encompassing fears about unauthorized third-party access, stigma associated with being continuously monitored, and the perceived intrusiveness of ambient sensors tracking behavioral patterns. Studies involving wearable devices similarly surfaced a concern specific to passive, always-on data collection. However, an exception was noted in a Swedish study on electronic care surveillance, where most participants (16/17) viewed the service positively, citing safety benefits, while only 1 participant expressed discomfort with constant monitoring.

Emotional and Social Impacts

Emotional and social impacts were identified in 21 (70%) papers. Reported issues included discomfort in virtual settings, such as receiving distressing news without perceiving empathy or lacking nonverbal cues (6/30, 20.0%). Concerns about losing personal connections with clinicians were expressed in 12 (40.0%) papers, and refusal to engage due to stigma or embarrassment—such as perceiving telemedicine use as a sign of dependence or incompetence—was noted in 7 (23.3%) papers. Specifically, in 1 (3.3%) mental health study, participants expressed uncertainty about the identity of the remote provider, which heightened distrust. A few secondary factors (eg, financial costs for users and organizational resource constraints in rural areas) were also noted but lacked sufficient empirical support for generalizable conclusions. This barrier was most documented in studies focusing on video consultations (5/30, 16.7%). In synchronous video communication, participants described an intensified sense of detachment resulting from screen-mediated interaction and a reduction in nonverbal cues. In contrast, emotional concerns arising from asynchronous communication primarily centered on a lack of human warmth and continuity.

Dimensions of Vulnerabilities

Across the 30 included studies, 4 primary categories of vulnerabilities related to telemedicine adoption among older adults were identified: low telemedicine literacy, dependence on social support, psychological and cognitive dispositions, and complex health conditions.

Low Telemedicine Literacy

Low telemedicine literacy was the most frequently documented vulnerability, identified in 29 (96.7%) papers. Three dominant subthemes emerged within this category. Limited knowledge of telehealth devices and services was reported in 22 (73.3%) studies, including insufficient understanding of device functions, data collection mechanisms, and service scope. Dependence on external guidance was observed in 16 (53.3%) studies, with participants requiring assistance from family members, caregivers, or clinical staff to operate devices, navigate platforms, or interpret data. Low self-management skills were noted in 14 (46.7%) studies, reflected in difficulties independently monitoring personal health indicators (eg, blood glucose and blood pressure) or adjusting health behaviors based on remote feedback.

Exceptional cases included a lack of access to telemedicine training resources (eg, absence of community workshops and insufficient user manuals), as reported in 4 (13.3%) studies. Additionally, 3 (10%) papers highlighted language barriers, such as limited English proficiency or the inability to describe symptoms without relying on nonverbal communication.

Dependence on Social Support

Dependence on social support was as prevalent as low telemedicine literacy, identified in 29 (96.7%) studies. This dependency manifests in 3 aspects. Reliance on family members or caregivers for device operation was reported in 21 (70.0%) studies. Participants required assistance with device setup (eg, pairing wearables with smartphones), troubleshooting technical issues, or entering health data. Dependence on clinical staff for health management was noted in 17 (56.7%) studies, encompassing reliance on clinicians for medication adjustments, interpretation of telehealth data, and guidance on disease management through remote channels. Living alone with limited immediate support was observed in 14 (46.7%) studies, where solitary living arrangements heightened concerns about delayed assistance during acute health events (eg, falls and sudden symptom exacerbations) when using telemedicine. Three (10.0%) papers suggested that older adults may lack intrinsic health behavioral drivers and rely more on external incentives to motivate participation in health-related activities.

Apart from artificial assistance, 5 (16.7%) papers reported financial dependency as a barrier to telemedicine access, such as the inability to afford devices or internet services. Additionally, 3 papers indicated difficulties accessing general practitioners due to structural barriers (eg, appointment shortages and geographic inaccessibility).

XSL•FO
RenderX

Psychological and Cognitive Disposition

Alongside factors of efficiency and convenience, the reviewed literature emphasized the importance of mental elements in building trust. Vulnerabilities related to psychological and cognitive disposition were noted in 22 (73.3%) studies. The most common subtheme was anxiety or depression related to disease uncertainty (15/30, 50%), with participants experiencing emotional distress over disease progression or the reliability of remote diagnosis. Cognitive impairment affecting decision-making was reported in 10 (33.3%) papers, encompassing memory decline, reduced attention span, and difficulty comprehending medical information—factors that hindered engagement with telemedicine processes (eg, scheduling appointments, following remote care plans). Low self-esteem or grief-related distress appeared in 6 (20%) studies, where negative self-perceptions (eg, feeling "technologically incompetent") or grief (eg, loss of independence) further reduced willingness to adopt telemedicine.

Complex Health Conditions

Older adults' prevalent physical disabilities and complex health conditions present distinct vulnerabilities within the telemedicine context (19/30, 63.3%), manifesting through 3 interconnected dimensions.

Twelve (40%) papers addressed older adults' chronic multimorbidity, including concurrent conditions such as diabetes, hypertension, and cardiovascular disease, which increased the complexity of remote health monitoring and management. Ten (33.3%) papers reported progressive physical decline, characterized by age-related frailty, reduced mobility, and heightened fall risk—factors that limited independent use of telemedicine devices (eg, wearable sensors and video consultation tools). Seven (23.3%) papers included complications requiring frequent care adjustments, such as acute exacerbations of chronic obstructive pulmonary disease or kidney disease, which necessitated timely in-person clinical intervention and reduced reliance on telemedicine alone. Older patients' heightened awareness of health risks and self-perceived vulnerability drive stringent expectations for health care accuracy, timeliness, and reliability (2/30, 6.7%).

Table 2 presents the co-documentation frequencies between the 4 trust barrier themes and 4 vulnerability dimensions across the 30 included studies. Each cell indicates the number of studies that simultaneously reported both constructs, based on the thematic coding documented in Multimedia Appendix 1. The high co-documentation frequencies across most cells reflect the interconnected nature of these constructs: vulnerabilities rarely map onto a single barrier in isolation, and multiple vulnerability dimensions frequently co-occur with each trust barrier theme within the same study. These patterns are consistent with the narrative findings, which emphasize that the relationships between trust barriers and vulnerabilities are layered and nonlinear rather than reducible to discrete one-to-one pairings.

Table . Co-documentation frequency matrix: trust barrier themes×vulnerability dimensions across included studies (N=30)[a].

Dimension	T1: technophobia and technical difficulties (n=28), n (%)	T2: preference for in-person care (n=26), n (%)	T3: privacy and data concerns (n=23), n (%)	T4: emotional and social impacts (n=21), n (%)
V1: low telemedicine literacy (n=29)	27 (90.0)	25 (83.3)	22 (73.3)	21 (70.0)
V2: dependence on social support (n=29)	27 (90.0)	25 (83.3)	22 (73.3)	20 (66.7)
V3: psychological and cognitive disposition (n=22)	22 (73.3)	19 (63.3)	18 (60.0)	16 (53.3)
V4: complex health conditions (n=19)	18 (60.0)	16 (53.3)	14 (46.7)	13 (43.3)

[a]Cell values represent the number (and percentage) of included studies simultaneously documenting each trust barrier-vulnerability pair, based on thematic codes in Multimedia Appendix 1. Marginal totals in parentheses indicate how many studies documented each construct independently; co-documentation frequencies should be interpreted in relation to these base rates. No directionality or causal relationship is implied.

Discussion

Principal Findings

The most significant finding of this scoping review is the identification of 4 interrelated vulnerability dimensions—technological literacy, health status, psychological or cognitive dispositions, and social support—that collectively underpin trust erosion in older adults' telemedicine use. By synthesizing evidence from previously fragmented studies, this review demonstrates that these vulnerabilities consistently align with 4 clusters of trust barriers: technophobia, privacy concerns, emotional and social impacts, and preference for in-person care. These vulnerabilities operate across 3 interconnected levels: at the individual level, low technological literacy and adverse psychological dispositions restrict autonomy; at the interpersonal level, diminished social support and technology dependence shift erode dignity and emotional validation; and at the systemic level, gaps in platform accessibility, privacy safeguards, and integration with in-person care exacerbate digital exclusion.

Together, these findings offer an integrative and organizing framework that consolidates previously fragmented evidence into a multilevel map of how vulnerability shapes trust dynamics in older adults' telemedicine use. Additionally, the synthesis provides a practical scaffold for targeted intervention design. Corresponding strategies were identified at each level, as detailed in subsequent sections.

XSL•FO
RenderX

Implications of Telemedicine Trust

Building on this framework, the evidence suggests that older adults' trust in telemedicine is eroded through layered "loss of control"—rooted in interconnected vulnerabilities across all 3 levels [64,72,73].

At the individual level, the loss of bodily control is central. Declining physical functioning increases reliance on technological devices and caregiver assistance, eroding bodily and informational autonomy. Telemedicine tools often feel intrusive (eg, forced disclosure of sensitive information) or impersonal, with standardized services failing to address complex needs. Uncertainty about remote diagnosis further weakens perceived control over health outcomes, directly undermining trust [73,74].

At the interpersonal level, the loss of identity control is pronounced. As older adults withdraw from the labor market, dependence on others for technology use redefines them from "independent" to "cared-for," threatening dignity—particularly among marginalized groups (eg, low educational attainment) [75-77]. Unlike in-person care, virtual interactions reduce emotional validation and social role confirmation, leading to feelings of loneliness, neglect, or diminished attachment [78,79].

At the systemic level, the loss of generational control reflects broader technological shifts. Telemedicine amplifies "digital exclusion" for older adults who are unfamiliar with platforms or cybersecurity, triggering anxiety [53,80,81]. Generational gaps in technological exposure deepen this divide: many individuals prefer in-person care, feeling sidelined in a system that prioritizes digital innovation over familiar health care relationships, further exacerbating their vulnerability [63,82].

In summary, the factors tied to individual autonomy, interpersonal identity, and systemic adaptability demonstrate that trust cannot be addressed through isolated fixes. The multilevel framework provides a cohesive foundation for targeted interventions across all 3 levels. Since this study broadens the age-based definition of "older adults," this framework is better suited as a descriptive map applicable to the broader older adult spectrum rather than a precision model for any single age cohort. In practice, clinicians and policymakers should develop tailored strategies for specific age subgroups rather than treating "older adults" as a homogeneous category.

Enhancing Inclusive Telemedicine

Translating the multilevel framework into practice, the following recommendations address trust barriers at each level, organized by the strength of evidence.

First, design and training can directly reduce individual barriers to trust. The included studies identified interface complexity and insufficient training as primary drivers of technophobia. To address technological vulnerabilities, telemedicine platforms should prioritize age-friendly interfaces with large fonts, voice-activated commands, and modular operation guides to improve usability [83-85]. Crucially, the included studies also emphasized that on-demand technical support must accompany these tools, as older adults' reluctance to engage often stems not from fixed incapacity but from a fear of making errors without accessible help.

Second, humanizing interactions can strengthen interpersonal connections, which are essential for trust. Multiple studies have identified the loss of the therapeutic relationship and the absence of nonverbal communication as central to emotional distrust in video consultations, pointing to the need for provider training in virtual communication skills. Training providers to use nonverbal cues (eg, nodding and expressive facial gestures) during video consultations adds warmth to virtual visits [86,87]. The evidence also consistently highlights the role of family members and informal caregivers. Involving authorized family members in virtual visits and providing shared record access can reduce recovery anxiety and sustain engagement, thereby reinforcing trust [88,89].

Third, systemic improvements must anchor these efforts, encompassing privacy, cultural adaptability, and accessibility [90,91]. Studies across multiple contexts identified privacy transparency as a foundational trust mechanism. To protect privacy, telemedicine platforms should provide visual guides that clarify the scope of data collection and enable users to customize sharing permissions through intuitive privacy dashboards [91-93]. Sensitive data (eg, mental health records or sexual health information) require double encryption to establish the credibility of data protection. Culturally and linguistically adapted services were also documented as important equity considerations. Multilingual interfaces (eg, Chinese and Spanish) and culturally relevant scheduling (eg, adjustments for Lunar New Year) can accommodate diverse linguistic and cultural needs.

These solutions must be reinforced by broader policy frameworks and practical support systems to achieve scalable impact. The evidence supports subsidizing community technology training and retaining low-tech alternatives (such as telephone-based consultations and printed care instructions) to ensure access for those who cannot or do not wish to use digital channels. Hybrid care models that combine telemedicine with in-person options were endorsed across multiple studies as a pragmatic means of accommodating diverse needs without forcing a binary choice. Such interventions align with the WHO's Decade of Healthy Aging (2021‐2030), which emphasizes digital inclusion as a pillar of equitable health care for older adults, aiming to protect their autonomy in digital health contexts.

Future Directions

This scoping review mapped the dynamics of trust and vulnerability across individual, interpersonal, and systemic levels, highlighting targeted paths for future research. First, longitudinal studies are necessary to track changes in the dynamics of trust in telemedicine among older adults. Future research can investigate how trust in telemedicine evolves over time for older adults, particularly as they gain experience with digital tools.

Second, effectiveness can be better evaluated, such as training programs or age-friendly redesigns, and should be assessed in terms of their ability to reduce trust barriers and improve

XSL•FO
RenderX

telemedicine adoption. Trust and vulnerability scales for telemedicine, based on empirical tests, have yet to be developed, indicating a need for more scientific measurement tools in future research.

Third, comparative cross-cultural and geographic comparisons remain insufficient. Future research should focus on understudied low- and middle-income countries and rural-urban divides to explore how systemic factors (eg, health care infrastructure) mediate trust-vulnerability links, thereby filling gaps in current regional data.

Fourth, future studies should examine how trust barriers differ across telemedicine modalities. The current evidence suggests that video consultations, wearable monitoring devices, telehealth apps, and electronic surveillance technologies may generate distinct trust concerns and vulnerability patterns. Comparative studies examining modality-specific trust dynamics would enable more targeted design and policy recommendations.

Limitations

This review has certain limitations. The heterogeneous age thresholds used across included studies represent a substantive methodological limitation that affects the precision of the review's conclusions. While justifications exist for this broader inclusion, the synthesis risks conflating the trust and vulnerability profiles of mid-life adults (50-64 y) with those of older adults (75+ y).

The search strategy constitutes a further methodological limitation. By requiring both "trust" and "vulnerability" as mandatory search terms, the review may have systematically excluded studies that address structurally similar phenomena under alternative conceptual labels. The evidence base synthesized here should, therefore, be understood as representing a theoretically bounded subset of the broader literature on older adults' telemedicine engagement. Future reviews should consider expanding search terms to include "digital exclusion," "digital divide," "autonomy," and "resistance" to capture this adjacent evidence.

In addition, most studies focused on primary medical care, overlooking particularly vulnerable populations, such as individuals with severe disabilities or those in underserved areas, thereby offering only a partial perspective on telemedicine experiences.

The restriction to English-language publications represents not only a practical constraint but also a potential source of cultural and regional bias. Studies conducted in non–English-speaking contexts may report trust barriers and vulnerability profiles that differ substantially from the predominantly Western and East Asian evidence synthesized here. Future reviews should deliberately include non-English literature to achieve more equitable geographic representation.

Another limitation concerns the aggregation of findings across heterogeneous telemedicine modalities. This review synthesized evidence from studies examining wearable devices, video consultations, telemedicine applications, electronic surveillance systems, and government digital health services under a unified thematic framework. While this approach enabled the identification of cross-cutting patterns, it necessarily obscures the trust dynamics specific to each modality.

Finally, the predominance of cross-sectional data restricted insight into the temporal evolution of trust and vulnerability.

Conclusions

This review highlights that trust in telemedicine among older adults is shaped by a complex interplay of vulnerabilities across individual, interpersonal, and systemic levels. These dynamics show that the erosion of trust is not just a result of technological barriers but also involves bodily autonomy, social identity, and the capacity to adapt to systemic change.

To address these challenges, this study proposes an inclusive telemedicine improvement strategy. "Inclusion" in telemedicine does not always mean "high tech"; rather, meaningful inclusion requires interventions tailored to all 3 levels: intuitive tools and training to empower individuals, humanized interactions to strengthen interpersonal bonds, and systemic policies that balance digital innovation with low-tech alternatives and cultural responsiveness. By centering on such layered solutions, telemedicine can evolve into a more equitable tool that respects older adults' diverse needs, improves health care equity, and enhances their healthcare experience by prioritizing trust, not just technology.

Acknowledgments

The authors declare the use of generative artificial intelligence (GAI) in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision: proofreading and editing. The GAI tool used was ChatGPT 5.3 and DeepL. Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Abstract

Background: Urinary incontinence (UI) is the most prevalent pelvic floor dysfunction, with incidence increasing with age. Numerous studies have demonstrated the effectiveness of pelvic floor exercises in improving UI. However, access to pelvic floor treatment remains limited due to lengthy waiting lists and poor adherence to prescribed exercises. Digital solutions incorporating behavior change techniques (BCTs), including gamification elements, may support self-management of bladder health for individuals aged 50 years and older who may face challenges in accessing conventional treatments.

Objective: This study aimed to identify mobile apps and websites integrating BCTs, including gamification elements, to facilitate bladder health self-management among adults aged 50 years and older.

Methods: The search was initiated in July 2024 and updated in January 2025 across three sources: (1) mobile app stores (Google Play Store and Apple App Store available in Spain, Lithuania, and the United Kingdom) using the keywords “pelvic floor,” “urinary incontinence,” and “bladder”; (2) websites; and (3) academic databases (PubMed, Scopus, CINAHL, and Google Scholar) for journal articles, book chapters, and conference papers published in English, Spanish, or Lithuanian. Inclusion criteria required that solutions be independently usable without health care supervision, incorporate at least one BCT (eg, training, education), be evidence-informed (ie, include participants aged ≥50 years in their design or piloting phase or explicitly target this demographic), and be available in Spain, the United Kingdom, or Lithuania. The Mobile App Rating Scale (MARS) was used to assess app quality, and the taxonomy of 93 BCTs was used for BCT classification. All review and data extraction processes were conducted in duplicate.

Results: Twenty-one studies met the inclusion criteria, identifying 8 eligible mobile apps and 1 website. Among the apps, only 2 were available on either Google Play or the Apple App Store. No apps were identified in Lithuania, whereas 1 app was found in Spain and 3 apps in the United Kingdom. Of these, 1 UK app was accessible on both Google Play and the Apple App Store, whereas the others were limited to a single platform. BCT extraction showed that the apps included between 9 and 16 BCTs (mean 12, SD 3.27). Regarding quality, all assessed apps obtained MARS scores ranging from 3 to 4 out of 5. Website searches did not identify any scientifically validated platforms across the 3 countries, except for 1 website cited in a scientific publication. UI reduction on the International Consultation on Incontinence Questionnaire ranged from –3.9 to –2.1 points, while perceived improvement reached 91.7% in the Tät app.

Conclusions: Evidence-based digital interventions for individuals aged 50 years and older remain limited. Existing apps suggest potential benefits in UI reduction and quality of life improvement; however, further research and development are needed to enhance accessibility and efficacy.

Introduction

The incidence of pelvic floor dysfunction is increasing, especially among older adults. Urinary incontinence (UI) is the most common dysfunction of the pelvic floor, and the incidence increases with age. UI is the involuntary loss of urine, affecting up to 36 million people in Europe [1-3].

The total direct cost in Germany, Italy, Spain, Sweden, and the United Kingdom has been estimated at €5 billion per year (€1=US $1.14 as of July 12, 2026), and this burden will increase with the projected 25% increase in UI prevalence by 2030 [2]. The mean annual per capita cost of its treatment is €300 - €600 per country [2].

The most frequent types of UI are stress urinary incontinence, which is characterized by the involuntary leakage of urine during activities that increase intraabdominal pressure, such as coughing or sneezing; urgency urinary incontinence, defined by a sudden and compelling need to urinate, usually accompanied by leakage before reaching the toilet; and mixed urinary incontinence, which combines features of both previous types [4].

Several studies have explored the effectiveness of pelvic floor exercises to improve UI and reduce the involuntary loss of urine [5,6]. A combination of behavioral therapies consisting of pelvic floor muscle training, bladder training, and practical tips is beneficial in the management of UI [5]. Also, several studies have indicated that low levels of physical activity (PA) and prolonged patterns of sedentary behavior represent risk factors for UI [7,8], with PA being defined by the World Health Organization as any bodily movement produced by skeletal muscles that requires energy expenditure [9]. Some individuals with UI cannot access pelvic floor treatment because there are barriers to uptake, including waiting lists that limit access to treatment, poor adherence to exercises [1,10], the price of the treatment, or embarrassment.

Ultimately, pelvic floor dysfunctions can reduce the quality of life of older people, with research showing that several interrelated factors can challenge the independence of older adults: primarily functional and cognitive impairment, chronic diseases, a diminishing social network, and a low level of PA [11].

Gamification should not be understood merely as the incorporation of game elements into nongame contexts, but rather as a process aimed at generating meaningful psychological experiences that enhance the perceived value for the user. This emphasizes that motivational affordances (such as points, levels, or badges) function in nongame contexts as stimuli designed to activate psychological needs and emotional states, with the purpose of influencing behavior and strengthening emotional engagement [12].

In contrast to gamification, video games constitute complete, self-contained interactive environments designed primarily for entertainment. While video games involve full game narratives, mechanics, and immersive worlds, gamification selectively integrates specific game design elements into health or behavioral interventions without necessarily creating a full game experience. This conceptual distinction is essential, as gamified interventions and video-game–based interventions may rely on different psychological mechanisms, levels of immersion, and theoretical foundations [13,14].

Grounded in motivational psychology, gamification fosters constructs such as self-efficacy, engagement, and habit formation, particularly through the promotion of autonomy, competence, and social relatedness [13]. These factors are directly linked to self-determination theory, which highlights the importance of satisfying basic psychological needs in order to sustain intrinsic motivation [13].

Furthermore, gamification is conceived as an attempt to increase the likelihood of the emergence of experiences of flow, challenge, or immersion [14], rather than as a fixed set of game mechanics. In this way, psychology becomes the central axis explaining how design elements are transformed into emotional and motivational experiences, which ultimately determine the effectiveness of gamification in creating value for the user [12].

In recent years, emerging evidence suggests that gamification may serve as a valuable tool in addressing health-related challenges among patients [15]. According to the meta-analysis conducted by Mazeas et al [15], gamified interventions are not only effective in modifying behavior, but also demonstrate greater efficacy compared to other behavioral approaches. Moreover, these interventions show promise in supporting the long-term maintenance of behavioral changes.

Another review highlights that supervised exercise programs incorporating game elements appear to increase PA levels more effectively than conventional exercise routines [16].

Behavior change techniques (BCTs) are defined as observable, replicable, and irreducible components of an intervention designed to modify behavior [17]. They represent the smallest active ingredients that can be applied individually or in combination to influence behavioral outcomes. BCTs, such as feedback or monitoring, can enhance the maintenance of behavior over time through instant feedback and improve performance in eHealth programs [18]. Behavioral treatment for pelvic floor dysfunctions can be an effective tool either on its own or in combination with medication to improve UI, urinary urgency, nocturia, and other conditions [19].

In the context of mobile technologies and web-based interventions targeting bladder and pelvic floor health, the application of the BCT taxonomy alongside gamification enables the identification of active ingredients that promote adherence, engagement, and sustained behavior change in adults and older populations.

XSL•FO
RenderX

Given the growing number of pelvic floor apps available online, this review focused on evidence-based programs to assess their actual effectiveness. A 2019 systematic review identified 840 pelvic floor–related apps, of which approximately 78% were not developed by healthcare professionals. This raises concerns regarding the usability and clinical efficacy of apps that lack a foundation in scientific evidence [20].

Rapid reviews have been recognized by the Cochrane Rapid Reviews Methods Group and the World Health Organization as an appropriate approach when timely evidence is needed to inform intervention development in fast-evolving fields [21,22]. In the context of digital health for bladder and pelvic floor self-management, technologies evolve quickly and new apps emerge each year, making a rapid review particularly suitable for providing up-to-date, actionable insights. To ensure methodological rigor despite the accelerated timeline, we followed established rapid review guidance, including the use of predefined eligibility criteria, structured search strategies, and transparent reporting of methodological shortcuts [21]

Technology can offer a solution to some of these challenges, such as UI. The willingness of older people to use technology depends on their perceived need. Initially, older people may believe that technology can be useful for others, but not for them. However, when they try it, they tend to want to continue using it [23]. Due to the increasing prevalence of pelvic floor disorders and the growing importance of technology in health and daily life, it is important to examine mobile technologies and websites designed for self-management among these populations. Therefore, the specific objective of this work was to synthesize the current literature and available apps in Spain, Lithuania, and the United Kingdom for the promotion of bladder health and/or the management of UI among adults aged 50 years and older.

Methods

Overview

This review is the first part of the KOKU Bladder project (ClinicalTrials.gov, NCT06583733), an international collaboration involving the University of Vic (Spain), Lithuanian Sports University (Kaunas, Lithuania), and the University of Manchester (United Kingdom). The review included mobile apps, websites, and academic databases from each participating country. Where possible, we adhered to the recommended 7-step method for conducting reviews of mobile health apps [24]. We used a similar approach to combining reviews of the evidence, smartphone apps, and websites as that used in a review conducted by McGarrigle et al [25]. The protocol was registered on October 4, 2024, in PROSPERO (reference CRD42024597624). The Population, Intervention, Comparison, and Outcome (PICO) framework was used to guide the formulation of the inclusion criteria. Pilot searches were conducted in July 2024 to identify appropriate search keywords, followed by the final search between October 2024 and January 2025.

The rapid review was conducted to preliminarily explore the available literature to lay the foundation for the project and guide the initial stages of work. To achieve this, a targeted search methodology was applied, examining a smaller number of databases compared to a traditional systematic review, which allowed for a faster process. In addition to databases, websites and app stores were also reviewed. The total duration of the study was four months, a shorter period than that required for more exhaustive reviews, but sufficient to obtain an overview of the existing evidence and support the project's initial decision-making.

Eligibility Criteria

The following criteria were used to select relevant digital solutions (apps or websites) across the three searches (Textbox 1).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Apps or websites that can be used by people independently, without supervision by a healthcare professional.
- Digital technologies (apps and websites) regardless of cost (eg, to download or to access in-app functions).
- Interventions including at least one behavior change technique (eg, training, education, monitoring, and prompting).
- Evidence-informed: resources appropriate for use with older populations (ie, they have included participants aged >50 years in the design or piloting phase or target this group). They do not have to exclusively include those aged >50 years, but rather be part of the study group.
- Available in Spain, the United Kingdom, or Lithuania and in English, Spanish, or Lithuanian.

Exclusion criteria:

- Apps or websites designed for pregnant or postpartum individuals, those aged <50 years, or health and social care professionals.
- Apps or websites only including pelvic floor muscle techniques and/or training.
- Apps or websites that require invasive devices (eg, intravaginal devices).
- Intended only for health care professionals.
- For the academic database searches, we excluded review studies, case reports, letters to the editor, editorials, conference abstracts, and personal opinions and/or commentaries.

XSL•FO
RenderX

Search and Screening

The entire review process was conducted by at least 2 researchers in each participating country. The search and retrieval of scientific papers were carried out by the Spanish research team (OA-G and JJ-R) in October 2024. All retrieved papers were subsequently uploaded to the Rayyan (Rayyan Systems Inc.) bibliographic management platform for review by the research team [26].

At the outset of the review process, duplicate records were identified and removed using Rayyan's automated detection system. Following this, the titles and abstracts of all papers were screened by the research team, ensuring that each paper was reviewed by a minimum of 2 independent reviewers. The selected papers were then downloaded, thoroughly read, and subjected to screening in duplicate. The initial review was conducted by 1 researcher from Spain (OA-G) and 1 from the United Kingdom (ES). A secondary review was carried out by the Lithuanian team (RS, EK, and LJ), comprising three researchers. Upon completion of this phase, a second Spanish researcher examined and resolved any conflicts (JJ-R), leading to the final selection of papers. The extracted data were subsequently organized into tables for analysis.

For the search of mobile apps and websites, at least 2 researchers conducted the process in each country: OA-G, JJ-R, and JRB in Spain; ES and NG in the United Kingdom; and RS, EK, and LJ in Lithuania. The search results were compiled and recorded in tables. Subsequently, OA-G and NG reviewed the findings, while JJ-R resolved any discrepancies or uncertainties.

App Market

A systematic search was conducted in the Google Play Store and Apple App Store in Spain, Lithuania, and the United Kingdom. Searches were performed on Android (Samsung Galaxy Note 20 Ultra, Android 11; Samsung Galaxy S24, Android 14 OS) and iPhone (iPhone 12, iOS 16.1.1). The search keywords included "pelvic floor," "urinary incontinence," and "bladder." Equivalent terms in Spanish and Lithuanian were used for searches within the respective app markets.

A peer review process was implemented for the app search to ensure consistency and accuracy. The final results from all 3 countries were compiled and compared in a comprehensive data table.

Websites

We searched for websites featuring interventions aimed at promoting behavior change related to bladder health (eg, UI) with supporting scientific evidence. The search was conducted in 3 countries and 3 languages, with each country searching in its native language. The search strategy was in English included the terms UI exercises, pelvic floor exercises, pelvic floor muscle training, and bladder exercises. In Spanish: ejercicios para la incontinencia urinaria, ejercicios de suelo pélvico, entrenamiento muscular del suelo pélvico, and ejercicios de vejiga. In Lithuanian: šlapimo nelaikymo pratimai, dubens dugno pratimai, dubens dugno raumenų treniravimas, and šlapimo pūslės pratimai.

The search was conducted using Google. We systematically reviewed the first 20 search results from each country for each keyword. This cutoff was based on user behavior research indicating that most users only explore the first few links in search engine results [27]. Rew et al [28] reported that the number of websites reviewed per keyword varies from 10 to 200, with the first 25 websites being a commonly used number.

All the websites identified were reviewed to determine whether they included scientific papers supporting the effectiveness of the site in reducing UI.

Academic Databases

A systematic search was conducted to identify scientific evidence supporting the included mobile apps and websites. The search was performed in the following academic databases: PubMed, Scopus, CINAHL, and Google Scholar.

Eligible sources included journal papers, book chapters, and full-length conference papers published in English, Spanish, or Lithuanian.

The search strategy in PubMed was ((“pelvic floor”) OR (urinary incontinence) OR (bladder)) AND ((app*) OR (mHealth) OR (eHealth) OR (game*)), in SCOPUS we limited to paper and aged, and the search strategy was: ((“pelvic floor”) OR (“urinary incontinence”)) ((app*) OR (mhealth) OR (ehealth) OR (technology)). In CINAHL we limited by source type (academic journal) and age (aged 80 years and older and middle-aged: 45 - 64 years years), and the search strategy was ((“pelvic floor”) OR urinary incontinence OR bladder) AND (app* OR mHealth OR eHealth OR game*)

Evaluation, Data Extraction, and Synthesis

Evaluation: Mobile App Rating Scale

The quality of the apps was evaluated using the validated Mobile App Rating Scale (MARS) [29] by 2 researchers in the United Kingdom (ES and NG) and in Spain (OA-G and JR). The criteria assess quality by considering engagement, functionality, esthetics, information quality, and subjective quality, leading to the development of 23 subcategories from which the 23 individual MARS [29] items are derived. Each item is rated on a 5-point scale (1=inadequate, 2=poor, 3=acceptable, 4=good, and 5=excellent), with descriptors provided for each rating anchor. In cases where an item was not applicable, a “not applicable” option was included. In this review, we used the first 19 subcategories and excluded the last category, “subjective quality.”

MARS [29] was used in duplicate, and we calculated the mean scores for the final results for each app.

Evaluation: BCTs

To analyze the BCTs in the apps, we used the taxonomy of BCTs developed by Michie et al [30]. The taxonomy includes a list of 93 BCTs, each evaluated with a score of “0” (absent) or “1” (present). Scores were then summed. The total score for each app ranged from 0 to 93, with higher scores reflecting a greater implementation of BCTs [30].

XSL•FO
RenderX

BCTs were also determined in duplicate, in the United Kingdom (ES and NG) and in Spain (OA-G and JR). Consensus was reached for any apps in which there was disagreement between the researchers.

Evaluation: Databases

During the review process, data from the included studies were extracted systematically into predefined tables. For each intervention study, we recorded key sample characteristics such as mean age, number of participants, educational level, and type of UI, as well as the assessment tools used and the main conclusions reported. This approach allowed us to compare study populations and to examine differences across the validated questionnaires used.

For the included studies, we collected demographic and clinical variables (sample size, age, education level, percentage of women, and UI type) to contextualize the populations targeted by each intervention. These characteristics are essential for assessing the applicability of digital tools to older adults, who often present heterogeneous clinical profiles and varying levels of digital literacy. In addition, we extracted the validated questionnaires used in each study (eg, International Consultation on Incontinence Questionnaire - Short Form (ICIQ-SF), International Consultation on Incontinence Questionnaire - Overactive Bladder (ICIQ-OAB), Patient Global Impression of Improvement (PGI-I), and Pelvic Muscle Physical Therapy (PMPT)), as these instruments represent the most widely accepted clinical and patient-reported outcomes in UI research.

Once the final set of eligible papers was identified, we conducted a structured data extraction process. All studies were read in full, and the relevant information was systematically recorded in predefined tables. For each intervention study, we extracted demographic and clinical characteristics of the sample, including mean age, number of participants, education level, and type of UI, as well as details on study design and the assessment instruments used.

Once the final set of eligible papers was confirmed, we refined the extraction through a structured, full-text review of each study. In parallel, information on the identified mobile apps was collected by analyzing both the app content and the associated scientific publications. App-related data included platform availability, version number, cost, country of origin, and study setting. BCTs were identified using the Behavior Change Technique Taxonomy, app quality was assessed using the MARS [29], and gamification elements were identified through direct inspection of the apps, noting features such as levels, progress tracking, rewards, or visual feedback. All extracted information was organized to ensure consistency and facilitate comparison across studies and apps.

The results were collected in 3 tables. Table 1 contains data related to the apps, the country in which they were found, app store, version number, developer name, price, study setting, number of BCTs, and MARS [29] outcome (Multimedia Appendix 1). Table 2 includes the general information for the selected papers: app name, sample size, mean age, educational level, percentage of women, study design, and percentage of IU (Multimedia Appendix 2). Finally, Table 3 provides the results of the papers and the different questionnaires (Multimedia Appendix 3).

Table . Technological and qualitative information of the apps.

Name of app	Country	App market	Version number	Developer name	Cost	Study setting	BCTs[a]	MARS[b]

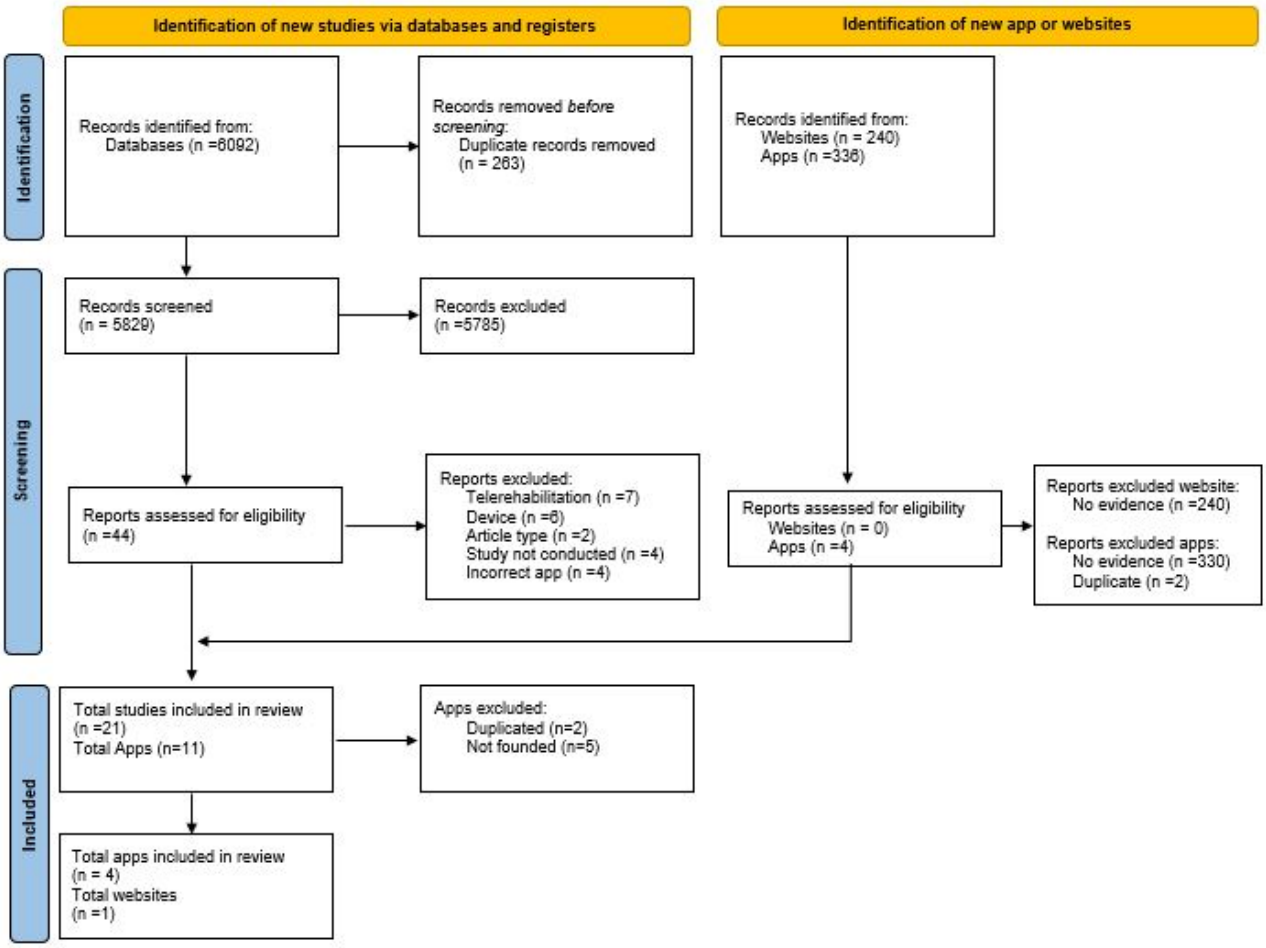
The selection of outcomes in this review was guided by the primary objective of identifying mobile apps and websites that integrate BCTs and gamification elements to support bladder health self-management among adults aged 50 years and older. Accordingly, we prioritized outcomes that capture both the behavioral components of the interventions and their practical relevance for end users. For the included apps, we extracted information on cost, study setting, presence of BCTs, MARS scores [29], country of origin, and app-store availability, as these indicators reflect accessibility, design quality, and behavioral content, which are key dimensions in evaluating digital self-management tools for older adults.

No specific methods for data preparation or synthesis, such as handling of missing summary statistics or data conversions, were required.

No additional analyses were conducted to explore heterogeneity (eg, subgroup analysis or meta-regression), nor were sensitivity

XSL•FO
RenderX



analyses performed to assess the robustness of the synthesized results. Likewise, no specific methods were applied to evaluate risk of bias due to missing results or reporting biases, and no formal assessment of certainty or confidence in the body of evidence was undertaken. These procedures were not applicable to our study.

Results

Overview

Following the screening process, 21 papers were deemed eligible for inclusion. These papers cover 7 distinct mobile apps and 1 website. The entire search process is illustrated in Figure 1 (flowchart).

Figure 1. Flowchart depicting the search and screening process.

Database Results

From the academic database searches, we identified seven apps with scientific evidence; however, we were only able to download two of them, Tät (eContinence AB) and URinControll (Curavista). The apps that we could not download or locate were Tät II (Curavista), MyHealtheBladder (U.S. Department of Veterans Affairs), Diário Saúde (Eliza Ferrari), Yoga of Immortals–YOI (Ishan Shivanand (originating from ShivYog), and iDry (Ruslan Pavliuchenko) apps. Although these apps have scientific evidence, they were unavailable for download from Google Play or the Apple App Store.

For the app search, no apps were found in Lithuania. In Spain, we identified only 1 app (URinControl; Curavista), while in the United Kingdom, we found 3 different apps (URinControl, URinControl4all, (Curavista) and BladderBoss (Amara Therapeutics)). BladderBoss was available on both Google Play and the Apple App Store (as different versions), whereas the other apps were available in only one app store. Table 1 presents the technological and qualitative information about the apps.

The website search did not identify any platforms with scientific evidence supporting their effectiveness across the 3 countries. In total, 80 webpages were reviewed in each country, but none met the inclusion criteria. Only 1 website with scientific evidence was found through the scientific paper from the search: the Tät website (eContinence AB) [51].

Following the completion of the search process, a total of 4 mobile apps were identified as having scientific evidence and were available for download via Google Play or the Apple App Store. UrinControl4all should be considered a version of URinControl because it is based on the same scientific paper and differs only by minor variations (eg, language). We extracted data from the final papers and compiled them into Tables 2 and 3 to facilitate comparison and readability.

In the clinical questionnaire results, Tät showed the greatest reduction in UI severity (ICIQ-SF score: –3.9 points) and in

XSL•FO
RenderX

symptom-related quality of life measured using the International Consultation on Incontinence Questionnaire Lower Urinary Tract Symptoms Quality of Life. [1](ICIQ-LUTS-QoL score: –4.8 points), together with a perceived improvement of 91.7% according to the PGI-I, indicating a statistically significant improvement. URinControl or URinControl4all showed reductions of –2.16 and –4.34 points, respectively, with a perceived improvement of 65.7%, while BladderBoss assessed questionnaires specific to overactive bladder (ICIQ-OAB score: –2.13 and ICIQ-OAB-QoL score: –22.04 points) and did not report PGI-I data.

BCT Results

In the BCT extraction, we identified that the apps had between 9 and 16 BCTs (mean 12, SD 3.27). All apps had BCTs related to goals and planning, feedback and monitoring, shaping knowledge, repetition and substitution, and comparison of outcomes. None had BCTs related to social support, regulation, antecedents, identity, scheduled consequences, or covert learning.

Regarding the distribution of BCT categories, the most frequently represented techniques were those associated with goals and planning, feedback and monitoring, shaping knowledge, repetition and substitution, and comparison of outcomes, each appearing six times, meaning that they were present in all the reviewed apps. In contrast, the techniques related to association and comparison of behavior appeared five times. Categories such as natural consequences showed a lower representation, appearing only twice, and the same frequency was observed for reward and threat, and self-belief. No BCTs were identified for social support, antecedents, regulation, identity, scheduled consequences, or covert learning. This pattern indicates that most apps emphasize self-regulatory and educational strategies rather than social or identity-based components.

MARS Results

The MARS evaluation results were obtained through a paired review of the apps. The highest-rated app was BladderBoss (Apple App Store), which achieved a good score of 4.0 (SD 0.20). The remaining apps received scores within the acceptable range. Specifically, Tät (Spain) obtained an acceptable score of 3.39; BladderBoss on Google Play also scored 3.39 (SD 0.02); URinControl received an acceptable score of 3.33 (SD 0.07), with identical ratings in Spain and the United Kingdom; and URinControl4all achieved an acceptable score of 3.0 (SD 0.20).

This rapid review did not include detailed assessments of risk of bias for individual studies or synthesis-level evaluations of bias. Similarly, investigations of heterogeneity (such as subgroup analyses or meta-regression), sensitivity analyses to test robustness, assessments of reporting bias due to missing results, and evaluations of certainty or confidence in the body of evidence were not undertaken. These procedures were not incorporated because they fall outside the scope and objectives of a rapid review, which prioritizes timeliness and streamlined synthesis over comprehensive methodological appraisal [53].

Discussion

Principal Findings

A systematic search was conducted to identify mobile apps and websites related to pelvic floor training. A total of 6092 papers, 240 webpages, and 336 apps were peer reviewed, resulting in only 4 apps that were available and met our inclusion criteria. All the apps identified received an “acceptable” rating on the MARS scale [29], and one achieved a “good” rating. Regarding the BCTs, all included between 9 and 17 BCTs, and some also incorporated elements of gamification.

A total of 11 apps were identified as having scientific publications supporting their efficacy. Of these, four apps met the criteria for both scientific validation and mobile availability: URinControl, Tät, URinControl4all, and BladderBoss. All were accessible via the Google Play Store, while BladderBoss was additionally available on the Apple App Store, suggesting a dominance of android-based development in this field. The URinControl and URinControl4all apps are based on the same scientific study to validate their effectiveness. They also have similar content, differing only in language and the way users access the same program. It is important to take this into account, as URinControl4all can currently be supported by the URinControl paper [35-37]; however, if both apps are updated, it is possible that these findings may no longer be applicable.

The search was conducted in Lithuania, the United Kingdom, and Spain. Notably, no relevant apps were identified in Lithuania. In contrast, 2 apps were found in Spain and 4 in the United Kingdom. A possible explanation for this discrepancy is that all identified apps were developed in English-speaking countries, potentially eliminating the necessity for translation into other languages. Indeed, market research conducted by the Organisation for the Review of Care and Health Apps (ORCHA) has reported that of the available 311,000 health apps worldwide, 227,500 (73%) are available in the United Kingdom [54].

Regarding MARS scores [29], all assessed apps scored between 3 and 4 out of 5, indicating acceptable quality. The highest-rated app was BladderBoss (version 1.8 for iOS). The most highly rated section across all apps appears to be the “Information” section, which provides high-quality content such as text, feedback, measurements, and references. However, in some cases, the app description in the App Store and the definition of measurable objectives could be improved. However, it is important to note that app evaluation frameworks do not always reflect real-world engagement [55], with MARS scores showing to have weak correlation with user retention after downloading an app [56]. Additionally, key parameters of interest, including the implementation of gamification, and the resolution of graphics are consistently well-rated across all apps. Conversely, most apps lack sufficient visual appeal and would benefit from a more detailed description of their functionalities.

The presence of BCTs within the apps was also assessed. BladderBoss demonstrated the highest incorporation of BCTs, scoring between 16 and 17 points, depending on the evaluated version. All analyzed apps incorporated at least 7 BCTs, highlighting their potential effectiveness in facilitating

XSL•FO
RenderX

behavioral modifications. Notably, all apps included BCTs related to goals and planning, feedback and monitoring, shaping knowledge, repetition and substitution, and comparison of outcomes. These techniques are fundamental in guiding users through behavioral change processes [23]. Furthermore, association and comparison of behavior were present in 5 out of the 6 analyzed apps, indicating a widespread inclusion of these techniques.

Conversely, none of the apps integrated BCTs associated with social support, regulation, antecedents, identity, scheduled consequences, or covert learning. This absence suggests potential areas for improvement in future app development to enhance user engagement and support. A study highlights the significance of behavior change and its influence on the adoption of home-based technology by older adults [11]. Specifically, the study emphasizes how personal perceptions and behavioral factors shape technology use in this population. Given the impact of these elements on technology acceptance, future research and app development should integrate strategies that address behavior change to enhance user engagement and long-term adoption. It is also important to consider that the effectiveness of an intervention is not solely determined by the number of BCTs used, but rather by their relevance and alignment with the behavioral change needs and characteristics of the target population.

Moreover, the findings of this review suggest that the combination of BCTs and gamification elements may play a key role in supporting adherence and sustained engagement in digital interventions for UI. Core BCTs such as goal-setting, self-monitoring, feedback, and guided repetition function as psychological mechanisms that facilitate habit formation and long-term behavioral maintenance [17], while gamification elements can amplify these effects by enhancing intrinsic motivation, perceived competence, and the visibility of progress [13]. This interaction is particularly relevant for older adults, who often require additional motivational support to maintain behavioral routines over time [11]. However, the variability observed in the selection and implementation of BCTs across the included apps highlights the need for future digital interventions to adopt more explicit theoretical frameworks and a systematic selection of BCTs aligned with the behavioral needs of people with UI.

Several BCTs appear particularly relevant for UI management. Social support can reduce stigma and feelings of isolation, thereby increasing motivation and adherence to pelvic floor muscle training. Regulation strategies, such as self-monitoring of symptoms and fluid intake, enhance patients' sense of control and facilitate consistent practice. Antecedents, including the identification and modification of triggers (eg, caffeine consumption or timing of fluid intake), help minimize risk situations and improve symptom management. Strengthening identity by fostering the role of the patient as an active self-manager promotes internalization of healthy routines and long-term commitment [57]. The use of scheduled consequences, such as rewards or positive feedback for adherence to exercises, reinforces behavior through operant conditioning. Finally, covert learning techniques, including guided imagery or mental rehearsal, allow patients to visualize successful execution of exercises and coping strategies, which can increase confidence and improve real-world performance. Together, these BCTs target mechanisms of motivation, self-efficacy, and habit formation, thereby supporting adherence and sustainable behavior change in UI interventions.

The gamification elements identified in the apps were limited, although all apps include some gamification element. URinControl and Tät still follow app models with drawings instead of images, while BladderBoss used real-life pictures and videos. In all the apps, exercises are classified by levels, and the user progresses from one level to another. For example, in URinControl, users receive a medal upon completing a level.

All the apps offer the option to view the evolution or progress of the exercises and urine leakage. None incorporate a game within the app or allow users to rate the exercises, receiving a score upon completion, view user ranking, or earn rewards, among other gamification elements.

Several of the studies reviewed provided a qualitative assessment of app use through interviews. These analyses identified that adherence directly influences the outcomes of the application, acting both as a barrier (eg, difficulty in finding the time to perform the exercises) and as a facilitator. Adherence itself was shaped by personal factors, app-related characteristics, and users' awareness. A frequently reported concern was the insecurity experienced by users when performing the exercises, as many were unsure whether they were executing them correctly.

On the positive side, the novelty of technology in this type of treatment was highlighted, together with its accessibility; patients do not need to wait on long lists to receive care, and exercises are always available. The apps were also valued as practical guides that support users in performing the exercises while preserving privacy. Many participants emphasized that the use of apps increased their awareness of symptoms and improved their education about the condition.

The scientific literature consistently supports the effectiveness of mobile apps in enhancing urinary continence, improving quality of life, and increasing patients' perception of symptomatic relief. However, variability in statistical significance was observed across studies. Specifically, interventions using the Tät [32,40-42] and Tät II [31,33,34] apps demonstrated statistically significant differences between groups, whereas URinControl [35,37,39] showed improvements that were not statistically significant.

Treatment outcomes were influenced by several factors, including users' adherence, personality traits, integration of exercises into daily routines, and previous experience with pelvic floor training. Conversely, the primary barriers identified were unrealistic patient expectations and individual difficulties in maintaining adherence.

These findings highlight the necessity of optimizing digital interventions to ensure greater personalization and clinical effectiveness. Key determinants such as symptom severity, age, educational background, and the impact of UI on quality of life should be integrated into the design of eHealth interventions to enhance their predictive validity and therapeutic outcomes.

XSL•FO
RenderX

Overall, the results emphasize the importance of developing mobile apps tailored to the specific needs of the target patient population to enhance adherence, improve usability, and ultimately contribute to better symptom management and quality of life.

In summary, although few evidence-based apps or websites are available for people aged 50 and over, existing tools suggest potential benefits in reducing UI and improving quality of life. However, the mixed statistical significance across studies underscores the need for further research to confirm these effects. Moreover, this review highlights the importance of personalizing digital interventions to maximize their effectiveness and ensuring that future apps incorporate a broader range of BCTs and more robust gamification strategies. Further studies are needed to verify the effectiveness of these apps and to expand the availability of high-quality, evidence-based tools specifically designed for this population

Limitations and Strengths

One of the main limitations of this study is that the review was conducted in only three countries, which may restrict the generalizability of our findings. Additionally, some apps were not available on the App Store, and we did not search all app markets (eg, Amazon or the Xiaomi App Store), leading to potential gaps in our evaluation. This limitation may have influenced our ability to provide a fully comprehensive analysis of all relevant apps in the field.

The study was limited by the absence of a structured instrument to objectively assess the presence of gamification in the different apps. Nevertheless, the development of such a tool holds considerable potential for future research and could contribute to more precise and standardized evaluations.

Despite these limitations, our study has several key strengths. A rigorous methodology was applied, ensuring the reliability of the findings, and the evaluation process was conducted in duplicate, involving several independent reviewers, which enhanced objectivity. Furthermore, all included apps were thoroughly assessed using the MARS [29] and BCT frameworks, providing a robust framework for evaluation. Additionally, in cases where no clear scientific evidence was available regarding an app's effectiveness, we proactively contacted the respective companies to inquire about any supporting research papers. This approach reinforced the credibility and transparency of our findings.

Abstract

Background: Perinatal mental health issues are widely recognized as a significant public health concern; however, fathers remain underrecognized and underserved within perinatal care systems. Existing reviews have largely focused on mothers, infants, couples, or general paternal mental health interventions, leaving limited synthesis of technology-based and digitally delivered support relevant to paternal perinatal depression. Digital interventions, including SMS programs, online groups, web-based platforms, mobile health apps, and hybrid digital follow-up, may offer flexible ways of engaging fathers; however, their evidence base remains unclear.

Objective: This scoping review aimed to map the available evidence on technology-based, digitally delivered, and hybrid interventions relevant to paternal postnatal depression and paternal perinatal mental health. Specifically, it examined the types of evidence available; how interventions varied by delivery mode, methodology, and population; how interventions were characterized in terms of format and duration; and what outcomes had been measured across studies.

Methods: This review was conducted in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) framework. A comprehensive search was conducted between February and April 2025 and updated in June 2026 across multidisciplinary electronic databases. Search terms covered 4 concepts: fathers or nonbirthing parents, perinatal mental health, digital or technology-based modalities, and intervention or evaluation purpose. Eligible studies were peer-reviewed English-language articles in which fathers, expectant fathers, new fathers, male partners, or nonbirthing parents were active participants, target users, or reported subgroups, and in which a digital, technology-based, or hybrid support strategy was described or evaluated. Data were charted and synthesized descriptively and comparatively.

Results: Six studies met the inclusion criteria. The evidence included a feasibility study of an SMS-based, father-specific program, randomized controlled trials of hybrid psychoeducational or paternal support interventions, a pilot randomized feasibility trial of an online cognitive behavioral therapy–based intervention for pregnant people and partners, a mixed methods online group intervention for new fathers, and a feasibility, acceptability, and usability study of a father-specific mobile health app. Delivery modes included SMS messaging, WhatsApp follow-up, online video, telephone follow-up, online groups, web-based intervention content, and mobile app features. Outcomes included depression, anxiety, stress, parenting stress, dyadic adjustment, marital quality, resilience, usability, acceptability, engagement, adherence, and qualitative user experience. Findings were most consistent for feasibility, acceptability, and engagement, while evidence for effectiveness in reducing paternal postnatal depression remained limited and mixed.

Conclusions: The current evidence base is small, heterogeneous, and preliminary. Digital interventions may offer acceptable ways to engage some fathers and partners during the perinatal period. However, there is insufficient evidence to draw firm conclusions about effectiveness, scalability, or suitability for fathers experiencing perinatal depression. Future research should prioritize father-specific, theory-informed, co-designed digital interventions using validated paternal outcomes, longer follow-up, transparent engagement reporting, and more diverse samples.

Introduction

The transition to fatherhood can be stressful and overwhelming. Along with the usual difficulties of new caregiver responsibilities, new fathers may face changes to their self-identities, their connection to their partners, and financial commitments [1]. Approximately 10% of new fathers experience depression or anxiety in the perinatal period, and paternal depression has been associated with reduced father involvement and poorer child development outcomes. Decreased paternal engagement in child-rearing can also lead to an increase in children with psychiatric disorders, behavioral issues, and lower academic achievement [2]. Despite this, most perinatal support is received by mothers and infants. Father-specific support is limited, and fathers are often treated as visitors before, during, and after the birth of their baby [3]. Due to stigma and societal perspectives on masculinity, fathers can tend to see themselves in a traditional provider, supporter, and caregiver role, which may create an invisible barrier to seeking emotional support from others [4].

Importantly, unlike the typical signs of mothers' depression, such as sadness, tearfulness, and withdrawal, new fathers are more likely to present with exhaustion, difficulty focusing, and irritability [5]. These gender differences may contribute to systematic underrecognition of paternal mental health problems. The lack of support can escalate challenges into more acute mental health issues, and fathers' mental well-being can impact the well-being of partners and children [6].

Existing reviews demonstrate the broader problem but do not yet provide a clear map of appropriate support for fathers' perinatal depression. Reviews of partner-inclusive or paternal perinatal interventions have found promising effects, but studies often involve mothers, infants, couples, or general parenting support rather than interventions designed primarily for the unique needs of fathers [7-10]. Reviews of paternal perinatal depression and anxiety consistently identify limited father-specific evidence, inconsistent outcome measures, and methodological weaknesses, but have stopped short of proposing a research agenda to overcome them [1,10]. While fathers have been included in some technology-based parenting programs, relatively few have focused on fathers as participants or as primary users of perinatal mental health support. This is significant because technology-based interventions may be well-suited to address the access barriers of fathers.

Digital and technology-based interventions may offer a relevant pathway for engaging fathers during the perinatal period; however, their efficacy and acceptability for this population remain understudied. Digital or technology-based interventions refer to interventions, support strategies, or service pathways in which information or communication technologies are used to deliver, reinforce, monitor, or facilitate mental health support. These may include messaging platforms, mobile health (mHealth) apps, web-based platforms, online groups, online videos, telephone or app-based follow-up, and gamified or game-informed tools.

These modalities may be particularly relevant, given that research has identified barriers to paternal help-seeking, including stigma, masculine norms, limited father-specific services, work and caregiving commitments, and reluctance to engage with conventional face-to-face support [4], highlighting the need for novel interventions to reach this population. Digital technologies may offer this novel, flexible, and private access to support [11], such as father-specific information aligned with perinatal milestones, self-care needs, supporting a partner, and caring for an infant. While digital parenting and online psychological interventions have been increasingly explored in perinatal contexts, fathers are often included as secondary participants rather than primary users [12,13]. Father-specific digital interventions may therefore provide flexible, private, timely, or context-specific support.

Existing perinatal reviews have focused almost exclusively on maternal and infant mental health, systematically excluding fathers as a population of concern. This leaves 2 critical gaps in existing literature. First, fathers are routinely excluded from perinatal interventions, which are primarily designed around mothers' experiences and needs, resulting in a scarcity of interventions specifically targeting paternal perinatal mental health. Second, the potential of digital delivery modalities to reach this underserved population remains unexplored and unmapped. In this review, the perinatal period is understood as the period from pregnancy through to the first 12 months after birth, which is commonly used in perinatal mental health research and reporting [14], and reflects the psychological continuity between pregnancy, birth, and the postpartum year.

This review aims to map and chart the extent of available evidence for technology-based and digitally delivered interventions for paternal perinatal mental health. The review addresses 3 research questions (RQs). First, what types of evidence exist and how do studies vary by delivery mode, methodology, and population? Second, how are the interventions characterized in terms of delivery mode, format, durations, and intervention components? Third, what outcomes have been measured across studies and what gaps remain in the evidence base?

Methods

Overview

This scoping review was conducted in accordance with the latest PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines (Checklist 1) [15]. The PRISMA-ScR checklist includes 20 essential reporting items and 2 optional items designed to ensure transparency and rigor in scoping review methodology. A comprehensive literature search was conducted between February and April 2025, and updated in June 2026, across 9 electronic databases. The screening process was conducted in 3 stages: title screening, abstract screening, and full-text screening. If eligibility could not be confidently determined at the title or abstract stage, the paper was advanced to the next stage for further review. Papers were assessed to ensure that they met all 5 inclusion criteria. Discrepancies or uncertainties during screening were resolved in discussion with a third reviewer, and consensus was reached in all cases after this discussion.

XSL•FO
RenderX

Protocol and Registration

This scoping review was conducted in accordance with the PRISMA-ScR framework. A protocol for this review was not prospectively registered; however, the review questions, eligibility criteria, search concepts, and data-charting categories were developed before data extraction to minimize bias.

Search Strategy and Study Selection

A scoping review format was selected in response to the limited research literature on digital interventions for paternal perinatal mental health. This approach enabled the timely integration of current evidence, highlighted gaps in the literature, and identified key areas for future research.

The search was conducted between February and April 2025 across 9 electronic databases, including technical databases (eg, ACM and IEEE Xplore), Scopus databases (eg, MEDLINE and PubMed), ScienceDirect, SpringerLink, and Wiley. An updated search was conducted in June 2026 to capture recent literature, including an additional search of the PsycINFO database. The search strategy was organized around 4 core concepts: population, mental health or well-being, technology modality, and intervention or evaluation purpose. Search terms included father-related terms, such as father*, paternal, new dad, expecting father, father-to-be, and non-birthing parent*; mental health and well-being terms, such as postnatal depression (PND), postpartum depression, perinatal mental health, anxiety, stress, psychological well-being, adjustment, help-seeking, and psychosocial support; technology terms, such as digital, online, web-based, internet, eHealth, mHealth, mobile app*, smartphone, telehealth, gamif*, game*; and intervention or evaluation terms, such as intervention, program, therap*, treatment, support, education, psychoeducation, feasibility, acceptability, usability, implementation, and evaluation. The query terms used in the search strategy are presented in Textbox 1.

An example search string was (father* OR paternal OR “new dad*” OR “expecting father*” OR “father-to-be” OR “male partner*” OR “non-birthing parent*”) AND (“postnatal depression” OR “postpartum depression” OR “perinatal mental health” OR anxiety OR stress OR wellbeing OR “parenting stress” OR adjustment OR “help-seeking”) AND (digital OR online OR web-based OR internet OR eHealth OR mHealth OR “mobile app*” OR smartphone OR SMS OR “text message*” OR WhatsApp OR telehealth OR gamif* OR game* OR “serious game*” OR “game-based”) AND (intervention* OR program* OR therap* OR treatment OR support OR education OR psychoeducation OR feasibility OR acceptability OR usability OR implementation OR engagement OR evaluation).

These terms were searched across titles, abstracts, keywords, and full texts. The search string was adapted to the syntax and functionality of each database. To enhance the search strategy and refine the RQs, faculty librarians with expertise in systematic and scoping review methodology were consulted.

Eligibility Criteria and Screening Process

This review focused on technology-based interventions targeting paternal perinatal mental health, and only papers that met the predefined inclusion and exclusion criteria were retained for analysis, as detailed in Textbox 2.

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Full-text, peer-reviewed studies published in English.
- Fathers, expectant fathers, new fathers, male partners, or nonbirthing parents were active participants, target users, or explicitly reported as a relevant subgroup, including parent or couple interventions, where paternal or partner outcomes were reported.
- Studies addressed paternal PND, perinatal mental health, psychological well-being, help-seeking, parenting stress, adjustment to fatherhood, partner support, or closely related outcomes during the perinatal period.
- Studies described a digital, technology-based service pathway or support strategy.
- Studies reported intervention design, protocol details, feasibility, usability, acceptability, implementation, engagement, screening, referral, or relevant outcome data.

Exclusion criteria

- Fathers or nonbirthing parents were not active participants, target users, or a reported subgroup.
- Paternal mental health or well-being was not targeted or meaningfully addressed.
- Studies were not peer-reviewed or not available in English.
- The intervention was primarily focused on clinical simulation or professional training rather than support for fathers in community or home contexts.

A total of 3223 records were obtained from the search strategy listed in Textbox 1. All records were initially screened for duplicates by author 1, resulting in 82.2% (2649/3223) unique papers. Author 1 then screened all titles using the inclusion criteria, identifying 1.2% (32/2649) potentially relevant papers for the review. Because only 32 papers remained after title screening, the review team proceeded directly to full-text screening rather than conducting a separate abstract screening stage, allowing for a more thorough assessment of eligibility. Full texts were independently assessed by 2 reviewers against the predefined inclusion criteria, with author 1 identifying 11 papers for potential inclusion and author 2 identifying 6 (reviewer agreement 84%, Cohen [16] κ=0.61). Discrepancies were resolved through discussion between the 2 reviewers and arbitration by author 3, who has extensive experience in digital technologies in health application research.

Although initial agreement was moderate, both reviewers agreed on all 6 studies included. The discrepancies arose because author 1, newer to review methodology, identified 5 additional studies that did not meet full criteria. Following discussion with author 2 and author 3, who have more experience in digital health research, consensus was reached that these additional studies did not meet eligibility criteria, resulting in full agreement (100%) on the final 6 included studies.

Data Extraction and Analysis

The following outlines the data extraction and analysis procedures for each RQ, corresponding to the structure of the *Results* section. Data were charted using a structured extraction form developed for this review. Extracted fields included author and year, country, study design, evidence type, population, sample size, intervention description, delivery mode, delivery format, delivery duration, digital component, theoretical or design basis, outcome measures, data collection method, key feasibility, acceptability, usability, engagement, or outcome findings. Data extraction was conducted by the first author, with uncertainties and interpretive decisions discussed collaboratively with the research team.

Findings were synthesized using a descriptive and comparative approach that focused on mapping the type and maturity of evidence, comparing delivery modes and formats, identifying how fathers were positioned within each study, summarizing measured outcomes, and identifying gaps in the evidence base. Consistent with the exploratory aims of a scoping review, and given the small number of studies and substantial heterogeneity across interventions, populations, and outcomes, a systematic review or meta-analysis was not considered appropriate for this evidence base.

Results

Six studies met the eligibility criteria for this scoping review. They varied in design and methodological purposes, reflecting a heterogeneous evidence base characteristic of an early-stage, emerging field of research. Studies were published between 2017 and 2025 and were conducted across Australia, the United States, the Netherlands, Turkey, and Israel. Table 1 presents the characteristics of each study, and Figure 1 details the specific numbers from each database.

Table . Overview of the included studies.

Author and year	Fletcher et al [17] (2017)	Missler et al [18] (2020)	Canfield et al [19] (2023)	Karakoç and Kalkan [20] (2024)	Kaner et al [21] (2024)	Teague et al [11] (2025)
Country	Australia	Netherlands	United States	Turkey	Israel	Australia
Delivery mode	Smartphone-based SMS/text-message intervention	Hybrid psychoeducational intervention with online and digital components	Online web-based intervention	Hybrid postpartum education+digital follow-up	Online group intervention	Mobile health app intervention
Delivery format	Short SMS messages with embedded links and mood-tracking questions	Booklet, online video, prenatal home visit, and postnatal telephone call	Self-administered online CBT[a]-based Mothers and Babies Online Course, delivered through Qualtrics	Paternal support training delivered before postpartum discharge, with WhatsApp follow-up	Father-only online discussion groups led by a male facilitator	Prototype app, Rover, including chatbot, mood tracking, goal tracking, CBT/mindfulness exercises, resources, notifications, and gamification
Delivery duration	From 12 weeks of gestation to 24 weeks after birth	Delivered during late pregnancy and early postpartum, intervention included prenatal components and a postnatal phone call	8-week course; one lesson per week recommended	Initial training within the first 48 hours postpartum; follow-up to postpartum day 10	Six weekly sessions, each approximately 75 minutes	Fathers used the app for 4 weeks; clinicians evaluated it for 1 week
Methodology	Feasibility and acceptability study	Randomized controlled trial	Mixed methods pilot randomized controlled feasibility trial	Randomized controlled trial	Mixed methods randomized controlled trial	Feasibility, acceptability, and usability study using a design science approach
Population	Soon-to-be and new fathers	Pregnant women and partners/expecting parents	Pregnant people with elevated depression or anxiety symptoms and their cohabiting partners	Married postpartum couples/fathers and mothers	New partnered fathers with an infant under 1 year	Fathers with pregnant partners or infants under 12 months; mental health clinicians
Sample size	520 enrolled fathers	138 pregnant women and 96 partners	30 dads; 15 intervention and 15 controls	80 fathers randomized; data collected from 160 couples	122 fathers; 62 intervention and 60 comparison	43 fathers and 10 mental health clinicians
Intervention focus	Supporting fathers' transition to fatherhood through father-infant connection, partner support, and fathers' self-care	Preventing postpartum parenting stress, depression, and anxiety, improving parental well-being and caregiving quality	Reducing perinatal mood and anxiety symptoms through online CBT-based psychoeducation and partner-inclusive support	Increasing paternal support and improving dyadic adjustment, happiness, and psychological resilience	Supporting fatherhood transition, normalizing experiences, reducing loneliness, increasing awareness of fatherhood role, and supporting couple relationship	Father-specific perinatal mental health support through mood tracking, mindfulness, goal setting, CBT-informed exercises, chatbot support, and gamified app design

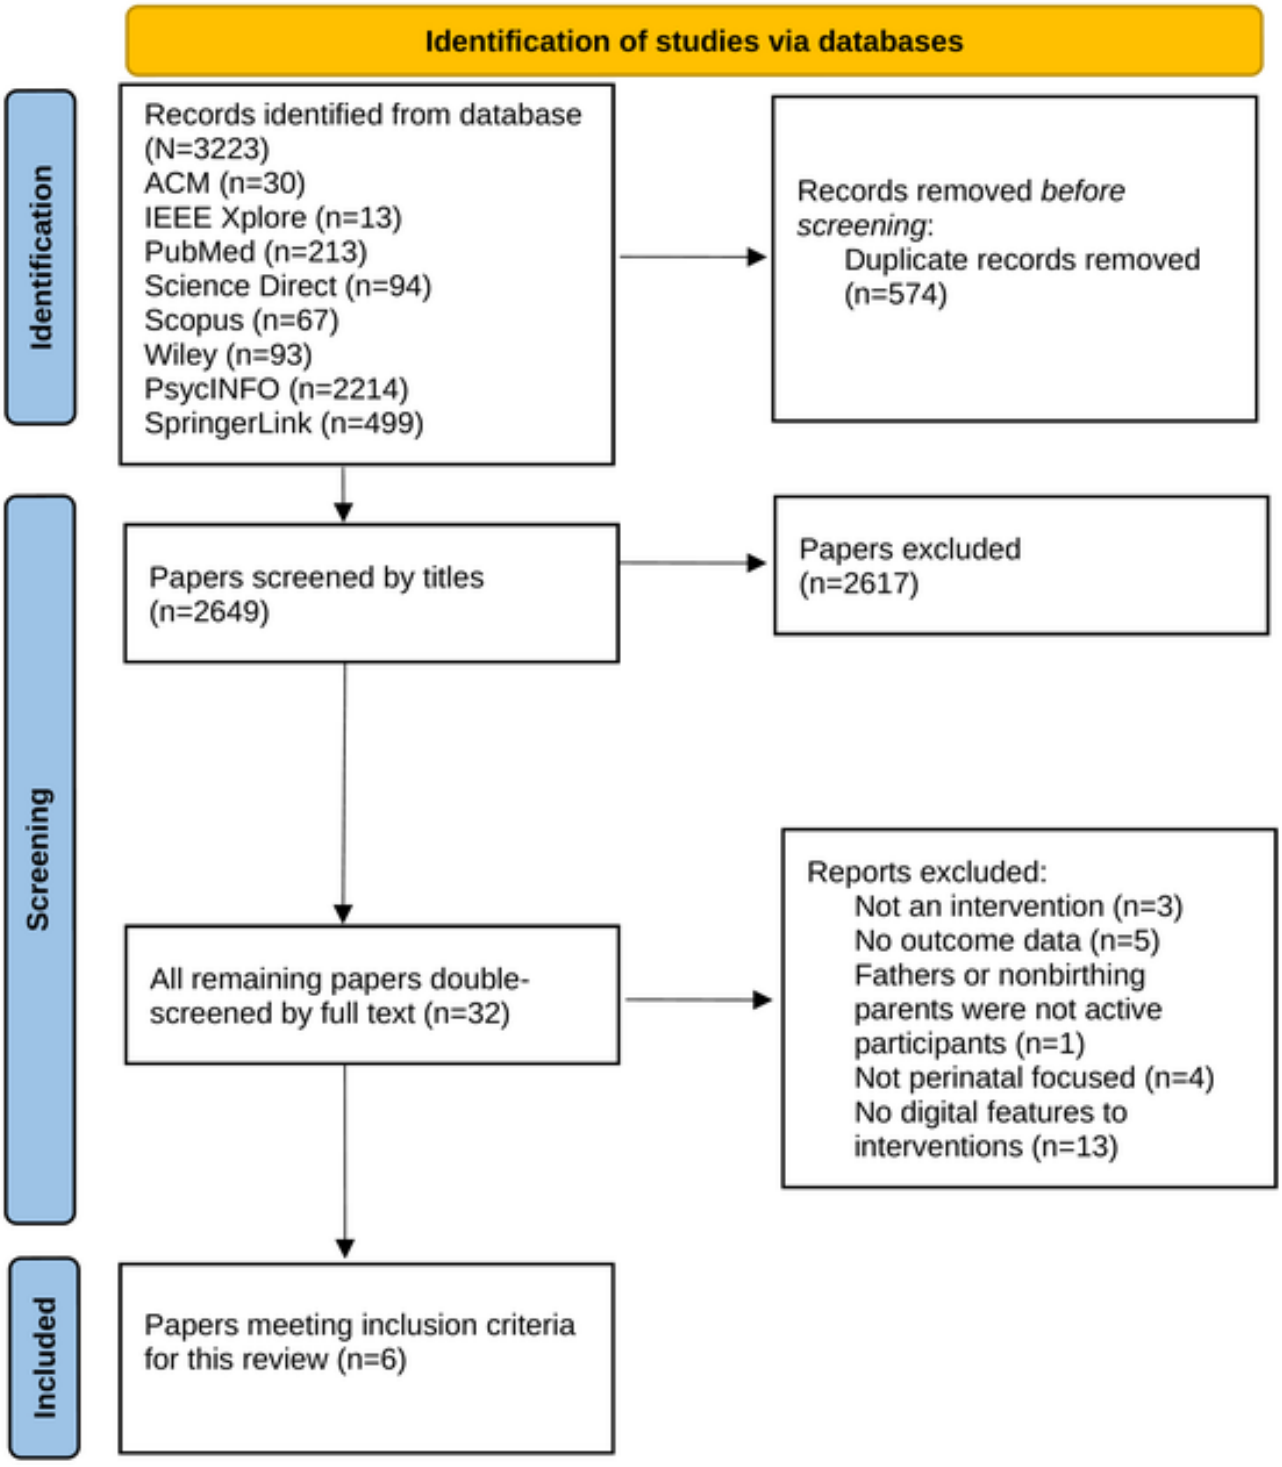
[f]PHQ-9: Patient Health Questionnaire-9.

[g]GAD-7: Generalized Anxiety Disorder-7.

[h]DASS-21: Depression Anxiety Stress Scales-21.

[i]eMB: electronic mothers and babies course.



The first RQ examined the types of evidence available and how studies varied by delivery mode, methodology, and population. Delivery modes varied substantially, including SMS messaging delivered to fathers' smartphones [17], WhatsApp-supported follow-up [20], online video within a multicomponent intervention [18], an asynchronous online cognitive behavioral therapy (CBT)–based course [19], synchronous online father-only groups [21], and a prototype mHealth app, called the Rover app [11]. Methodologically, the studies varied in the extent to which digital delivery was central to the intervention. In the SMS4dads feasibility study [17], the digital component was the main intervention mechanism, delivered through text messages to fathers' smartphones. Similarly, the Rover app study [11] placed digital design at the center of the intervention by evaluating a father-specific mHealth app. The online group intervention [21] and online CBT-based dyadic intervention [19] also used digital delivery as the primary access pathway. In contrast, the psychoeducational intervention [18] and paternal support training [20] used digital elements as supplementary components, such as online video, telephone follow-up, or WhatsApp follow-up. The target populations also varied. Several studies were explicitly father-focused, including SMS4dads, the online father group intervention, and the Rover mHealth app [11,17,21], while other studies included fathers or partners within couple, dyadic, or expectant-parent interventions [18-20].

The second RQ examined how the interventions were characterized in terms of delivery mode, format, duration, and intervention components. The interventions can be grouped into 3 delivery models: fully digital, online group-based, and hybrid interventions with digital reinforcement. The fully digital interventions, SMS4dads [17] and the Rover mHealth app [11], were accessed independently of face-to-face health services. SMS4dads delivered stage-based text messages and embedded links across pregnancy and early fatherhood, while Rover offered app-based features such as mood tracking, goal tracking, mindfulness exercises, chatbot interaction, resources, and gamified elements.

The online group [21] and online CBT-based [19] intervention used digital delivery to create structured support spaces. The former comprised 6 weekly father-only group sessions led by a male facilitator, focused on peer normalization and fatherhood identity; the latter was an 8-week structured course for pregnant people and partners targeting perinatal mood and anxiety symptoms.

XSL•FO
RenderX

Figure 1. Screening and inclusion process.

The hybrid interventions [18,20] used digital components to reinforce nondigital support. The psychoeducational intervention [18] combined a booklet, online video, prenatal home visit, and postnatal telephone call, while the paternal support training [20] included WhatsApp follow-up after an initial in-person session.

Duration also varied: SMS4dads [17] spanned from pregnancy to postpartum; Rover [11] was evaluated over 4 weeks, the online group intervention [21] ran 6 weeks, the CBT course [19] ran 8 weeks, and the hybrid interventions [18,20] involved shorter, more targeted contact around late pregnancy and early postpartum.

The third RQ examined what outcomes have been measured across studies and what gaps remain in the evidence base. All 6 studies reported completed intervention, feasibility, acceptability, usability, or outcome evaluations [11,17-21]. Across the included studies, outcome measurement clustered around 4 broad domains: mental health symptoms, relational or dyadic functioning, feasibility and engagement, and acceptability or usability. Mental health symptoms were the most commonly measured domain. Five studies included measures of psychological distress, depression, anxiety, stress, or parenting stress [11,17-19,21]. The Edinburgh Postnatal

XSL•FO
RenderX

Depression Scale (EPDS) was the most frequently used depression-related measure, appearing across several studies. Other symptom measures included the Kessler Psychological Distress Scale-6, Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, Hospital Anxiety and Depression Scale anxiety subscale, and Depression Anxiety Stress Scales-21 anxiety and stress subscales.

Relational, dyadic, and family-functioning outcomes were also represented, but they were measured inconsistently. Some studies assessed dyadic adjustment, marital quality, partner relationship quality, happiness, psychological resilience, parenting self-efficacy, parent-infant bonding, or caregiving quality [18,20,21].

Feasibility and engagement were measured in several studies [11,17,19,21], particularly those evaluating digital or app-based interventions. SMS4dads reported completion, retention, link-click engagement, and responses to mood-tracking questions. The online CBT-based intervention collected adherence data through platform analytics, while the Rover mHealth app collected app usage statistics. The online father group intervention reported attendance rates, and other studies collected data on intervention usefulness or feedback.

Acceptability, usability, and user experience were also commonly examined, but mainly in studies where the digital component was central to the intervention. The Rover app study used validated usability and app-quality measures, including the System Usability Scale, Mobile App Rating Scale, and Mobile Agnew Relationship Measure, alongside qualitative feedback [11]. SMS4dads [17] and the online CBT-based intervention [19] also collected postintervention feedback or acceptability data. Other hybrid studies assessed perceived usefulness or qualitative experiences [18,20,21].

Several gaps were evident in outcome measurement across the included studies. Father-specific outcomes, such as paternal help-seeking intention, stigma, paternal self-efficacy, or engagement with professional support pathways, were rarely measured; most studies instead relied on general mental health, relational, or usability measures. In studies where fathers were included within broader couple-based or expectant-parent interventions, paternal outcomes were not always reported separately from maternal or dyadic outcomes. Most studies relied on self-report measures, and follow-up periods were generally short, with no studies reporting outcomes beyond the early postpartum period.

Discussion

Principal Findings

This scoping review identified 6 studies examining technology-based, digitally delivered, or hybrid interventions relevant to paternal perinatal mental health. Overall, the evidence is best understood as an emerging intervention landscape rather than a mature effectiveness literature. Several studies focused primarily on feasibility, acceptability, usability, engagement, or intervention design, while others reported early outcome evaluation. This indicates that the field is beginning to move beyond protocol-level intervention development, but it has not yet produced a consistent or robust evidence base from which firm conclusions about effectiveness can be drawn.

A key distinction concerns the role of digital delivery within the intervention model. Because digital tools functioned as the primary support mechanism in some studies and as only a supplementary component in others, the effectiveness of the digital component cannot be interpreted uniformly. In hybrid interventions, observed outcomes may reflect the combined effects of face-to-face, printed, professional, relational, and digital components, rather than the independent contribution of digital delivery itself.

The interventions also differed in design logic, ranging from brief, low-intensity, repeated contact (such as SMS prompts and mood-tracking check-ins) to more structured formats (such as a multiweek course or a multifeature app), with Rover [11] representing the clearest example of a father-specific digital design. These differences suggest that digital technology is not being used in a single consistent way across the literature; rather, it functions variously as a delivery platform, engagement tool, follow-up mechanism, self-monitoring system, or design feature.

Outcome measurement varied considerably across the 6 studies. Mental health symptoms were the most commonly measured domain, with several studies using validated measures such as the EPDS, Kessler Psychological Distress Scale-6, Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, Hospital Anxiety and Depression Scale, or Depression Anxiety Stress Scales-21. This suggests partial convergence around depression and psychological distress measurement, particularly through the EPDS. However, there was no shared outcome framework across studies. Relational and adjustment-related outcomes, including dyadic adjustment, marital quality, psychological resilience, parenting self-efficacy, caregiving quality, and parent-infant bonding, were measured inconsistently and often reflected the specific focus of each intervention. Engagement outcomes were also operationalized differently, including attendance, retention, link clicks, app interactions, mood-tracker responses, lesson adherence, and qualitative feedback. This variation limits comparison across studies and makes it difficult to identify which intervention formats or components are associated with stronger engagement or more meaningful outcomes.

Across the evidence base, findings were more consistent for feasibility, acceptability, usability, and engagement than for clinical effectiveness. SMS delivery, online group discussion, mobile app features, brief digital contact, and digital follow-up were generally reported as acceptable or usable by participants. Features such as father-specific messaging, humor, baby-centered content, mood tracking, mindfulness activities, goal setting, peer normalization, and male facilitation appeared to support engagement in some studies. However, these features were not systematically evaluated across all included studies, and positive acceptability should not be interpreted as evidence of effectiveness. While several studies reported promising engagement or user experience findings, evidence that these interventions produce sustained behavioral change, improved help-seeking, or reduced paternal perinatal depression remains limited.

XSL•FO
RenderX

Effectiveness findings were mixed and should be interpreted cautiously. Some studies reported improvements or protective effects in relational and well-being–related outcomes, such as dyadic adjustment, happiness, psychological resilience, marital quality, or perceived social connection. However, effects on depression, anxiety, parenting stress, and other mental health outcomes were less consistent. In addition, several studies measured paternal mental health indirectly or as a secondary outcome, and follow-up periods were generally short. This limits the extent to which conclusions can be drawn about whether technology-based or hybrid interventions specifically reduce paternal perinatal depression.

Included studies also varied in the extent to which they targeted father-specific outcomes, such as paternal help-seeking, stigma reduction, paternal self-efficacy, parenting confidence, or engagement with professionals, which limits the interpretation of relevance to fathers; a literature gap addressed further in the *Limitations* section below.

Implications for Digital Intervention Design

The gaps identified in this scoping review point to several priorities for future research. Most pressing is the need for primary studies designed specifically to address paternal perinatal mental health, rather than positioning fathers as secondary participants in mother-focused or general parent-focused interventions. Father-specific interventions should explicitly address fathers' mental health needs, barriers to help-seeking, stigma, paternal identity transition, partner communication, and father-infant bonding.

Future studies should also articulate a clear theoretical basis for intervention design. At present, the included studies vary in whether and how they describe theoretical foundations or mechanisms of change. Clearer theoretical grounding would allow comparison across interventions and help identify which components are most likely to influence outcomes such as mental health literacy, help-seeking intention, emotional regulation, relational support, and engagement with professional care. In addition, future studies should use validated, father-specific outcome measures where possible and have longer follow-up periods to determine whether any benefits are sustained beyond the immediate postpartum period.

A promising avenue for future research includes serious games and gamified interventions. Although 1 included study incorporated gamification elements, no study evaluated a fully developed serious game for paternal perinatal mental health. Game-based approaches may offer novel ways to support mental health literacy, emotional reflection, coping practice, help-seeking attitudes, partner communication, and a means of addressing known barriers to fathers' help-seeking such as time and stigma.

Limitations of the Included Studies

The included studies have several limitations that affect interpretation of this review. First, although the updated search identified 6 studies, the evidence base remains small and heterogeneous, limiting direct comparison across studies and preventing firm conclusions about the effectiveness, scalability, or suitability of digital interventions for paternal perinatal depression.

Second, not all included studies positioned fathers' postnatal mental health as the primary intervention target. Some studies were designed specifically for fathers, whereas others included fathers or partners within broader couple-based or expectant-parent interventions. While these studies are relevant to paternal postnatal mental health, they do not always isolate paternal outcomes or address fathers' unique barriers to help-seeking, stigma, masculine norms, fatherhood identity, or father-infant bonding. As a result, conclusions about father-specific digital intervention design should be interpreted with caution.

Third, most studies relied heavily on self-report data and short follow-up periods. While self-report measures are appropriate for assessing perceived symptoms, usability, and acceptability, they may be affected by recall bias, social desirability bias, or participant expectations. The limited duration of follow-up also means that little is known about whether digital interventions can produce sustained changes in paternal mental health, help-seeking behavior, relationship functioning, or parenting confidence beyond the early postpartum period.

Fourth, the diversity and representativeness of participants were limited across the included evidence. Several studies used relatively small, educated, partnered, or culturally homogeneous samples. This restricts the generalizability of findings to fathers from diverse cultural, socioeconomic, geographic, linguistic, or family-structure backgrounds. Further research is needed to understand whether digital interventions are acceptable, accessible, and relevant for fathers who may experience additional barriers to support, including fathers in low-resource settings, nonresidential fathers, same-sex parents, and fathers from culturally and linguistically diverse communities.

Limitations of This Review

Although the search strategy was broad to capture digital, online, mobile, SMS-based, and game-informed interventions, relevant studies may still have been missed due to variation in terminology across digital health, perinatal mental health, and fatherhood research. The review was limited to peer-reviewed English-language publications, which may have excluded relevant gray literature, non-English studies, service evaluations, or unpublished digital health projects.

The search did not include CINAHL or Web of Science in the database searches due to resource constraints, both of which index nursing, allied health, and interdisciplinary literature. Given the overlap between these databases and those searched, it is unlikely that a substantial amount of relevant literature was missed; however, some relevant studies may have been overlooked as a result. Future reviews could include broader database coverage to minimize the risk of omission.

In addition, title screening was conducted by a single reviewer, which may have introduced selection bias, although later stages of screening involved independent review and consensus discussion. Consistent with scoping review methodology, this review aimed to map the available evidence rather than formally appraise study quality or pool effect sizes. Therefore, the

XSL•FO
RenderX

findings should be interpreted as a descriptive and interpretive overview of an emerging evidence base, rather than as evidence of clinical effectiveness.

Conclusion and Future Work

While the limited evidence base precludes definitive conclusions, the 6 included studies tentatively suggest that digital modalities may offer feasible and acceptable ways of engaging some fathers and partners during the perinatal period. Digital modalities may help reduce father-specific barriers related to time, geography, stigma, and reluctance to attend face-to-face services; however, future research is required to systematically evaluate and confirm these potential advantages.

Intervention features such as father-specific messaging, humor, baby-centered content, brief digital contact, mood tracking, goal setting, mindfulness activities, and peer normalization were described as potentially supportive of engagement. However, the evidence that these features translate into sustained behavior change, improved help-seeking, or reduced paternal PND remains limited. Acceptability and usability findings should therefore be understood as early design evidence that still requires proof of clinical effectiveness.

The current evidence base remains too small and heterogeneous to support firm conclusions about the scalability, suitability, or effectiveness of digital interventions for fathers experiencing perinatal mental health challenges. Future research should prioritize father-specific digital interventions that are theory-informed, co-designed with fathers, and evaluated using rigorous methods, including validated father-specific outcomes, longer follow-up periods, transparent reporting of engagement and attrition, and more diverse participant samples.

Fathers remain a consistently underserved population despite the prevalence of paternal perinatal mental health challenges. Digital interventions offer a promising and timely avenue for future research, with the potential for innovative, father-tailored solutions that could meaningfully advance both clinical practice and public health initiatives in this critical area.

Acknowledgments

The authors acknowledge the use of generative AI (GenAI), namely Grammarly's "Superhuman Platform" and OpenAI's GPT-5 in the writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to GenAI tools under full human supervision: text generation, proofreading and editing, reformatting, and publication support. All critical interpretation, analysis, conceptualization, and conclusions presented in this work were conducted by the authors and responsibility for the final manuscript lies entirely with the authors.

Abstract

Background: Digital medication adherence interventions for individuals diagnosed with chronic conditions have been developed, but their long-term efficacy in improving medication adherence has been limited. Exploring mechanisms and contexts related to outcomes of digital medication adherence interventions is important for these to be effectively tailored for different populations and contexts. A realist review was conducted to assess which intervention components might work for whom, and under what circumstances.

Methods: A realist review of literature published between 2002 - 2024 was conducted. Studies reporting digital medication adherence interventions for people diagnosed with chronic diseases and experiencing unintentional medication nonadherence issues were included. MEDLINE, CINAHL, PsycInfo, Web of Science, Scopus, Embase, and gray literature databases, Overton, and Policy Commons were searched. Data regarding contexts, mechanisms, and outcomes were extracted and synthesized into program theories. Program theories from the realist review were triangulated with findings from two rounds of workshops (three workshops in each round), in which context-mechanism-outcome (CMO) configurations were cocreated with various stakeholders of a project aimed at implementing a digital medication adherence intervention to reduce unintentional nonadherence among people with chronic diseases. There were 12 participants in each round.

Results: The analysis of 83 papers and content of the cocreation workshops led to 35 CMOs theories in seven theory areas, which were (1) building and maintaining medication intake habits; (2) solving medication-related barriers to adherence; (3) enabling collection of prescription medications on time; (4) supporting people with unpredictable health conditions and sensory or motor impairments; (5) supporting individuals with high anxiety, low medication self-efficacy, and low social support; (6) supporting individuals who are uncomfortable with technology; and (7) economic, policy, and organizational factors affecting implementation of smart medication devices. Fourteen CMOs came from both the literature and workshops, 7 CMOs from the literature alone, and 14 CMOs from the workshops alone.

Conclusions: Analysis of the program theories suggested a range of intervention components considering contextual factors that may improve medication adherence of individuals. These were used to form recommendations for intervention developers and implementers. Further studies are required on policy and economic factors affecting large-scale implementation of digital medication adherence interventions in different settings. Future interventions should report intervention content and delivery in detail and codevelop effective implementation strategies with professionals who can support the implementation of the intervention.

RenderX

Introduction

Medication adherence is defined as the extent to which individuals' medication intake is consistent with their health care providers' recommendations [1]. Medication nonadherence is particularly common among individuals diagnosed with long-term health conditions. Consequences of medication nonadherence include worsening of disease symptoms, increased rate of hospitalization, and mortality [2,3].

Medication adherence is a complex phenomenon, and nonadherence occurs in a range of different scenarios: if individuals do not start taking their prescribed medications (primary nonadherence) to begin with; take wrong doses at the wrong time; skip doses (nonconforming); or stop taking the medications against health care providers' recommendations (nonpersistence) [4,5]. Medication nonadherence could be intentional, whereby an individual actively decides not to take medications as prescribed due to factors such as severe side-effects, or being nonintentional, which is an unplanned behavior possibly because of forgetfulness [1]. The barriers to medication adherence fall under 5 dimensions [2]: social and economic factors (eg, low socioeconomic status); health system/health care related factors (eg, patient-provider relationship); therapy related factors (eg, complexity of medication regimen); condition-related factors (eg, severity of symptoms and comorbidities); and patient related factors (eg, patient's beliefs about perceived need for medications). It has been recommended that personalized interventions that target patients' barriers to medication adherence in all 5 dimensions can help improve medication adherence [2].

However, the findings of a systematic review by Yap et al [6] highlighted the conflicts in evidence regarding the factors associated with medication adherence and showed that barriers to medication adherence could vary among different contexts. This highlights the importance of understanding how contextual factors may influence adherence and designing tailored interventions for specific contexts [7,8].

Digital interventions have been developed to improve medication adherence, such as providing text message reminders to take medications [8,9]. Digital interventions have the potential to contribute to more equitable delivery of care, helping improve health care for patients living in remote or rural areas and facilitating more frequent communication with patients; for example, medication reminders can be sent more frequently through digital interventions [10]. However, systematic reviews have highlighted the lack of evidence of long-term efficacy of digital medication adherence interventions in improving medication adherence among individuals with chronic illnesses. Interventions tailored to individual patients, targeting multiple dimensions of medication nonadherence [1,8] as recommended by the World Health Organization [2], are also lacking.

Systematic reviews have also highlighted the difficulties in understanding the mechanisms by which the interventions may have led to improvement in medication adherence, as the studies included were heterogeneous in terms of populations and content and delivery of the interventions [10,11]. Additionally, systematic and scoping reviews provide information about the efficacy or inefficacy of interventions but rarely provide a detailed analysis of contexts and mechanisms related to intervention efficacy or inefficacy [12]. To advance understanding, we need to study such contexts and mechanisms related to outcomes of digital medication adherence interventions.

To enable this understanding, we used realist review methods. A realist review aims to understand the mechanisms of *how* complex interventions work or do not work in different contexts as opposed to just *whether* they work or not [13]. Contexts (circumstances or conditions in which mechanisms can work and lead to the outcomes), mechanisms (elements of the interventions which can potentially lead to the outcomes), and outcomes are presented together as program theories to explain how interventions work [13]. As opposed to systematic reviews, realist reviews use a wider range of evidence, including gray literature, to understand what works for whom and under what conditions [12,13]. Thus, this study aimed to explore the contexts and mechanisms related to the efficacy or inefficacy of digital medication adherence interventions in improving medication adherence among patients with chronic illnesses experiencing unintentional medication adherence issues. To the best of the authors' knowledge, this is the first realist review to assess contexts and mechanisms related to outcomes of digital medication adherence interventions and provide recommendations for designing and implementing similar digital medication interventions.

Methods

Overview

This study was preregistered on PROSPERO (International Prospective Register of Systematic Reviews; CRD42025641383) and has been reported according to the RAMESES (Realist and Meta-Narrative Evidence Syntheses: Evolving Standards) [14].

The glossary of terms used to describe the steps undertaken to carry out this review has been presented in Table 1.

XSL•FO
RenderX

Table . Glossary of terms used to describe the process of this realist review.

Terms	Description
Contexts	Conditions in which the intervention operates, including factors related to individuals receiving the intervention and social, cultural, economic, or policy level factors [13,15].
Mechanisms	The underlying processes that make the intervention work, which operate in certain contexts/situations to lead to outcomes. These can be classified as "mechanism resources," the resources provided by the interventions, and "mechanism responses," the responses that the intervention resources elicit among participants of the intervention [16].
Outcomes	The intended and/or unintended results of an intervention [14].
CMO[a] configurations	A CMO configuration is a heuristic used in realist research to show patterns of how an intervention generates outcomes and the mechanisms that operate in contexts associated with them [14].
Program	Interventions or services under investigation [17]. In this realist review, the program refers to the digital interventions that aimed to improve medication adherence or reduce unintentional nonadherence.
Program theories	Explanations about how specific interventions work. CMOs represent individual program theories. This realist review also presents overarching program theories, which refer to the integration of individual CMO configurations into explanatory models.
Initial program theories	Initial ideas regarding the program theories of an intervention. These CMO configurations are further refined during the realist review process [15].

[a]CMO: context-mechanism-outcome.

The following 5 steps were taken to conduct the realist review.

Development of Initial Program Theory

Initial program theories were cocreated in workshops with the stakeholders of a pilot project that aimed to explore the efficacy of a smart medication device called the "Medybox" in improving medication adherence among domiciliary care recipients and hospital discharge patients in a region in Northern England, United Kingdom. In the workshops, the stakeholders hypothetically discussed the features of the Medybox (a modified electronic pillbox) as an example of a digital medication adherence intervention, which informed the realist review that explored the program theories of all types of digital medication adherence interventions to reduce unintentional medication nonadherence. These stakeholders were presented with a summary of the features of the device and its implementation process, summarized as follows:

- Potential recipients of this device were adults diagnosed with any chronic disease who were unintentionally nonadherent to their medication regimens.
- Domiciliary care providers, short-term re-enablement services, and hospital discharge teams were to identify individuals who needed support to improve their medication adherence and refer them to use the device.
- The Medybox device was a modified electronic pillbox in that the device did not store medications according to individual doses. Instead, it safely stored all types of medications (except injectables and medications that needed refrigeration), including larger liquid medications. The device provided light and sound reminders for medication intake and transmitted real-time responses to the reminders (opening of the device by the participants), allowing the device providers to remotely monitor individuals' medication adherence and provide feedback on it. The device had a built-in SIM card and did not require a Wi-Fi connection. It was to be provided to individuals for 6 - 12 weeks, and during this time the device was intended to help individuals form effective habits of taking their medicines correctly and independently, after which it would be taken away. After that, the device providers planned to recommend other types of interventions or technologies to maintain recipients' medication adherence, such as mobile apps, with a return to caregiver support as one option.

Six cocreation workshops of approximately 2 hours each in 2 workshop rounds (3 workshops and 12 participants in each round) were conducted to generate ideas for program theories for the implementation of this particular device. Stakeholders included members of the regional National Health Service integrated care board (ICB) who were former health care professionals (nurses) but currently working on a digitizing adult social care program, device providers who were implementing the intervention, ICB pharmacists, managers of domiciliary care organizations, individuals receiving care for their medication intake and their informal or family caregivers. Most of the stakeholders were women (10/12, 83%) and 83% (10/12) were White British (consistent with the ethnicity of the population in the local area).

In keeping with qualitative methods, a small number of appropriate stakeholders were recruited purposively via word of mouth and contacts of the research team, the ICB, and the device providers. Stakeholders were "experts by experience" as they had lived experiences of receiving or providing care to individuals requiring help with medication adherence. ICB professionals were also knowledgeable about possible contextual factors that could lead to unintended outcomes of the program

XSL•FO
RenderX

[13,18]. The same group of professionals and care recipients were invited to participate in the second round of workshops. Additionally, participants were recruited if a certain group of stakeholders was underrepresented in the first round. One of the device providers involved in the implementation of the program dropped out after the first round. Therefore, the researchers recruited an ICB pharmacist in the second round to maintain numbers and improve diversity of the stakeholders involved in the workshops (see Saha et al [19] for detailed information about cocreation workshops). The workshops did not include academic researchers as stakeholders.

The discussions were facilitated by the research team, who provided participants with prompts regarding potential contexts (eg, technological literacy of individuals), mechanisms (medication intake reminders), and outcomes (eg, medication adherence) that were derived from the emerging findings of this review. Specific parts of the workshop discussions were audio- or audio-and-video-recorded, and the research team made notes of the workshop discussions. The context-mechanism-outcomes (CMOs) derived from the first round of workshops were presented to the participants in the second round of workshops to further refine them. A list of initial ideas of CMOs derived from workshop discussions was triangulated with the findings from the realist review. This was an iterative process in which the workshop discussions informed the realist review and vice versa. Further details about the device and the prompts used to facilitate workshop discussions are presented in Multimedia Appendix 1. This method of conducting cocreation workshops has been used to explore initial program theories by other realist reviews [20].

Literature Search

Searches were conducted on the following databases from January 2002 till December 2024: MEDLINE, CINAHL, PsycInfo, Web of Science, Scopus, Embase, and gray literature databases called Overton and Policy Commons. Hand searching of reference lists of reviews was conducted to identify any additional studies. The research team started searching from January 2002, as technologies such as smart pillboxes (devices that store and dispense scheduled medication doses at correct times, provide medication intake reminders, and monitor medication adherence by recording when the user opens the pillbox), for example, Pivotell, were first used extensively in the United Kingdom in that year [21]. Thus, these search dates increased the likelihood of inclusion of studies related to recent digital technologies designed to improve medication adherence such as smart pillboxes, automated interactive voice recognition, and mobile apps [22]. The search terms were decided based on the population (eg, multiple chronic conditions), intervention (eg, digital intervention), and outcomes (eg, medication adherence) explored in this review. The full search terms are presented in Multimedia Appendix 2.

Screening and Selection

The papers were assessed for eligibility based on the inclusion and exclusion criteria presented in Table 2.

Titles and abstracts were screened by the first author using the web-based systematic review platform Rayyan [23] and around 10% (200/2152) of the papers were also screened by the other members of the research team for inclusion. Any disagreements were resolved through discussion.

XSL•FO
RenderX

Table . Inclusion and exclusion criteria used for selecting studies in the review.

	Inclusion	Exclusion
Population	Adults diagnosed with a chronic disease and taking long-term medicines to manage it.	• Individuals receiving medication adherence support in nursing homes and in-patient settings such as hospitals and prisons, as the medications are managed by professionals in these contexts [24,25]. • Individuals younger than the age of 18 years. • Individuals having fluctuating capacity to consent, such as those diagnosed with dementia or substance abuse disorders. • Studies that focus on one specific illness diagnosis, as the CMOs[a] from the review were triangulated with those from the cocreation workshops, and the workshop discussions were centered around a device aimed at improving adherence for people diagnosed with any type of chronic illness. Additionally, papers focusing on only one type of chronic illness are unlikely to provide detailed information for program theory development as the information reported would be relevant to specific chronic illness diagnoses only.
Intervention	Studies reporting an intervention to improve medication adherence or reduce unintentional nonadherence with at least one digital component such as websites, mobile apps, or other digital devices. No restrictions were applied on the type of digital adherence intervention to reduce unintentional nonadherence.	• Digital medication adherence interventions that only include content designed to reduce intentional nonadherence, such as education about the importance of taking prescribed medications correctly. This was based on previous studies that have consistently shown that multicomponent interventions are more effective in improving adherence as compared to interventions involving patient education only [26,27]. This criterion was also used because the workshop discussions (added qualitative data) were aimed at developing CMOs of an example device aimed at reducing unintentional nonadherence.
Outcomes	Studies assessing changes in medication adherence or unintentional nonadherence and/or contexts and mechanisms and outcomes of the interventions.	• Did not report medication adherence and/or unintentional nonadherence and/or their related contexts, mechanisms, and outcomes.
Document types	Consistent with the guidelines for conducting realist reviews [14,28], no restrictions were placed on study designs. Reviews, opinion papers, and gray literature reports were included if they provided sufficient information about contexts, mechanisms, and outcomes.	• Conference abstracts, paper corrections, intervention protocols, retractions, and book reviews as they are unlikely to have sufficient information for program theory development.

[a]CMO: context-mechanism-outcome.

Data Extraction

A data extraction sheet was used to document details regarding authors, year of publication, study title, document type (eg, systematic review and pre-post intervention study), participants, and rigor, richness, and relevance scores. The data extraction sheet is presented in Multimedia Appendix 3 [3,9-11,29-107]. The rigor of the studies was judged based on the credibility and trustworthiness of the methodology, for example, sample size, data collection, and analysis methods [13]. The rigor of gray literature, opinion pieces, and book chapters was assessed based on significance, objectivity, coverage of the topic, authority, and accuracy [28]. Relevance was judged by assessing the extent to which papers presented information related to the topic of the review and provided evidence for program theory development. Richness was judged by assessing the extent to which papers provided details regarding mechanisms, contexts, and outcomes of the interventions [12,13]. The scoring criteria used in the realist review by Waldron et al [12] were used to assess the rigor, relevance, and richness. Studies were scored on a scale of 0 (very poor) to 3 (very good) in terms of relevance

XSL•FO
RenderX

and rigor, and 0 (nothing of interest or not focused on design, implementation, or use) to 4 (much valuable data) in terms of richness. This helped in understanding the extent to which each study contributed to program theory development and the extent to which each program theory was supported by relevant and rigorous evidence [12,13].

Data Synthesis

The lead author manually annotated the papers for program theory ideas with the help of NVIVO (Lumivero, version 14) software. Data from the literature and workshops were analyzed separately. Patterns of context, mechanisms, and outcomes from the studies included were explored by using inductive and deductive logic, and relevant text to support each program theory was documented. The recordings of the workshop discussions were transcribed verbatim. The lead author reviewed the transcripts and the participant and facilitator notes of the workshop discussions and coded the patterns of contexts, mechanisms, and outcomes. Anonymized participant quotes and participant and facilitator notes supporting each CMO were documented.

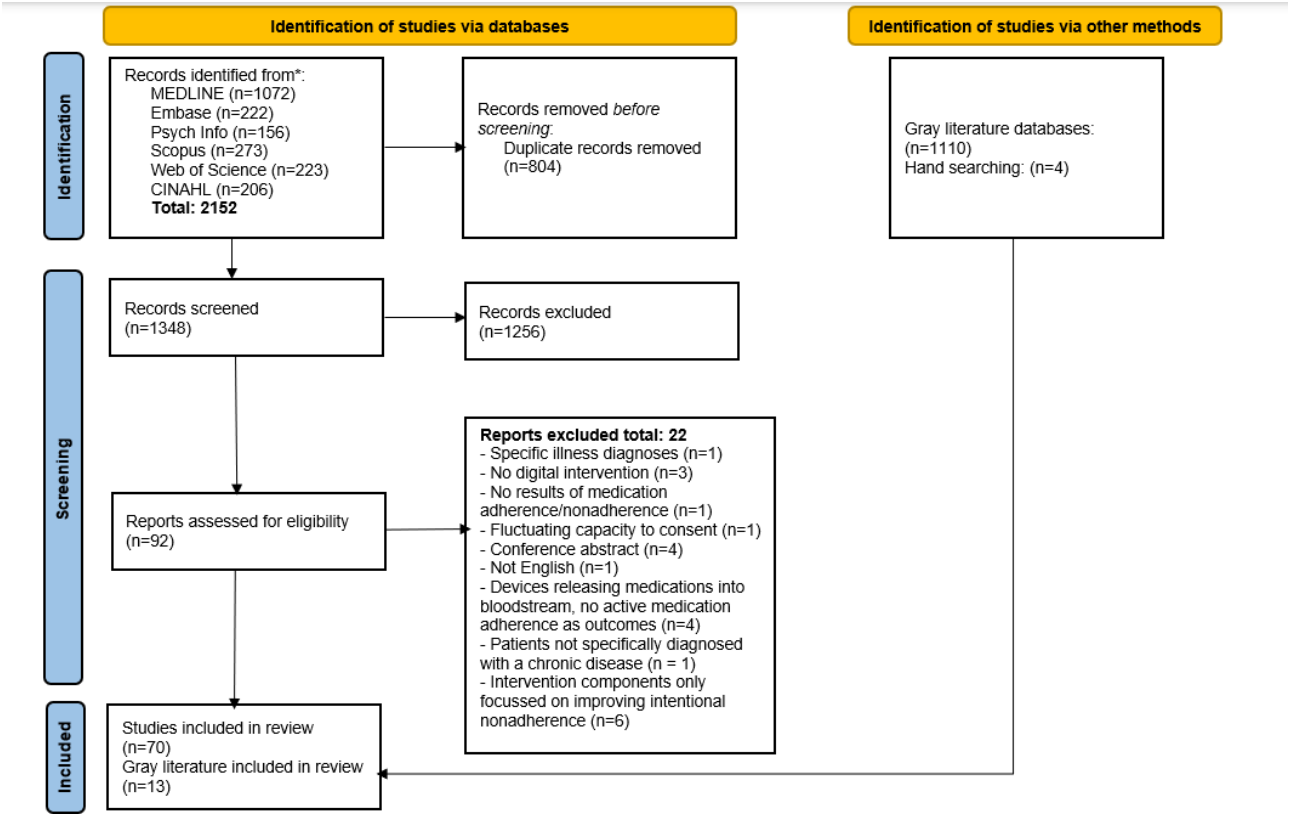
The CMOs from the realist review were then triangulated with the CMOs from the cocreation workshops by noting the extent to which the CMOs from the workshops corroborated or not with the CMOs derived from the literature. After that, a final list of program theories in different theory areas and the number of CMOs from the literature, workshops, or both were noted. After the initial CMOs were created, an iterative process of revising and refining was conducted through discussion with the research team.

Ethical Considerations

This study received ethics approval from the Clinical Research Sponsorship ethics committee at Lancaster University and the Health Research Authority and Health and Care Research Wales ethics committee on February 4, 2025 (ethics board: social care; reference number: 24/IEC08/0037).

Results

Characteristics and Quality of Studies



Eighty-three studies were included in this review. Figure 1 depicts the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram with details about the search and screening process.

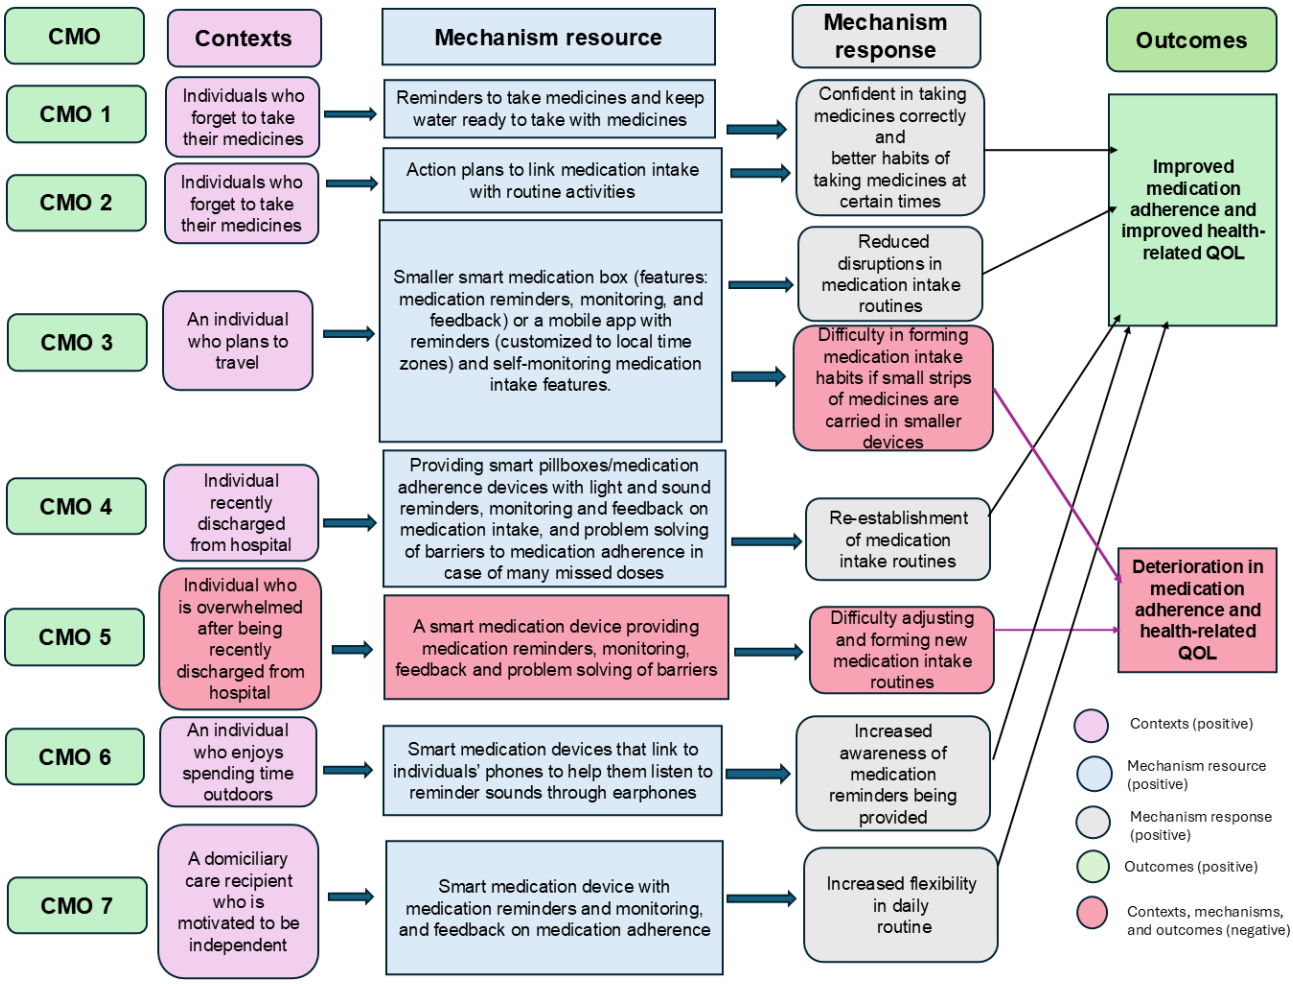
Eighty-three papers, including peer-reviewed research papers (n=70) and gray literature (n=13), were included in the review. Of the research papers, 44 were narrative, systematic, or scoping reviews or meta-analyses, and 3 papers were expert opinion pieces. Of the 23 primary studies included, the largest number were conducted in the United States (n=9), with studies also conducted in Canada (n=4), Spain (n=2), the United Kingdom (n=2), China (n=2), Australia (n=1), and Switzerland (n=1). The country in which the study was conducted was not reported by 2 studies [29,30]. The primary studies included 17 intervention studies [3,10,29-44]. The rest were qualitative or quantitative studies that explored participants' views (where participants were individuals diagnosed with chronic conditions, informal caregivers of patients diagnosed with chronic conditions, and health care professionals) regarding the components of digital medication adherence interventions [43-48].

Most of the studies were assigned a score of 3 in the "rigor" domain. However, approximately 60% (50/83) of the studies were assigned a score of 1 or 2 in the richness domain due to lack of detail regarding contexts and mechanisms related to the outcomes of the interventions. This was primarily because these studies did not report the content and delivery of the interventions in sufficient detail. Approximately 24% (20/83) of the studies were assigned a score of 1 in the "relevance" domain due to lack of data for program theory development. The authors triangulated data from studies that had low "rigor" scores with the data from studies that had higher scores while developing program theories [13,108]. The studies that had low "relevance" and "richness" scores were included in the review if they provided enough information for program theory development and if the data provided by them could be supported by the studies that were assigned high scores in these domains. The authors also transparently reported if a certain program theory was not supported adequately by rigorous, relevant, and rich data [108]. Details about the studies included in the review are presented in Multimedia Appendix 3.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [109] with details regarding the inclusion of studies.

Thirty-five CMOs grouped in 7 theory areas were derived from the review, cocreation workshops, or both. A narrative summary of the CMOs derived from the literature, cocreation workshops, or both in each theory area is presented in the following section. The CMOs are presented in Multimedia Appendix 4 [32,35,38,40-42,45,47,48,52,56,74,79,87,97,100,106], along with specific quotes to support them that were derived from workshop discussion recordings and/or studies in this review.



Theory 1: Building and Maintaining Medication Intake Habits

Overview

This theory area includes the CMOs related to ways by which digital interventions facilitate the development and maintenance of effective medication intake habits. The overarching program theory based on the CMOs of theory 1 is presented in Figure 2 (see also Multimedia Appendix 4).

XSL•FO
RenderX

Figure 2. The overarching figure showing the CMOs in theory 1: building and maintaining medication intake habits. CMO: context-mechanism-outcome; QOL: quality of life.

CMOs Derived From Both Literature and Workshops

Providing medication intake reminders using various devices, including mobile apps, text messages, or smart medication dispensers, can help individuals to form effective medication intake habits [10,31-46,49-97]. Additionally, workshop participants suggested that it was important to prompt individuals to keep water ready and near the smart medication device, as this can help individuals to establish habits of undertaking the necessary actions before medication intake. However, it is important to tailor the frequency and timing of reminders according to individual needs. Providing reminders at the exact times when patients plan to take their medicines was recommended to avoid excessive intrusiveness in individuals' lives (CMO 1) [58].

Monitoring individuals' medication adherence using smart medication devices or mobile apps and collaboratively developing action plans with them to link their medication intake with daily routine tasks, such as mealtimes [9,30,39,87,95], can also help in forming effective medication intake habits. Over time, these tasks could act as cues for medication intake, resulting in lower chances of forgetfulness and improved adherence (CMO 2).

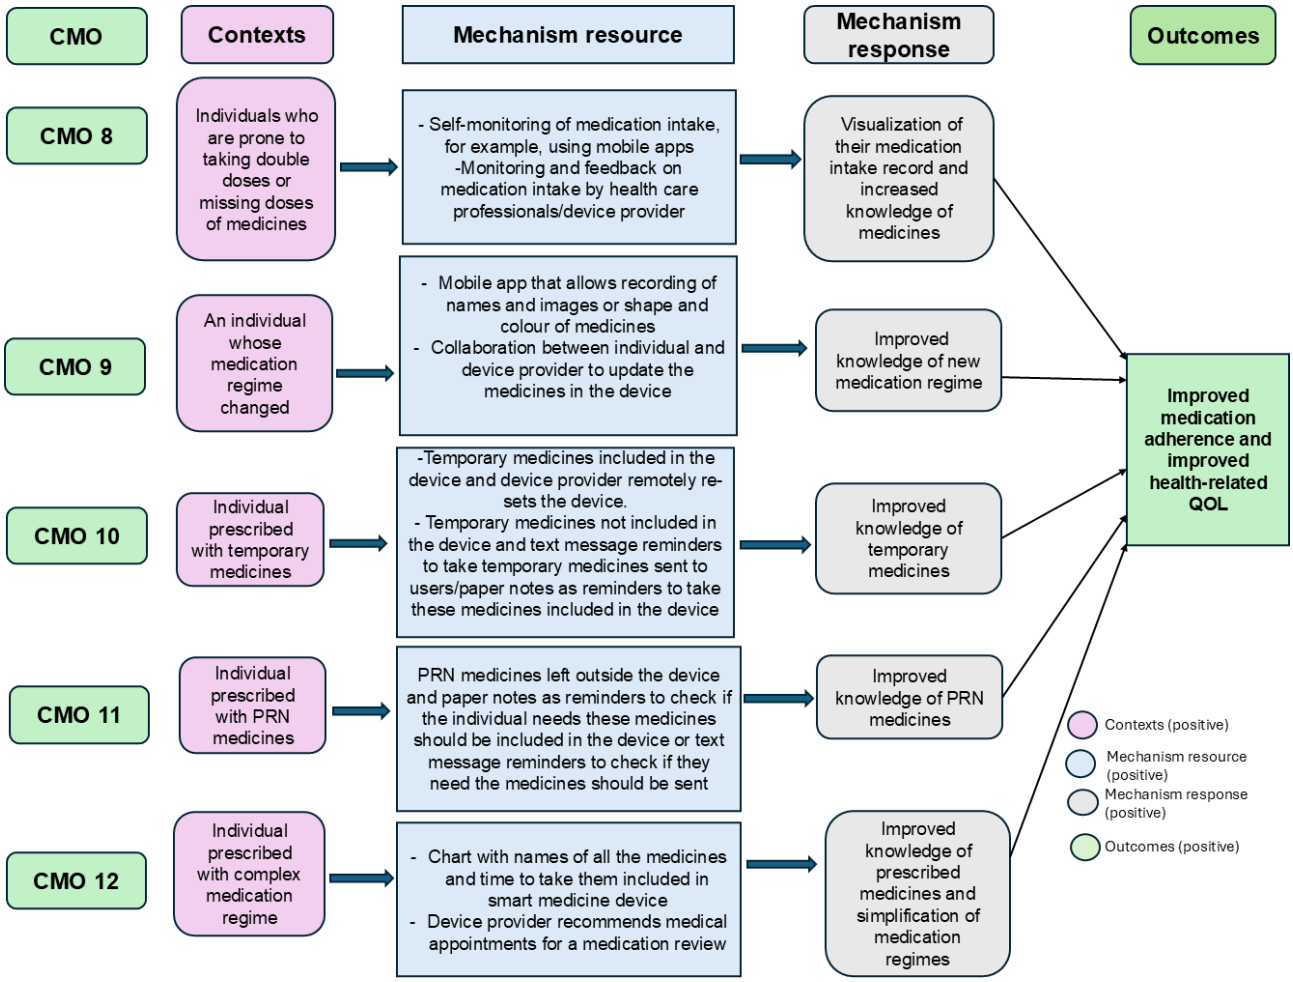
Certain situations could disrupt existing habits related to medication intake. Hospitalization was identified as one such situation, and it could be difficult to form new and effective medication intake habits after hospital discharge, as hospitalization commonly results in medication regimen changes [35]. Thus, providing patients with smart medication devices that provide medication intake reminders and allow monitoring and feedback on medication adherence can lead to the re-establishment of effective medication intake habits and improvement in adherence (CMO 3 [35]). However, some individuals may be overwhelmed by the recent hospitalization and may not want any more changes to their routines after discharge, resulting in refusal to use smart medication devices. This could be a risk if the individual does not have any informal caregivers or care providers to help them take their medications correctly, which can potentially result in poor medication adherence and rehospitalization (CMO 4) [35].

Traveling could also lead to disruption in medication intake habits. The workshop discussions centered around a device big enough to effectively store all the prescribed medications, including liquids, but too difficult to carry while traveling. Therefore, it was suggested that the device should be left at home while traveling and individuals could use a mobile app to receive medication intake reminders and self-monitor their medication intake. Additionally, a qualitative study highlighted that mobile apps should provide medication intake reminders that are customizable to match local time zones when the individual is traveling [40]. The use of smaller smart medication

XSL•FO
RenderX

devices while traveling was also suggested by a few workshop participants. However, this could lower medication adherence if an individual takes out small strips of medications to carry with them, as they would not have access to instructions regarding medication intake that are printed on medication boxes (CMO 5).

CMOs Derived Only From Workshops



Domiciliary care providers often visit domiciliary care recipients to prompt them to take their medications on time. Therefore, workshop participants mentioned that this device could help care recipients be more independent and flexible as they do not have to wait for care providers to visit them to take their medications (CMO 6). Workshop participants also discussed how medication reminder sounds provided by the device may not be heard by some individuals if they spend a lot of time outdoors, for example, in their garden. Thus, it was suggested that the device could be connected to individuals' mobile phones so that they could hear the reminder sounds through earbuds while engaging in activities outdoors (CMO 7).

Theory 2: Solving Medication-Related Barriers to Adherence

Overview

This theory area includes the CMOs related to ways by which digital interventions help in solving medication-related barriers to adherence, such as complex regimens. The overarching program theory presented in Figure 3 is based on the CMOs of theory 2 presented in Multimedia Appendix 4.

Figure 3. The overarching figure showing the CMOs in theory 2: solving medication-related barriers to adherence. CMO: context-mechanism-outcome; QOL: quality of life; PRN: pro re nata.

CMOs Derived From Both Literature and Workshops

Some individuals may be more prone to frequently missing doses of medications or taking double doses due to factors such as forgetfulness. Digital medication adherence interventions such as mobile apps can help in improving adherence by allowing individuals to self-monitor their medication intake. This can reduce chances of double doses or missed doses of medications due to individuals' increased awareness of their own medication intake [3,11,45,46,48,52,54-56,63,73,88,96,98]. Smart medication devices, which allow a health care professional or provider of the smart medication device to monitor and provide feedback on an individual's medication adherence, can also help in reducing chances of missed doses and double doses, as they can increase individuals' knowledge of their medications (CMO 8) [9,29,30,39,48,52,59,63,79,85,86,89,93,96,98].

Individuals' medication adherence can also be reduced because of medication regimen changes, as new medication intake habits may need to be established. In this context, mobile apps that enable recording of medication images or that include an option

XSL•FO
RenderX

of adding the shape and color of medications along with names of the medications can help improve the recognition of new prescribed medications [32,40]. Mobile apps that announce medication names and show the pictures of the medications while providing medication intake reminders can also help in improving medication adherence by improving recognition and knowledge of the medications [40]. Additionally, workshop participants suggested that there should be collaboration between the device provider and the user of the smart medication device to update the device with the new medicines (CMO 9). This could be done effectively if the device provider regularly reminds the user to report any changes in medication regimens.

Prescription of temporary medicines such as antibiotics can also lead to reduction in medication adherence due to required changes in medication intake habits. An intervention study that provided patients with smart pillboxes before hospital discharge [35] did not include temporary medications inside the pillbox and instead provided individuals with text message reminders to take their temporary medications. Similarly, workshop participants also suggested that the temporary medications should be kept outside the smart medication devices as they could interfere with monitoring of the adherence of other medicines, and a note could be included inside the device to remind them to take their temporary medications. Alternatively, workshop participants suggested that these medicines could be kept inside the device, and the device provider could remotely reset the device after the individual no longer needs to take them (CMO 10).

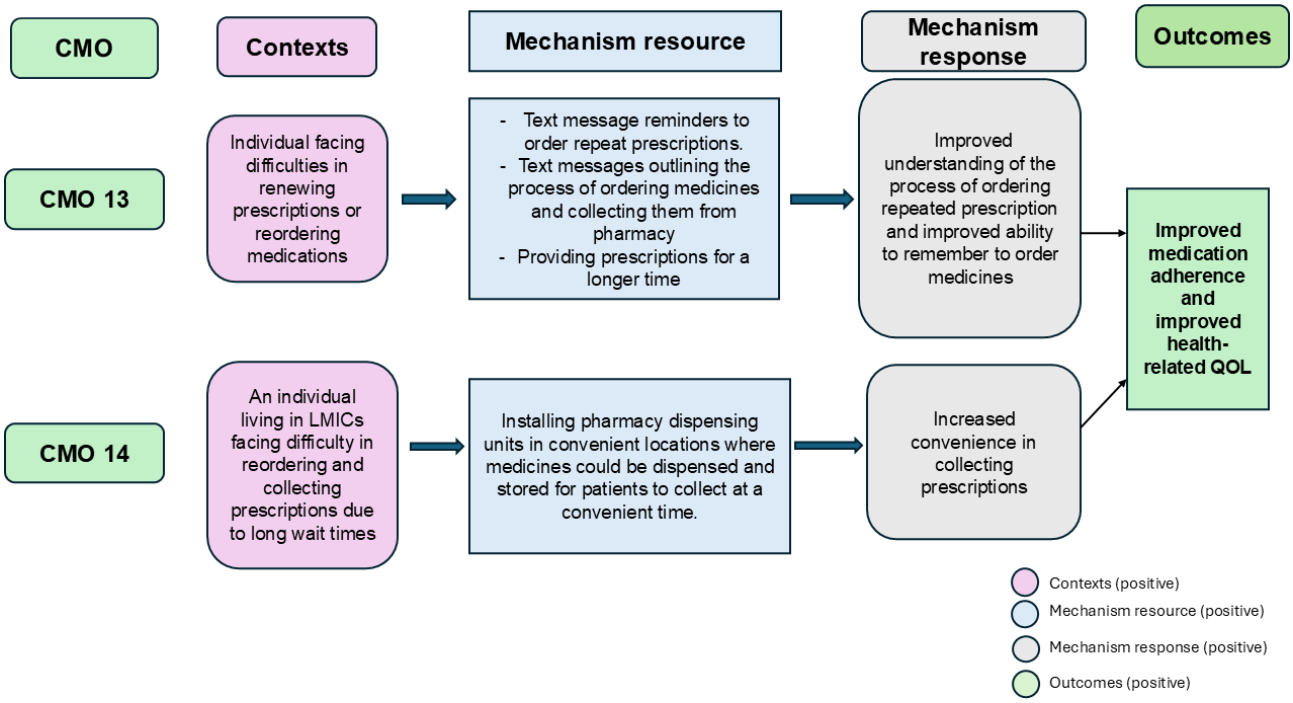
Workshop participants also suggested that pro re nata (PRN) or "when required" medicines such as laxatives should be kept outside the smart medication devices as they can interfere with monitoring of other medicines. Participants also suggested that hand-written notes reminding individuals to check if they need to take the PRN medicines should be included in the device (CMO 11). Similarly, the intervention study by Shahani et al [35] that provided patients recently discharged from hospital with smart pillboxes also did not include PRN medications inside the pillboxes. Individuals were instead sent text message reminders to check if they needed to take these medications.

CMO Derived Only From Workshops

Workshop participants acknowledged that complex medication regimens could make medication adherence challenging. The smart medication device that they were discussing provided users with reminders to take medications but did not specify the name of the medication and the time to take it. Thus, participants suggested that a written chart of the names of medications and the correct time to take each medicine should be included in the box. This can improve individuals' knowledge of medication regimens and medication adherence. Additionally, the device providers mentioned that they would recommend the individual schedule an appointment with the pharmacist or general practitioner for a potential medication review to simplify medication regimes (CMO 12).

Theory 3: Enabling Collection of Prescription Medications on Time

Overview



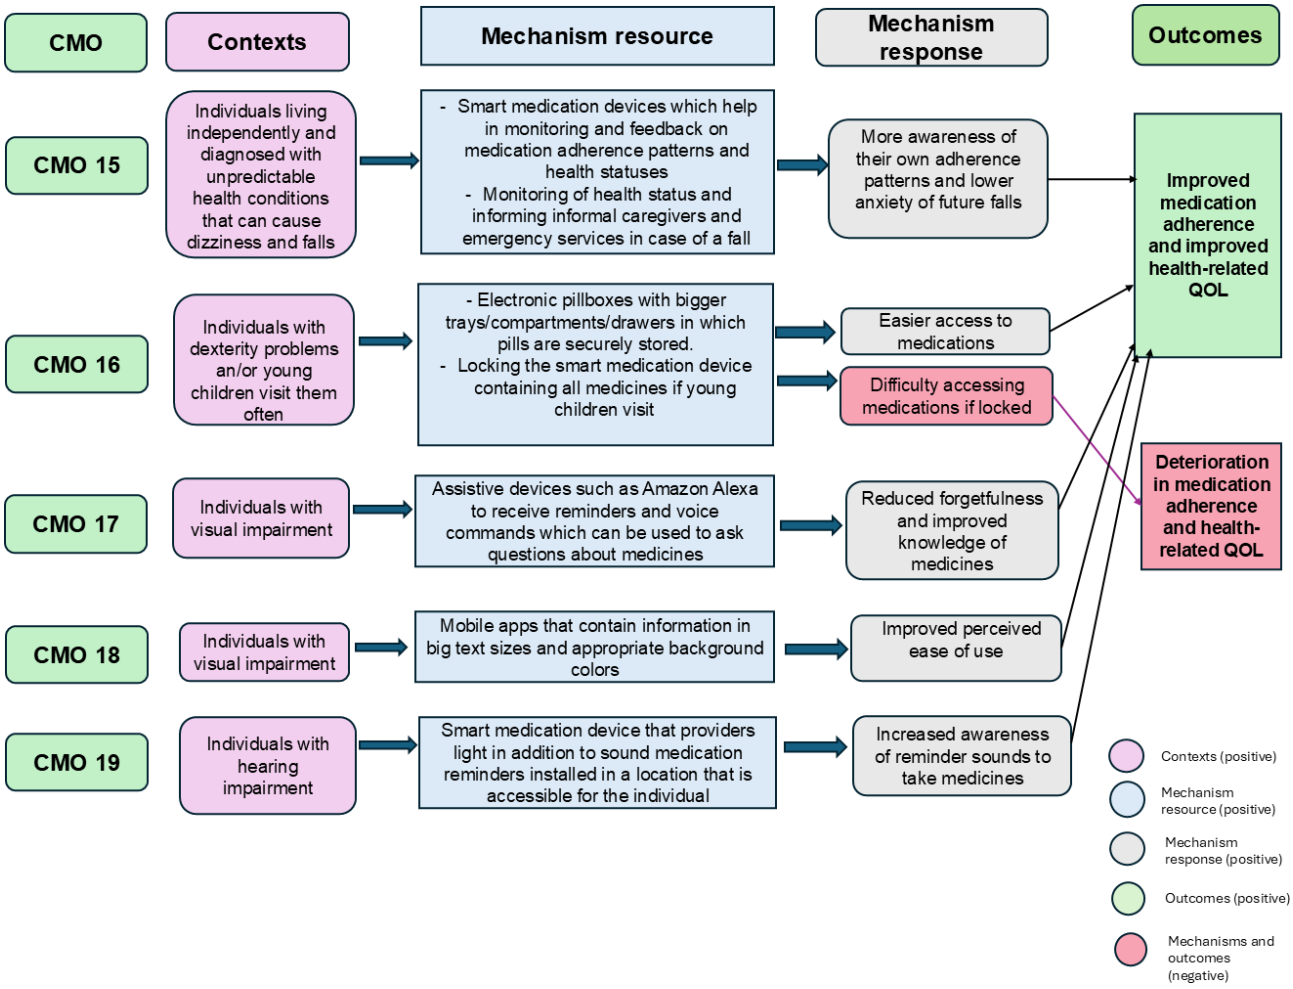
This theory area includes the CMOs related to ways by which digital interventions can improve collection of prescription medications on time. These CMOs were derived from the literature only. The overarching program theory presented in Figure 4 is based on the CMOs of theory 3 presented in Multimedia Appendix 4.

Studies have highlighted the importance of enabling easier access to prescription medications to prevent primary nonadherence. Text message reminders or reminders from mobile apps to order prescription medications on time and outlining the exact process of ordering prescriptions and collecting them can improve medication adherence. This would be helpful for individuals who forget to order prescriptions or who are unable to understand the process of ordering repeated prescriptions. Additionally, in the context in which frequent medication reviews are not required, providing repeat prescriptions for longer periods of time can improve medication adherence as it would reduce the frequency of ordering prescriptions (CMO 13) [48,68,79,80,99].

Mash et al [100] suggested that collecting prescription medications on time could be particularly challenging for individuals living in low- and middle-income countries (LMICs) due to limited human resources and poor infrastructure in primary health care services, resulting in long waiting periods to collect prescriptions. Thus, this study [100] suggested the installation of pharmacy dispensing units which allow remote dispensing of medications (medication dispensing can be requested online by patients) and storage of medicines in password-protected lockers in convenient areas. This can allow patients to collect their medicines at a convenient time and help in improving medication adherence (CMO 14). However, installation of pharmacy dispensing units requires high start-up costs. Additionally, the long-term efficacy, feasibility, and acceptability of these technologies are yet to be determined, as these have been piloted on a very small scale only in South Africa [77,100].

XSL•FO
RenderX

Figure 4. The overarching figure showing the CMOs in theory 3: enabling collection of prescription medications on time. CMO: context-mechanism-outcome; LMIC: low- and middle-income country; QOL: quality of life.



Theory 4: Supporting People With Sensory or Motor Impairments and Unpredictable Health Issues

Overview

This theory area includes the CMOs related to ways by which digital medication adherence interventions can improve the adherence of people with unpredictable health conditions and sensory and motor deficits. The overarching program theory presented in Figure 5 is based on the CMOs of theory 4 presented in Multimedia Appendix 4.

XSL•FO
RenderX

Figure 5. The overarching figure showing the CMOs in theory 4: supporting people with sensory or motor impairments and unpredictable health issues. CMO: context-mechanism-outcome; QOL: quality of life.

CMOs Derived From Both Literature and Workshops

Smart medication devices that allow health care professionals and device providers to monitor medication adherence and provide feedback on adherence patterns based on the monitoring can improve individuals' adherence by increasing their awareness of their adherence patterns. Changes in the health status of individuals could be detected by observing any changes in the frequency of individuals' use of devices (CMO 15). If an individual misses several doses of medications, a timely intervention could be provided [30,33-35,42,52,56,57,60,61,64,65,73,78,81-83,86,88,95,99,101-103]. Emergency services and informal caregivers could be contacted in the context of severe deterioration of health or a fall. Thus, these devices can also be used for effective telecare monitoring in situations where older adults live alone [52].

However, some individuals with dexterity issues, for example, people with arthritis, may struggle to use devices such as smart pillboxes, as it may be difficult for them to take the medicines out of the containers. Providing these individuals with smart pillboxes with bigger compartments or pill trays could enable easier access to medications [34,42,56,73,74]. Additionally, workshop participants highlighted that if an individual is visited often by young children, the smart medication devices might need to be locked or kept out of reach of children. However, if an individual has poor dexterity and struggles to open locks, they might struggle to unlock the devices to access their medications, resulting in poor medication adherence (CMO 16).

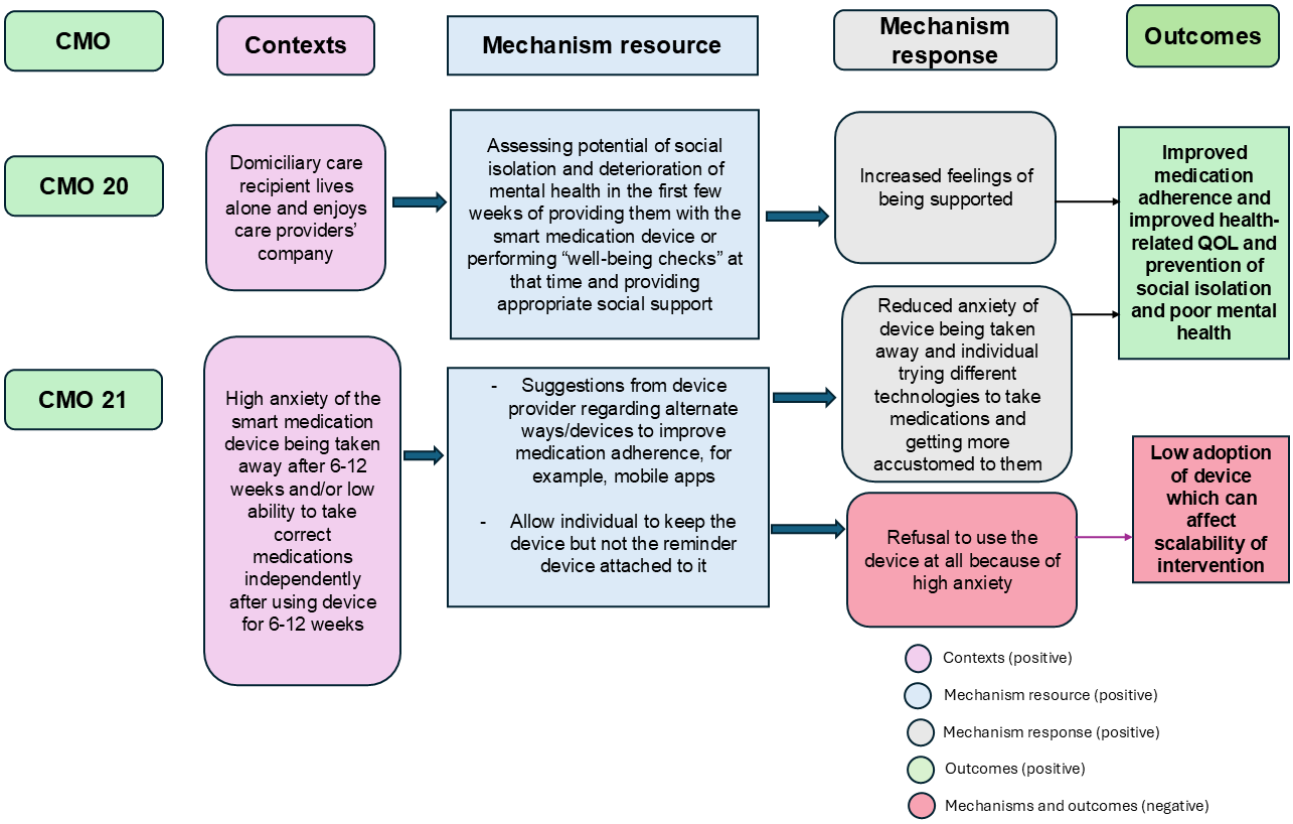
CMOs Derived Only From the Literature

Several studies recommended that the mobile apps aiming to support individuals' medication adherence should include bigger text sizes and appropriate backgrounds to enable individuals with visual impairments to see the content properly (CMO 17) [40,91]. Devices such as Amazon Alexa that provide auditory medication intake reminders can also be helpful in improving medication adherence among individuals with visual impairment (CMO 18). These devices also have voice command features which can be used to ask questions regarding the prescribed medications, which can enable a better understanding of the prescribed medicines, thereby improving medication adherence [41,74].

CMO Derived Only From Workshops

As described earlier (Methods section), the smart medication device discussed in the workshops provided light and sound medication intake reminders. Thus, participants felt that the device was suitable for individuals with visual and hearing impairments. However, participants mentioned that individuals with hearing impairment may not be able to hear the reminder sounds if it is not installed in an accessible location. Thus, installing the device at an accessible location in individuals'

XSL•FO
RenderX



homes was identified as a useful mechanism to improve the adherence of individuals with hearing impairment (CMO 19).

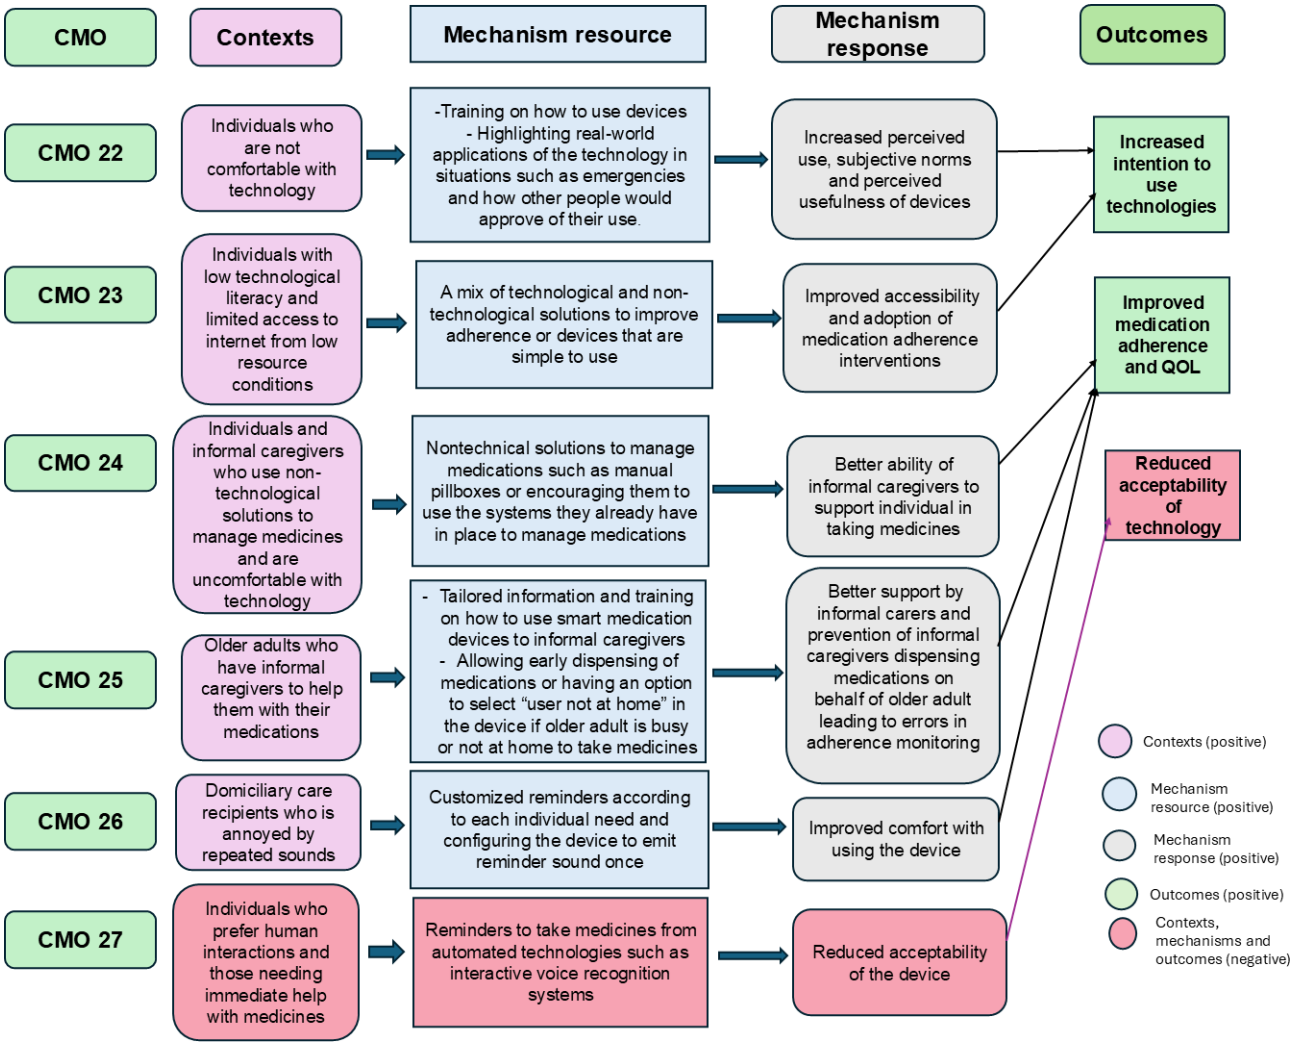
Theory 5: Supporting Individuals With High Anxiety, Low Medication Self-Efficacy, and Low Social Support

This theory area includes the CMOs related to how the smart medication device that was provided to domiciliary care recipients and hospital discharge patients in the United Kingdom could help in improving the medication adherence of patients with high anxiety, low self-efficacy, and low social support. The CMOs in this section were derived from the workshop discussions only. The overarching program theory presented in Figure 6 is based on the CMOs of theory 5 presented in Multimedia Appendix 4.

Domiciliary care recipients in the United Kingdom who have difficulties with medication adherence are generally visited by care providers to prompt them to take their medications. Therefore, participants discussed that if a domiciliary care recipient lives alone and has low social support, they may enjoy the company of care providers and look forward to their visits. These care recipients may feel isolated if the care providers' visits are reduced when they self-manage their medicines. Thus, participants suggested that the device provider should assess the mental health and the potential for social isolation of these individuals and provide appropriate social support after the device is installed in their homes. This is especially important for individuals with a prior history of mental health diagnoses such as depression (CMO 20).

Figure 6. The overarching figure showing the CMOs in theory 5: supporting individuals with high anxiety, low medication self-efficacy, and low social support. CMO: context-mechanism-outcome; QOL: quality of life.

As mentioned in the Methods section, this device was provided to the recipients for only 6 - 12 weeks, and during that time, the device was aimed at helping them to develop effective medication intake habits, after which the device was taken away. Participants mentioned that the removal of the device could cause anxiety among some individuals as they may become dependent on it for maintaining their medication adherence. Participants recommended that users could be allowed to keep the device that stores all the medicines safely, but the electronic reminder, which is used to provide medication intake reminders and monitor individuals' adherence (the costly part of the device), could be taken away by the device provider. This could ensure that all the medicines are stored in the same place and strengthen individuals' habits of taking medications from the same place, resulting in reduced anxiety and maintenance of medication adherence. However, some individuals with high anxiety may refuse to use the device at the outset if they are informed that it would be taken away after 6 - 12 weeks. This could reduce the large-scale adoption and scalability of the intervention. The device provider also mentioned that they could suggest, following removal, alternative devices to maintain their medication adherence, for example, mobile apps. This could help individuals to try different types of technology to manage their medications and improve their comfort with technology (CMO 21).



XSL•FO
RenderX

Theory 6: Supporting Individuals Who Are Uncomfortable With Technology or Certain Aspects of Technology

Overview

This theory area includes CMOs related to mechanisms by which digital medication adherence interventions can improve the adherence of individuals who are uncomfortable with technology or certain aspects of technology, such as repeated reminder sounds for taking medications. The overarching program theory presented in Figure 7 is based on the CMOs of theory 6 presented in Multimedia Appendix 4.

Figure 7. The overarching figure showing the CMOs in theory 6: supporting individuals who are uncomfortable with technology or certain aspects of technology. CMO: context-mechanism-outcome; QOL: quality of life.

CMOs Derived From Both Literature and Workshops

Workshop participants mentioned that it was important to provide some training on how to use the smart medication device, especially to individuals who were uncomfortable with technology (CMO 22). This was corroborated by the results of a qualitative study [40] which showed that providing hands-on training on the use of a mobile app intervention in small groups could increase the perceived ease of use of the technology. Additionally, highlighting the usefulness of the mobile app in real-world situations such as health emergencies can increase perceived usefulness. Highlighting how their family members or doctors may approve of their use of the app to improve their adherence could improve subjective norm (individuals' perception of how others would perceive their behavior). According to the Technology Acceptance Model, an increase in perceived usefulness, perceived ease of use, and subjective norms can increase the intention to use the technology to improve medication adherence [40].

Workshop participants also highlighted the importance of providing some training on how to use smart medication devices to informal caregivers or family members so that they can better support the person they care for. Additionally, some of the smart medication dispensers that provide medication intake reminders, allow monitoring of adherence, and dispense medications according to individual doses may need to be adapted for use if informal caregivers support individuals with their medication intake [42]. Some of these devices assume that the medication has been taken by the individual correctly once the device has been opened and medications are dispensed [42]. However, if the individual is busy or not at home, informal caregivers may dispense the medication on behalf of the individual. Therefore, these devices should have an option to select "user not at home" to indicate that the individual is not at home or is busy [42] to

XSL•FO
RenderX

improve the accuracy of medication adherence monitoring (CMO 23).

Some studies suggested that nontechnological solutions or a combination of technological and nontechnological solutions may be more suitable to improve the adherence of individuals living in low-resource conditions and LMICs. This is important as poor infrastructure, low internet access, and technological literacy among individuals are common in these contexts [46,77,104,105]. This was corroborated by workshop discussions as participants noted that one of the advantages of the smart medication device discussed was that it had a built-in SIM card and no Wi-Fi was needed to use it, which made it more accessible for individuals living in low-resource conditions (CMO 24).

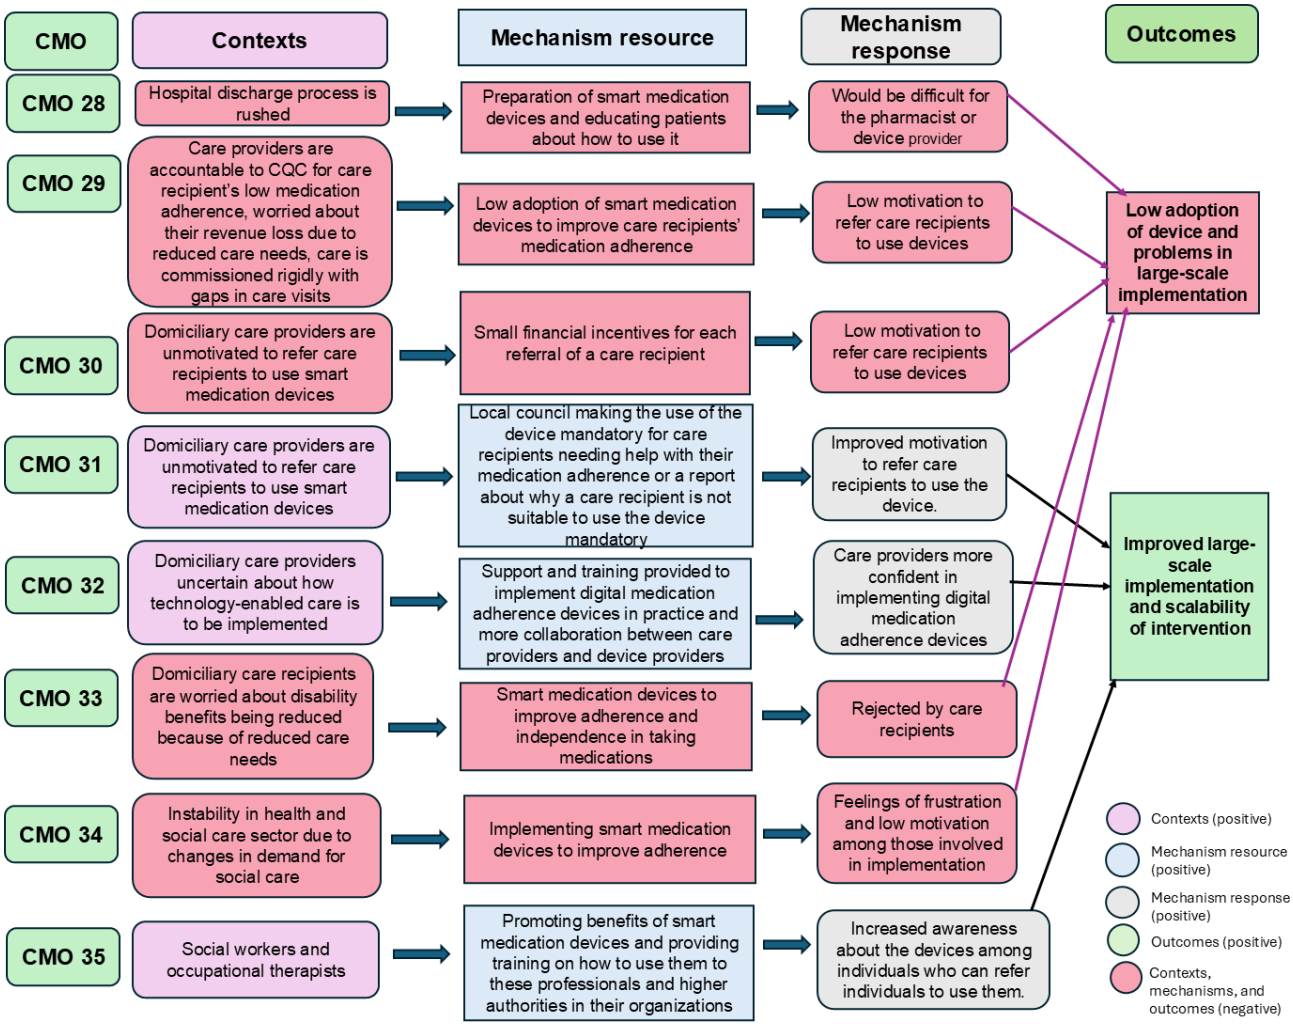
CMOs Derived Only From the Literature

A qualitative study conducted with informal caregivers of older adults [47] showed that many informal caregivers already had established nontechnical methods of supporting medication adherence of the person they were caring for (eg, paper medication lists with descriptions of medicines and information about when to take medicines and a box to store all the medicines). Thus, the informal caregivers were unwilling to learn and use technologies such as mobile apps to support medication adherence as they felt that use of these technologies would increase caregiver burden. In these contexts, encouraging individuals to use these nontechnological solutions may be more suitable (CMO 25).

CMO 26 highlighted the low acceptability of automated technologies such as interactive voice recognition systems and automated telephone communication systems to receive medication intake reminders [38,74,85,106] among patients who preferred speaking to a person. These technologies are also unsuitable for patients needing immediate support regarding their health condition or medication intake, and using these technologies can result in lower medication adherence for these individuals [38,106].

CMO Derived Only From Workshops

A few care recipients who participated in the workshops mentioned that repeated medication intake reminder sounds from the device may be annoying, and this could negatively affect medication adherence of individuals if they open the device and take the wrong medications to stop the reminder sounds. Thus, participants suggested that to increase individuals' comfort with using the technology, the reminder sounds should be customized to individual needs, and the frequency of the reminders should be reduced to only once if required (CMO 27).



Theory 7: Economic, Policy, and Organizational Factors Affecting Implementation of Digital Medication Interventions

Overview

This theory area includes CMOs related to the wider economic, policy, or workplace organizational factors that affect large-scale implementation of digital medication adherence interventions. The overarching program theory presented in Figure 8 is based on the CMOs of theory 7 presented in Multimedia Appendix 4.

XSL•FO
RenderX

Figure 8. The overarching figure showing the CMOs in theory 7: economic, policy, and organizational factors affecting implementation of digital medication interventions. CMO: context-mechanism-outcome; CQC: Care Quality Commission; NHS: National Health Service.

CMO Derived Only From the Literature

An intervention study which provided patients with smart pillboxes before hospital discharge [35] highlighted that there were several barriers at the organizational level relating to implementation of the intervention. The rushed nature of hospital discharge made it difficult for pharmacists to prepare the pillbox and demonstrate the use of the pillbox before patients were discharged. Thus, the authors recommended that organizational changes such as early communication between prescribing clinicians and pharmacists preparing the pillboxes and early provision of the discharge medications are required for successful implementation in the context of hospital discharge (CMO 28) [35].

CMO Derived Only From Workshops

The workshop participants who were involved in implementing the device highlighted several barriers to the large-scale implementation of the device. The number of individuals who were being referred to use the device from domiciliary care provider organizations and short-term re-enablement services that provide care to patients recently discharged from hospitals in the United Kingdom was very low [110].

Participants felt that the scalability of the intervention was potentially reduced because obtaining referrals from domiciliary care organizations was particularly difficult because care providers were anxious about potential revenue loss for them. Their anxiety was further increased because of a recent increase in the number of care providers locally as compared to the demand for their services (CMO 29). Additionally, care providers have to undertake more administrative tasks to identify the care recipients who were suitable to use the device and refer them to the team implementing the device. Care providers would also have to report any lapses in medication adherence among care recipients to the Care Quality Commission that regulates the domiciliary care services in the United Kingdom [111]. Care providers were worried that they may be held accountable for any lapses in medication adherence of care recipients. Care provision is generally commissioned in the United Kingdom with rigid specifications of tasks and times of visits, with several gaps between the care visits. Early morning and late-night visits are common. Care providers prefer to undertake some medication prompting visits during the rest of the day to increase the hours of their work shift and their financial compensation.

The device provider mentioned that they offered care organizations small financial incentives (£25 - £30; a currency exchange rate of £1=US $1.35 was applicable) for each referral.

XSL•FO
RenderX

However, this did not improve care providers' motivation to refer care recipients to use the device because of fear of long-term revenue loss. A higher value of financial incentives would have also limited the cost savings that could have been achieved from this intervention (CMO 30).

Thus, participants felt that the local councils that commission care services should make the use of the device a part of usual care for care recipients needing support with their medication adherence. If an individual is not suitable for using the device, a report from care providers outlining the reasons for that should be required. Participants felt that this may have improved the implementation of the intervention (CMO 31). Additionally, the local councils were aiming to increase technology-enabled care provision [111], but care providers were uncertain about how to implement it in their care provision. Thus, participants felt that local councils should support care providers to implement technologies such as smart medication devices in their care provision and encourage more collaborations between them and care providers (CMO 32).

Participants also highlighted that care recipients may not be motivated to use the device because they could be anxious about the potential reduction of their disability benefits if they require less support for daily living tasks and mobility due to a reduction in the care providers' visits (CMO 33) [112].

Overall, participants felt that the instability in the health and social care sector in the United Kingdom in recent years contributed to the problems with implementation. The number of care providers available and demand for their services fluctuated significantly in the previous years due to the national government's efforts to improve their recruitment and retention. This resulted in a reduced demand for their services in the local area when the project was delivered [111,113]. Thus, participants suggested that future projects should allocate enough time at the beginning to assess contextual factors and to form effective partnerships with organizations that can help improve the implementation of devices (CMO 34). Participants also suggested that the benefits of this device should be promoted to professionals such as social workers and occupational therapists as they regularly assess the care needs of individuals. It was also important to promote the device among the higher authorities of the organizations in which these professionals work to get leadership support for the implementation (CMO 35).

Discussion

Summary of Findings

Thirty-five CMOs in 7 theory areas were identified. CMOs within theory 1 demonstrated ways in which devices can help establish and maintain medication intake routines, such as by providing medication intake reminders. Theory 2 presented CMOs related to solving medication-related barriers to adherence, for example, self-monitoring of medication adherence to reduce double or missed doses. Theory 3 presented CMOs related to enabling collection of prescription medications on time, for example, by sending text message reminders to collect prescriptions on time. Theory 4 included CMOs related to improving the medication adherence of individuals with sensory and motor impairments and unpredictable health conditions, for example, encouraging individuals with visual impairments to use assistive devices with voice command features such as Alexa to receive medication intake reminders. Theory 5 presented CMOs related to customizing smart medication devices according to the needs of individuals with high anxiety and low social support and low medication self-efficacy, such as assessing the mental health of individuals who are socially isolated and providing them with appropriate social support. Theory 6 presented CMOs related to supporting individuals who are uncomfortable with technology, for example, providing training on how to use smart medication devices. Theory 7 presented CMOs related to policy and economic factors that were barriers to the large-scale implementation of smart medication devices, such as a lack of suitable incentives for care providers to refer domiciliary care recipients to use the device.

CMOs were derived from both the literature and workshops (14/35, 40%), with a proportion derived only from the literature (7/35, 20%) and a proportion only from the workshops (14/35, 40%). CMOs derived from workshops provided important information about implementing smart medication devices in the United Kingdom and in the context of domiciliary care and hospital discharge. CMO 14 (enabling easier access to prescriptions in LMICs) was not adequately supported by high-quality evidence, and further research is needed to support it. After assessing the "rigor" at a program theory level, the authors excluded a CMO that was initially developed regarding ingestible digital pills for monitoring and providing feedback on medication adherence because these have recently been discontinued due to low acceptability and adoption [114].

Comparison With Prior Work and Implications for Practice and Policy

The results of the current realist review are consistent with those of a qualitative study [114] in which patients diagnosed with cardiovascular diseases acknowledged that medication intake reminders and reminders for keeping water ready to take with medications helped in maintaining effective medication intake habits. Similarly, the importance of tailoring the timing and frequency of the reminders according to individual preferences to prevent "alert fatigue" and annoyance related to receiving repeated reminders was also highlighted [115]. The importance of action planning related to medication intake by linking it with daily routine tasks such as mealtimes [116,117] was also supported by previous studies.

Previous studies have also found that self-monitoring and monitoring and feedback on adherence by health care providers could help in improving adherence, including reducing the possibility of missed doses [118,119]. Smart pillboxes or medication dispensers that allow monitoring of adherence have also been recommended by previous studies as an effective device for telecare monitoring of older adults and individuals diagnosed with unpredictable health conditions living independently. However, these devices should also be tailored for people with visual, hearing and dexterity problems [120]. A related issue shown in a previous qualitative study highlighted

XSL•FO
RenderX

the importance of locking smart medication devices to prevent any interference by children [121], but it should still be easy to open for people with dexterity problems. However, all digital medication interventions should address privacy concerns [42,45,49,59,88,103,104]. Terms and conditions educating users on data protection and ways to protect their privacy, password protection of data, and an option to consent to the collection and use of their personal data should be included [64,108].

There was only 1 study included in the review that reported factors influencing large-scale implementation and scalability of a digital medication adherence intervention [35]. However, the workshop discussions identified several economic and policy factors that significantly hampered the large-scale implementation of the smart medication device that was provided to the patients at hospital discharge and domiciliary care recipients in the ICB region, United Kingdom. Examples of this included a recent decline in demand for adult domiciliary care services resulting in care providers' fears of revenue loss, care providers' fears of being held responsible for medication errors by care recipients [111], and care recipients' fears of losing disability benefits due to reduction in their care [112]. As a higher value of financial incentives would have also limited the cost savings from this intervention, policy changes to make the use of the device the usual care for individuals requiring medication prompting visits from care providers should be considered right from the beginning of any person's care plan.

Directions for Future Research

Only 1 study [35] included in this review focused on re-establishing effective medication intake habits after hospital discharge; this was also the only study included in the review that assessed and reported factors affecting the large-scale implementation of the intervention. While the program theories derived from the workshop discussions filled this gap to an extent, future digital medication adherence intervention studies should explore and report the wider social, policy, and economic contextual factors that affect the scalability of the interventions. This is important as insights into factors affecting scalability of previous interventions can help in developing more effective implementation strategies for future interventions [122]. Further research is also needed to explore health system and policy changes needed to effectively implement medication adherence devices in the context of hospital discharge.

Lessons learned from the cocreation workshops were that it was essential for future studies to assess the wider social, economic, and policy factors that can potentially affect the scalability before starting the implementation of an intervention. It was also important to allocate enough time at the beginning of projects to develop effective relationships with key professionals in the community who can support the effective implementation of smart medication devices. Effective implementation strategies could be co-designed with key professionals who could support large-scale implementation of digital medication adherence interventions in the community at the beginning of the project [123].

Additionally, assessment of "richness" of the studies showed that details regarding the content and delivery methods of medication adherence interventions were lacking in some studies, which somewhat hindered the exploration of additional CMOs [9,29,30,35,43,44,49,53,56,58,62,69-72,75-77,80-84,86,88,92-94,96-98,100,103-106,108]. Thus, it is recommended that future medication adherence intervention studies describe the context, content, and delivery of the interventions in detail [123]. Moreover, the wide variation in the methods used in assessing adherence made it difficult for reviews to compare results among studies [83,106]. Some studies assessed adherence using only self-report measures, which are prone to bias and overestimation of adherence. There are drawbacks in using objective methods as well; for example, many digital tools can only assess when the packaging is opened and closed but do not measure if the medication has been ingested. Therefore, assessing adherence by using a combination of objective and self-report measures has been recommended for a comprehensive assessment of adherence [124,125].

Strengths and Limitations

A key strength of this study was its rigorous adherence to Medical Research Council guidelines [123] to uncover the contexts and mechanisms related to the efficacy or inefficacy of digital medication adherence interventions using realist synthesis. Additionally, cocreation workshops with diverse stakeholders of a project aiming to implement a digital medication adherence intervention led to the identification of CMOs of the intervention, which led to triangulation of the data. It also led to a better understanding of the implementation of such interventions in the community in the United Kingdom. Given the rapidly changing social policy and social care environment, a further strength was the use of the repeated workshops at approximately a 3-month interval with the same participants, which also gained insights as the implementation of the device evolved.

However, a limitation is that the CMOs developed from the workshop discussions could not be empirically verified and further refined using the cost-effectiveness and the effectiveness data of the device in improving medication adherence and quality of life because of the challenges in recruiting participants to use it. Nevertheless, one of the strengths of this study was that it highlighted that, in the future, when designing potential projects for interventions of this nature, it is important to assess the wider contexts and design some kind of flexibility into any project plans so that if wider contextual changes emerge, there is scope for the project to change as well.

This study focused on individuals who had adequate capacity to self-manage medication intake, and so papers which focused on medication adherence of people with severe mental illnesses, dementia, and substance use were excluded. Thus, the program theories derived from this review may not be applicable for medication adherence interventions for these populations. Only program theories associated with improving medication adherence among unintentionally nonadherent individuals were included; therefore, these program theories may not be generalizable for interventions designed for individuals who are intentionally nonadherent.

XSL•FO
RenderX

Conclusions

Digital interventions are commonly used to improve medication adherence; however, their efficacy may be limited because of a lack of effective tailoring for different populations and contexts [8]. Thus, this realist review addresses this gap in the literature by providing recommendations for tailoring digital medication adherence interventions effectively. Medication intake reminders and reminders for keeping water ready before medication intake, self-monitoring, and monitoring and feedback on medication adherence by device providers or health care professionals were the main active ingredients of interventions to reduce unintentional nonadherence across all theory areas. That said, intervention developers and implementers should adapt these active ingredients for specific contexts and patient subgroups by considering the recommendations provided in the CMO configurations identified in this study. This is important as the same active ingredients will not be effective across contexts because of how contextual factors or patients' responses interact with the mechanism resources. For example, a person with visual impairment may be better supported by a device that provides auditory medication intake reminders (eg, Alexa) rather than pillboxes or mobile apps. Some CMOs in this paper suggest different delivery methods of medication adherence interventions in specific contexts; for example, CMO 11 suggests not including PRN medicines in medication devices and instead providing text message reminders or including written notes in the device as reminders to take them. In these situations, the intervention implementers should choose the delivery methods that align with the patients' needs and preferences [123] and avoid implementing the mechanisms that can potentially result in unintended or negative consequences.

The review also provided insights into the economic, policy, and organizational factors affecting implementation and ways to overcome them. However, further studies exploring these factors are required, especially in the context of domiciliary care provision and hospital discharge. Future interventions should report intervention content and delivery in detail and codevelop effective implementation strategies with professionals who can support the large-scale implementation [123].

Acknowledgments

We are grateful to the Lancashire and South Cumbria Integrated Care Board for its support throughout this project. We thank all the participants who took part in the logic model workshops. The authors state that there was no use of generative AI technology in the generation of text, figures, or other informational content of this manuscript.

Funding

This work was funded through the Adult Social Care Technology Fund, provided by the Department of Health and Social Care (DHSC) and distributed by NHS (National Health Service) England, who offer strategic oversight and implementation support to funded projects. The views expressed in this paper are those of the authors and not necessarily those of the funder.

Abstract

Background: Over the past 2 decades, concerns have arisen about the distinction between health span and lifespan, highlighting that longevity does not necessarily equate to good health, a concept often referred to as “healthy longevity.” While various strategies have been explored to promote healthy aging and achieve healthy longevity, it remains uncertain which practices are most effective.

Objective: This scoping review identifies the existing and emerging practices and interventions that promote healthy longevity, identifies the key components of these practices and interventions, and considers how stakeholders contribute to these practices and interventions.

Methods: A scoping review of the literature was conducted using Arksey and O’Malley’s 6-stage framework. The Joanna Briggs Institute Population-Concept-Context framework was used to define the eligibility criteria and select studies reporting practices or interventions aimed at achieving a long health span or promoting healthy longevity carried out in the community. Data were manually extracted by 2 independent reviewers to detail the characteristics of these practices and interventions and guide the data charting process and narrative synthesis. Six databases (PubMed, Web of Science, Embase, Scopus, CINAHL, and Google Scholar) were searched for academic papers published between January 2010 and February 2025.

Results: A total of 21 studies met the inclusion criteria. Most studies (n=15, 71%) were published after 2020 and were predominantly conducted in high-income settings (n=17, 81%) across North America, Europe, and Asia. Four study types were identified: interventional (n=7, 33%), intervention development (n=4, 19%), association (n=5, 24%), and descriptive (n=5, 24%). Interventional and intervention development studies primarily described multicomponent programs targeting individual and social determinants of health and generally reported beneficial effects on physical, cognitive, and psychosocial outcomes. Association studies linked micro-, meso-, and macro-level factors (eg, nutrition, household expenditure, housing quality, health insurance, and public financing policy) to healthy longevity indicators. Descriptive studies highlighted themes across the micro and meso levels, including finance, physical activity, mental and spiritual health, digital literacy, independent living, safety, social support, and health care support.

Conclusions: The identified community-based strategies, practices, and policies that extend health span represent the joint efforts of multiple stakeholders and disciplines. The implementation of these practices and policies is worthy of being supported. More studies in diverse socioeconomic contexts are needed.

Introduction

Background

The concept of health span has increasingly attracted considerable attention within communities as longevity rises; however, not all individuals experience good health in their later years. Health span is defined as the duration of life spent in good health, encompassing psychological well-being, functional independence, cognitive integrity, and the absence of overt disease and disability [1]. These conditions are generally perceived positively within communities, as older adults tend to use fewer resources, such as health care services, rehabilitation, and social care support. An extended health span is highly esteemed due to its association with overall well-being, enhanced quality of life, and increased levels of life satisfaction in late adulthood [1,2].

In the past 2 decades, concerns have emerged regarding the distinction between health span and lifespan, emphasizing that longevity does not inherently equate to health, often termed "healthy longevity." Some researchers argue that the gap between lifespan and health span is widening [3]. Lifespan refers to the duration of an individual's life from birth to death, focusing solely on the number of years lived, irrespective of health conditions. Although lifespan has increased, many individuals spend the latter decade of their lives contending with significant health challenges [3]. Consequently, these individuals experience what is termed a "long lifespan but short health span," suffering the consequences of prolonged ill health that necessitates intensive care or rehabilitation. This disparity between health span and lifespan is increasingly recognized as a global phenomenon. Recent data indicate that the health span-lifespan gap has expanded among 183 World Health Organization (WHO) member states, averaging 9.6 years, posing significant challenges to healthy longevity worldwide [3]. Notably, women exhibit a larger health span-lifespan gap compared to men, primarily owing to a greater burden of noncommunicable diseases [3].

To narrow the health span-lifespan gap, governments have sought to promote healthy aging by mobilizing community members and resources to support individuals to lead healthy and independent lives. This initiative aims to address declines in intrinsic capacity and maximize functional ability through interactions with the environment. Key strategies for promoting healthy aging include encouraging regular exercise, maintaining a healthy diet, and increasing social interaction among older adults. The United Nations Decade of Healthy Aging (2021 - 2030) seeks to shift the global focus from mere longevity to healthy longevity [4,5]. Investments in initiatives that support healthy aging are crucial for preventing health deterioration alongside increasing longevity, which can lead to functional dependency and disability. Ultimately, such efforts benefit society by reducing overall health care costs.

Joint efforts from the community to achieve healthy longevity (or a long health span) have been consistently advocated. Some community-based practices are culturally specific and initiated by Indigenous Peoples, rooted in their beliefs and local resources. While these practices may be descriptive and lack thorough efficacy analysis, they should nonetheless be valued and respected. Additionally, initiatives from nonhealth sectors, such as housing and finance, contribute important perspectives to the concept of healthy longevity. However, the most effective practices or interventions to support healthy longevity for community-dwelling older adults—enabling them to maintain health, safety, and independence while engaging in cherished activities—remain unclear. To date, no scoping review has been conducted to examine existing and emerging practices and interventions that promote healthy longevity. This study addresses this critical knowledge gap by identifying useful practices and interventions, thereby providing a theoretical foundation to guide healthy longevity initiatives.

Objective

This scoping review aims to identify existing and emerging practices and interventions that promote healthy longevity, highlight the key components of these interventions, and describe the actions stakeholders should take for the development and implementation of these practices or interventions in the community.

Methods

Design

A scoping review was chosen instead of a systematic review because it is particularly suited to exploring emerging topics, such as practices that promote healthy longevity, for which conceptual and empirical clarity is still limited [6]. This approach provides a comprehensive overview of the existing literature on the subject, reviews evidence rapidly, and identifies knowledge gaps. The scoping review process followed the guidance of the 6-stage framework described by Arksey and O'Malley [7] and further refined by subsequent authors, including (1) identifying the research questions; (2) identifying relevant studies; (3) selecting studies; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) the consultation exercise. The review protocol was not preregistered. Ethical approval was not required for this review of the existing literature. The review was reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist (Checklist 1). A retrospective protocol was registered on OSF [8].

Scoping Review Questions

The specific review questions were as follows: (1) What existing or emerging community-based practices and interventions support healthy longevity? (2) What are the key components of these practices and interventions? (3) How do different stakeholders contribute to these practices and interventions? Framework Stage 1: Identifying the Research Questions.

Inclusion and Exclusion Criteria

Eligibility criteria were defined according to the Joanna Briggs Institute Population-Concept-Context framework [9].

Population: The included studies focused on middle-aged and older populations (aged 50 years and older), irrespective of gender, socioeconomic status, or health conditions.

XSL•FO
RenderX

Concept: The scope of this review was informed by the conceptual distinction between lifespan and healthy longevity and by the WHO's healthy aging framework [10]. Lifespan refers to the duration of an individual's life from birth to death [11], whereas healthy longevity, health span, or healthy lifespan emphasizes the period of good health and performance [12]. WHO defines healthy aging as the process of developing and maintaining the functional ability that enables well-being in older age. This framework emphasizes home, community, and broader societal environments as key contexts that support older adults' functional ability [10].

In line with these frameworks, this review focused on practices, programs, strategies, or interventions intended to enhance health span, healthy aging, healthy longevity, or healthy life expectancy in community or home settings. Studies focusing solely on biological lifespan extension, or antiaging pharmacological or medication treatments were excluded because they did not address the community-based and health span–oriented focus of this review. Similarly, studies targeting a single clinical risk or disease outcome without reference to broader healthy aging or health span–related aims were outside the scope of this review. Such studies were eligible only when they were explicitly framed as contributing to healthy aging, health span, healthy longevity, or healthy life expectancy or when relevant outcomes related to these concepts were reported.

In this review, practices were defined as activities adopted by older individuals or communities, including those shaped by cultural beliefs, values, or everyday routines. Interventions were defined as structured activities, programs, strategies, or initiatives developed based on empirical evidence, theories, or pilot tests in selected populations. Interventions that were under development or being evaluated in trials were also eligible.

Context: All geographic locations and countries across various income levels (low-, middle-, and high-income) were included. Consistent with the WHO healthy aging framework, this review focused solely on strategies, programs, and initiatives that took place in community or home settings. Practices in institutions, including hospitals, clinics, long-term care institutions, or residential care homes, were excluded because resources in these in settings differ from those everyday living environments.

All study designs (such as randomized controlled trials, quasi-experimental studies, cohort studies, observational studies, and qualitative research) were included to capture the breadth of the literature. Only studies published in English between January 2010 and February 2025 were considered for inclusion. These studies had to explicitly indicate that the aims or outcomes of the practices or interventions were related to improving health span, healthy lifespan, healthy longevity, or healthy aging, be published in peer-reviewed English-language journals, and be conducted in community settings. Animal studies and in vitro research were excluded. Framework Stage 2: Identifying Relevant Studies.

Search Methods

A comprehensive search and review of the literature published between January 2010 and February 2025 were conducted using databases and platforms including PubMed, Web of Science, Embase, Scopus, CINAHL, and Google Scholar, and searched the reference lists of the included studies. Proximity operators were used in the search strategy (eg, longev* was used to search for longevity).

The search strategy was intentionally bounded by the WHO healthy aging framework and the distinction between lifespan and health span. The aim was to identify community- and home-based practices, programs, strategies, and interventions that support health span, healthy aging, or healthy longevity, rather than biological lifespan extension alone. The Boolean search combined 3 concept blocks: (1) healthy longevity–related terms referring to the review of the health span definition [12], (2) intervention or practice-related terms, and (3) settings. The core search string was: (healthspan OR healthsp* OR "healthy aging" OR "healthy aging" OR "healthy ag*" OR "healthy longevity OR "healthy longev*" OR "healthy life expectancy" OR "healthy life exp*") AND (intervention* OR practice* OR program* OR program*) AND (community OR home) NOT (hospital OR clinic OR "institutional setting" OR "residential care homes" OR institutions), including MeSH and keywords. The term "longevity" was retained as a supplementary broad aging term to capture studies in which health span–related outcomes were described. Search strings were adapted to the syntax and field tags of each database. The search was further refined using relevant subject categories, such as Health Care Science Services, Health Policy Services, and Good Health and Wellbeing, wherever it was available in the database. Framework Stage 2: Identifying Relevant Studies.

Search Selection and Outcome

Following the search, all identified articles were collated in EndNote [13] and uploaded into the online systematic review software Covidence [14]. Two authors independently screened titles and abstracts against the inclusion criteria, followed by full-text review. Any disagreements between the authors at each stage of the selection process were resolved through discussion. If consensus could not be reached, a third author reviewed the study to make a final decision. Studies that did not meet the Population-Concept-Context criteria were excluded. Framework Stage 3: Selecting Studies.

Data Extraction and Abstraction

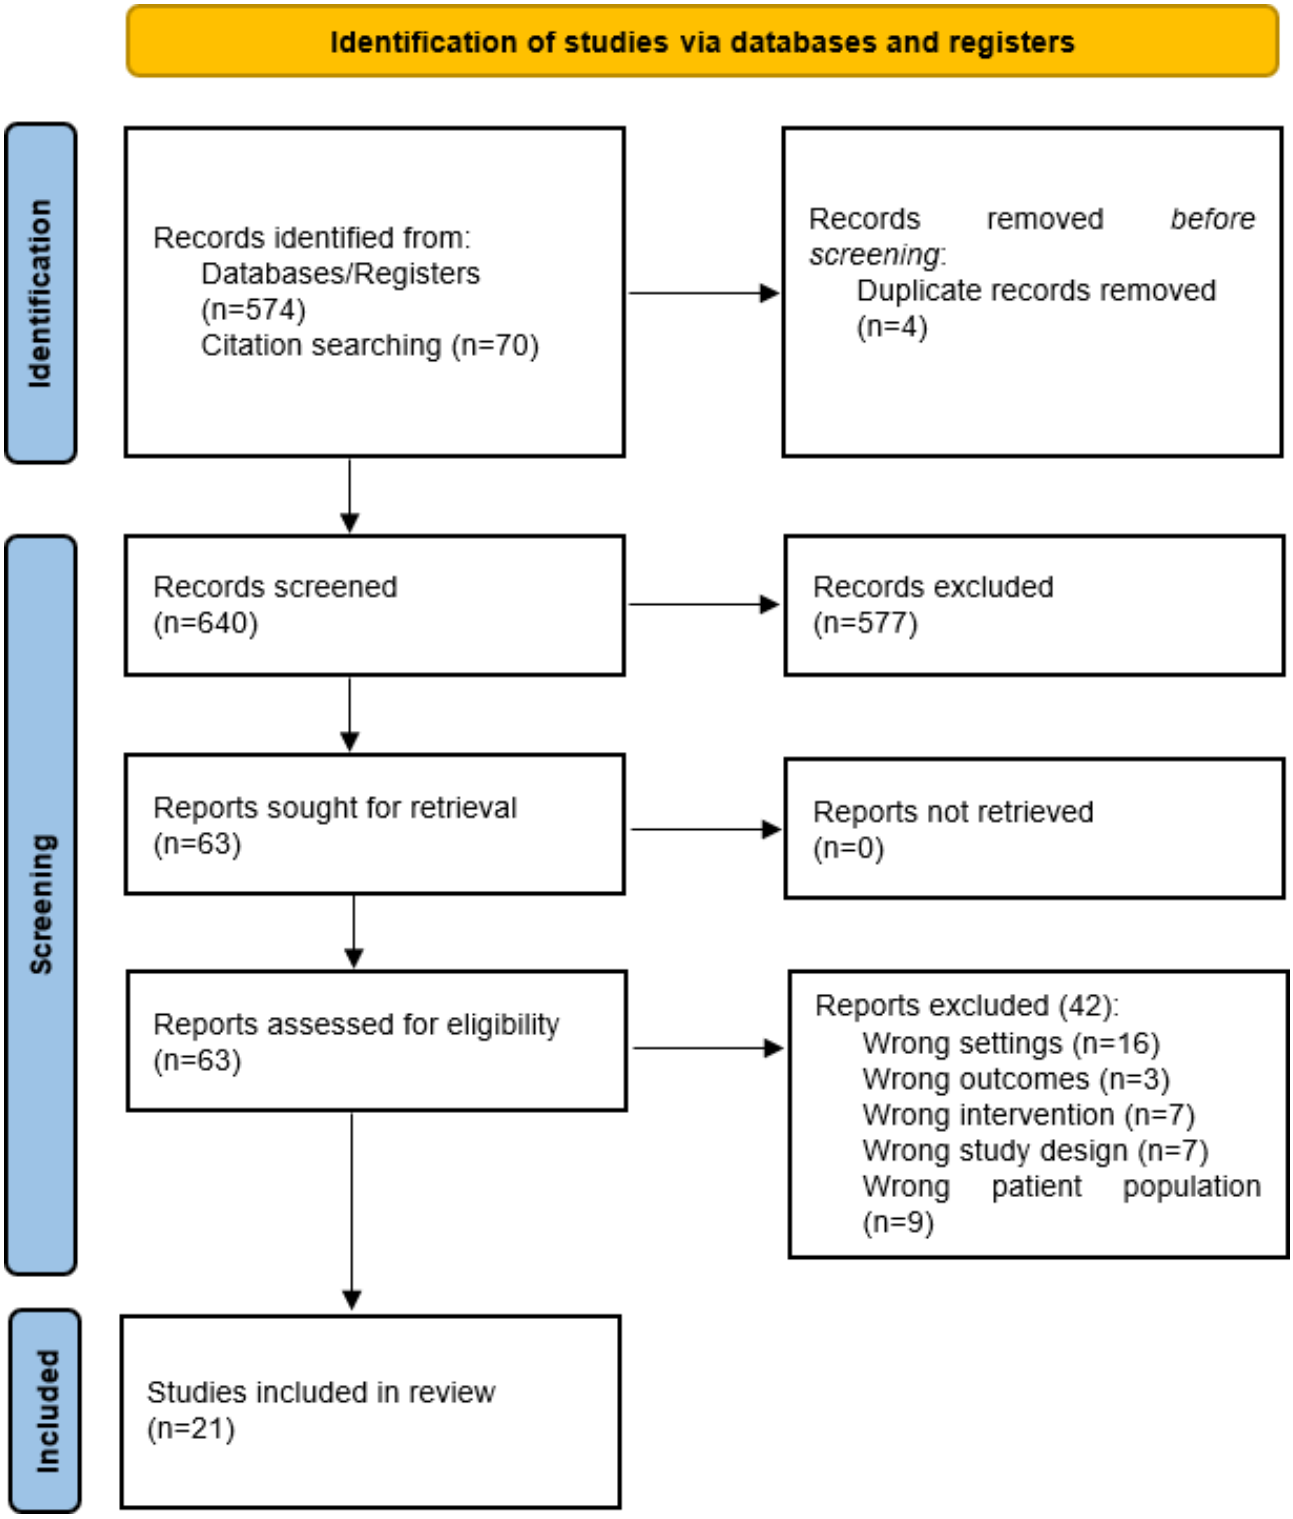
After selection, the included articles were extracted by 2 authors using a predesigned data extraction form in Microsoft Excel. Study characteristics included the following details: authors, year, country, income level, study design, age, other conditions, and sample size. Additional details were extracted based on the study type. For interventional studies, we extracted the following information: authors, year, study design, funding of the program, and strategies, practices, or policies related to healthy aging. For intervention development studies, we recorded authors, year, study design, framework, and strategies, practices, or policies. For association studies, we extracted authors, year, study design, outcomes, and significant or nonsignificant factors related to healthy longevity. Additionally, the key themes identified in descriptive studies were categorized into micro-, meso-, and macro-level framework. Any discrepancy between the 2 reviewers was resolved through discussion, or by an additional member of the project team. Formal quality appraisal

XSL•FO
RenderX

of the included studies was not undertaken, consistent with common practice in scoping reviews. These data are presented in the *Results* section. Framework Stage 4: Charting the Data.

Synthesis

The recurring themes identified in the reviewed studies focused on the key components of the practices (interventions), the individuals involved in their delivery, the strategies employed, and the outcomes observed following implementation. Next, we conducted a narrative synthesis of the charted data. Strategies, practices, policies, and associated factors identified were mapped onto micro-, meso-, and macro-level determinants of healthy longevity to summarize patterns across study types (Framework Stage 5: Collating, Summarizing, and Reporting the Results). Using the micro-, meso-, macro-level framework, we applied established definitions for each level: the micro level is about individuals and one-on-one interactions, the meso level is about the community level, and the macro level is the societal level, including policy [15]. The optional Framework Stage 6 (Consultation Exercise) was not undertaken in this review.



Results

Study Selection

A total of 644 titles and abstracts were identified and screened to remove duplicates. After title screening, 504 articles were excluded. Sixty-three full-text articles were retrieved, of which 42 were excluded as they did not fulfill the eligibility criteria. Finally, 21 articles were included in this scoping review. Figure 1 details the results of the search, and the inclusion process is reported in full according to the PRISMA-ScR flow diagram [16].

XSL•FO
RenderX

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flowchart of the literature search strategy.

Study Characteristics

The studies included in this review were published between January 2010 and February 2025, with most published after 2020 (15/21, 71.4%). Most of the studies were conducted in high-income countries or economies (17/21, 81.0%), and the rest were in middle-income countries (4/21, 19.0%), with about one-third in North America (8/21, 38.1%), one-third in Europe (7/21, 33.3%), and Asia (6/21, 28.6%). Four of 21 (19.0%) studies were conducted in rural or low-income communities. Studies conducted in low-income communities mainly focused on basic preventive health risk practices using existing resources, while programs in other affluent settings implemented multidomain approaches. Among the 20 studies recruiting participants, 15 (75%) recruited participants or informants aged 60 years or older, and 10 (50%) studies had additional criteria for target participants: had chronic diseases, lived independently at their own home or lived alone, or lived in low-income areas.

XSL•FO
RenderX

In the review, we identified 4 approaches to the study of interventions for healthy aging: interventional studies (n=7), intervention development studies (n=4), association studies (n=5), and descriptive studies (n=5). First, interventional studies are those that used experimental designs to assess the impact of a specific intervention to improve healthy aging outcomes, including active aging, physical performance, cognitive performance, preventive health behaviors, survival rate, and health service utilization. Second, intervention development studies include those that reported the development of a specific intervention for healthy aging without empirical examination of its impact. Third, association studies used longitudinal studies examining factors associated with measures of healthy aging, such as mortality, disability-adjusted life years (DALYs), Activities of Daily Living/Instrumental Activities of Daily Living, and depression. Fourth, descriptive studies using qualitative methods illuminated participant perspectives and identified themes associated with interventions of healthy aging, such as safety environment, finances, and support systems. Each of these four approaches offers important insights into interventions affecting healthy aging. The sample sizes ranged from 30 to 462 for the 7 interventional studies, 18 to 112 for 4 intervention development studies, and were at least 3000 in 4 of the 5 association studies which had provided the information. For the descriptive studies, the sample sizes ranged from 19 to 47. Details of study characteristics are provided in Table 1.

Interventional and Intervention Development Studies

Seven studies described specific interventions to improve healthy aging, with various study designs, including RCTs or cluster RCTs (n=3), quasi-experiment with control group (n=2), and a predesign and postdesign (n=2) (Table 2). No study aimed at the macro level, 1 study targeted integration of care at meso level [22], 2 studies targeted lifestyle modifications at the micro level [20,21], and the remaining 4 studies examined multidomain interventions, with most components at the micro level, including physical exercise, nutrition, stress/depression management, and preventive health behaviors, and also one component (social contact/engagement) at the meso level [17-19,23]. Outcome measures were divided into two categories: (1) epidemiological outcomes such as active aging scores [17], survival rate [21], and disability-free life expectancy [23], and (2) physio-psychosocial outcomes: physiological measures [18], cognitive performance [20], social engagement [17,19,23], and mental health [23].

[b]AEEP: Arthritis Foundation Exercise Program.

[c]RCT: randomized controlled trial.

[d]QoL: quality of life.

Six out of 7 studies involved physical activity in interventions [17-21,23] for healthy aging program. One quasi-experimental study found that Tai Chi participation could significantly increase survival duration especially in male participants [21]. This suggests that demographic characteristics, such as sex, should be explicitly considered when designing and targeting healthy aging interventions. The only cluster RCT in this review showed that preventive interventions addressing hypertension and diabetes control, lifestyle modification, and social contacts could be executed by community health workers, resulting in improvement in mobility, arthritis outcomes, blood pressure, and blood glucose [19]. Another pre-post intervention study using similar preventive strategies for chronic condition management, delivered by local medical staff and community health counselors, also demonstrated improvements in goal attainment for low-density lipoprotein cholesterol, blood pressure control, blood glucose control, and colon cancer screening [18]. These 2 studies illustrate the manpower needed to support health span or healthy aging in communities.

Another illustrative intervention for promoting aging-in-place and minimizing health disparity is the pilot cohort study in America, in which a university unit partnered with a housing operator to set up a primary care clinic in a low-income housing development. One-year follow-up showed that the use of ancillary services (such as physiotherapy, nutritional counseling, etc) increased significantly [22]. This indicates the importance of the removal of transportation barriers to accessing health services in the community.

Three RCT studies designed and implemented a multidomain health promotion education program incorporating components on nutrition [17,20], physical activity [17,20,23], smoking and tobacco control [17], mental well-being [17,23], social communication [17,23], spiritual activities [17], and chronic condition management [20]. These interventions significantly improved active and healthy lifestyles, physical health, and social participation [17,23], reduced physio-cognitive syndrome as well as cognitive and mobility impairment [20], and extended disability-free life expectancy [23]. These findings indicate that, beyond the macro-level strategies, active and healthy aging can be effectively promoted through multidimensional interventions at the micro- and meso-levels, underscoring the need for person- and community-level programs in routine practice. Among these interventions, 57% (4/7) of interventions demonstrated significant improvements in health outcomes. Improvements were effective when they incorporated multidimensional supports, involved participants with preserved functional capacity, and were delivered in settings backed by local community infrastructure.

Four studies reported the development of interventions designed to promote healthy aging (Table 3). All of them were multicomponent, with 1 study covering only components at the micro level (cognition, nutrition, depression, and physical performance) [27], and the other 3 studies intending to address components at the micro- and meso-levels [24-26]. One study emphasized the combination of in-person visits with technology in preparing personalized intervention for physical activity, self-management, social engagement, and digital literacy [24]. Another study focused on a culturally appropriate intervention to promote physical and mental health and spiritual issues at the micro level and social engagement and safety at the meso level [25]. Three studies developed their interventions based on a conceptual framework [24,25,27].

Association Studies

We found 5 studies that reported associations of important variables with various measures of healthy aging [28-32]. In these studies, measures were used to conceptualize healthy aging, such as Chinese Healthy Aging Index, Activities of Daily Living or Instrumental Activities of Daily Living, depression, DALYs, and biological age. These studies included 5 variables at the micro level, 2 at the meso level, and 5 at the macro level (Table 4). At the micro level, 4 out of the 5 variables were statistically and significantly associated with measures of healthy aging. Two variables, household expenditure and nutrition, were positively related to measures of healthy aging [28,32]. One study showed alcohol consumption and overwork were positively correlated with DALY, whereas eating habits showed nonsignificance [31]. People with more limitations in Activities of Daily Living were more likely to acquire housing adaptations at Meso level [29]. At the macro level, low housing quality, such as housing poverty, was associated with decreased healthy aging [28], while health insurance coverage and public financing policies were negatively associated with unhealthy ageing [30,31].

Themes From Descriptive Studies

Five studies were descriptive studies that explored participants' perceptions of healthy aging [33-37]. A total of 6 themes at the micro level and 5 at the meso level were identified, but none at the macro level, and they were similar to the interventional components in the interventional, intervention development, and association studies. The 6 micro-level themes included finance, nutrition, physical activity, mental and psychological management, spiritual aspect, and digital literacy, whereas the 5 meso-level themes were independent living/housing, safety, communication, support systems, and health care support (Table 5).

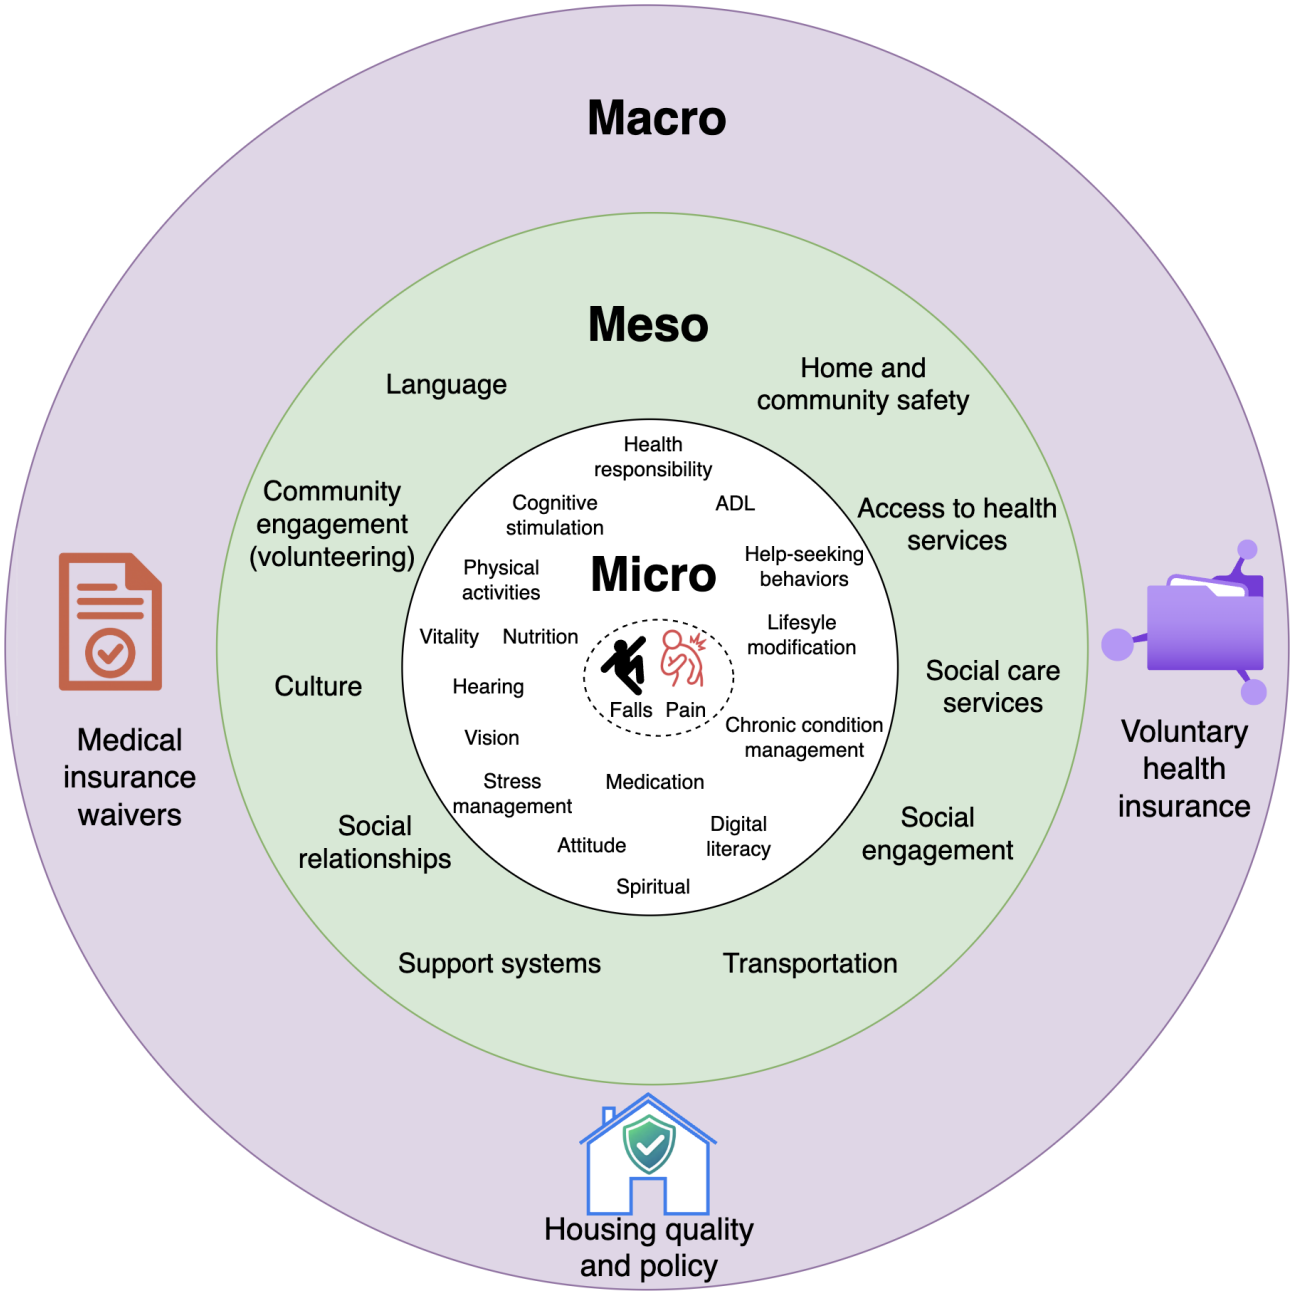

Figure 2 summarizes the key findings of this review.

Table . Descriptive studies (n=5).

Discussion

Principal Findings

This scoping review mapped the existing evidence on practices and interventions for healthy aging and health lifespan between 2010 and 2025. We identified 21 studies, of which 15 (71%) were published after 2020 and all studies were conducted in high- and middle-income countries, with 17 (81%) in high-income communities. Four study designs were evident: interventional studies, intervention development studies, association studies, and descriptive studies. Among these practices and interventions, 13 (62%) focused on micro-level factors (eg, physical activity, nutrition, mental and psychological management, spirituality), 11 (52%) focused on meso-level factors (eg, social engagement, support systems, housing and health care support). Very few practices (n=2, 9.5%) addressed macro-level determinants such as public financing or policy. Overall, the findings suggest a growing interest in multidomain programs that integrate micro- and meso-level components, but with important gaps in evidence from low-resource settings and in macro-level strategies.

Micro- and Meso-Level Factors

Multidomain interventions, including physical exercise, nutrition, emotional management, lifestyle modification, and social engagement, were the most frequently reported interventions that bring benefits to older people to extend health span. This finding is consistent with previous research, showing that interventions can improve physical performance, cognitive function, nutritional status, mood, cardiovascular risk profiles, and overall quality of life at-risk of functional decline [38-40]. From a mechanistic perspective, the rationale for multidomain interventions is also plausible. Aging is driven by multiple

XSL•FO
RenderX

hallmarks, resulting from both endogenous and exogenous stress [41]. Multidomain interventions may act simultaneously on several of these hallmarks [42]. For example, physical activity and nutrition can enhance metabolic regulation, cognitive and social engagement can reduce neuroinflammation, and psychological support can improve stress resilience. Although the included studies rarely measured biological mechanisms directly, this framework provides an explanation for why interventions targeting multiple domains can produce broader benefits of healthy longevity [41].

Nevertheless, multidomain interventions should not be implemented as fixed, one-size-fits-all packages. Their effects may vary according to population characteristics, delivery modes, study settings, intervention intensity, and outcome measures [43,44]. Therefore, how practices and interventions are delivered appears to be important. In this review, evidence across interventional, developmental, associative, and descriptive studies further highlighted the importance of social environmental factors at the meso level, including culture [25], home and community safety [25], housing conditions [29], support systems [35], social care services [26], access to health services [22], and social engagement, etc. Culturally adapted interventions can improve adherence because they are more likely to fit older adults' language, food habits, family structure, religious beliefs, and social expectations [45,46]. Similarly, housing quality and neighborhood safety are important for aging in place. Large-scale analyses have shown that environmental factors account for a substantially greater proportion of variation in mortality risk than genetic predisposition (around 17% vs <2%) [47]. Poor housing may increase exposure and exert particularly strong effects on diseases of the lung, heart, and liver [47], while unsafe homes and communities may increase falls, disability, and hospitalization [48]. In contrast, safe and accessible neighborhoods may support social engagement, mental health, and quality of life [49,50]. Moreover, community-based interventions create opportunities for social interaction to mitigate loneliness and social isolation and thereby influence both psychosocial and biological pathways [51,52]. Given the heterogeneity in intervention components observed in this review, more studies can examine which combinations and dosages of multidomain interventions are most effective for specific populations and delivery conditions.

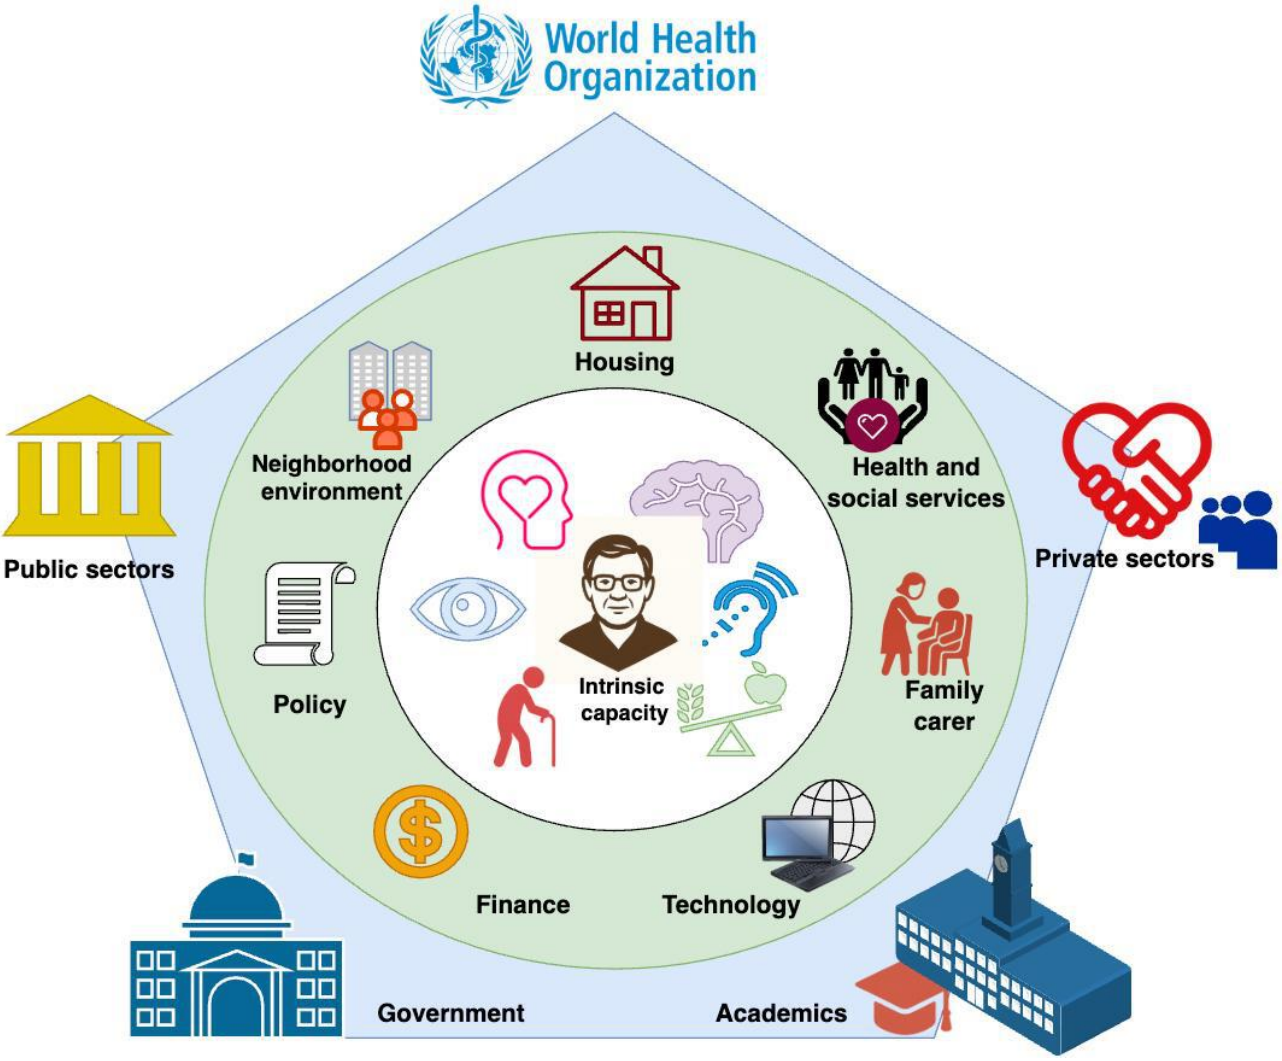
Our review found that interventions delivered by community health workers improved preventive health behaviors and increased the use of health services [18,22]. These findings indicate that healthy aging interventions also need to be supported by accessible community services and local workforce capacity. Considering both micro- and meso-level factors, future interventions should adopt person-centered designs that match components to older adults' intrinsic capacity, goals, preferences, and social environments, etc. Personalized approaches, such as the ICOPE (Integrated Care for Older People) framework [53], may support the codevelopment of tailored care plans and help translate multidomain interventions into routine practice.

Macro-Level Factors

At the macro level, long-term care financing policy and health system financing policy, such as medical insurance waiver programs and voluntary health insurance, influence healthy lifespans by reducing financial barriers and improving access to care. Similar to previous multicountry studies, this review found that universal health coverage was positively associated with both life expectancy at birth and healthy life expectancy [54]. Evidence from China further showed that health insurance was associated with higher end-of-life medical expenditure among older adults, suggesting improved access to medical services [55]. However, because all the involved studies were from high-income countries, unequal insurance benefits across different income settings need to be further explored. In addition, none of the interventional and qualitative studies targeted macro-level practices. Future research should move beyond micro- and meso-level approaches and examine how policy, public hospital authority intervention, financing systems, support for low-income housing, and equitable access to services can support healthy longevity. This gap is also important from a life-course perspective. Although most included studies focused on later-life practices and interventions, protection policies are needed to ensure that health-promoting environments and resources are available throughout the life course [56]. Early macro-level interventions aimed at reducing socioeconomic disparities helped narrow health gaps in older age [57]. This is particularly important for older adults living in low-income, rural, minority, or otherwise underserved communities.

Evidence Gaps in Low-Resource Settings

All studies included in this review were from high- or middle-income countries. While evidence from low-income countries was limited. This limits our understanding of how healthy longevity interventions operate in settings with fewer financial, technological, and service resources. Studies conducted in low-income communities in this review appeared to focus mainly on basic health risk prevention and the use of locally available resources, whereas programs in more affluent settings were more likely to adopt multidomain, service-integrated, or technology-enhanced approaches. This disparity is worthy of attention. Limited financial, health workforce, and technological capacity constrains the feasibility of multidomain interventions in resource-poor settings, which places populations at risk of widening inequalities in access to healthy aging support [37]. Therefore, there is a genuine need for developing and testing low-cost, high-reach strategies for healthy aging, such as community-based, peer-led, and integrated primary care to support older people's functional capacities. Sustained strategies that promote health span require integrated care and collaboration across sectors, including health care professionals, social workers, community organizations and policymakers, particularly for older adults with lower socioeconomic status and multimorbidity. As discussed above, ICOPE is a potential approach [53] to enhance access to care and support intrinsic capacity, but its implementation depends on cross-sector collaboration. Pilot programs in several regions have demonstrated feasibility and acceptability [58]. Future research should draw on implementation science and mixed methods approaches to systematically document the facilitators



XSL•FO
RenderX

and barriers to intersectoral collaboration, assess readiness and feasibility of related models in diverse health care systems [59]. These steps are crucial to move from small-scale trials toward sustainable system-level practice.

Future Directions

Based on the findings of this review, we propose a conceptual framework that summarizes how healthy aging and healthy lifespan may be supported through multilevel practices (Figure 3). At the center of the framework is intrinsic capacity, which is shaped by individual-level behaviors and multidomain interventions, meso-level environments and services, and macro-level policies and financing systems. The framework also highlights the importance of cross-sector collaboration among government, public and private sectors, academia, communities, and international organizations.

Figure 3. Conceptual framework summarizing multilevel practices supporting healthy aging and healthy lifespan.

Limitations

This scoping review had a few limitations. First, we focused on studies that explicitly framed their practices or interventions around health span, healthy aging, lifespan, or longevity. So, treatment-oriented interventions such as fall prevention, frailty intervention, or multimorbidity management may have been excluded if they did not explicitly use health span or related terminology, even though such interventions may contribute to healthy longevity. Therefore, the findings should be interpreted as mapping explicitly health span or healthy aging-oriented practices rather than providing a comprehensive review of all interventions that may promote healthy longevity. Second, the components of some initiatives were not well-documented, which may lead us to overlook key elements necessary for extending health span. Third, most included studies (17/21, 81.0%) were conducted in high-income settings, which may limit generalizability. The results should therefore be interpreted with caution, particularly when applying these findings to low-resource contexts. Fourth, the terminological fragmentation observed across studies, where terms such as healthy aging, active aging, successful aging, and healthy life expectancy were used interchangeably. This inconsistent concept may hinder evidence synthesis. Therefore, establishing more standardized terminology would enhance comparability and translation of evidence into practice. Finally, healthy longevity practices or programs that are not documented in peer-reviewed literature were not included. Expanding this review to include gray literature could provide a broader understanding of effective practices in healthy longevity, including those executed by underrepresented populations.

XSL•FO
RenderX

Conclusion

This scoping review identified key components of community-based strategies, practices, and policies aimed at extending health span and promoting healthy longevity, which warrant further testing and implementation. Overall, the existing evidence suggests that promoting healthy longevity in the community requires cooperation among multiple stakeholders, as well as the provision of integrated, multilevel services or support for older people. Contributions from different sectors and disciplines across all levels are equally important.

Existing interventions remain concentrated in high-income settings and at the micro level, particularly through the use of technology and multidomain integrated services to support older people in living independently and healthily within their communities. In contrast, strategies in low-income contexts largely focus on basic health risk prevention and the mobilization of local resources, such as volunteers, family members, and neighbors to support older people.

Macro-level strategies are especially critical, as policies at this level can promote health equity and reduce socioeconomic inequalities. There is an urgent need to further investigate and develop meso- and macro-level interventions across diverse socioeconomic contexts.

Abstract

Background: Intervention studies frequently report that fewer than half of adolescent participants complete digital health interventions as intended, yet a systematic synthesis of the factors driving this low adherence across lifestyle domains is lacking. Understanding these factors is essential for informing the design of interventions that can sustain adherence and achieve meaningful behavioral outcomes.

Objective: This systematic review identified and analyzed factors influencing adherence to digital health interventions targeting key adolescent lifestyle domains: physical activity, dietary habits, obesity management, alcohol consumption, and tobacco use.

Methods: We systematically searched PubMed, PsycINFO, Embase, and CINAHL in March 2024, with the search updated in June 2026, for studies of digital interventions targeting adolescents (10 - 19 years). Studies were included if they reported adherence outcomes. Data on intervention characteristics, user-related factors, and adherence outcomes were extracted and narratively synthesized using a framework distinguishing intervention-related and user-related factors across 3 evidence types (statistical, descriptive, and qualitative). Study-level attrition was additionally pooled in a random-effects meta-analysis.

Results: A total of 116 studies, comprising 46,029 participants, were included. The average completion rate (binary measure) was 66.9% (SD 26%), while average adherence to individual intervention components was 55.2% (SD 25.5%). A meta-analysis of attrition across 108 comparisons yielded a pooled dropout of 16.9% (95% CI 13.6 - 20.9), with very high between-study heterogeneity and no significant moderators. Consistently reported facilitators included personalization, user-friendly design, reminders, goal setting, gamification, and human support (particularly health coaching and parental involvement). The most common barriers were technical difficulties and poor system usability. Evidence regarding the effects of intervention duration and social components on adherence was inconsistent.

Conclusions: Given that adolescents frequently underuse digital health interventions, completing only about half of intervention components on average, the effectiveness of these interventions is fundamentally constrained by adherence challenges. Adherence is primarily driven by user-centered design features and robust technical performance, while the impact of social and user-related factors varies by health domain and study context. Future research should adopt standardized adherence frameworks and reporting standards to enable meaningful cross-study comparisons and the development of evidence-based engagement strategies.

Introduction

Digital health interventions, including web-based platforms, mobile apps, wearable device interfaces, and technology-integrated school programs, are increasingly used to promote behavioral change among adolescents. The proliferation of these interventions is driven by several factors: adolescents' high affinity for digital technologies, the scalability and cost-effectiveness of digital delivery models, and the growing recognition that health-promoting behaviors established during adolescence serve as foundational determinants for preventing noncommunicable diseases across the lifespan [1,2]. Recent meta-analytic evidence, however, suggests that the effects of digital health interventions on adolescent lifestyle behaviors are small and often short-lived, with limited sustained impact on outcomes such as physical activity, dietary behavior, and substance use [3]. Despite these modest effect sizes, the development and deployment of digital health interventions for adolescents continues to accelerate, propelled by commercial interest, low-cost dissemination through social media channels, and the accessibility of app-based delivery for a population that increasingly turns to digital solutions before seeking in-person support [4]. This trajectory makes it important to understand why these interventions often fail to achieve their intended outcomes.

A key factor underlying the limited effectiveness of digital health interventions is suboptimal adherence. Research consistently shows that many users discontinue digital health apps prematurely, directly compromising intervention efficacy and therapeutic outcomes [5,6]. For the purposes of this review, we adopt the conceptual framework proposed by Perski et al [7], which distinguishes between behavioral engagement (the extent of usage, ie, the amount of the intervention that is used) and experiential engagement (the subjective experience of using the intervention, eg, interest, attention, and affect). We focus specifically on the behavioral dimension of engagement, hereafter referred to as adherence, defined as the extent to which adolescents engage with digital interventions as intended by the developers, including frequency of use, completion of prescribed activities, and sustained participation over the intended duration. We do not systematically assess subjective engagement experiences (eg, satisfaction and perceived helpfulness), though these are noted where reported in included studies. This focus aligns with established frameworks for measuring engagement in digital behavior change interventions [8,9]. The challenge of sustaining adherence is particularly pronounced among adolescents, who may require engagement strategies tailored to their developmental stage to maintain consistent participation [4].

Adherence to digital health interventions has been extensively studied in adult populations, particularly in the context of mental health and chronic disease management, where systematic investigations have identified key predictors including user motivation, intervention design characteristics, and technology usability factors [5,10]. However, adolescents differ from adults in developmentally significant ways that may affect their engagement with digital technologies. Adolescents are navigating a critical period of identity formation and social development, during which cognitive functions including sustained attention, impulse control, and decision-making capacity are still maturing [11,12]. These developmental characteristics suggest that determinants of adherence identified in adult populations may not directly apply to adolescent users, necessitating a population-specific evidence synthesis.

Several categories of factors have been proposed as influencing adherence to digital health interventions among adolescents. At the individual level, intrinsic motivation, self-efficacy beliefs, and developmental readiness for behavioral change have been identified as potential determinants, while household-level factors such as parenting practices, family support structures, and socioeconomic considerations may also play a role [13,14]. At the intervention level, technical design elements including personalization algorithms, automated reminder systems, intuitive user interfaces, goal-setting mechanisms, and self-monitoring capabilities have been proposed as critical determinants of sustained engagement [15,16]. Various strategies to enhance engagement have also been suggested, including participatory co-design approaches, adaptive personalization protocols, and just-in-time intervention delivery [4]. However, the empirical evidence for these factors has not been comprehensively synthesized for adolescent populations specifically.

While previous systematic reviews and meta-analyses have examined the overall effectiveness of digital health interventions for adolescents [2,17] and investigated determinants of adherence in mobile health apps among general adult populations [5,18], no comprehensive synthesis exists that specifically focuses on factors influencing adherence within digital health interventions targeting lifestyle behaviors among adolescents. This represents a significant knowledge gap. Without such a synthesis, researchers and developers lack an evidence base to inform the design of interventions that can sustain adolescent adherence, which is a prerequisite for achieving meaningful behavioral outcomes. Given that average adherence rates in digital health interventions are around 50%, even modest improvements in sustained adherence could substantially enhance intervention effectiveness at the population level.

This systematic review therefore aims to identify, categorize, and synthesize the empirical evidence on factors that influence adherence to digital lifestyle interventions among adolescents aged 10 - 19 years. By examining evidence across multiple health domains, namely physical activity, dietary habits, obesity management, alcohol consumption, and tobacco use, we provide a cross-domain synthesis that reveals both consistent determinants and domain-specific patterns. The findings are intended to generate actionable insights for researchers, intervention developers, and policymakers working to design digital health interventions that achieve sustained adherence among adolescent populations.

Methods

Identification of Studies

The review was guided by the following Population-Exposure-Outcome (PEO) framework: Population: adolescents aged 10‐19 years; Exposure: digital health interventions (web-based, app-based, or text message–based) targeting one or more of 5 lifestyle health domains (physical activity, dietary habits, obesity management, alcohol consumption, and tobacco use); Outcome: adherence to the digital intervention, operationalized as the extent of use relative to intended use parameters specified by intervention developers, including completion rates and component-level adherence metrics.

A comprehensive literature search was conducted across 4 electronic databases: PubMed, PsycINFO, CINAHL, and Embase in March 2024. No restrictions were applied regarding publication date, language, or geographic region. The search strategy was developed iteratively by one researcher (NB) and used combinations of controlled vocabulary terms (MeSH, Emtree, CINAHL Subject Headings, and PsycINFO Thesaurus terms) and free-text keywords across 3 key concepts: adherence or engagement, digital health interventions, and specific health domains (physical activity, diet, obesity, alcohol, and tobacco). While our inclusion criteria encompassed internet-, computer-, and smartphone-based interventions, the term "digital interventions" is used throughout this review for the sake of brevity. The initial screening process involved reviewing titles and abstracts, followed by a detailed assessment of full-text articles for studies that potentially met our inclusion criteria. Two researchers from our team independently performed the search and screening processes, resolving any discrepancies through discussion until consensus was reached (OS and PdR). Discrepancies at each stage were resolved through discussion between the two reviewers. In cases where consensus could not be reached, the senior members of our team (NB and SH) were consulted. The complete search strategy, including detailed search strings, can be found in Multimedia Appendix 1. The search was updated on June 22, 2026, to capture studies published since the original search. Using the identical search strings across the same 4 databases (PubMed, PsycINFO, CINAHL, and Embase), we retrieved records covering the period from March 2024 to June 2026. The deduplicated updated records were screened against the original eligibility criteria; title and abstract screening, full-text screening, and data extraction of the newly included studies were performed by 2 researchers (IDY and NB), with discrepancies resolved through discussion. This systematic review was conducted and reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines [19].

Eligibility Criteria

Studies examining digital interventions targeting adolescents aged 10‐19 years (as defined by the World Health Organization [WHO]) were required to focus on at least one of the following 5 specified health domains: physical activity, diet, obesity management, alcohol use, and tobacco use. Studies including some participants older than 19 years were retained when the intervention primarily targeted adolescents or youth and the sample mean age was within or very close to the 10‐to 19-year adolescent age range. These 5 health domains were selected based on their established role as modifiable lifestyle factors associated with the prevention of cancer. The selection was informed by the SUNRISE project (Sustainable Interventions and Healthy Behaviours for Adolescent Primary Prevention of Cancer with Digital Tools; Horizon Europe, Grant Agreement Number 101136829), within which this review was conducted.

These domains were selected based on their established links with chronic disease (eg, cancer, cardiovascular disease, diabetes, and so on) prevention and represent modifiable lifestyle factors that have been shown to reduce cancer risk throughout life. Eligible studies were required to provide qualitative or quantitative data on the intended use parameters or actual adherence patterns with digital intervention components as defined by the developers.

No restrictions were applied regarding publication date or language. Interventions had to implement digital health promotion strategies as the primary therapeutic component; studies in which digital strategies merely supplemented in-person interventions were deemed ineligible. Intended use was operationally defined as the minimum level of digital platform interaction specified by the intervention developers as necessary for achieving therapeutic adherence. Actual use, on the other hand, encompassed the adherence patterns that were empirically measured within the study population. Studies combining multiple intervention modalities, such as automated messaging platforms integrated with counseling calls, were included, provided adherence measures could be isolated and attributed specifically to digital components. Supplementary elements were categorized as "personal support."

To focus on primary empirical evidence, we excluded systematic reviews and meta-analyses. Single-session interventions were excluded as they preclude meaningful longitudinal adherence assessments, resulting in universal participation rates that provide limited insight into sustained adherence patterns. Studies that used digital platforms solely for communication (eg, email-based coaching or video consultation sessions) were excluded as they represent interpersonal rather than digital behavioral intervention modalities. Additionally, studies that primarily targeted families or other populations rather than adolescents directly were deemed to be outside the scope of this review.

Data Extraction

Data from studies included in the initial systematic literature search were extracted independently by 2 researchers (OS and PdR), while data for studies identified through the updated systematic search were extracted independently by 2 researchers (IDY and NB). Any discrepancies were resolved through discussion. The following information was extracted for each included study: general study characteristics, study population characteristics, intervention characteristics, and information on intervention use.

General study characteristics included the country, study design, and health domain. Study population characteristics comprised

XSL•FO
RenderX

mean age, gender distribution (in %), target group (high school students, university students, and others such as adolescents not enrolled in formal education, those in vocational training programs, community-based youth groups, or clinical populations), intervention setting (online, school-based, home-based, community-based, or clinic-based), presence of clinical diagnosis, number of participants, and inclusion and exclusion criteria. Intervention characteristics included the intervention name, delivery type (web-based, through an app, and through text messages), presence and type of personal support, and provision of participant incentives. Information on intervention use encompassed study duration, number of modules, intended use, actual participant adherence, and attrition rate. Additionally, we extracted data on intervention effectiveness and all reported factors influencing adherence. These factors were classified as either intervention-related, that is, modifiable elements of the intervention design, or user-related, that is, inherent characteristics of the participants. The synthesis of studies identified through the initial systematic search was conducted by OS and reviewed by PdR, whereas the synthesis of studies identified through the updated systematic search was conducted by IDY and reviewed by NB. Factor categorizations and evidence classifications were cross-checked against the original study manuscripts. Any disagreements were resolved through discussion with the senior team members (NB and SH).

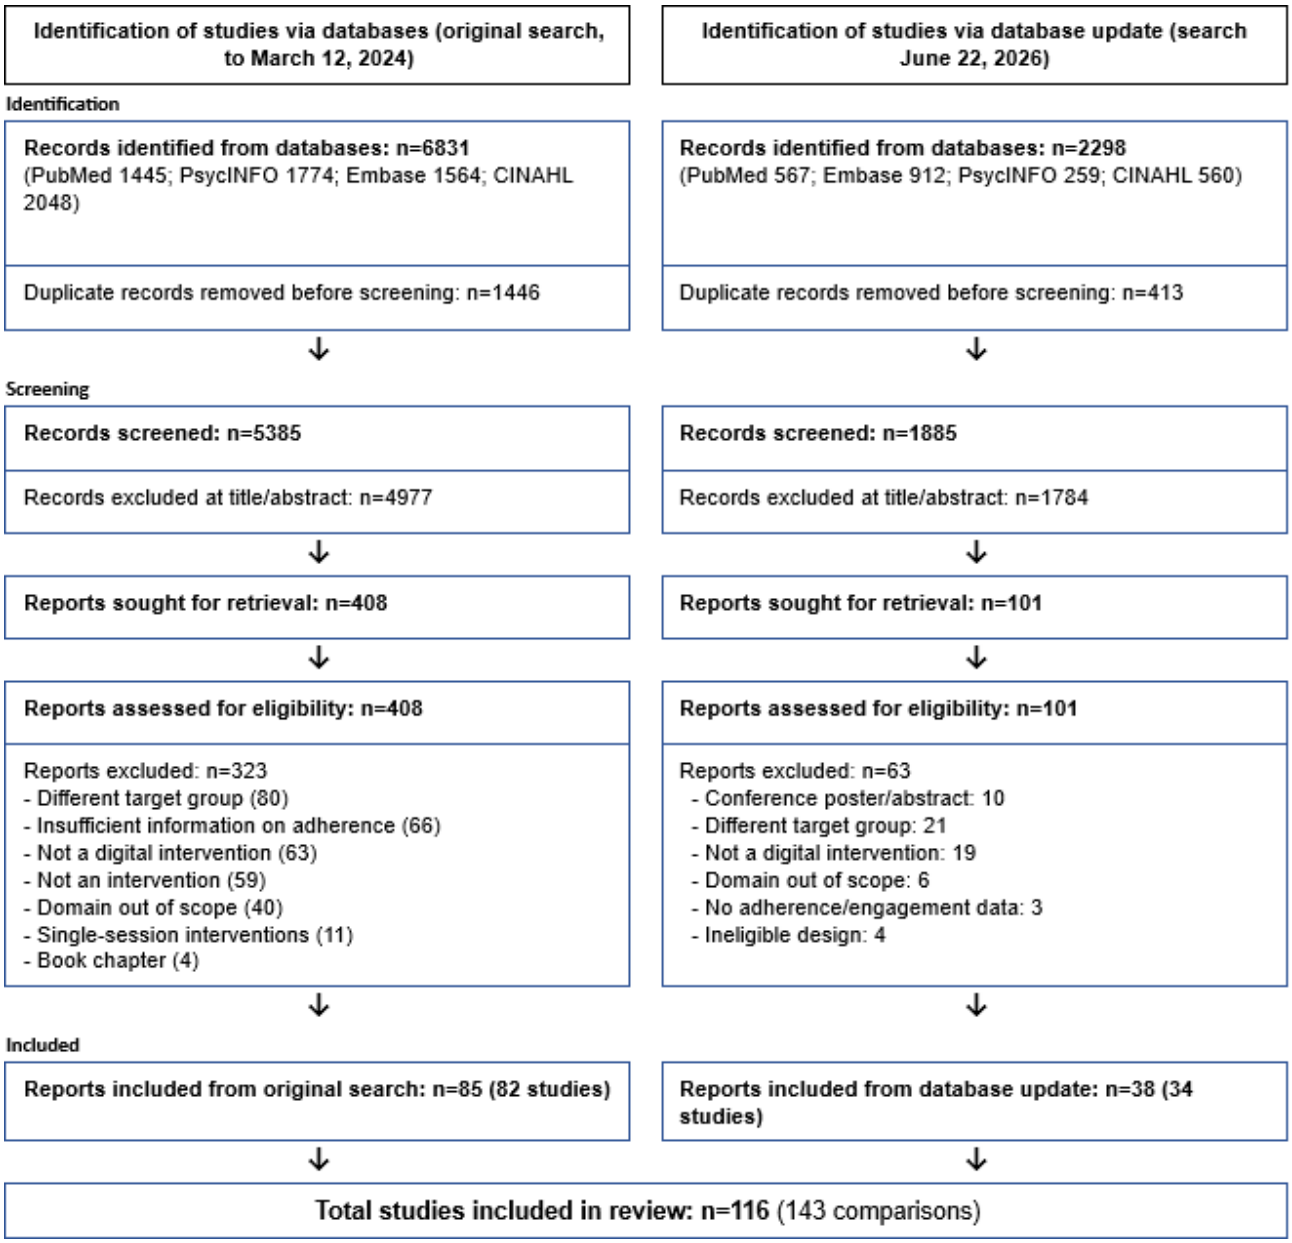
Data Synthesis

To guide our synthesis, we adopted a framework informed by the conceptualization of engagement with digital behavior change interventions proposed by Perski et al [7], which distinguishes between behavioral engagement (extent of usage) and experiential engagement (subjective experience). This review focuses on behavioral engagement, operationalized as adherence: the degree to which participants used the intervention as intended by developers. Adherence was captured through two primary metrics where reported: (1) completion rate, defined as the proportion of participants who completed the entire intervention program (binary measure), and (2) component adherence, defined as the mean proportion of individual intervention components completed by participants (continuous measure). The factors influencing adherence were categorized as intervention-related (modifiable elements of intervention design and delivery) or user-related (participant characteristics), and further classified by evidence type: statistical (inferential testing, $P<.05$), descriptive (quantitative patterns without significance testing), or qualitative (interviews, focus groups, and open-ended responses).

As a first step, the identified studies were categorized according to their respective health domains. In the second step, factors influencing adherence reported in the reviewed articles were qualitatively evaluated and summarized in individual tables for each health domain (Tables S1-S6 in Multimedia Appendix 1 [20-110]). These factors were then categorized into intervention-related factors that acted as either facilitators or barriers to adherence, as well as user-related factors that either facilitated or hindered adolescents' adherence to digital interventions. In the third step, the factors were analyzed based on 3 types of evidence: statistical significance (findings derived from inferential statistical analyses with $P<.05$), descriptive evidence (quantitative patterns identified through descriptive statistics without formal significance testing), and qualitative evidence (findings from interviews, focus groups, and open-ended survey responses). The compiled tables present an integrated view of these 3 evidence types to provide a comprehensive understanding of factors influencing adherence.

To complement the narrative synthesis, we conducted a quantitative synthesis of attrition. For each intervention arm reporting sufficient data, we calculated the proportion of enrolled participants lost during the intervention and meta-analyzed the logit-transformed proportions using a random-effects model, with the between-study variance estimated using restricted maximum likelihood and CIs calculated using the Knapp-Hartung adjustment [111]. Summary estimates and CIs were backtransformed to the proportion scale. Heterogeneity was quantified using τ^2, I^2, and a 95% prediction interval. Robustness was examined in sensitivity analyses using a binomial-normal generalized linear mixed model with a logit link [112,113], and a 3-level random-effects model in which estimates from multiple intervention arms were nested within studies [114]. Subgroup analyses and random-effects meta-regression examined health domain, delivery modality, level of personal support, provision of incentives, intervention duration, and mean participant age as potential moderators. Potential small-study effects were explored using funnel plots and an Egger-type regression test [115] because conventional funnel-plot methods may be misleading in meta-analyses of proportions; these analyses were considered exploratory. Reported adherence determinants were not quantitatively pooled because of substantial heterogeneity in their measurement. Instead, we summarized the direction and consistency of each determinant across health domains and evidence types and reported this synthesis in accordance with the Synthesis Without Meta-analysis (SWiM) reporting guideline [116]. Analyses were conducted in R (version 4.5.3; R Core Team) [117] using the *metafor* package [118].

Results



Selection and Inclusion of Studies

The original search of the electronic databases was performed on March 12, 2024, and yielded 6831 records. After removal of duplicates, 5385 records remained for title and abstract screening, and the full texts of 408 articles were subsequently examined, of which 85 records (82 studies) [20-76,119-146] were included. The search was updated on June 22, 2026, across the same 4 databases and identified 2298 records; after removal of 413 duplicates, 1885 records were screened by title and abstract, of which 101 were sought for retrieval and assessed as full texts. Of these, 63 were excluded (10 conference posters or abstracts, 21 for an ineligible population, 19 because the digital component was not the primary intervention, 6 for a health domain outside the review scope, 3 for reporting no adherence or engagement data, and 4 for an ineligible study design), leaving 38 newly included records. These corresponded to 34 additional study entries after publications reporting on the same participant cohort were combined, yielding a total of 116

XSL•FO
RenderX

included studies [20-69,71-109,119-144,147]. Figure 1 visualizes the selection process and reasons for exclusion for both the original and updated searches.

Figure 1. Flowchart for inclusion of studies.

Characteristics of Included Studies

The 116 included studies comprised several designs: 77 (66.4%) were randomized controlled trials (RCTs) [20,23,25,27,29,30,32-34,36,37,41,43,44,46,48,49,51,53,55,57,58,60,62,63,65,66,68,69,71,73,74,76,78,79,81,83,84,86,88,89,91,93,94,96,98,99,101,103,105,107,109,119,121,123,125,127,128,130,131,133,135,137,139,141,143,144,147] 36 (31%) were quasi-experimental studies [20,21,23,25,27,29,30,32-34,36,37,42,44,45,47,50,52,54,61,62,64,65,67,70,72,80,82,84,88,91,93,98,103,108,122,130,141,142], and 3 (2.6%) were observational studies [56,86,95].

Geographically, the included studies spanned 26 countries across 5 continents, with persistent regional disparities. The United States remained the single largest contributor, accounting for 43.1% (50/116) studies, followed by Canada, Spain, and Australia. European studies again formed a substantial group, and the updated search broadened the geographic spread by adding studies from countries not previously represented, including Brazil, Uzbekistan, Vietnam, Taiwan, India, Turkey, and Portugal.

The analysis included 143 comparisons from the 116 included studies, as 23 studies [22,26,35,39,40,52,57,67,81,82,85,87,89,91,97,104,107,108,126,129,134,136,147] contained more than one intervention group relevant to our systematic review (21 contributed 2 intervention arms and 2 [85,108] contributed 4 intervention arms). Studies published on the same participant cohort were combined into single entries in the tables and handled as one study. The median intervention duration was 84 (IQR 42-135; range 2-730) days, with 27/143 (18.9%) comparisons lasting 1 - 30 days, 54/143 (37.8%) lasting 1 to 3 months, 44/143 (30.8%) lasting 3 to 12 months, and 4/143 (2.8%) lasting 1 year or longer. Fourteen comparisons out of 143 comparisons (9.8%) did not report intervention duration. Of the 143 comparisons, 79 (55.2%) provided no incentives to

XSL•FO
RenderX

participants, 44 (30.8%) offered monetary or material rewards such as cash, gift cards, vouchers, prize draws, or a retained device, and 20 (14%) offered nonmonetary incentives such as academic credit or gamified points. A detailed description of the study characteristics can be seen in Tables S7-S18 in Multimedia Appendix 1 [20-110,119-144,147].

Characteristics of Study Populations

The included studies comprised a total of 46,029 participants summed across intervention and control arms, with a median of 52.5 (IQR 28-232; range 10-5260) participants per study. Of the 142 comparisons that reported exact participant numbers, 91 (64.1%) included fewer than 100 participants, 33 (23.2%) had between 100 and 500 participants, 9 (6.3%) included 500 to 1000 participants, and 9 (6.3%) had more than 1000 participants. The overall mean age was 14.48 (SD 2.07) years. Across the studies reporting participant sex, female participants comprised 59.1% of the combined sample (115 [20-69,71-87,90-109,119-144,147] of 116 studies reported sex), essentially unchanged from the original cohort's 59.2.

The great majority of studies enrolled adolescents with no prior clinical diagnosis. Among studies recruiting clinically defined populations, obesity or overweight remained the most common, followed by childhood cancer, congenital or coronary heart disease, type 1 diabetes mellitus, and juvenile idiopathic arthritis. The update introduced clinical populations absent from the original synthesis, including single studies of chronic kidney disease, cystic fibrosis, elevated blood pressure or cardiovascular risk, and adolescents recruited through mental health services, together with a larger group of studies enrolling adolescents who used nicotine or electronic cigarettes.

Characteristics of Digital Interventions

Across the 143 reviewed comparisons, 71 (49.7%) were delivered through location-independent digital platforms accessible via smartphones or personal devices, 33 (23.1%) were school-based, 19 (13.3%) were home-based, 11 (7.7%) were clinic-based, 5 (3.5%) were community-based, and 4 (2.8%) combined settings such as summer camp plus online or school plus mobile delivery.

Regarding delivery mode, 51 (35.7%) comparisons were app-based and 50 (35%) were internet- or web-based, together accounting for roughly 7 in 10 interventions; 13 (9.1%) paired a wearable activity tracker or accelerometer with a smartphone or web platform, 11 (7.7%) relied exclusively on text messaging, 9 (6.3%) were computer- or software-based, 8 (5.6%) used a mixed multimodal approach, and 1 (0.7%) delivered exercise through immersive virtual reality.

Personal support beyond initial recruitment was provided in 72 comparisons (50.3%), most commonly through research-team contact, health-professional input, or coaching, while the remaining 71 (49.7%) offered no personal support or relied solely on automated prompts and reminders.

Effectiveness was determined based on whether studies demonstrated statistically significant improvements in their prespecified primary outcomes, distinct from adherence metrics; 52.8% (47/89) of the interventions evaluated for effectiveness were reported as effective. The mean intervention completion rate across the 68 comparisons reporting it was 66.9% (SD 26%), and component adherence averaged 55.2% (SD 25.5%) across the 66 comparisons that reported it, with the remaining comparisons not reporting full completion or quantitative adherence data.

Characteristics of Health Domains

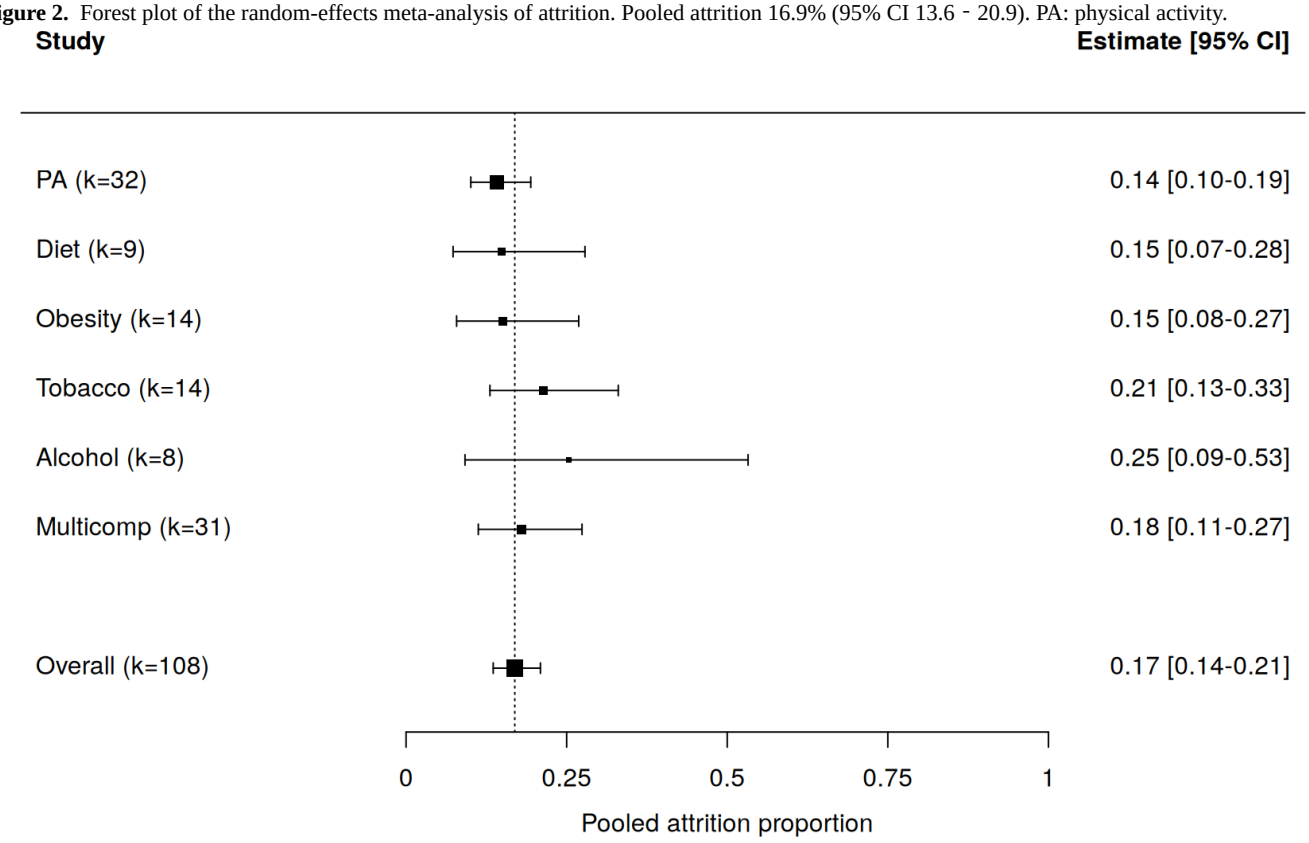
As displayed in Tables S7-S18 in Multimedia Appendix 1 [20-110,119-144,147], the included studies were categorized into 5 distinct health domains based on their intervention focus (physical activity, diet, obesity, alcohol use, and tobacco use), with an additional category for multicomponent lifestyle interventions that targeted multiple health domains. Of the 116 included studies [20-69,71-109,119-144,147], 31 (26.7%) [61-69,71-76,98-109,141-143,147] were multicomponent lifestyle interventions, 32 (27.6%) [20-33,77-86,119-125,144] focused on physical activity, 19 (16.4%) [34-48,127-130] targeted obesity, 14 (12.1%) [55-57,90-94,131-136] targeted tobacco use, 10 (8.6%) [49-54,87-89,126] focused on diet, and 10 (8.6%) [58-60,95-97,137-140] addressed alcohol use.

Within the 31 multicomponent lifestyle interventions, the most common combination was diet and physical activity (12 studies, 38.7% [61,62,64-66,68,74,76,102,104,107,142]), followed by alcohol and tobacco (5, 16.1% [63,69,71,72,143]), diet and obesity (4, 12.9% [100,101,105,147]), all 4 of alcohol, diet, physical activity, and tobacco simultaneously (4, 12.9% [73,75,103,109]), diet, physical activity and obesity (3, 9.7% [67,98,99]), physical activity and obesity (2, 6.5% [106,108]), and diet, physical activity, and tobacco (1, 3.2% [141]).

Across the health domains, dietary interventions showed the highest mean intervention-completion rate (83.9%, SD 21%) and alcohol-focused interventions the lowest (48.4%, SD 35.4%); for component adherence, dietary interventions again showed the highest mean rate (63.7%, SD 23%, essentially level with physical activity interventions at 62.8%), while obesity interventions showed the lowest (45.9%, SD 22.5%). These domain-level figures rest on small and unevenly distributed numbers of reporting comparisons (n=4 - 24 per domain) and on widely overlapping ranges, and are therefore indicative rather than definitive. In the meta-analysis of attrition, pooled dropout was lowest for physical activity and highest for alcohol interventions, as detailed in the "Quantitative Synthesis of Attrition" section.

The findings presented below are organized according to 3 distinct levels of evidence synthesis: statistical evidence, descriptive evidence, and qualitative evidence. Where individual studies did not generate all 3 types of evidence, only the categories of evidence that were empirically identified are reported and analyzed in the subsequent sections. For a detailed description of all the reported quantitative adherence values, please refer to Tables S8, S10, S12, S14, S16, and S18 in Multimedia Appendix 1 [20-110,119-144,147].

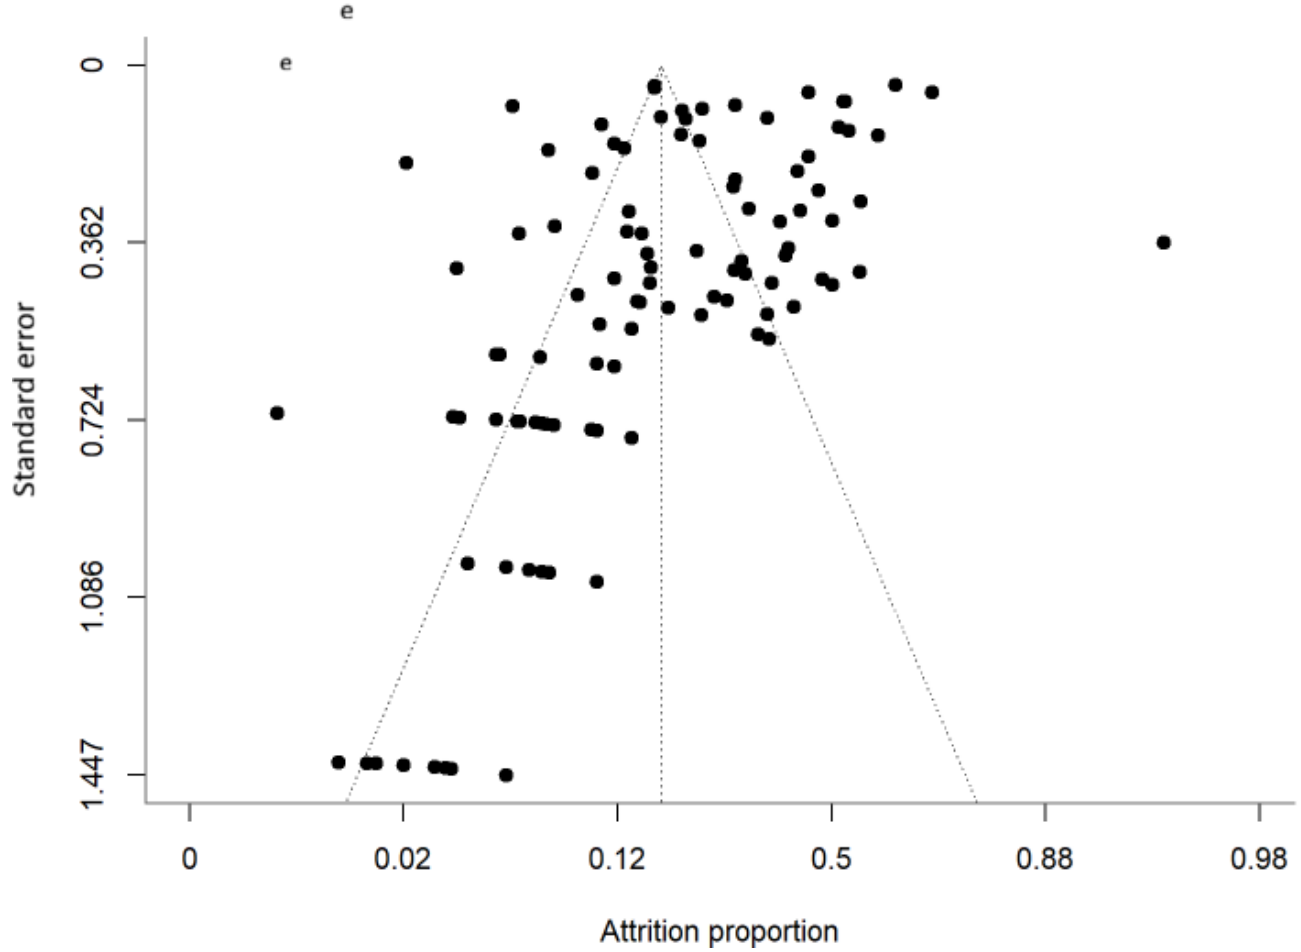
Quantitative Synthesis of Attrition



Across the included studies, 108 comparisons (88 studies [illegible] 30,956 participants) reported extractable attrition data. The

XSL•FO
RenderX

pooled attrition proportion was 16.9% (95% CI 13.6-20.9). Heterogeneity was very high (I^2=98.3%; τ^2=1.51), and the 95% prediction interval was correspondingly wide (1.7-70.3), indicating that attrition varied substantially across study contexts. Estimates were robust to model choice (exact binomial-normal model: 14.3%, 95% CI 11.1-18.2; 3-level model accounting for the nesting of multiple intervention arms within studies: 17.3%, 95% CI 13.6-21.7).



Pooled attrition was lowest for physical activity (14.1%, 95% CI 9.9-19.7; k=32), diet (14.9%, 95% CI 6.2- 31.5; k=9), and obesity (15.1%, 95% CI 7.3-28.4; k=14) interventions, intermediate for multicomponent interventions (17.9%, 95% CI 11.1-27.8; k=31), and highest for alcohol (25.3%, 95% CI 7.0-60.5; k=8) and tobacco (21.4%, 95% CI 11.9-35.5; k=14) interventions, although the CIs overlapped substantially (Figure 2). None of the examined moderators reached significance in the omnibus Wald-type tests of the meta-regression models (QM): health domain (QM_5=0.79, *P*=.56), delivery modality (QM_3=1.22, *P*=.30), personal support (QM_1=0.57, *P*=.45), incentives (QM_1=1.03, *P*=.31), intervention duration (QM_1=2.60, *P*=.11), or mean participant age (QM_1=0.62, *P*=.43), with each moderator explaining essentially none of the between-study variance. An Egger-type regression test indicated possible small-study effects (z=−2.75, *P*=.007), with smaller studies tending to report lower attrition, although this test should be interpreted cautiously at this degree of heterogeneity (Figure 3).

Figure 2. Forest plot of the random-effects meta-analysis of attrition. Pooled attrition 16.9% (95% CI 13.6 - 20.9). PA: physical activity.

XSL•FO
RenderX

Figure 3. Funnel plot for the attrition meta-analysis (Egger-type test z=–2.75, *P*=.007).

Notably, pooled attrition (approximately 17%) was considerably lower than the degree of underuse implied by the completion and component-adherence metrics, under which roughly one-third of participants did not complete the full intervention, and approximately 45% of intervention components went unused. This pattern indicates that many adolescents remained nominally enrolled while substantially under-using the intervention, so that retention statistics alone overstate true adherence. Overall, attrition in adolescent digital lifestyle interventions is substantial but highly heterogeneous and is not explained by standard study-level characteristics.

Physical Activity

Intervention-Related Factors

Several intervention design features were associated with adherence to physical activity interventions. Statistical evidence indicated higher adherence during daytime hours [20] and on weekdays versus weekends [21], while longer study duration was negatively associated with adherence [20,22]. Descriptive evidence reinforced the importance of specific program features, with activity trackers [23-25], outdoor and solitary usage [26], and targeted components including workout missions, storylines, parent-child activities, physical activity education, run logging, and week-runs [26] all showing positive associations with adherence. Further descriptive facilitators included the “Kids Zone” interface [24], coaching sessions [25], and coach reminder messages [21]. Conversely, descriptive evidence identified technical difficulties and equipment dissatisfaction [23,27], social intervention features [26], weekly challenges and Facebook videos (Meta Platforms, Inc) [28], poorly timed text messages during class time [28], educational modules [25], and excessive video duration [21] as barriers.

Qualitative evidence provided the richest insights into design-related facilitators and barriers. Participants consistently endorsed goal-setting components [28,29], tracking and monitoring features [26,28], flexible goal reminders [30], clear instructions with progressive difficulty scaling, encouragement, and immersive app design [26], and engaging activities including gamification elements and peer competition [27,28]. The provision of activity trackers (eg, Fitbits) was viewed positively [24], as were activity logging and local resource information [29], incentives [31], and diverse content including varied video and sports options [20,22]. However, qualitative data also revealed substantial technical barriers, including synchronization issues, device charging logistics, and website login difficulties [24,28,29,31,32], as well as equipment dissatisfaction due to perceived device inaccuracy [27,28,30]. Participants reported competition from alternative systems and information sources [24,28], unappealing website design with excessive text and insufficient youth-oriented content [24,29], limited social components [29], inadequate reward systems [31], and specific features such as message boards and expert forums that reduced adherence [29]. Participants expressed preferences for text

XSL•FO
RenderX

messages over emails, which often went unread due to spam filtering [32].

The updated search added 10 physical activity studies that broadly reinforced these design-related patterns while adding nuance around support and gamification. Personalization again emerged as a facilitator, with tailored nurse feedback [77] and readiness-based content routing [78] supporting engagement, whereas a lack of customization lowered perceived usability [79]. Human support in its various forms was consistently valued, including nurse-led monitoring [77], weekly coaching calls [80], and live remote supervision [81], while the absence of therapist support was experienced as a barrier [78]. Gamification remained largely facilitative but was not uniformly positive, as competitive leaderboards discouraged lower-ranked users [82]. Technical and logistical friction continued to undermine adherence, with device charging and synchronization problems and simply forgetting to wear trackers reported repeatedly [83,84], whereas embedding the intervention in a familiar platform and delivering it remotely helped overcome access and geographic barriers [77,80].

User-Related Factors

User-related factors associated with adherence to physical activity interventions spanned demographic, motivational, and practical dimensions. Statistical evidence revealed that Hispanic ethnicity was positively associated with adherence [20]. Descriptive evidence identified gender-based motivational differences, with boys engaging primarily for enjoyment and girls participating to combat boredom [33], while injury, illness, and pain were associated with lower adherence [23]. Qualitative evidence highlighted that opportunities for family participation [28] and users' perception of personal benefits [26] enhanced adherence, whereas lack of interest in the intervention [26,27], time constraints [23,26], and short-term motivation [28] acted as barriers. Practical challenges, including limited access to Wi-Fi or mobile data [28], insufficient device storage [32], and simply forgetting to engage with the intervention [31,32], were also reported as obstacles to sustained use.

The new physical activity studies extended the user-related picture, particularly for motivation, age, and clinical burden. Intrinsic motivation and perceived benefit again facilitated engagement, including satisfaction of competence and autonomy needs [85] and perceived health gains [78,80], whereas waning motivation and loss of interest drove disengagement [77,80,81]. The direction of age was not uniform, as older participants reported a higher intention to reuse a virtual exercise program than younger participants [86]. A new and distinct theme was illness burden in clinical samples, where fatigue, pain, comorbidities, hospitalizations, and fear of hypoglycemia limited participation [79-81]. Time constraints from school and competing demands, together with the poor fit of frequent device charging with busy routines, were again reported as obstacles [77,80,83].

Obesity Management

Intervention-Related Factors

Several intervention design features were associated with adherence to digital obesity management interventions. Statistical evidence indicated that communication with a health coach [34,35], social voting polls [35], parental participation [35,36], online food journaling [37], reinforcement messages [38], primary recruitment sites [39], and in-class program delivery versus homework-based delivery [40] were significantly associated with increased adherence. Adherence was also significantly higher during the first half compared to the second half of interventions [36,41]. Descriptive evidence supported higher adherence rates associated with health coach communication [39,42], specific program features (My workouts, My steps, and My goal functions) [43], and the initial intervention phase [37,39,44]. Conversely, statistical evidence indicated that self-esteem and stress management message components [38] and the AppAlone program compared to the AppCoach program [39] were associated with reduced adherence. Descriptive evidence revealed barriers including the ineffective "my motivation" function [43] and the selected self-monitoring tool [36].

Qualitative evidence highlighted several facilitating features: informative videos covering topics such as nutrition label reading, heart rate measurement, and screen time health effects [45], daily encouragement with real-time feedback, gamification elements, peer competition, and accessible health care professional communication [46]. Users also positively perceived daily reminders, craving management strategies, and weekly coach phone calls [39]. However, qualitative evidence also revealed barriers including insufficient individualization and support, limited exercise variety, and inadequate in-person resources and group activities [47], technical difficulties [40,48], excessive and repetitive messaging [43], overly demanding training requirements regarding frequency and duration [48], and educator concerns about lesson length and reading volume [40].

User-Related Factors

User-related factors associated with adherence to obesity management interventions encompassed demographic, psychological, and behavioral dimensions. Statistical evidence demonstrated positive associations between adherence and successful BMI reduction in the initial 12 weeks [47], female gender [40], and younger age [40,44]. Additional significant predictors included intrinsic motivation, healthier parenting practices, and higher household income [44]. Conversely, statistical evidence indicated lower adherence associated with authoritative parenting style and depression [41,44]. Descriptive evidence revealed contrasting findings regarding socioeconomic status, with one study suggesting that lower household income was associated with better adherence [39]. Further descriptive evidence identified greater weight and shape concerns and white ethnicity [37], higher weight status, interfering activities, and scheduling conflicts such as being too busy, tired, or away from home [48] as barriers to adherence. Qualitative evidence revealed lost motivation as an additional barrier [48].

Dietary Habits

Intervention-Related Factors

Several intervention design features were associated with adherence to dietary habit interventions. Statistical evidence

XSL•FO
RenderX

indicated that text message frequency of 2 - 3 messages per week was positively associated with adherence [49]. Descriptive evidence demonstrated positive effects from online resources and interactive quizzes [49], while a declining participation pattern was observed across the study duration [50]. Qualitative evidence supported the effectiveness of music integration, goal-setting functionalities, practical tips and recipes, food diary capabilities, and reminder systems [51,52], feedback mechanisms, device comfort, and visual design elements [52], as well as video content quality, language appropriateness, and overall layout structure [53]. However, qualitative evidence also revealed barriers including limited scenario applicability in dining hall settings and insufficient video content [53], inability to pause videos and excessive session duration [54], restricted reward options with specific requests for more song choices, and constrained food logging capabilities that only allowed tracking of fruits and vegetables [52].

Three new dietary studies reinforced the importance of tailoring, gamification, and content quality while highlighting reward-design pitfalls. Culturally and developmentally appropriate tailoring facilitated sustained use, including a slide-bar feature for shared family meals [87] and age-relevant rather than adult-oriented messaging [88]. Gamification elements such as badges, team goals, and social sharing were again linked to engagement [87], and credible, concise content was valued, although unmet requests for more recipes and features tempered enthusiasm [88]. Reward structures could backfire, however, as unattainable high-value rewards and delayed or embarrassing reward distribution discouraged engagement [89]. Technical and access constraints, including an Android-only app and limited school computer time, further limited use [89].

User-Related Factors

User-related factors associated with adherence to dietary interventions encompassed behavioral, psychological, and practical dimensions. Statistical evidence indicated positive associations between adherence and higher education levels, healthy snack consumption patterns, elevated self-efficacy scores for healthy eating, and perceived competence in app usage [50]. Descriptive evidence showed positive relationships with lower sensitivity to reward scores and maintenance of adherence among users experiencing positive emotional responses to the app [50]. Descriptive evidence also indicated that time constraints due to academic workload and general lack of available time hindered adherence [52].

The new dietary evidence on user characteristics was consistent with the previously established picture. Excessive or poorly understood notifications and overly long assessments were experienced as barriers that competed with adolescents' limited time and attention [88]. Practical constraints on when and where the intervention could be used, such as restrictions on phone use at school, again shaped engagement [87,89].

Tobacco Use

Intervention-Related Factors

Few intervention design features were identified in relation to adherence to nicotine use interventions. Descriptive evidence indicated that ease of use, engaging content, and the presence of a narrator enhanced adherence [55]. Statistical evidence demonstrated significant participant dropout on the designated "quit day" [56], and qualitative evidence identified technological implementation issues as barriers to adherence [57].

The updated search markedly strengthened the tobacco evidence, which had been sparse, adding 5 studies that clarified the roles of prompts, peer support, platform integration, and third-party technical dependencies. Multiple well-timed prompts significantly raised engagement among historically underengaged users [90], and integrating the intervention into clinical workflows or the electronic health record supported high overall engagement [90], as did opting participants in during an in-person visit rather than through later automated texts [91]. Peer-delivered support was a recurring facilitator, including counselor-facilitated group chats that raised perceived support [92] and peer-written messages that generated the highest engagement [93], although reactive rather than proactive peer coaching limited engagement [93]. Dependence on third-party platforms introduced new technical barriers, as mobile carriers automatically blocked a large share of outreach texts as spam [91] and changes to social media rules and handles drove attrition [92]. Low production quality and a single storyline also constrained engagement with a peer-video intervention [93].

User-Related Factors

User-related factors associated with adherence to nicotine use interventions were primarily identified through descriptive evidence. Facilitating characteristics included higher academic performance, regular school attendance, English as the home language, having internet access at home, and nonsmoking status [57]. Additional facilitators included extended prequit duration and multiple previous quit attempts (2 or more) [56]. Conversely, being a current or former smoker [57] and geographical location, specifically residing in the southern United States [56], were associated with lower adherence.

The new tobacco studies also enriched the user-related picture, which had previously rested on a single study, and introduced several within-domain contradictions. Higher baseline risk, including greater vaping frequency, dependence, and internalizing-symptom severity, predicted nonresponse [94], and non-susceptible never-smokers engaged more with prompts [90]. Motivation mattered, as low confidence to quit predicted nonresponse [94] and a quitting-centered framing did not resonate with adolescents who did not identify as smokers [91]. Gender associations pointed in opposite directions across studies, with male gender predicting nonresponse in one program [94] but female gender associated with greater attrition in another [92]. A distinctively adolescent barrier was privacy, as participants were reluctant to text a clinician while at school or near a parent, and home delivery of nicotine replacement risked forcing disclosure to parents [91].

Alcohol Use

Intervention-Related Factors

Few intervention design features were identified in relation to adherence to alcohol consumption interventions. Descriptive evidence supported that message frequency, particularly 1 - 3

XSL•FO
RenderX

messages per week, was associated with higher adherence [58]. Conversely, descriptive evidence showed that home-based booster sessions, compared to school settings, were associated with lower adherence [59]. Qualitative evidence revealed technical barriers impacting adherence, including ineffective email delivery resulting in messages being directed to spam folders and general logistical difficulties [59].

Three newly identified alcohol studies reinforced the roles of usability, tailoring, and prompts while adding contradicting evidence on self-monitoring. A positive overall evaluation of an eHealth game predicted higher usability ratings, and its attractive layout and gamified avatars, rewards, and stories were well received [95], while tailored feedback supported engagement in a web-based program [96]. A peer-to-peer nudge strongly predicted program completion [97]. Counterbalancing the facilitative view of self-monitoring, one program found no dose-response between content exposure and outcomes [96]. Over-long or repetitive elements, including film lectures and baseline questionnaires, and a logout-and-break structure that discouraged reengagement, were reported as barriers [95,96].

User-Related Factors

User-related factors associated with adherence to alcohol consumption interventions spanned demographic and behavioral dimensions. Statistical evidence demonstrated higher adherence among females, younger individuals, and those with higher educational levels [60], as well as participants of Spanish nationality [59]. Descriptive evidence indicated additional facilitating characteristics, including younger age [58,59], Dutch nationality [60], female gender, and higher maximum drinks per occasion [58]. Furthermore, descriptive evidence suggested that lower weekly alcohol consumption was linked to better adherence [59,60]. Conversely, descriptive evidence identified barriers including commencement of workplace placements during the intervention period, logistical challenges related to school commitments, and lower educational attainment [59].

The newly identified alcohol studies broadened the user-related determinants, especially around baseline risk, family factors, and socioeconomic status. Contrary to the prior pattern, adolescents reporting binge drinking rated the program more positively and engaged more with its action-planning content [95], while depression was linked to low adherence in a highly distressed sample [96]. Family and socioeconomic factors were prominent, as parental communication self-efficacy and open communication predicted completion and retention, higher household income raised initiation, and full-time parental employment aided retention [97]. Age and gender associations were mixed, with younger teens showing greater retention and completion [97] but older adolescents more likely to recommend the program [95]. Notably, self-identification with an ethnic category other than White was associated with greater retention [97], a facilitator direction that contrasts with the barrier role of minority status seen in the tobacco domain.

Multicomponent Lifestyle Interventions

Intervention-Related Factors

Several intervention design features were associated with adherence to digital multicomponent lifestyle interventions. Statistical evidence indicated that high parent engagement [61], self-regulation and narrative components [62], and reminder messages [63] were significantly associated with increased adherence. Descriptive evidence highlighted several facilitating factors: comfortable equipment [64], easy handling [65], incentives, access to new information, and progress feedback [66]. Additional positive effects were observed from point systems [67], quizzes [68,69], recipe provision [68], SMS prompts, prizes, and 4-month program duration [69,70]. The social skills component showed high participation rates [69,70], with peak interaction times observed between 3 PM and 1 AM on weekdays and weekends [71]. Conversely, statistical evidence demonstrated reduced adherence associated with smoking cessation stage-of-change assessments and contest prompts [72], as well as picture and message contests [69,70]. Descriptive evidence identified barriers including uncomfortable heart rate monitors [64], limited new website content [66], and declining participation rates over extended study durations [61,68,71].

Qualitative evidence supported the effectiveness of a concise baseline questionnaire and platform design [73], friendly health competitions and small altruistic rewards [74], and motivational support features [75]. However, qualitative evidence also revealed challenges related to poorly timed surveys [64], time-intensive baseline questionnaires, and technical difficulties encountered during the intervention [75].

Twelve newly identified multicomponent studies substantially expanded this domain and, in several cases, complicated the earlier facilitator picture. Gamification and reward mechanics were again linked to engagement, including health coins, streaks, and unlockable content associated with high weekly logins [98] and smartwatch reward displays that motivated use [99], whereas the absence of gamification was experienced as a barrier [106]. The clearest complication concerned self-monitoring: although tracking with feedback facilitated engagement in some programs [99,100], the perceived burden of daily self-monitoring reduced adherence and conferred no advantage over paper records in one trial [101], and self-monitoring components saw low or only partial uptake elsewhere [102,103,110]. Parental involvement remained facilitative, with caregiver-adolescent engagement correlated [104] and a mother a more acceptable co-participant than a friend [105]. Engagement typically declined over time, with effects lost by 18 months and most participants stopping after a few weeks [105,106], while shorter duration and completion incentives reduced dropout [107]. Incentives showed mixed effects, raising short-term motivation that faded on withdrawal [104] and, when coercively grade-linked, degrading app perception with heavier use [108].

User-Related Factors

User-related factors associated with adherence to multicomponent lifestyle interventions were extensive. Statistical evidence showed higher adherence among females, individuals with weaker intentions to consume fruits and vegetables, and British nationals [73], as well as those with less exercise at baseline, lower BMI, and better health status [75]. Additional statistical predictors included mothers versus fathers in parent-child dyads and parents with high education [61], younger participants [76], those who had been drunk in the past

XSL•FO
RenderX

month, and previous users of the internet for health purposes [63], as well as individuals with higher perceived benefits of quitting [72]. Descriptive evidence indicated increased adherence among males [74], individuals with higher risk perception of drugs, lower alcohol and tobacco consumption, and fewer family-related alcohol and drug abuse problems [63], as well as younger participants, females, and those with nonproblematic drinking patterns [69,70]. Qualitative evidence highlighted enhanced adherence when participants felt part of a larger initiative and enjoyed learning about health and engaging in personal challenges [64].

Conversely, statistical evidence identified lower adherence among adolescents from nonacademic educational tracks compared to academic tracks [62], those with religious affiliation [63], and individuals with older age, binge drinking behavior, and immigration background [72]. Descriptive evidence revealed barriers including time constraints [66], perceived lack of behavioral change when using the app, subjective perception of already maintaining a healthy lifestyle, and insufficient environmental motivation [62], concurrent use of alternative lifestyle tracking apps and channels [62,63], lost login credentials [68], lack of interest [63,68], engagement in extracurricular activities, school absences, relationship status, and preference for alternative communication channels [63], and immigration background [69,70]. Qualitative evidence highlighted additional barriers including time limitations [74], insufficient device storage capacity, and the perception of mandatory participation [62].

The newly identified multicomponent studies also enriched the user-related determinants and reinforced several barriers. Lower socioeconomic position was again implicated, as noncompleters had significantly lower paternal education [101]. Loss of interest and waning motivation were among the most common reasons for dropout [98,101,106], and competing demands on adolescents' time, including school examinations, travel distance, and parental work, repeatedly limited engagement [99,101,103,110]. Access and device constraints, including device dependency and exclusion of adolescents without smartphones, raised digital-divide concerns [98,99]. A recurring adolescent-specific theme was privacy, which cut in both directions: a private, user-controlled interface reduced fear of judgment [101], yet a program that felt too private discouraged involving a friend and some adolescents preferred passive, nonsocial participation [102,105]. A late-responder subgroup with a mixed risk profile further illustrated that engagement timing varies across adolescents [109].

Twenty-six of the included studies contributed only to the descriptive synthesis of study characteristics and, where attrition data were extractable, to the quantitative synthesis of attrition; no factors influencing adherence were reported in these studies, and they therefore do not appear in the factor-level synthesis presented in Tables S1-S6 Multimedia Appendix 1. They comprised studies of physical activity [119-125], dietary habits [126], obesity management [127-130], tobacco use [131-136], alcohol use [137-140], multicomponent lifestyle interventions [141-143], and the study by Parker et al [147].

Discussion

Principal Findings

This systematic review synthesized evidence from 116 studies to identify the factors influencing adherence to digital lifestyle interventions for adolescents. Our analysis revealed that, although just over half (47/89, 52.8%) of the interventions successfully achieved their primary behavioral outcomes, this effectiveness is likely to be undermined by significant adherence challenges. On average, participants completed 66.9% (SD 26%) of the interventions (the mean completion rate across the 68 comparisons that reported it). Mean adherence to individual intervention components was lower still: 55.2% (SD 25.5%) (across the 66 comparisons that reported it). This disparity highlights a critical issue, namely that an intervention is unlikely to be effective if users do not engage with it as intended [148]. Therefore, understanding the drivers of adherence is crucial.

Intervention-Related Determinants of Adherence

Several intervention-related elements were consistently effective in promoting adherence across multiple health domains. Personalization capabilities, intuitive user interfaces, strategically timed reminder systems, goal-setting functionalities, and gamification elements were found to be particularly influential design features. These findings align with and extend research on adult populations. For instance, the importance of personalization and user-friendly design echoes findings from systematic reviews on digital mental health interventions for adults [10]. However, our review indicates that for adolescents, these elements may need to be combined with gamification and engaging activities to be successful. This is consistent with self-determination theory, which posits that supporting autonomy (personalization), competence (usability and goal-setting), and relatedness (human support) fosters the intrinsic motivation crucial for sustained engagement [5,149]. The effectiveness of gamification elements, such as music integration, interactive quizzes, and competitive features, suggests that interventions that leverage intrinsic motivation through enjoyable activities may achieve better adherence outcomes than purely informational approaches [150]. Importantly, while gamification and "engaging activities" are related, they are operationally distinct in the included studies. Gamification refers to the application of game-design elements (eg, points, badges, leaderboards, and competition) to nongame contexts [151], whereas engaging activities encompass a broader category of design features intended to sustain interest, including interactive quizzes, music integration, narrative storylines, and varied content formats. Both contributed to adherence, but through different mechanisms: gamification primarily leverages extrinsic motivational pathways through reward and competition, while engaging activities may support intrinsic engagement through enjoyment and curiosity.

The prominent role of human support elements, which is particularly evident in obesity interventions through health coach communication and parental involvement, highlights the ongoing importance of interpersonal connections in digital health contexts [5,152]. This finding supports the emphasis placed on social support as a critical determinant of behavior

XSL•FO
RenderX

change maintenance in social cognitive theory [153,154]. However, the mixed evidence regarding the effectiveness of social intervention components, such as message boards and expert forums, suggests that not all forms of social interaction enhance adherence. The effectiveness of human support may depend on the quality, timing, and perceived relevance of the interaction, rather than on the mere availability of social features.

Implementing comprehensive human support presents significant scalability challenges, particularly for universal prevention programs, where providing individual attention becomes logistically and economically unfeasible. Constraints on resources in health care and education systems often prevent the provision of sustained professional support for large groups of participants. While hybrid models combining digital tools with personal support can optimize adherence in clinical or targeted prevention contexts, alternative strategies deserve consideration for population-level implementations. These could include peer mentoring systems, AI-driven personalized feedback mechanisms, or tiered support models where human interaction is strategically deployed for participants showing signs of early disengagement or elevated risk [155].

Technical implementation barriers consistently emerged as substantial obstacles to sustained adherence in all health domains, regardless of the focus of the specific intervention. Synchronization difficulties, authentication problems, and inappropriately timed notifications emphasize the importance of robust technological infrastructure and comprehensive, user-centered design principles. These technical challenges were particularly evident in interventions targeting physical activity and alcohol use, potentially due to the real-time tracking requirements and environmental context sensitivity inherent to these health domains. The consistent finding of declining adherence over the duration of interventions [156], particularly in dietary and multicomponent domains, suggests the necessity of adaptive engagement strategies that evolve dynamically to maintain user interest and combat habituation effects.

User-Related Determinants of Adherence

The synthesis revealed complex and occasionally contradictory relationships between demographic characteristics and adherence patterns. This indicates that associations are context-dependent and cannot be easily generalized. While some studies identified higher adherence among female participants and younger adolescents, these relationships demonstrated considerable variability across health domains and study contexts. This suggests that demographic predictors may be moderated by intervention characteristics, the health domain in question, and cultural factors. This heterogeneity is consistent with ecological systems theory, which emphasizes the multifaceted influences on adolescent behavior, including individual, family, peer, and broader societal factors [157].

Socioeconomic indicators, particularly educational attainment and household income, exhibited more consistent associations with adherence; however, the nature of these relationships varied across health domains. Higher educational levels were associated with better adherence to dietary and alcohol interventions, which may reflect enhanced health literacy and digital competency. However, conflicting evidence regarding the effects of household income on obesity interventions was found, suggesting that socioeconomic influences may operate differently across behavioral targets. These findings emphasize the importance of considering the implications for health equity in the design of digital interventions and the potential need for differentiated implementation strategies across socioeconomic groups.

These socioeconomic patterns in adherence have important implications for health equity that extend beyond the adolescent-specific literature examined here. Systematic reviews examining digital health interventions in adult populations have identified similar socioeconomic gradients in engagement. Szinay et al [158] found that the uptake, engagement with, and effectiveness of mobile interventions for weight-related behaviors were not equally distributed across socioeconomic groups, raising concerns that digital health interventions may inadvertently widen health inequalities. Western et al [159] further argued that the “digital health divide” operates at multiple levels, including individual digital literacy, infrastructure access, and the socioeconomic context of health domains. Our findings in adolescent populations echo these adult-focused reviews and suggest that the equity implications of digital health interventions may emerge early in the lifespan. Interventions targeting adolescents from lower socioeconomic backgrounds may require differentiated design and implementation strategies, such as offline functionality, reduced data requirements, or integration with existing community infrastructure, to ensure equitable engagement.

Psychological factors, particularly intrinsic motivation and the perceived personal benefits of the intervention, emerged as powerful and consistent facilitators. This is particularly relevant for adolescents, who, as noted in the literature, are in a critical period of identity formation during which their cognitive decision-making and critical thinking functions are still maturing [11,12]. Interventions that do not align with their developing personal values or are not perceived as immediately relevant or beneficial are likely to be abandoned, which is consistent with motivation theories that emphasize the need for perceived efficacy and value alignment to encourage long-term participation [149,160]. However, the frequent reporting of loss of motivation and declining interest as barriers to adherence, particularly in the obesity and physical activity domains, highlights the difficulty of maintaining initial enthusiasm throughout extended intervention periods.

Domain-Specific Adherence Patterns

Adherence-related outcomes varied across health domains, illuminating the different challenges and motivators associated with specific behavioral targets. In the quantitative synthesis of attrition, dropout was lowest in physical activity interventions, potentially reflecting the immediate feedback and tangible outcomes associated with movement tracking, and highest in alcohol and tobacco interventions, possibly reflecting the sensitive nature of substance-use disclosure and the complex psychological factors surrounding these behaviors in adolescents. Completion and component-adherence rates also differed across domains, although the wide and overlapping

XSL•FO
RenderX

ranges caution against overinterpreting any single domain ordering.

Multicomponent lifestyle interventions illustrate the tension between comprehensiveness and adherence. While targeting multiple risk factors simultaneously is theoretically appealing, the expanded evidence base indicated that such programs frequently encountered engagement decline, self-monitoring burden, and competing demands, suggesting that they may present unique adherence challenges that require specialized design considerations to maintain participant involvement across diverse behavioral targets.

Quantitatively synthesizing attrition reinforced and sharpened the narrative findings. Although a substantial minority of adolescents (pooled 16.9%) dropped out of the included studies, the between-study heterogeneity was extreme (I^2>98%) and was not explained by health domain, delivery modality, human support, incentives, intervention duration, or participant age. The level of disengagement is highly context-specific and is not predicted by the broad design characteristics that are typically reported, which supports our central recommendation that the field should adopt standardized adherence metrics. The contrast between modest attrition (approximately 17%) and lower intervention use, with mean completion of approximately two-thirds and mean component adherence of approximately one-half, is equally instructive. Adolescents tend to remain nominally enrolled while ceasing to engage with the intervention as intended, so that retention statistics alone substantially overstate true adherence.

These quantitative patterns are consistent with recent syntheses reporting low and declining real-world engagement with digital interventions among young people and a comparable facilitator and barrier structure [161-164].

Limitations

This systematic review has several important limitations. First, the study protocol was not prospectively registered, and we did not conduct forward or backward citation searching, which may have resulted in the omission of relevant studies not indexed in the searched databases. Second, we did not conduct formal risk of bias assessments of included studies. While validated tools exist for assessing risk of bias across different study designs (eg, the revised Cochrane Risk of Bias tool for randomized trials [RoB 2] [165] and the Risk Of Bias In Non-randomized Studies of Interventions [ROBINS-I] tool [166]), our primary objective was to identify and categorize factors reported as influencing adherence rather than to evaluate intervention effectiveness. Because we do not aggregate effect estimates or draw causal conclusions about intervention efficacy, a formal risk-of-bias assessment of each study's primary outcomes would not directly inform our narrative synthesis. We acknowledge, however, that this means findings from studies with varying methodological rigor receive equal weight in our synthesis. Third, this review focused on 5 lifestyle-related health domains selected based on their relevance to cancer prevention. The findings may not be generalizable to digital interventions targeting other health domains, such as mental health or sexual health, where the developmental and behavioral contexts differ substantially. Finally, although attrition could be meta-analyzed, the pooled estimates should be interpreted in light of very high between-study heterogeneity and the inconsistent operationalization of attrition and adherence across studies; the estimates are descriptive, are not weighted by study-level risk of bias, and the small-study-effect test should be read cautiously at this level of heterogeneity. Completion and component-level adherence were reported too heterogeneously to support a defensible pooled estimate and were therefore synthesized descriptively and through the SWiM approach rather than meta-analytically.

Implications for Future Research

The findings of this review have several implications for future research and practice. First, the considerable heterogeneity in adherence measurement and reporting represents a fundamental barrier to advancing the field. We recommend that future studies adopt standardized adherence metrics, distinguishing at minimum between completion rates (proportion completing the intervention) and component-level adherence (engagement with specific intervention elements), and report both measures alongside their operationalization. Second, the consistent role of intervention design features across multiple health domains suggests that these elements should be considered core components in the design of digital health interventions for adolescents. Third, the mixed evidence regarding social features highlights the need for experimental research that systematically varies the type, timing, and intensity of social components to determine optimal configurations for different target groups. Fourth, the clear impact of technical barriers across all domains underscores the importance of rigorous usability testing and iterative design processes in intervention development. Finally, future research should explicitly examine the dose-response relationship between adherence and intervention effectiveness. Meta-analyses of individual participant data could provide enhanced statistical power for identifying optimal intervention parameters while accounting for participant-level moderators of adherence [167].

Conclusion

This systematic review provides a comprehensive overview of the factors influencing adherence to digital lifestyle interventions among adolescents. The findings show that intervention-related design features and user-related characteristics consistently affect adherence patterns, although these relationships are often context- and domain-specific. Complementing this narrative synthesis, a random-effects meta-analysis of attrition across 108 comparisons produced a pooled dropout of approximately 17%, but with extreme between-study heterogeneity that none of the examined study-level moderators explained, reinforcing that the degree of disengagement is highly context-specific rather than predictable from broad design features. The substantial variation in adherence rates and measurement approaches highlights the urgent need to establish standardized reporting frameworks that incorporate validated measures and clearly defined usage parameters. Such methodological advancements are essential for synthesizing robust evidence and translating research findings into effective, engaging digital health interventions for adolescent populations.

Acknowledgments

The authors would like to acknowledge the researchers who conducted the primary studies and systematic reviews that form the evidence base for this work. We also extend our gratitude to the adolescent participants whose involvement in the original studies made this synthesis possible.

No generative AI tools were used to design the study, conduct the analyses, interpret the findings, generate scientific content, or identify references. Because some authors are not native English speakers, DeepL was used to assist with translation and grammatical and stylistic language editing. All resulting text was critically reviewed and revised by the authors, who take full responsibility for the accuracy and integrity of the manuscript.

Funding

This study was supported by the SUNRISE (Sustainable Interventions and Healthy Behaviours for Adolescent Primary Prevention of Cancer with Digital Tools) project that has received funding from the European Union's Horizon Europe research and innovation program under Grant Agreement Number 101136829. Furthermore, this work received funding from the Swiss State Secretariat for Education, Research and Innovation (SERI). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Abstract

Background: Tabletop exercises (TTXs) are commonly used to enhance prehospital readiness for mass casualty incidents (MCIs). However, evidence on their design, facilitation, and evaluation remains scattered. TTXs simulate organized interactions at 3 levels: among individual responders and response protocols, within interdisciplinary teams, and across organizations and systems. While existing reviews cover tabletop simulation generally, they do not specifically focus on the prehospital MCI interface or assess whether evaluation methods match the exercise objectives.

Objective: This scoping review aimed to explore how TTXs are designed, facilitated, and evaluated in prehospital MCI preparedness. It classified outcomes using the Kirkpatrick Evaluation Model and analyzed how evaluation methods align with the purpose of each exercise.

Methods: We performed a scoping review following Arksey and O'Malley's framework, with enhancements from Levac et al, along with PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) and PRISMA-S (PRISMA Extension for Reporting Literature Searches) guidelines. Searches across PubMed, Embase, Scopus, PsycINFO, CINAHL, the Cochrane Library, ClinicalTrials.gov, Google Scholar, and references were limited to English peer-reviewed and gray literature published from 2015 to May 2026. Eligible studies focused on TTXs related to prehospital disaster or MCI preparedness and reported measurable educational, clinical, or system outcomes. The review protocol was registered beforehand on Protocols.io. Two reviewers (PP and AA) independently screened records, extracted data, and classified outcomes using Kirkpatrick levels, with an added level 2+ (Applied Learning) category for structured performance evaluation during exercises.

Results: Thirteen studies from 9 countries were included. They were categorized into a preliminary 3-tier typology called the TTX Design Spectrum, representing increasing levels of interaction: algorithm-rehearsal exercises (n=2) focused on individual responders' interaction with triage protocols, scenario-based decision-training exercises (n=7) aimed at multidisciplinary team decision-making under realistic conditions, and systems integration exercises (n=4) centered on interagency coordination and system-level preparedness. Facilitation varied by exercise purpose, from standardized assessment-focused approaches to expert-led and multidisciplinary facilitation. Evaluation primarily targeted Kirkpatrick level 1: Reaction (n=10), level 2: Learning (n=10), and level 2+ (Applied Learning) (n=8), with fewer studies examining level 3: Behavior (n=2) or level 4: Results (n=3). Operational frameworks were reported more consistently than formal educational design or assessment frameworks. Additionally, natural disaster scenarios and evidence from resource-limited settings were underrepresented.

Conclusions: TTXs for prehospital MCI preparedness should be viewed as a collection of related exercise types rather than a single, uniform intervention. This review introduces an initial typology called the TTX Design Spectrum, along with the level 2+ (Applied Learning) classification, which operationalizes the distinction between in-training performance and behavioral transfer. These tools aim to help align exercise purpose, facilitation, and evaluation strategies. Future research should focus on validating this typology, enhancing follow-up assessments of behavioral transfer, and adapting TTX design for natural disaster and resource-limited settings.

Introduction

Mass casualty incidents (MCIs) and disasters continue to challenge health systems because they demand quick coordination, prioritization, and adaptation amid uncertainty, time constraints, and limited resources. The Sendai Framework for Disaster Risk Reduction emphasizes the importance of preparedness for effective response in modern disaster management [1]. Prehospital readiness involves personnel and systems managing triage, incident command, scene coordination, interagency communication, resource management, and treatment prioritization. This preparedness significantly impacts outcomes when systems are overwhelmed. As a result, health care simulation use has increased [2,3], and recent tabletop and disaster education research highlights incident command, triage, surge management, communication, and resource allocation as essential skills that require practice before real emergencies [4-6].

Tabletop exercises (TTXs) stand out among simulation methods because they are structured, discussion-driven activities where participants can rehearse plans, roles, communication, and operational choices without the logistical challenges of full-scale or functional exercises [5,7]. They are also versatile, being customizable to an organization's specific risks with adaptable goals, scope, and difficulty levels [2,5], making them a popular tool for improving disaster and MCI preparedness [4,8-10].

The existing literature indicates that TTXs are not a uniform type of intervention. Some primarily concentrate on practicing triage algorithms, while others focus on team decision-making, interagency communication, or organizational coordination [2,4-6]. This variation is expected because exercises serve different educational and operational goals. The challenge lies in the fact that the term "tabletop exercise" is often used to describe quite different activities. Without a common framework for describing the purpose of each exercise, educators and planners struggle to determine whether an evaluation method fits the exercise's objectives and find it difficult to compare findings across studies that use the same term for different types of activities.

At their core, TTXs are organized interactions involving individual responders, the protocols they follow, professionals from various disciplines, and different organizations, agencies, and systems. The specific level of interaction an exercise aims to rehearse determines who participates, how it is facilitated, and what metrics should be used for evaluation. Consequently, a typology of exercise purposes also reflects the types of interactions being trained. This shared vocabulary helps determine whether an evaluation method is appropriate for a particular exercise and allows for comparison of evidence across studies.

Recent review literature highlights the need for a more targeted synthesis. Frégeau et al [7] conducted a comprehensive scoping review of tabletop simulations in medical emergencies, analyzing 70 studies across various settings, specialties, formats, and learner groups. They found that reported outcomes mainly focused on the Kirkpatrick reaction and learning levels [7]. Emaliyawati et al [8] reviewed 12 tabletop disaster exercise studies involving health care workers and students, concluding that TTXs enhance knowledge, attitudes, preparedness, confidence, and performance. Although these reviews are valuable, they address TTXs broadly, rather than focusing specifically on the prehospital interface. They do not analyze how prehospital MCI competencies are distributed across different exercise designs, nor do they systematically link exercise purpose with facilitation style and evaluation depth. As far as we know, no published review has specifically synthesized TTXs for prehospital MCI preparedness while examining the alignment among exercise design, facilitation, and evaluation [7,8].

This scoping review aimed to map the existing literature and clarify how TTXs function within prehospital MCI preparedness, considering them as a group of related but distinct interventions. The objectives included systematically investigating how TTXs have been used to evaluate or enhance prehospital readiness for MCIs; classifying reported outcomes according to the Kirkpatrick Evaluation Model, including structured performance within exercises; describing key design, delivery, and facilitation features along with the competencies they target; and pinpointing gaps in the evidence. The review seeks to develop a preliminary typology called the TTX Design Spectrum, which aims to guide purpose-aligned design, facilitation, and evaluation in prehospital disaster preparedness.

Methods

Study Design and Methodological Framework

Overview

This scoping review, part of the Mass-Casualty Incident, Prehospital Emergency Response project, systematically maps evidence related to TTXs for prehospital disaster preparedness. Our methodology follows Arksey and O'Malley's [11] framework, with modifications by Levac et al [12], and adheres to PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) reporting standards [13]. The protocol was registered on Protocols.io (July 3, 2025) [14] and published as a preprint [15], ensuring transparency and reproducibility. Stakeholder consultation, recommended by Levac et al [12] for knowledge translation, was not carried out because the study primarily focused on evidence mapping for research synthesis rather than developing practice guidelines.

Stage 1: Identifying the Research Question

This scoping review was based on 2 main research questions and 3 subsidiary questions. The primary questions explored how TTXs are used to assess or enhance prehospital preparedness for MCIs, and which Kirkpatrick evaluation levels

XSL•FO
RenderX

(Reaction, Learning, Behavior, and Results) are most frequently reported in prehospital MCI TTX studies. The secondary questions investigated the key design and delivery features of these TTXs, the competencies and operational areas they target, and identified gaps in evidence concerning evaluation methods and their effectiveness.

Stage 2: Identifying Relevant Studies

Search reporting followed the PRISMA-S (PRISMA Extension for Reporting Literature Searches) extension for literature search reporting [16], along with PRISMA-ScR. A completed PRISMA-ScR checklist is included in Checklist 1. We searched several multidisciplinary databases, including PubMed, Embase, Scopus, PsycINFO (via APA PsycNet), CINAHL, Cochrane Library, and ClinicalTrials.gov, to cover biomedical, educational, and allied health research. Each database and registry was searched individually; no multidatabase search was performed simultaneously. We also reviewed Google Scholar for gray literature and manually screened reference lists of included studies and relevant reviews. No contact was made with study authors, experts, manufacturers, or external contacts to gather additional records or data. Our search methods included only database searches, Google Scholar, and manual reference list screening.

On June 10, 2025, we established a detailed search strategy based on the Population-Concept-Context framework (Table 1), which was subsequently updated on May 15, 2026. The Population targeted prehospital health care workers such as paramedics, emergency medical technicians, emergency physicians, and nurses, as well as emergency system administrators involved in MCI responses. The Concept focused on TTXs used for training and preparedness, with outcomes measurable at the educational, clinical, or system levels. The Context covered prehospital systems that respond to mass-casualty incidents and disasters across various geographic areas.

Table . Search strategy overview using the Population-Concept-Context framework. Representative controlled vocabulary and free-text terms are displayed. Detailed database-specific search strings are available in Multimedia Appendix 1.

Category	Keywords	Search strategy
Population	“Emergency Medical Services” [MeSH]; “Emergency Medical Technicians” [MeSH]; “Allied Health Personnel” [MeSH]	paramedic*; “first responder*”; “first responder”; “first responders”; ambulance*; “emergency medical service*”; “emergency medical service”; “emergency medical services”; EMS[a]
Concept	“Simulation Training” [MeSH]; “Patient Simulation” [MeSH]; “Computer Simulation” [MeSH]; “simulation training”; “tabletop simulation”; “tabletop exercise”	tabletop exercise*; table-top exercise*; tabletop simulation*; tabletop drill*; discussion-based exercise*; scenario-based simulation*; preparedness exercise*; board game*; simulation game*; gamified exercise; paper-based exercise
Context	“Mass Casualty Incidents” [MeSH]; “Disaster Planning” [MeSH]; “Emergency Preparedness” [MeSH]; “Triage” [MeSH]; “mass disaster”; “field triage”; “incident command”; “prehospital care”	emergency preparedness; disaster preparedness; mass casualty incident*; MCI[b]; field triage; incident command; prehospital care; disaster simulation; response coordination; crisis; disaster response; multi-casualty; multiple casualty

[a]EMS: emergency medical services.

[b]MCI: mass casualty incident.

We used a combination of controlled vocabulary (MeSH) and free-text terms with Boolean operators in search strings tailored to each database, refining them iteratively to improve sensitivity and specificity (Table 1). An information specialist or librarian peer-reviewed the search strategy following the Peer Review of Electronic Search Strategies criteria before final implementation [17]. No published search filters were used, nor were previous review strategies reused or adapted; instead, prior reviews helped identify relevant references through citation screening. Details about platforms and complete database-specific search strings, including the full PubMed strategy, are available in Multimedia Appendix 1.

Stage 3: Study Selection

Retrieved records from various sources, including citation searches and gray literature, were imported into Covidence [18], where they were pooled and deduplicated before screening. Two reviewers, PP and AA, independently examined all records through a 2-stage process: first screening titles and abstracts and then reviewing full texts. Any disagreements were resolved through discussion or, if necessary, by consulting a third reviewer. These disagreements were systematically recorded in Covidence and addressed through structured discussions with documented reasons.

Eligibility Criteria

Overview

We included studies that assessed TTXs in prehospital disaster or MCI preparedness and reported measurable educational, clinical, or system outcomes. These were peer-reviewed papers or gray literature published in English between January 2015 and May 2026. For this review, “prehospital” was mainly defined by the medical phase and operational functions of MCI or disaster response, rather than solely by participant role or physical setting. This encompassed EMS (emergency medical services) care, field triage, scene coordination, casualty distribution, transport decisions, and the transition from prehospital to hospital care. Eligible study designs included quantitative, qualitative, mixed methods, quasi-experimental,

XSL•FO
RenderX

pre-post, randomized, observational, descriptive, pilot, feasibility, and implementation studies. We excluded systematic reviews, narrative reviews, editorials, commentaries, opinion pieces, conference abstracts without full texts, studies lacking full-text access, non-English studies, studies published before 2015, and studies where TTXs were not the primary focus. Additionally, studies focused on nonmedical TTX applications, such as military, corporate, cybersecurity, or other non–health care settings, were excluded unless they included a relevant medical prehospital or MCI response component. Studies involving hospital personnel were included only if they addressed prehospital medical functions, EMS coordination, transport, casualty distribution, or the hospital transition process.

We chose papers from 2015 onward because initial scoping indicated limited peer-reviewed literature before 2015 on TTX outcomes in prehospital MCI settings. Furthermore, reporting standards for simulation-based education improved significantly during this period [19], and the 2015 Sendai Framework for Disaster Risk Reduction [1] provided a current policy context for disaster preparedness research.

Stage 4: Data Charting

Before starting the formal data extraction, we tested a standardized data-charting form with 2 reviewers (DN and AO) across 5 studies to verify that the extraction fields were clear, comprehensive, and consistently understood. During this pilot, reviewers independently extracted data, compared their entries, discussed any discrepancies, and refined the form before proceeding with full extraction. The finalized form included study details (ID, country, design, population, and sample size), TTX features (targeted competencies, duration, scenario design, and preparatory instruction), facilitation aspects, evaluation methods, Kirkpatrick levels addressed, and the underlying training, assessment, and operational frameworks.

After the data-charting form was finalized, 2 reviewers (DN and AO) independently extracted data from all included studies. They compared their extractions, resolving any discrepancies through discussion and consensus. If they could not reach an agreement, a third reviewer was consulted. Microsoft Excel was used to manage, review, and organize the extracted data.

Outcomes were categorized using the Kirkpatrick Evaluation Model [20,21]. Beyond the 4 standard levels, we added a level 2+ (Applied Learning) subcategory to differentiate structured performance assessments within the exercise setting from knowledge acquisition and actual behavioral transfer in real-world contexts. This subcategory helps operationalize, for TTX outcome mapping, distinctions outlined in earlier frameworks: the updated (“New World”) Kirkpatrick model’s focus on skills shown during training [22], Miller’s “shows how” level of assessment [23], and translational science models of simulation-based education outcomes (T1-T3), which differentiate in-simulation performance from later behavior and patient or system results [24]. Each outcome was classified independently; thus, a single study could contribute to multiple Kirkpatrick levels. Detailed definitions, decision rules, and examples for classification are available in Multimedia Appendix 2.

Stage 5: Collating, Summarizing, and Reporting the Results

We used a combination of descriptive and narrative approaches appropriate for scoping reviews. Quantitative information was summarized using frequencies and counts, while qualitative and contextual data, such as exercise design, scenario features, facilitation processes, targeted skills, and evaluation techniques, were synthesized narratively. The extracted data were categorized into 7 domains: general study details, population traits, TTX features and elements, facilitator responsibilities, data collection methods, training results, and frameworks that inform training design, assessment, and operational practice.

Through iterative cross-study comparison, we discovered common patterns in exercise design, facilitation, and evaluation. To categorize these patterns, we created the TTX Design Spectrum, which classifies exercises into 3 tiers based on their primary purpose and scope: tier 1 focuses on algorithm rehearsal, tier 2 on scenario-based decision training, and tier 3 on systems integration testing. Facilitation methods and evaluation patterns were summarized descriptively rather than formalized into additional models. This typology was developed inductively during synthesis rather than being predefined; it is an initial organizational tool and not a validated framework. Definitions can be found in Multimedia Appendix 2.

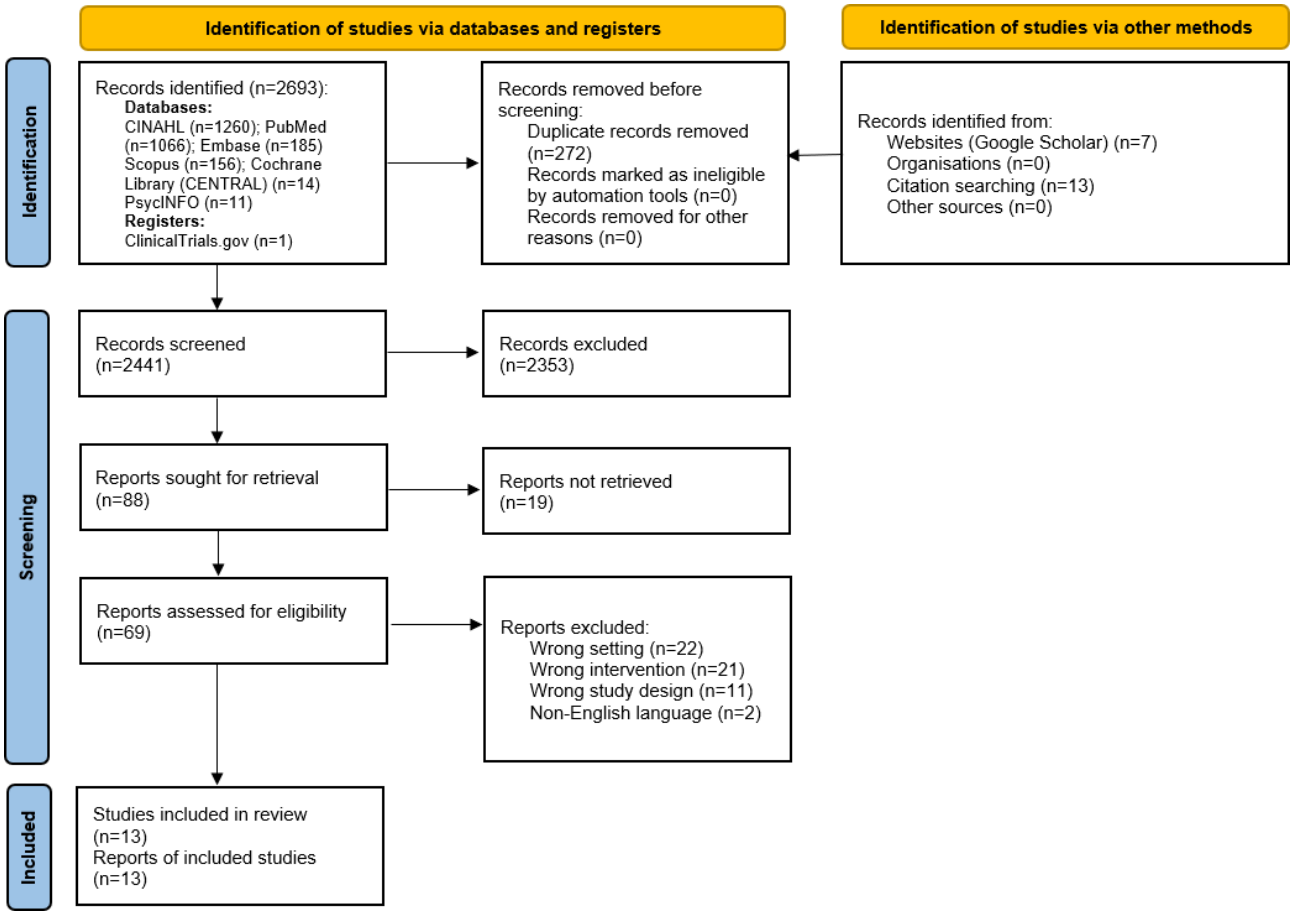
Protocol Deviations

This review was based on a prospectively registered protocol [14,15]. Two post hoc analytical refinements were introduced: the creation of the TTX Design Spectrum typology, which provides a descriptive overview of facilitation and evaluation patterns during stage 5, and the addition of the level 2+ (Applied Learning) subcategory in outcome classification during stage 4. Neither of these changes was specified in the protocol; both were developed through iterative comparison and synthesis of data. Importantly, there were no deviations that affected the search strategy or eligibility criteria.

Ethical Considerations

This scoping review summarized publicly accessible, previously published literature without direct involvement of human participants. Therefore, ethical approval was not required. We adhered to established ethical research principles, such as transparent reporting, proper attribution and citation, and preventing plagiarism and duplicate publications.

Results



Literature Search and Study Selection

Our search identified 2693 records from databases and trial registers, along with 20 additional records from other sources. After removing 272 duplicates, we screened 2441 records by title and abstract, excluding 2353. We attempted to retrieve 88 full-text reports; of these, 19 were conference abstracts without full publications. Metadata for these 19 records (author, year, title, and source) is provided in Multimedia Appendix 3. The publication years and geographic origins of unretrieved records were similar to those of the retrieved records (Multimedia Appendix 3). Of the 69 full-text reports assessed for eligibility,

XSL•FO
RenderX

56 were excluded (wrong setting, n=22; wrong intervention, n=21; wrong study design, n=11; and non-English, n=2). Thirteen studies met the inclusion criteria and were included in the final analysis. Figure 1 illustrates the study selection process.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram for study selection. Records were identified through 6 databases, 1 register, and other methods. Of these, 13 studies met all inclusion criteria and were categorized into 3 tiers of the Tabletop Exercise Design Spectrum.

Study Characteristics

Thirteen studies published between 2016 and 2026 were included, with most publications in 2020 (n=3). The studies took place in various countries: 4 in the United States, 2 in Thailand, and 1 each in the United Kingdom, Saudi Arabia, South Korea, Qatar, Spain, Sweden, and Japan. The research designs comprised 4 pre-post evaluations, 3 quasi-experimental studies, 2 reliability assessments, 2 mixed methods investigations, 1 randomized controlled trial, and 1 descriptive report. The sample sizes varied from 12 to 230 participants; 1 study did not specify the number of fellows involved (refer to Table 2, footnote).

XSL•FO
RenderX

Table . Characteristics of Included Studies (N=13).

Study	Country	Design	Participants, n	Population	Duration	Scenarios
Tier 1: algorithm rehearsal (n=2)						
Cheng et al (2022) [25]	United States	Reliability study	107	Prehospital EMS[a] professionals	4 - 11 minutes per set	1 (pediatric bus crash, 25 patients; 6 triage algorithms compared)
McGlynn et al (2020) [26]	United States	Reliability study	NR[b]	Pediatric emergency medicine fellows	Not reported	3 (10-, 100-, and 1000-victim MCI[c] scenarios; 253 patient cases)
Tier 2: scenario-based decision training (n=7)						
Kim et al (2021) [27]	South Korea	Pre-post	40	Physicians, nurses, and public health officers	25 minutes + 10 minutes debrief	1 (hydrofluoric acid explosion at chemical plant)
Phattharapornjaroen et al (2020) [28]	Thailand	Pre-post	52	Emergency physicians	2-day course	3 (building fire, terrorist bombing, and riots or active shooter)
Sena et al (2021) [4]	United States	Pre-post	18	Emergency medicine residents	2 hours	1 (explosion or mass shooting with fire)
Farhat et al (2022) [29]	Qatar	Pre-post	12	Physicians, nurses, and paramedics	3 hours	4 (biological, chemical, radiological, and nuclear CBRNE[d])
Alakrawi et al (2024) [30]	Saudi Arabia	Quasi-experimental	45	Senior paramedic students	Not reported	1 (multivehicle accident, 15 patients)
Chumvanichaya et al (2025) [31]	Thailand	RCT[e]	83	Paramedic students	40 minutes	3 (10 simulated victims: SIEVE[f], SORT[g], and START[h] protocols)
Cuartas-Alvarez et al (2026) [32]	Spain	Quasi-experimental	27	Primary care professionals (doctors and nurses)	2 hours	1 (MCI scenario: collapse with multiple victims; PHCT[i]-led prehospital response with ECC[j] or resource coordination)
Tier 3: systems integration testing (n=4)						
Anan et al (2016) [33]	Japan	Quasi-experimental	230	Physicians, firefighters, police officers, and emergency responders	60 - 85 minutes per scenario	3 (fire → chemical recognition → decontamination → triage)
Cicero et al (2019) [34]	United States	Descriptive	27	EMS, nurses, physicians, hospital administrators, and emergency managers	Not reported	1 (school bus rollover, pediatric MCI)
Skryabina et al (2020) [35]	United Kingdom	Mixed methods	125	Prehospital, hospital staff, and emergency planners	Not reported	1 (suicide bombing + marauding terrorist firearm attack)

XSL•FO
RenderX

Study	Country	Design	Participants, n	Population	Duration	Scenarios
Zimmerman et al (2026) [36]	Sweden	Mixed methods	16	Physicians, residents, specialists across emergency medicine, anesthesiology, internal medicine, surgery, psychiatry, radiology, and ophthalmology	Not reported	Not reported

[a]EMS: emergency medical services.

[b]The participant number is not clearly reported (NR); there were 253 patient cases available for triage across the scenario sets.

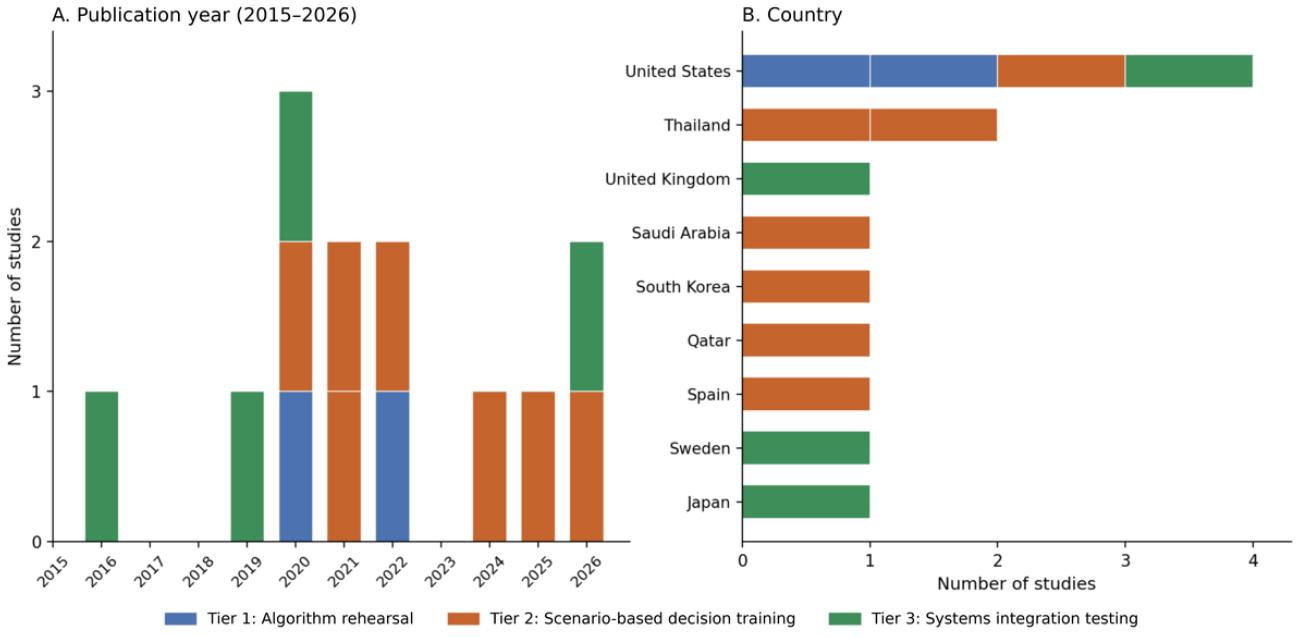
[c]MCI: mass casualty incident.

[d]CBRNE: Chemical, Biological, Radiological, Nuclear, Explosive.

[e]RCT: randomized controlled trial.

[f]SIEVE: Sieve (UK Major Incident Primary Triage).

[g]SORT: Secondary Triage (UK Major Incident).



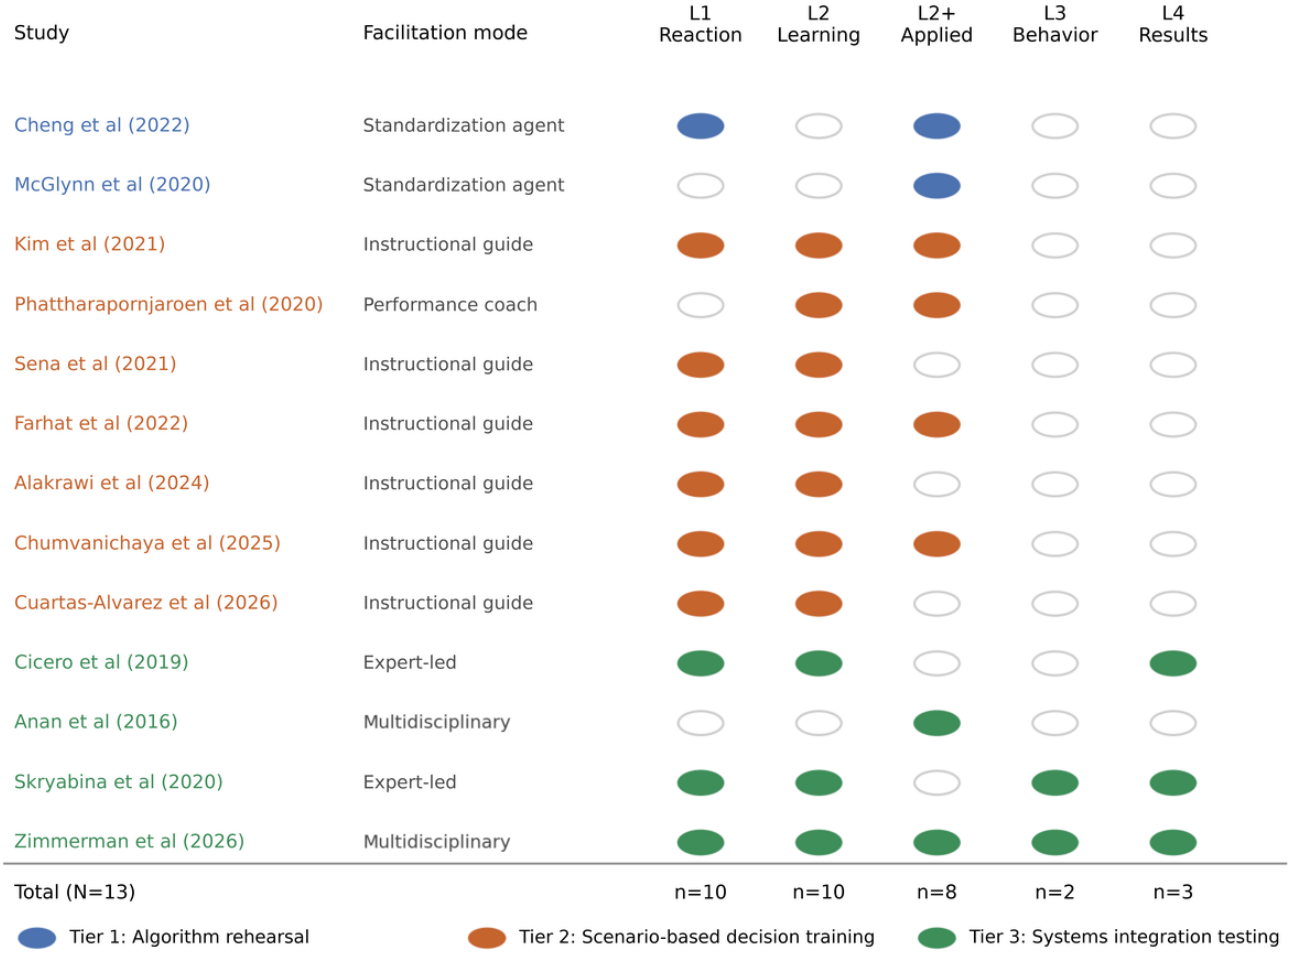
[h]START: Simple Triage and Rapid Treatment.

[i]PHCT: primary health care team.

[j]ECC: emergency coordination center.

The study populations were diverse, comprising EMS personnel, paramedics, paramedic students, physicians, emergency medicine residents, pediatric emergency specialists, nurses, and public health officers. Additionally, 3 studies specifically included nonclinical stakeholders: hospital administrators and emergency managers [34], firefighters and police officers [33], and emergency planners [35]. Table 2 provides a summary of the main study characteristics, while Figure 2A and B illustrate the distribution of the studies over time and across different regions.

Figure 2. Temporal and geographic distribution of included studies (N=13). Panel A shows the count of included studies by publication year from 2015 to 2026, while panel B illustrates the geographic distribution across countries. In both panels, the bar segments are color-coded to represent the Tabletop Exercise Design Spectrum tiers: tier 1 for algorithm rehearsal, tier 2 for scenario-based decision training, and tier 3 for systems integration testing.



Organization of the Synthesis

Figure 3 offers a visual overview that clarifies the relationship between the classification systems and how the results are organized. In this review, “tiers” specifically refer to the TTX Design Spectrum, which relates to exercise purpose and scope, while “levels” exclusively denote Kirkpatrick outcome levels, indicating evaluation depth. Facilitation modes describe how facilitators engaged participants. In the discussion, we use descriptive names such as algorithm rehearsal, scenario-based decision training, and systems integration testing to refer to tiers, thereby keeping the 2 numbering systems distinct.

XSL•FO
RenderX

Figure 3. Study-level matrix of tabletop exercise (TTX) tier, primary facilitation mode, and Kirkpatrick levels assessed (N=13). Each row represents a study included, color-coded by TTX Design Spectrum tier, highlighting its main facilitation mode and the Kirkpatrick outcome levels evaluated (level 1, Reaction; level 2, Learning; level 2+, Applied Learning; level 3, Behavior; and level 4, Results). Filled circles denote assessed levels; column totals match those in Table 3. Each study is assigned to 1 tier and 1 primary facilitation mode but can contribute to multiple outcome levels [4,25-36].

The TTX Design Spectrum: 3 Tiers of Exercise Purpose

Overview

Through iterative comparison across studies, we grouped the 13 included studies into 3 initial tiers based on each TTX's primary goal and scope. This grouping was consistent across 3 key dimensions: learning objectives, participant makeup, and outcome focus. Tier 1 involved proficiency with single-skill triage algorithms among relatively uniform prehospital groups, tier 2 covered integrated decision-making involving multiple competencies within multidisciplinary clinical teams, and tier 3 included nonclinical stakeholders, focusing on system readiness, organizational coordination, and policy changes. These tiers are preliminary patterns derived inductively and should be validated with larger samples.

Tier 1: Algorithm Rehearsal

Two studies examined how individual responders interacted with a triage protocol by using TTXs to practice and assess specific procedures in controlled settings [25,26]. These exercises evaluated triage accuracy, used standardized scoring, and tested performance within short time frames. McGlynn et al [26] used patient groups of 10, 100, and 1000 casualties, while Cheng et al [25] compared 6 pediatric triage algorithms. Participants were mainly prehospital professionals trained in the relevant protocols. This phase focused on measuring individual accuracy and the correct application of algorithms rather than on team coordination or broader decision-making contexts.

Tier 2: Scenario-Based Decision Training

Seven studies focused on interaction within interdisciplinary teams, using TTXs to enhance multicompetency decision-making under realistic operational constraints [4,27-32]. These exercises went beyond triage to involve incident command, team coordination, resource management, CBRNE (Chemical, Biological, Radiological, Nuclear, Explosive) response, leadership, and ethical reasoning. Duration varied from 25 minutes to 2 days, with 1 - 4 scenarios per session. Scenarios were tailored to specific contexts and included incidents such as a hydrofluoric acid chemical plant explosion [27]; fire, terrorism, and active shooter events [28]; mass shootings and fires [4]; 4 CBRNE situations [29]; a multivehicle accident [30]; triage across multiple disaster protocols [31]; and a building-collapse MCI scenario [32]. Participants were typically multidisciplinary, comprising prehospital personnel, emergency department staff, primary care providers, and sometimes public health officials. This tier prioritized integrated team decision-making under time constraints and uncertain information, rather than isolated skill assessment.

XSL•FO
RenderX

Tier 3: Systems Integration Testing

Four studies examined interorganizational and agency interactions through TTXs to evaluate coordination, collaboration, and policy response strategies [33-36]. These exercises engaged multiple agencies beyond clinical staff, such as hospital leaders, emergency services, firefighters, police, and other government entities. The scenarios included pediatric MCI management after a school bus crash [34], a CBRNE response with decontamination and triage [33], a combined suicide bombing and terrorist attack involving firearms [35], and postgraduate disaster medicine training focused on leadership and system coordination [36]. Unlike tiers 1 and 2, this level prioritized organizational preparedness, clarifying agency roles, formal after-action reviews, policy documentation, memoranda of understanding, and ongoing postexercise system improvements over immediate individual training.

Facilitation Approaches Across Tiers

Across the 13 studies, 5 recurring facilitation modes were identified, each associated with particular tiers and learning goals. These modes reflected differences in the facilitator's main role, such as guiding participants through a scenario, providing feedback on performance, ensuring consistent assessment, or supporting postexercise review. The following subsections describe the characteristics of each mode and its use across the 3 tiers.

Instructional Guide (Tier 2 Predominant)

Six tier 2 studies incorporated active instructional guidance in exercise scenarios [4,27,29-32]. Facilitators managed the scenario flow by providing timed information, posing clarifying questions, and offering prompts when decision-making slowed. They also adjusted scenario elements such as casualty numbers, resource availability, and time constraints to enhance learning. After each scenario, structured debriefings took place, often led by facilitators who asked questions to reinforce essential learning points.

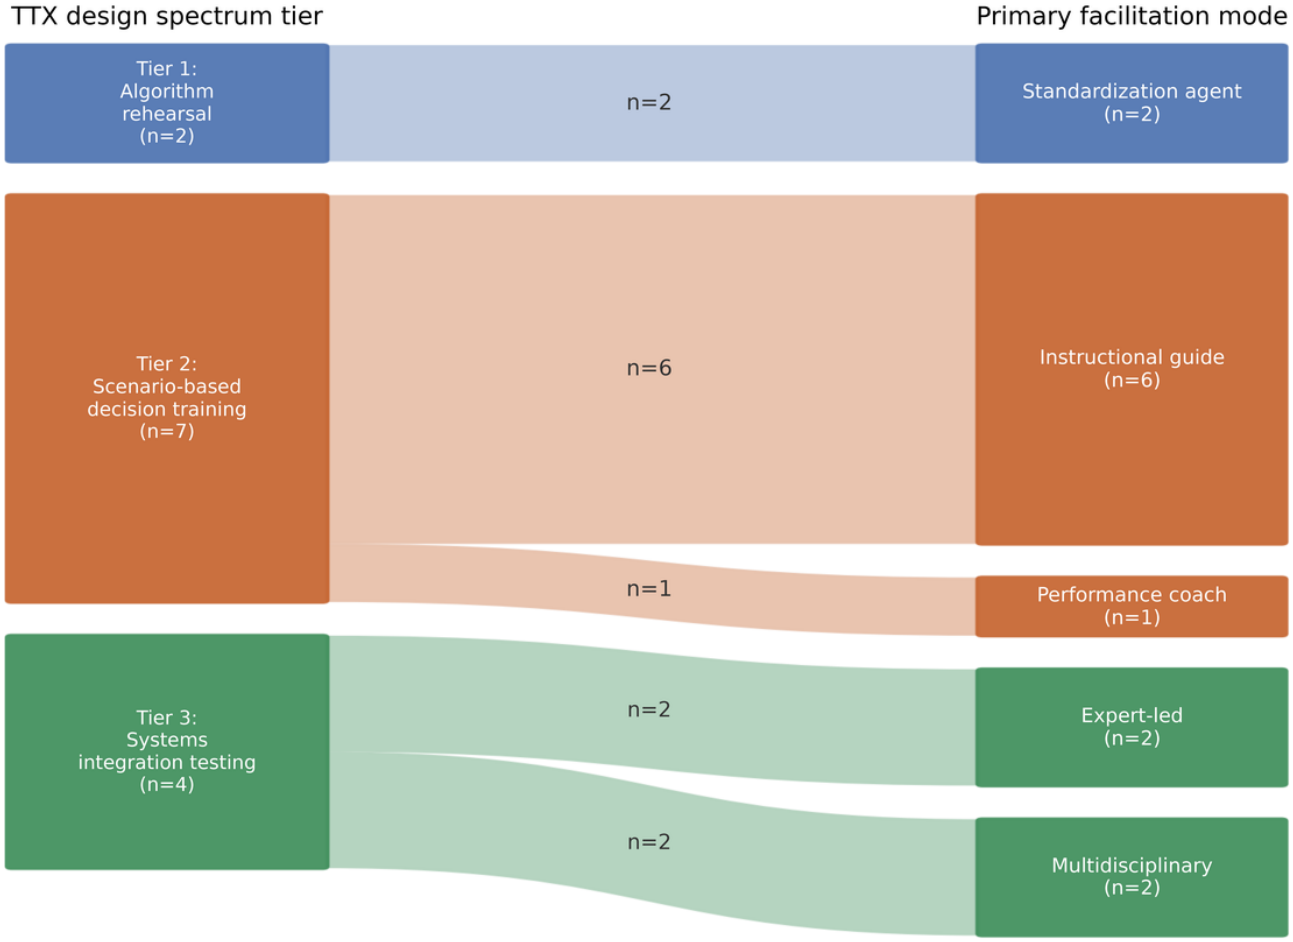
Performance Coach (Tier 2)

The study by Phattharapornjaroen et al [28] involved placing 2 supervisory personnel in each exercise group, explicitly tasked with observing and giving iterative feedback on team leadership behaviors and decision-making quality, using a combination of live observation and structured feedback.

Standardization Agent (Tier 1 Predominant)

McGlynn et al [26] and Cheng et al [25] emphasized measurement consistency and the reliability of assessments by using standardized facilitation protocols [25,26]. Facilitators underwent rater calibration training, used reference sheets and standardized scoring guides, and followed scripted scenario presentations to ensure interrater reliability.

Expert-Led Facilitation (Tier 3)



Cicero et al [34] and Skryabina et al [35] involved senior clinicians and emergency preparedness specialists in conducting exercises and guiding after-action reports. Their role therefore extended beyond scenario delivery to postexercise review, consistent with tier 3's focus on organizational preparedness and interagency coordination.

Multidisciplinary Facilitation (Tier 3)

Anan et al [33] and Zimmerman et al [36] employed multidisciplinary facilitation teams from various agencies to guarantee scenario realism and credibility within each participant's operational setting. In both modes, tier 3 facilitation emphasized interagency collaboration and systems-level learning over individual skill evaluation. Figure 4 shows the alignment between TTX tiers and facilitation modes.

XSL•FO
RenderX

Figure 4. TTX tier–facilitation mode alignment (N=13). Alluvial diagram illustrating the connection between TTX Design Spectrum tiers (on the left) and primary facilitation modes (on the right). Blue represents tier 1 (algorithm rehearsal), brown represents tier 2 (scenario-based decision training), and green represents tier 3 (systems integration testing). The lighter-shaded flows retain the color of their source tier, and flow width corresponds to the number of studies. Each study is linked to 1 specific tier and 1 primary facilitation mode. TTX: tabletop exercise.

Evaluation Strategies and Kirkpatrick Mapping

Data Collection Instruments and Timing

The 13 studies used diverse data collection methods. Tools for Kirkpatrick levels 1‐2 included knowledge tests (used in 8 studies), satisfaction ratings (7 studies), confidence assessments (5 studies), and self-reports on knowledge, competency, or preparedness (also 5 studies). Reaction measures extended to perceived usefulness, usability, and relevance ratings. Multimedia Appendix 4 details the specific instruments mapped to each outcome level [4,25-36]. For level 2+ (Applied Learning), assessment methods included scoring triage accuracy and speed against reference standards [25,26,31], structured observation to evaluate team behaviors, task performance, decision quality during exercises [27-29,36], and after-action reports assessed across sequential scenarios [33].

Level 3 (Behavior) evidence includes documented use of exercise-based skills in real operational contexts. Two studies reported this level of evidence. Skryabina et al [35] observed that participants used exercise-based knowledge and decision-making during the Manchester Arena bombing response. Zimmerman et al [36] described postprogram role application, with participants taking on roles such as departmental preparedness coordinator and simulation instructor-candidate, suggesting early signs of transferring practice beyond the exercise environment.

Level 4 data pertain to organizational change. Cicero et al [34] developed hospital preparedness metrics based on a 2-year postexercise follow-up. Skryabina et al [35] observed improvements in casualty distribution across the system and enhanced operational efficiency during the actual MCI response. Zimmerman et al [36] noted early organizational impacts, such as establishing a structured simulation platform, conducting additional course iterations, holding refresher meetings, engaging in alumni follow-up activities, and continuously refining contingency plans. Most studies used pre- and postassessment timings, with some also including during-exercise measurements such as triage accuracy and incident command compliance. Additionally, 1 study incorporated a 1-week delayed posttest to assess knowledge retention [31].

Kirkpatrick-Tier Mapping

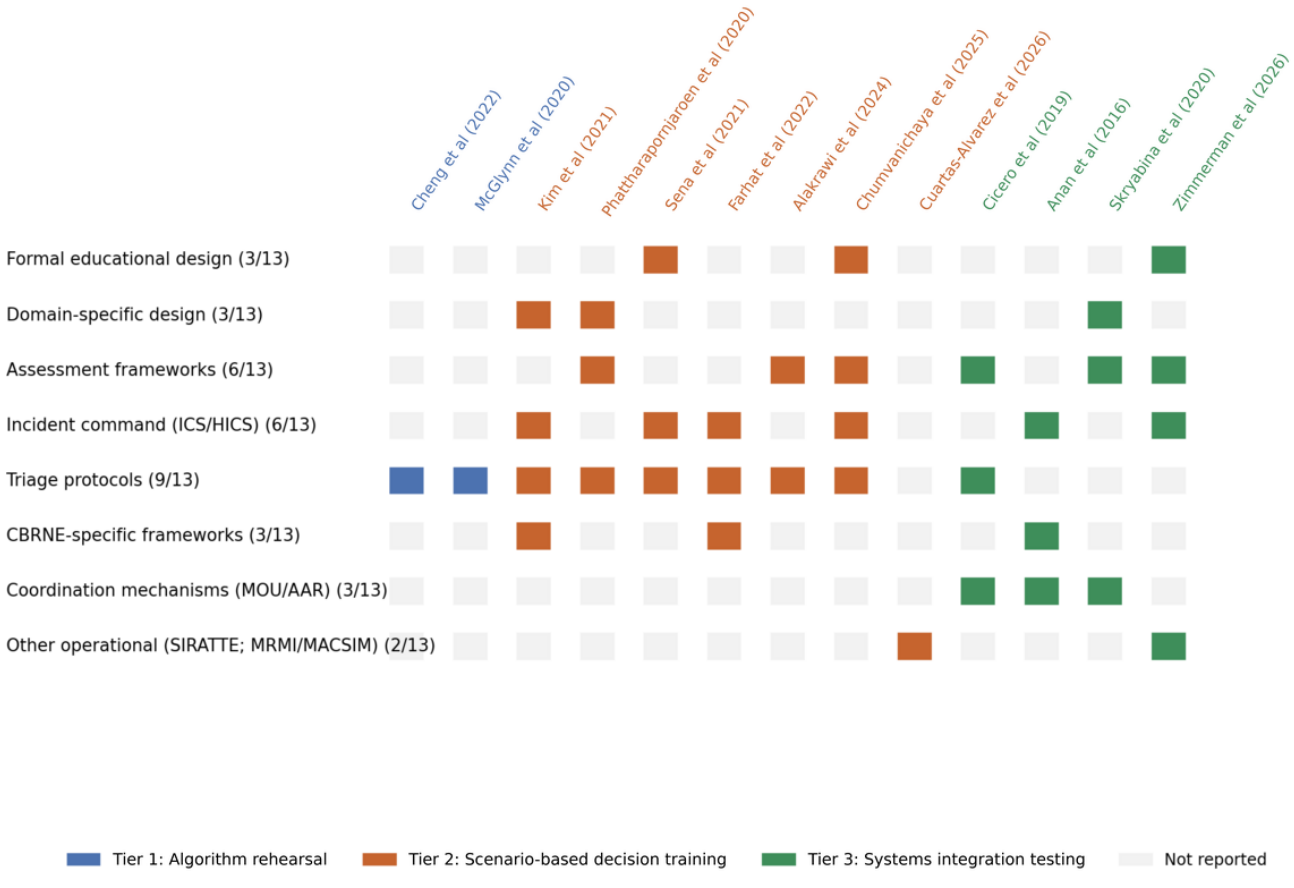
Across the 13 studies, the distribution of Kirkpatrick levels was as follows: level 1 (Reaction) n=10, level 2 (Learning) n=10, level 2+ (Applied Learning) n=8, level 3 (Behavior) n=2, and level 4 (Results) n=3. The level 2+ category indicates a measurement pattern that the standard 4-level model does not clearly depict. The study-level distribution of Kirkpatrick

XSL•FO
RenderX

outcome assessments across tiers is shown in Figure 3, with detailed outcome mapping by study available in Multimedia Appendix 4. Evaluation depth varied between tiers (Table 3). Outcomes for levels 3 and 4 were assessed solely in systems integration (tier 3) studies [34-36], aligning with this tier's emphasis on systems-level readiness and real-world validation opportunities.

Table . Kirkpatrick outcome assessment by Tabletop Exercise Design Spectrum tier (number of studies assessing each level).[a]

Tier	Studies	Level 1: Reaction	Level 2: Learning	Level 2+ (Applied Learning)	Level 3: Behavior	Level 4: Results
1: algorithm rehearsal	2	1	0	2	0	0
2: scenario-based decision training	7	6	7	4	0	0
3: systems integration testing	4	3	3	2	2	3
Total (N=13)	13	10	10	8	2	3



[a]Cell values represent the number of studies evaluating each level; a single study can contribute to multiple levels. Level 2+ (Applied Learning) indicates structured performance assessments conducted within the exercise environment (Multimedia Appendix 2).

Frameworks Guiding Exercise Design and Evaluation

Overview

Figure 5 provides a summary of how training design, assessment, and operational frameworks are reported across the 13 included studies. Operational frameworks were documented most consistently, while specific educational design and assessment frameworks appeared less frequently.

Figure 5. Framework reporting landscape across included studies (N=13). Matrix chart displaying framework reporting across studies, categorized into 8 groups: formal educational design, domain-specific design, assessment frameworks, and 5 operational areas: incident command (ICS/HICS), triage protocols, CBRNE-specific frameworks, coordination mechanisms (such as memoranda of understanding and after-action reports), and other operational frameworks (such as SIRATTE; MRMI/MACSIM). Columns represent individual studies, color-coded by TTX Design Spectrum tier; filled cells denote reported frameworks, while light gray cells show frameworks not reported [4,25-36]. AAR: after-action report; CBRNE: Chemical, Biological, Radiological, Nuclear, Explosive; HICS: Hospital Incident Command System; ICS: Incident Command System; MACSIM: Mass Casualty Simulation System; MOU: Memorandum of Understanding; MRMI: Medical Response to Major Incidents; SIRATTE: Security, Information, Roles, Areas, Triage, Treatment, and Evacuation.

XSL•FO
RenderX

Training Design Frameworks

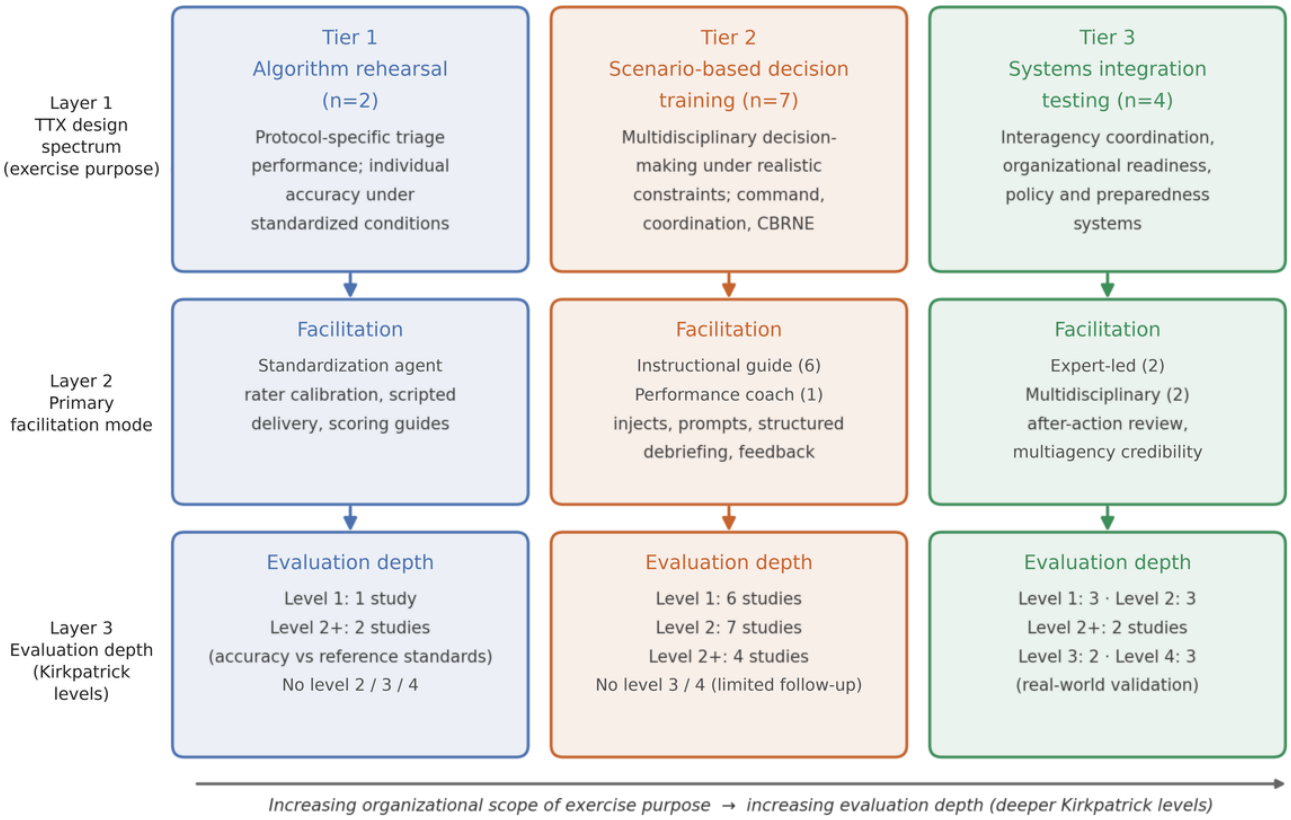
Out of 13 studies, only 3 explicitly described formal educational training frameworks. Chumvanichaya et al [31] used backward design, focusing the exercise on previously identified preparedness gaps. Sena et al [4] applied Kolb's [37] experiential learning model and adult learning principles to shape scenario development and debriefings. Zimmerman et al [36] integrated disaster medicine education and competency frameworks into postgraduate training. Seven studies did not specify any formal educational design framework [25,26,29,30,32-34]. Meanwhile, 3 studies used domain-specific frameworks instead of broad educational models: Kim et al [27] organized CBRNE response phases around the Chain of Chemical Survival, Phattharapornjaroen et al [28] applied the 3LC (3-Level Collaboration) framework with Major Incident Medical Management and Support or Medical Response to Major Incidents triage protocols, and Skryabina et al [35] based their approach on the Emergency Preparedness Cycle and Emergo Train System. Overall, most research relied more on disaster response or operational frameworks than on explicit educational design theories.

Assessment Frameworks

Assessment frameworks were described more clearly than training design frameworks. Phattharapornjaroen et al [28] used the CSCATTT (Command, Safety, Communication, Assessment, Triage, Treatment, Transportation) framework to organize and assess incident command performance. Cicero et al [34] used the Hospital Pediatric Disaster Preparedness Checklist and after-action reports to evaluate organizational readiness. Skryabina et al [35] integrated Kirkpatrick levels with the Promoting Action on Research Implementation in Health Services framework to analyze both training outcomes and implementation processes. Other studies used specific structured tools for assessments: Chumvanichaya et al [31] applied the Attention, Relevance, Confidence, Satisfaction Motivation Model to measure participant engagement, Alakrawi et al [30] adapted the Competency Level Use in Triage Scale to evaluate triage competency, and Zimmerman et al [36] used a 29-item questionnaire along with CSCATTT-anchored instructor scores to assess applied performance during simulations.

Operational Frameworks

Operational frameworks were reported more consistently than educational design frameworks. Six studies mentioned the Incident Command System or Hospital Incident Command System [4,27,29,31,33,36]. Triage protocols, such as Simple Triage and Rapid Treatment; Sort, Assess, Lifesaving Interventions, Treatment/Transport; Sieve (UK Major Incident Primary Triage); Secondary Triage (UK Major Incident); JumpSTART; CareFlight; Pediatric Triage Tape; and Sacco triage, were the most common operational frameworks used across different tiers [4,25-31,34]. Three studies used CBRNE-specific response frameworks: the Chain of Chemical Survival [27], CBRNE workshop competencies [29], and the MCLS-CBRNE course framework [33]. Tier 3 studies more frequently included coordination mechanisms such as memoranda of understanding, centralized dispatch protocols, interagency responsibilities, and after-action reports [33-35]. Cuartas-Alvarez et al [32] used SIRATTE, a prehospital MCI framework that covers Security, Information, Roles, Areas, Triage, Treatment, and Evacuation, in the MassCas tabletop game. Zimmerman et al [36] incorporated several operational and collaborative frameworks, such as Incident Command System, CSCATTT, 3LC, Medical Response to Major Incidents, and Mass Casualty Simulation System, into its postgraduate disaster medicine program.



Discussion

Principal Findings

The main conclusion of this scoping review is that TTXs in prehospital MCI preparedness should be viewed as a group of related exercise types, each serving different educational and operational goals, rather than a single, uniform intervention. These purposes are categorized into 3 tiers: algorithm rehearsal, scenario-based decision training, and systems integration testing. Outcomes are mapped using the Kirkpatrick framework, with level 2+ indicating structured performance during the exercise that lies conceptually between knowledge acquisition and real-world application. These tiers represent increasing levels of interaction: between individual responders and protocols, among interdisciplinary team members, and across organizations and agencies. Facilitation modes involve intentionally designed interactions between facilitators and participants. While diverse exercise designs are common and often suitable, the key message is that the purpose, facilitation, and evaluation of the exercise must be explicitly aligned. Without a shared typology of purpose, evidence from exercises with different goals cannot be meaningfully compared. As shown in Figure 6, the literature indicates a pattern where exercise purpose, facilitation mode, and evaluation depth progress together.

XSL•FO
RenderX

Figure 6. Integrated overview of TTX purpose, facilitation, and evaluation depth across included studies (N=13). The figure outlines the included studies across 3 interconnected layers: (1) the TTX Design Spectrum tier, (2) the main facilitation modes associated with each tier, and (3) the evaluation depth categorized by Kirkpatrick levels, including level 2+ (Applied Learning). CBRNE: Chemical, Biological, Radiological, Nuclear, Explosive; TTX: tabletop exercise.

The tier typology should be seen as an initial guideline rather than a confirmed classification. Nonetheless, it clarifies why studies labeled as TTXs often appeared quite different in practice: algorithm-rehearsal exercises focused on standardized practice of specific skills [25,26], scenario-based decision training involved integrated clinical and command decisions in discussion settings [4,27-32], and systems-integration exercises targeted organizational coordination and system readiness [33-36]. Exercises aimed at rehearsing an algorithm, enhancing team decision-making, or testing system coordination do not share the same facilitation approach or outcome metrics.

The Design Spectrum should be aligned with existing exercise doctrine. The HSEEP (Homeland Security Exercise and Evaluation Program) connects exercise goals to structured assessments using capability-based exercise evaluation guides and standardized after-action reports [38]. However, HSEEP treats TTXs as a single, uniform discussion-based type. The current typology offers a more detailed classification within that category, identifying different types of TTXs that require varied facilitation and evaluation approaches. This typology is designed to complement HSEEP objectives and not replace them.

This has a practical implication for anyone designing or assessing a TTX: the evaluation approach should be aligned with the exercise's goal, not judged by a universal standard of assessment thoroughness. A focused protocol rehearsal may rightly prioritize structured performance metrics such as decision accuracy and interrater reliability, without necessarily claiming to measure organizational impact [25,26]. Meanwhile, a decision-training exercise might aim to improve knowledge, confidence, communication, and role clarity but should ideally incorporate follow-up methods if it seeks to influence future practice [4,29,32]. A systems-centered exercise should analyze after-action processes, coordination structures, and readiness outputs, as these are its core focus [34-36]. The key point is not whether every TTX achieves the highest Kirkpatrick level but whether the chosen level is appropriate for the capability being tested.

Separating Applied Learning From Behavioral Transfer

The level 2+ subcategory is valuable because it differentiates between applied performance during the exercise and behavioral transfer outside of it. Multiple studies have assessed applied performance during the tabletop, providing evidence of learning in a simulated environment [25-29,31,33,36]. While this evidence is educationally significant, it does not necessarily reflect practice change in real settings. Making this distinction helps prevent overinterpreting simulation results as proof of real-world transfer. This differentiation is not new; models such as the revised Kirkpatrick framework, Miller's framework, and translational science models of simulation-based education outcomes all recognize it [22-24]. However, its systematic application to prehospital MCI tabletop evidence has not been reported before. Broader reviews have generally shown clustering at the Reaction and Learning levels without separating structured in-exercise performance from actual operational transfer [7,8].

XSL•FO
RenderX

This distinction also assists in understanding the limited occurrence of specific behaviors and outcome results. Their absence should not be automatically interpreted as failure. In prehospital disaster education, actual events are rare, unpredictable, and difficult to tie to a single training session [39], making it challenging to observe behavioral transfer even when learning has occurred. Additionally, follow-up methods in scenario-based decision-training studies were often limited [4,29,30,32], with only a single delayed posttest after 1 week [31], which hampers the ability to determine whether these exercises impacted later operational reasoning. This does not imply that such exercises are ineffective but rather that they lacked sufficient follow-up relative to their expected outcomes, highlighting a gap in evaluation data rather than a flaw in design.

Timing, Transfer, and Facilitation

The study by Skryabina et al [35] provides rare naturalistic evidence that exercise learning can be applied in real responses when training is close to deployment. It found that participants reported using knowledge from the TTX during the Manchester Arena incident, which occurred soon afterward. Although this single uncontrolled observation cannot establish causality, it aligns with the literature on distributed practice, which shows that the spacing and timing of learning opportunities influence retention and transfer [40], and with the advice by Cicero et al [34] to exercise every 6 months [34]. While single-exposure TTXs may support learning, lasting behavior change likely depends more on repetition and deliberate timing than on a one-time exposure. This remains an open question for future research rather than a definitive conclusion of this review.

Facilitation findings consistently indicate that it is a strategic design choice rather than a neutral delivery method, and that it varies with the exercise's purpose (Figure 4). More directive, standardized facilitation is better suited for narrowly focused rehearsal activities, while expert-led, coaching, or multidisciplinary facilitation is typically used in broader scenario-based and system-level exercises [4,27,34,36]. There is no single facilitation style that is universally superior; instead, the facilitator's role should be aligned with the exercise's goals, whether to standardize performance, encourage collaborative reasoning, identify coordination gaps, or foster organizational reflection.

Frameworks and Implementation

Operational frameworks were described more consistently than educational or assessment frameworks (Figure 5). Only a few studies explicitly detailed formal educational frameworks such as experiential learning, backward design, or competency-based disaster medicine education [4,31,36]. While the field is grounded in operational principles, its pedagogical aspects are less well articulated. Operational doctrine can effectively shape scenarios, but inconsistent reporting of educational and assessment approaches hampers reproducibility and obscures which design choices actually enhance learning or transfer. Notably, the combination of the Kirkpatrick model with the Promoting Action on Research Implementation in Health Services implementation framework by Skryabina et al [35] stands out, as it connects training outcomes with implementation processes rather than viewing evaluation as an isolated end point [35,41,42]. This approach demonstrates how exercise evaluation can more systematically contribute to system-level preparedness improvements.

These findings generally align with earlier review literature but offer a more specific interpretive perspective. Frégeau et al [7] observed outcomes primarily at lower Kirkpatrick levels in medical emergency contexts, while Emaliyawati et al [8] noted that tabletop disaster exercises enhance knowledge, confidence, preparedness, and performance. This review differs by focusing on the prehospital MCI interface, introducing the level 2+ category, and suggesting that the main challenge is purpose-aligned evaluation rather than measurement deficiencies. This distinction is practically valuable, helping educators and planners determine the kind of evidence they can reasonably expect from various exercises.

The clearest takeaway from practice is that TTXs should be designed starting from the desired capability. If the aim is to rehearse algorithms, then structured in-exercise performance measures might suffice as end points. For scenario-based decision training, evaluation should go beyond participant satisfaction and include follow-up methods such as delayed case-based testing, repeated scenarios, structured interviews, or local practice audits. If the focus is on systems integration, exercises should connect to after-action reviews, policy updates, coordination metrics, or preparedness planning [34-36]. This review advocates for a proportional evaluation approach: not every exercise needs maximum evaluation depth, but each should have an evaluation strategy aligned with its purpose. Multimedia Appendix 5 summarizes these pairings, listing typical objectives, facilitation modes, evaluation targets, example instruments from the studies, and suggested data to record [25-28,31,33-36].

Future Research

Future research should focus on refining this purpose alignment approach instead of merely questioning whether TTXs "work" in general. One key area is to develop practical methods for measuring transfer following scenario-based decision-training exercises without relying on the occurrence of a real MCI: options include repeating scenarios, using follow-up decision vignettes, conducting interval audits of triage or command processes, and linking short-format exercises as possible next steps. Another important area is to investigate whether repeated or ongoing exposure to related TTXs enhances retention and transfer more than isolated sessions. This is especially relevant since the current review does not establish a dose-response relationship; however, the training-transfer literature suggests that this is plausible because transfer relies on reinforcement, opportunities for application, and workplace conditions [43,44].

A third priority involves stakeholder-based implementation research, engaging EMS leaders, emergency preparedness officers, public health partners, hospital interface stakeholders, and simulation faculty in designing exercise objectives and follow-up plans. This ensures that evaluations align with real operational needs. It should also include a more structured, comparable collection of evaluation data, such as observation ratings, accuracy scores, and after-action findings, using existing templates such as HSEEP's Exercise Evaluation Guides and

XSL•FO
RenderX

standardized reporting [38]. A fourth priority is expanding scenarios beyond specific, bounded incidents. Predictable hazards such as storms, wildfires, floods, or hurricanes could be especially valuable, as threat windows can sometimes be forecasted. Advances in satellite hazard assessments, artificial intelligence–enabled risk estimation, and forecasting may help identify these periods and enable more realistic timing of training relative to operational demand [39,45]. These designs could also examine whether training closer to deployment improves transfer.

Limitations

Several limitations should inform how these findings are interpreted. First, the evidence base was limited in size and diverse in nature, so the proposed tiers and alignment patterns should be viewed as preliminary, hypothesis-generating concepts rather than confirmed frameworks. Specifically, since the tier definitions partly depended on participant composition and outcome scope, the link between tier and evaluation depth is partly inherent and should not be seen as an independent empirical correlation. Second, this was a scoping review without formal critical appraisal; thus, the findings depict the state of the literature rather than comparing the effectiveness of different TTX designs. Most studies included used pre-post, quasi-experimental, descriptive, or mixed methods approaches, which restrict causal conclusions.

Third, the study reporting was inconsistent. The definitions of outcomes, facilitation descriptions, and framework reporting varied, leading to interpretive uncertainty when aligning studies across tiers and Kirkpatrick levels. The level 2+ subcategory enhances conceptual clarity, but its assignment still relied on reviewer judgment. Fourth, the literature was mainly from high-income or upper-middle-income settings and focused on human-caused or bounded hazard scenarios, restricting its applicability to resource-limited environments and prolonged natural disasters (Figure 2). Additionally, limiting the review to English-language sources might have excluded important evidence.

Two of the review's more speculative points rely on limited evidence. The idea that temporal proximity between training and real events might facilitate transfer primarily derives from a single naturalistic case [35]. While interesting, it remains unconfirmed. Similarly, the notion that short, time-limited tabletop formats may lack the functional fidelity, according to the definition by Hamstra et al [46], to simulate long-term, evolving disasters that disrupt infrastructure is speculative. The existing literature primarily involves bounded incidents and does not directly test this idea. Both points are presented as suggestions for future research rather than confirmed explanations.

Conclusions

TTXs for prehospital MCI preparedness should not be seen as a single, uniform approach. Their success mainly depends on how clearly the designers define the expected level of interaction. Whether it is an individual following protocols, a multidisciplinary team working together, or organizations coordinating efforts, facilitation and evaluation should be tailored accordingly. By concentrating on the prehospital MCI literature and differentiating between applied learning during exercises (level 2+) and actual behavioral transfer, while considering variations through the lens of design–evaluation alignment, this review offers a targeted synthesis of the prehospital MCI interface that complements earlier, broader tabletop reviews [7,8]. When used carefully, TTXs can remain a scalable and strategic component of prehospital disaster preparedness, with further research needed to determine when and how they promote lasting practice change and system readiness.

Acknowledgments

The authors express gratitude to Dr Sarah Kazim, chair of emergency medicine at Dubai Health, for her support and for creating a departmental environment conducive to this work. They also appreciate Mohammed Bin Rashid University of Medicine and Health Sciences for its support and collaboration, Graduate Medical Education for assisting the residents, Shakeel Tegginmani of the Al Maktoum Medical Library for helping with the literature search, and the Institute of Learning for providing research support. Generative AI tools, such as ChatGPT and Perplexity, were used solely for editorial tasks, such as enhancing language clarity, readability, grammar, and organization, as well as brainstorming visual presentation ideas for data already extracted and analyzed by the authors. AI was not used for data generation, literature searches, study screening, data extraction, outcome classification, analysis, interpretation, or forming scientific conclusions. All AI-suggested edits were carefully reviewed, revised, and approved by the authors. The authors assume full responsibility for the accuracy, integrity, and final content of the manuscript.

Funding

This research was supported by the Mohammed Bin Rashid University of Medicine and Health Sciences via the Dubai Health Collaborative Stimulus Research Grant for the MCIPHER project. The funding body had no role in the study design, data analysis, or manuscript writing.

Abstract

Background: Sepsis causes deaths worldwide each day, with hemodynamic resuscitation being central to management. Guidelines recommend a 65-mm Hg mean arterial pressure (MAP) target, yet the evidence for elevated targets remains fragmented across mortality, renal, and splanchnic outcomes.

Objective: This review aims to comprehensively appraise the impact of elevated MAP targets on splanchnic ischemia, mortality, and organ-specific outcomes in septic resuscitation.

Methods: Following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines, we systematically searched PubMed, the Cochrane Library, and Google Scholar for studies comparing MAP targets in septic shock. Risk of bias was assessed using the Cochrane Risk of Bias 2 (RoB 2; randomized controlled trials [RCTs]) and the Newcastle-Ottawa Scale (nonrandomized studies). The findings were synthesized narratively according to the Synthesis Without Meta-Analysis guidelines, with random-effects meta-analysis for mortality outcomes. Evidence certainty was graded using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) framework.

Results: From 3254 records, 11 studies (2895 patients; 4 RCTs, 7 nonrandomized) met the inclusion criteria. Pooled 90-day mortality across 3 trials showed a nonsignificant trend toward higher mortality with elevated MAP targets (320/720, 44.4% vs 280/722, 38.8%; OR 1.31, 95% CI 0.97 - 1.77). Pooled 28- or 30-day mortality showed a similar nonsignificant trend (OR 1.25, 95% CI 0.98 - 1.61), which was robust to sensitivity analysis. Narratively, mortality findings across nonpooled observational studies were inconsistent; some linked low MAP to higher death risk, and others found no significant association. Renal outcomes were inconsistent, with some studies showing reduced renal replacement therapy or improved acute kidney injury recovery at higher targets, particularly in hypertensive or cirrhotic subgroups. Elevated MAP targets consistently increased vasopressor exposure and were associated with more arrhythmias and fewer organ support–free days. No study reported splanchnic ischemia as a discrete outcome; mesenteric ischemia rates were low and similar between arms. Overall certainty of evidence was very low.

Conclusions: Higher MAP targets show no clear mortality or splanchnic perfusion benefit and may increase overall harm, though select subgroups, chronic hypertension, and cirrhosis, may benefit, supporting individualized, risk-stratified MAP targeting over uniformly elevated-target strategies.

Introduction

Sepsis affected an estimated 48.9 million people and caused 11 million deaths worldwide in 2017 (nearly 1 in 5 deaths globally), equating to more than 30,000 deaths per day [1]. Globally, sepsis incidence rose by 230% among individuals aged 15 years and older between 1990 and 2021, with a further 30% surge during 2020 - 2021 alone amid the COVID-19 pandemic, underscoring an urgent, sustained need for advances in sepsis therapy [2]. Due to socioeconomic difficulties and a lack of thorough epidemiological surveys, sepsis mortality continues to exist in low-income countries [3].

Maintaining a mean arterial pressure (MAP) of 65 mm Hg is advised by current sepsis management recommendations, which state, as a strong recommendation based on moderate-quality evidence, that there is no appreciable additional benefit to targeting a higher MAP in patients with septic shock [4]. An MAP of more than 70 mm Hg has been shown in several trials to improve microcirculation during septic shock and to avoid acute renal damage [5,6]. In patients with sepsis, hemodynamic control is an essential part of the overall therapeutic strategy [7], as it plays a critical role in early vital sign stabilization, anticipating disease progression, and avoiding further tissue and organ failure [8]. However, maintaining a high MAP may need higher doses of vasoactive medications, which might result in further issues and bodily harm [9].

Despite guideline endorsement of a 65-mm Hg MAP target in septic shock, the evidence base for elevated MAP targets remains fragmented and outdated. Leone et al [8] synthesized only studies through 2014, predating 3 pivotal trials, with the latter halted early for harm, leaving current practice uninformed by the most recent and arguably most consequential data. Dari et al [10], while more recent, pooled only 4 randomized controlled trials (RCTs) and excluded observational and cohort evidence entirely, yielding a narrower and potentially incomplete effect estimate. A study by Kattan et al [11] offered valuable mechanistic and monitoring insight but remained a narrative review, lacking quantitative synthesis or a dedicated, pooled assessment of splanchnic and mesenteric outcomes. Critically, no prior review has directly synthesized splanchnic or mesenteric ischemia as a discrete, cross-study outcome nor systematically reconciled short- and long-term mortality signals alongside renal, hemodynamic, and organ-support end points across both randomized and observational designs. Our review addresses these gaps by incorporating the most contemporary RCTs and observational cohorts, applying sensitivity analyses to resolve heterogeneity, and explicitly evaluating splanchnic perfusion alongside mortality. The aim of this review is to comprehensively and quantitatively appraise the impact of elevated MAP targets on splanchnic ischemia, mortality, and organ-specific outcomes in septic resuscitation.

Methods

Study Design

This systematic review was conducted and reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines and checklist (Checklist 1) [12]. The review protocol was developed a priori, with the research question, eligibility criteria, search strategy, and outcome hierarchy defined before data extraction commenced. The review was not registered prospectively on PROSPERO, which is acknowledged as a limitation.

Eligibility Criteria

Inclusion Criteria

The inclusion criteria were as follows:

- Adult patients (≥18 y) diagnosed with sepsis, severe sepsis, or septic shock according to Sepsis-2 or Sepsis-3 consensus definitions.
- Patients admitted to the intensive care unit (ICU) requiring vasopressor-supported hemodynamic resuscitation.
- Studies involving septic shock in patients with underlying comorbidities (eg, cirrhosis, chronic kidney disease, or chronic hypertension) were eligible provided that MAP-related clinical outcomes were reported separately.
- RCTs, quasi-randomized trials, prospective interventional studies, post hoc analyses of clinical trials, and prospective or retrospective observational cohort studies.
- Studies evaluating different MAP targets or achieved MAP levels during septic shock resuscitation, including higher MAP targets (generally ≥75 - 85 mm Hg), standard MAP targets (generally 60 - 70 mm Hg), or analyses of MAP as a continuous or categorical exposure variable.
- Studies reporting at least one of the following outcomes:
  - Primary outcomes: all-cause mortality or splanchnic perfusion- or ischemia-related outcomes.
  - Secondary outcomes: acute kidney injury (AKI), renal replacement therapy (RRT), organ dysfunction (eg, Sequential Organ Failure Assessment [SOFA] score), lactate, hemodynamic parameters, vasopressor requirements, mechanical ventilation, ICU or hospital length of stay, or adverse events.

Exclusion Criteria

The exclusion criteria were as follows:

- Studies involving nonseptic populations, or mixed populations in which data for patients with septic shock could not be extracted separately.
- Pediatric populations (<18 y).
- Studies evaluating vasoactive therapy without reporting MAP targets or achieved MAP levels.
- Case reports, case series with fewer than 10 patients, editorials, letters, narrative reviews, conference abstracts without full text, protocols, animal studies, and in vitro studies.
- Studies not reporting any predefined primary or secondary clinical outcome relevant to this review.
- Duplicate publications or secondary analyses of the same dataset, unless they reported additional relevant outcomes not available in the primary publication.

Information Sources and Search Strategy

A comprehensive systematic literature search was conducted across 3 electronic bibliographic databases: MEDLINE (via

XSL•FO
RenderX

PubMed), Google Scholar, and the Cochrane Library. No restrictions were placed on publication date or language during the initial search. However, due to resource limitations, only studies with full-text articles available in English were included in the final review, which may have introduced language bias.

The search strategy was developed using a combination of MeSH and free-text keywords based on the Population, Intervention, Comparator, and Outcome (PICO) framework. For PubMed, the following search strategy was applied: ("Sepsis"[Mesh] OR "Shock, Septic"[Mesh] OR sepsis OR "septic shock" OR "severe sepsis") AND ("Blood Pressure"[Mesh] OR "Mean Arterial Pressure" OR MAP OR "mean arterial pressure" OR "blood pressure target" OR "higher MAP" OR "high MAP" OR "elevated blood pressure" OR "hemodynamic resuscitation" *OR vasopressor* OR norepinephrine OR vasopressin) AND ("Splanchnic Circulation"[Mesh] OR "Mesenteric Ischemia"[Mesh] OR splanchnic OR "splanchnic perfusion" OR "splanchnic ischemia" OR mesenteric OR gut OR intestinal OR gastrointestinal OR gastric OR hepatic OR liver OR renal) AND ("Mortality"[Mesh] OR mortality OR death OR survival OR "Organ Dysfunction Scores"[Mesh] OR "organ dysfunction" OR "multiple organ failure" OR "acute kidney injury" OR AKI OR lactate).

For the Cochrane Central Register of Controlled Trials (CENTRAL), an adapted search strategy using free-text terms was applied: (sepsis OR "septic shock" OR "severe sepsis") AND ("mean arterial pressure" OR MAP OR "blood pressure target" OR "higher MAP" OR "high MAP" OR "elevated blood pressure" OR "hemodynamic resuscitation" OR vasopressor OR norepinephrine OR vasopressin) AND (splanchnic OR "splanchnic perfusion" OR "splanchnic ischemia" OR mesenteric OR intestinal OR gastrointestinal OR gastric OR hepatic OR liver OR renal) AND (mortality OR death OR survival OR "organ dysfunction" OR "multiple organ failure" OR "acute kidney injury" OR AKI OR lactate).

Database-specific syntax and Boolean operators were adapted as appropriate for each platform. For Google Scholar, a simplified combination of key search terms based on the PICO framework was used, and the first 400 results, sorted by relevance, were screened because of the platform's limitation in exporting large numbers of citations. In addition, the reference lists of all included studies and relevant review articles were manually searched to identify any additional eligible studies that were not retrieved through the electronic database searches.

Study Selection

Overview

Search results from all databases were collated and deduplicated using reference management software. Two independent reviewers screened titles and abstracts against the prespecified eligibility criteria. Studies judged potentially eligible at the abstract screening stage were retrieved as full-text articles and subjected to detailed eligibility assessment. Disagreements between reviewers at any stage of screening were resolved through discussion and, where necessary, by referral to a third reviewer. The reasons for exclusion at the full-text stage were documented and are summarized in the PRISMA flow diagram. Pettilä [13] et al (TARTARE-2S, 2026) was excluded as it randomized a composite tissue-perfusion-guided protocol (capillary refill, skin mottling, temperature, lactate) rather than a fixed or isolated MAP target, with MAP serving only as a subordinate safety limit.

Data Extraction

Data were extracted independently by 2 reviewers using a standardized, prepiloted extraction form, with disagreements resolved through discussion and, when necessary, consultation with a third reviewer. Extracted variables included study characteristics (design, setting, and sample size), participant demographics and baseline clinical characteristics, relevant comorbidities (eg, chronic hypertension, chronic kidney disease, and cirrhosis), MAP intervention targets or observational exposure measures, vasopressor type and dose, and reported outcomes. Primary outcomes comprised all-cause mortality at the reported follow-up time points and splanchnic perfusion parameters. Secondary outcomes included AKI, RRT, serum creatinine, urine output, hemodynamic variables, vasopressor requirements, organ support–free days, SOFA scores, length of stay, and adverse events. Where applicable, subgroup analyses reported within individual studies were also extracted. Data presented only in graphical format were estimated from figures, and unpublished data were not requested from study investigators.

Risk of Bias Assessment

Methodological quality was assessed independently by 2 reviewers using validated tools according to study design, with disagreements resolved by consensus. RCTs were evaluated using the Cochrane Risk of Bias 2 (RoB 2) tool, which assesses bias arising from the randomization process, deviations from intended interventions, missing outcome data, outcome measurement, and selection of the reported results [14]. Nonrandomized studies were assessed using the Newcastle-Ottawa Scale (NOS), which evaluates study quality across the domains of selection, comparability, and outcome assessment, with a maximum score of 9 points. Overall study quality was categorized according to the respective assessment tools [15].

The remaining nonrandomized study involving 2 actively assigned MAP-targeted groups was assessed using the Risk of Bias in Non-randomized Studies of Interventions (ROBINS-I) tool, evaluating bias due to confounding, selection of participants, classification of interventions, deviations from intended interventions, missing data, outcome measurement, and selection of the reported result [16]. The single-arm, within-subject titration study lacking a comparator group was assessed using the Joanna Briggs Institute (JBI) Critical Appraisal Checklist for Quasi-Experimental Studies, a 9-item tool suited to pre-post designs without a control arm [17]. Overall quality was categorized per the respective tool applied, and studies were synthesized with attention to how these quality differences might affect confidence in the findings.

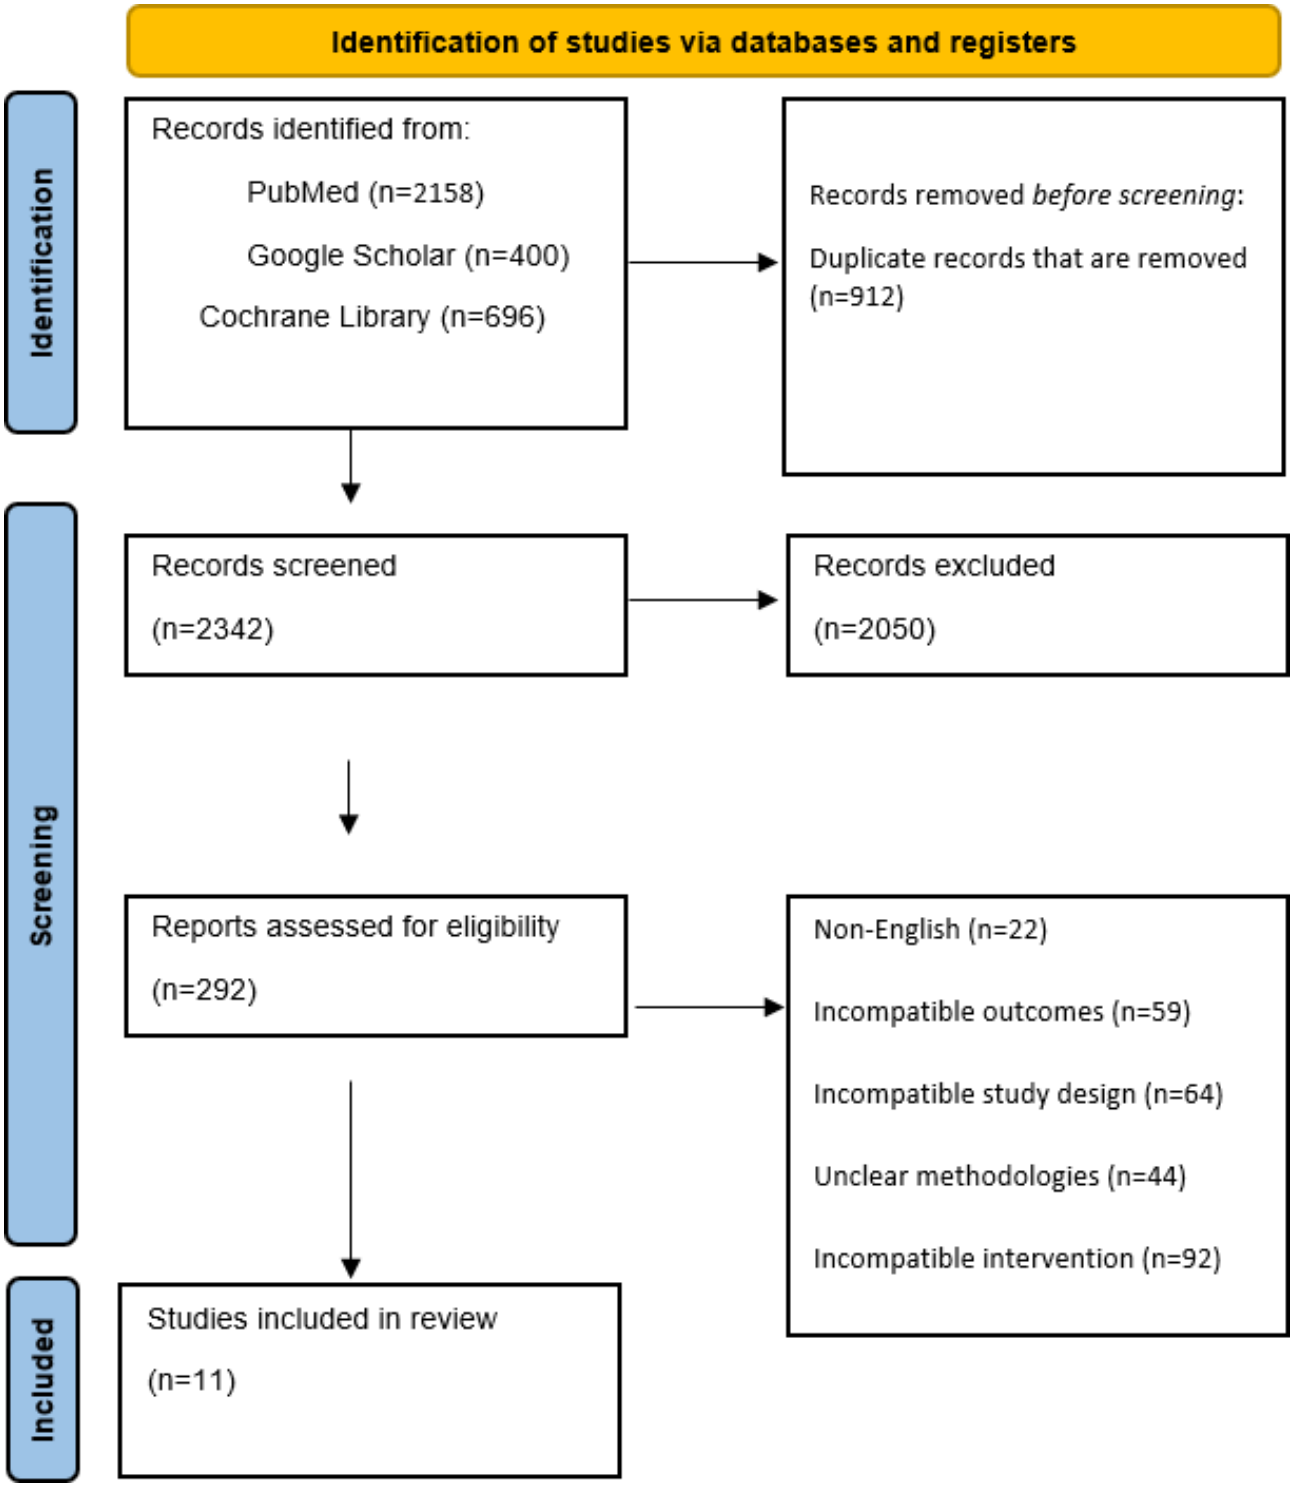
XSL•FO
RenderX

Data Synthesis

Given the substantial clinical and methodological heterogeneity among the included studies, the findings were synthesized narratively in accordance with the Synthesis Without Meta-Analysis reporting guideline [18]. Studies were grouped according to study design and outcome domains, with evidence from RCTs presented before nonrandomized studies. Quantitative meta-analysis was performed only for all-cause mortality because sufficient comparable interventional data were available. Separate random-effects meta-analyses were conducted for 90-day mortality and 28-day mortality, with an additional sensitivity analysis incorporating studies reporting analogous 30-day mortality. Pooled effect estimates were expressed as odds ratios (ORs) with 95% CIs, and statistical heterogeneity was assessed using Cochran *Q* test and the I^2 statistic. Meta-analysis was not undertaken for renal, hemodynamic, organ-support, or adverse event outcomes because of a lack of reported statistics, differences in study populations, MAP targets, intervention protocols, follow-up durations, and outcome definitions. Subgroup findings reported within individual studies were synthesized narratively but were not quantitatively pooled because they were primarily exploratory or post hoc analyses.

Certainty of Evidence

The overall certainty of the evidence for the primary outcomes was assessed using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) framework [19]. Evidence from RCTs was initially considered of high certainty and downgraded, where appropriate, for risk of bias, inconsistency, indirectness, imprecision, and publication bias. Evidence from nonrandomized studies was initially considered of low certainty and was upgraded only when justified by large effect estimates, evidence of a dose-response relationship, or when residual confounding was unlikely to explain the observed findings. Publication bias was assessed qualitatively given the small number of studies (n=3 - 4) available for each pooled outcome, which precluded the reliable use of funnel plot asymmetry testing or Egger regression; this qualitative assessment considered the comprehensiveness of the search strategy, inclusion of published literature identified through multiple databases and manual reference screening, and comparison of effect directions and magnitudes across studies of differing design and setting, with no evidence suggestive of publication bias (eg, selective reporting or a disproportionate predominance of positive findings) identified. The overall certainty of evidence for each primary outcome was classified as high, moderate, low, or very low and is reported alongside the corresponding results.



Results

Study Selection

A systematic search was conducted across PubMed or MEDLINE, the Cochrane Library, and Google Scholar from inception through April 2026, using predefined search terms related to MAP targets, septic shock, splanchnic ischemia, and resuscitation outcomes. A total of 3254 records were identified through database searching and manual reference screening, of which 912 duplicates were removed. Following title and abstract screening, 292 full-text articles were assessed for eligibility against the prespecified inclusion criteria. Studies were excluded due to nonseptic populations, absence of a discrete MAP target comparison, insufficient outcome reporting, or nonhuman design. Ultimately, 11 studies met all inclusion criteria and were incorporated into the qualitative synthesis. The full selection process is summarized in the PRISMA flow diagram (Figure 1).

XSL•FO

Study Characteristics

Overview

Eleven studies (2895 patients) examined MAP targets in septic shock, including 4 RCTs and 7 nonrandomized studies (including prospective and retrospective observational cohorts, a post hoc analysis, and a physiological crossover study), with sample sizes ranging from 10 to 776. Populations were generally older adults with high illness severity (Acute Physiology and Chronic Health Evaluation II [APACHE II] 15 - 29, Simplified Acute Physiology Score II [SAPS II] 38 - 58, SOFA 7 - 12.5), although age ranged from younger patients with cirrhosis (~45 y; Maiwall et al [20]) to an older adults-only cohort (≥65 y). Four studies compared fixed high- versus low-MAP targets (typically 80 - 85 mm Hg vs 65 - 70 mm Hg, except TARGET-C, which compared 80 - 85 mm Hg vs 60 - 65 mm Hg), whereas the remaining studies evaluated MAP as a continuous exposure or through individualized targets rather than fixed intervention arms. Comorbidities varied across cohorts, with chronic hypertension reported in 9% to 53% of patients, alongside chronic kidney disease, diabetes, coronary artery disease, and, in 1 RCT, cirrhosis with AKI (Table 1).

Quality Assessment

Among the 4 RCTs, 2 studies were judged to have a low overall risk of bias [24,25], whereas Bourgoin et al [21] and Maiwall et al [20] were rated as having some concerns. The main limitations were related to deviations from intended interventions, missing outcome data, and outcome measurement in the open-label trials (Figure 2).

The methodological quality of the 7 nonrandomized studies ranged from very low to good. NOS scores varied between 2 and 8, with Poukkanen et al [23] demonstrating the highest quality (8/9). Badin et al [22], Varpula et al [29], Dünser et al [27], and Dünser et al [30] achieved moderate-to-good quality (7/9; Table 2).

Of the 9 JBI items, 7 were satisfied. The 2 unmet criteria, absence of a control group (item 4) and lack of similar cotreatment across comparisons (item 3, driven by unadjusted concurrent dopamine or dobutamine use in over half the cohort), represent the principal sources of bias in this study and preclude a “low risk of bias” classification despite its otherwise rigorous, objectively measured, complete-follow-up design. The study is therefore judged to carry a moderate-to-high risk of bias, consistent with its role in this review as hypothesis-generating, physiological or mechanistic evidence rather than a source of causal effect estimates [26] (Table 3).

Kuragayala et al [28] scored 5 “Serious,” 1 “Moderate,” and 1 “Critical” domain on ROBINS-I, yielding an overall critical risk of bias due to the absence of any reported effect estimates, so the study is retained for descriptive purposes only (Figure 3).

Table . Joanna Briggs Institute (JBI) Critical Appraisal Checklist for Quasi-Experimental Studies.

Item	Judgment
1. Is it clear in the study what is the "cause" (MAP[a] titration) and what is the "effect" (perfusion or hemodynamic response)?	Yes
2. Were the participants included in any comparisons similar?	Yes
3. Were the participants included in any comparisons receiving similar treatment or care, other than the exposure or intervention of interest?	No
4. Was there a control group?	No
5. Were there multiple measurements of the outcome, both before and after the intervention or exposure?	Yes
6. Was follow-up complete, and if not, were differences between groups in terms of their follow-up adequately described and analyzed?	Yes
7. Were the outcomes of participants included in any comparisons measured in the same way?	Yes
8. Were outcomes measured in a reliable way?	Yes
9. Was appropriate statistical analysis used?	Yes
Overall appraisal	7/9 "Yes"

[a]MAP: mean arterial pressure.

Figure 3. Quality assessment of nonrandomized study by Risk of Bias in Non-randomized Studies of Interventions (ROBINS I) [28].

GRADE

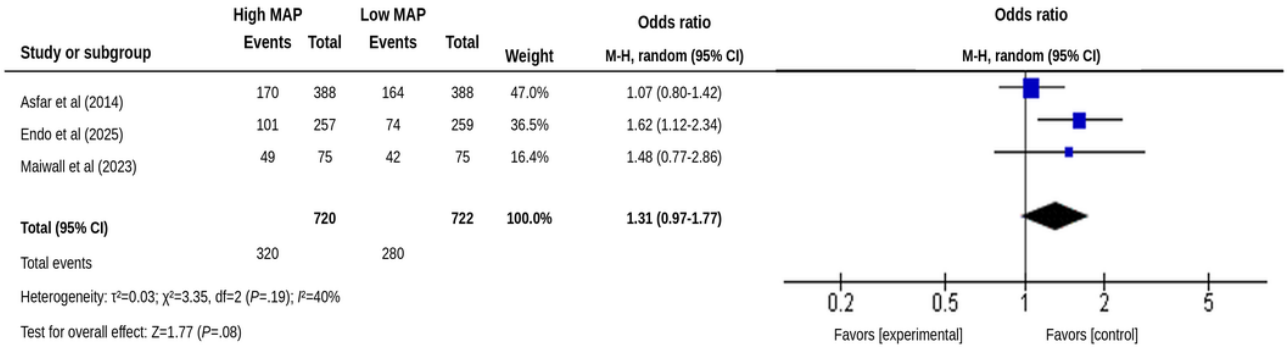
The certainty of evidence for both mortality and renal outcomes was rated as very low (Table 4). Evidence was downgraded because of methodological limitations, substantial inconsistency in the direction of treatment effects across studies, indirectness related to heterogeneous populations and MAP targets, and imprecision arising from several small studies. Consequently, the overall confidence in the effect estimates remains limited.

Table . Grading of Recommendations Assessment, Development, and Evaluation (GRADE) assessment.

Outcome	Risk of bias	Inconsistency	Indirectness	Imprecision	Publication bias	Certainty
Mortality	Serious	Very serious	Serious	Serious	Not detected	⊕ very low
AKI[a] or renal outcomes	Serious	Very serious	Serious	Serious	Not detected	⊕ very low

[a]AKI: acute kidney injury.

Primary Outcome: All-Cause Mortality



90-Day Mortality

Three trials reported 90-day all-cause mortality comparing a higher versus a lower or standard MAP target and were pooled using a random-effects (Mantel-Haenszel) model [20,24,25] (Figure 4). Across 1442 patients, mortality occurred in 320 of 720 (44.4%) patients in the high-MAP arm versus 280 of 722 (38.8%) in the low-MAP arm, yielding a pooled OR of 1.31 (95% CI 0.97-1.77; z score=1.77; P=.08), a nonsignificant trend toward higher mortality with higher MAP targets. Moderate heterogeneity was present (τ^2=0.03; χ^2_2=3.35, I^2=40%; P=.19). The effect was driven mainly by Endo et al [24], whose Optimal Blood Pressure in Septic Shock (OPTPRESS) trial was stopped

early for harm (OR 1.62, 95% CI 1.12-2.34) and, to a lesser extent, by Maiwall et al [20] (OR 1.48, 95% CI 0.77-2.86), while Asfar et al [25] showed an effect close to unity (OR 1.07, 95% CI 0.80-1.42; Figure 4).

Figure 4. Forest plot of 90-day all-cause mortality and high- versus low-mean arterial pressure (MAP) target [20,24,25].

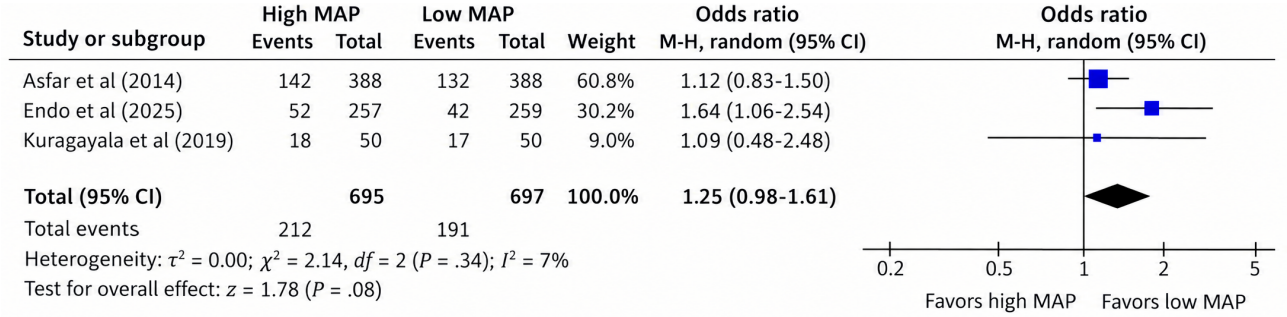
28-Day Mortality and Sensitivity Analysis

Two trials directly reported 28-day all-cause mortality by MAP-target arm [24,25]. Because Kuragayala et al [28] reported an analogous 30-day mortality comparison, a sensitivity analysis was performed with this study both added to and removed from the pooled estimate.

With Kuragayala et al [28] included (Figure 2), pooled 28- or 30-day mortality across 3 studies (695 high-MAP, 697 low-MAP patients) was 222 of 695 (32.0%) versus 191 of 697 (27.4%), giving a pooled OR of 1.25 (95% CI 0.98-1.61; z score=1.78 P=.08), with low heterogeneity (χ^2_2=2.14, I^2=7%; P=.34; Figure 5).

With Kuragayala et al [28] excluded (Figure 3), the pooled estimate from Asfar et al [25] and Endo et al [24] alone (645 patients with high-MAP, 647 patients with low-MAP) was OR of 1.31 (95% CI 0.90-1.89; z score=1.43; P=.15), with heterogeneity rising to I^2 of 51% (χ^2_1=2.04; P=.15; Figure 6).

Figure 5. Forest plot of 28- or 30-day mortality including Kuragayala et al [28] in the sensitivity analysis. MAP: mean arterial pressure [24,25,28].



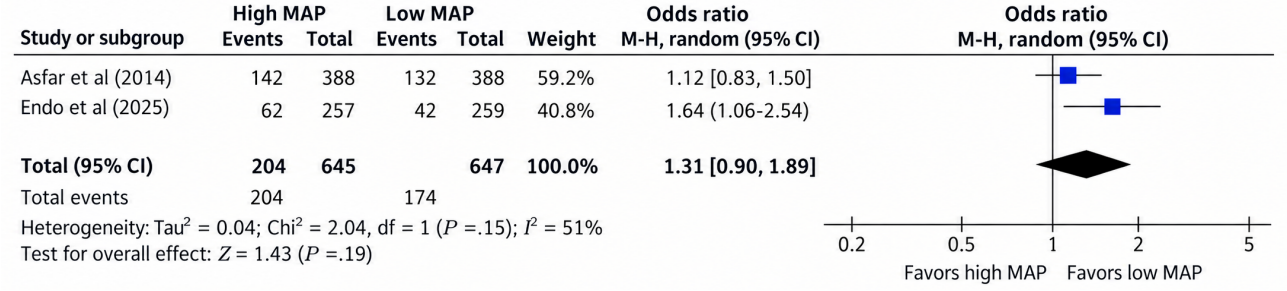


Figure 6. Forest plot of 28-day mortality with Kuragayala et al [28] removed in the sensitivity analysis. MAP: mean arterial pressure [24,25].

Adding Kuragayala et al [28] reduced between-study heterogeneity substantially (I^2 from 51% to 7%) without materially changing the point estimate or altering statistical significance, indicating the short-term mortality result was robust to this study's inclusion. Neither the 28- or 30-day nor the 90-day pooled estimate reached statistical significance, though both trended toward higher mortality with higher MAP targets.

Mortality Data Not Amenable to Pooling

Several included studies reported mortality descriptively or as a regression outcome rather than as a direct between-arm comparison and could not be pooled. Bourgoin et al [21] did not assess mortality, as the trial's 8-hour observation window was designed only for physiologic and renal endpoints. Badin et al [22] reported ICU mortality of 35% and hospital mortality of 39% across the whole cohort without a formal statistical comparison by MAP exposure. In the Finnish Acute Kidney Injury Study (FINNAKI) substudy, Poukkanen et al [23] found

XSL•FO
RenderX

that 90-day mortality was significantly higher in patients whose AKI progressed (32.7% vs 18.9%; *P*=.001), though this reflected an AKI-progression subgroup rather than a randomized MAP-target comparison. In the post hoc 546C88 cohort, Dünser et al found no significant association between MAP quartile and 28-day mortality after adjustment (risk ratio [RR] 0.99, 95% CI 0.95-1.04, *P*=.82), although patients excluded for failing to sustain MAP ≥70 mm Hg had markedly higher 28-day mortality (76.5%) than the included cohort (42.1%). Conversely, Dünser et al [27] found that MAP was among the strongest independent predictors of 28-day mortality in both 6-hour (*P*=.001) and 48-hour (*P*=.01) logistic regression models, with the largest area under the receiver operating characteristic curve (AUC) for time spent below MAP 60 mm Hg (AUC=0.779) and no significant difference in discriminative performance between MAP thresholds of 60 and 75 mm Hg [30]. Similarly, Varpula et al [29] found that each 1 mm Hg decrease in mean 48-hour MAP was independently associated with an approximate 16% increase in the odds of death (Exp[B]=1.156; *P*=.01).

Secondary Outcomes

AKI and RRT

Renal outcomes were reported with heterogeneous definitions across 7 studies, precluding meta-analytic pooling. Bourgoin et al found that acutely raising MAP from 65 to 85 mm Hg over 4 hours did not change urine flow, serum creatinine, or creatinine clearance [21]. Badin et al [22] identified an MAP range of 72 to 82 mm Hg as the best discriminator of AKI progression at 72 hours, but only in patients with septic shock with early (6-h) renal impairment (AUC=0.83 - 0.84); no MAP-AKI association was found in patients without early AKI. In the larger FINNAKI substudy, Poukkanen et al [23] reported that a time-adjusted MAP below 73 mm Hg was independently associated with AKI progression after adjustment for chronic kidney disease, lactate, furosemide dose, and dobutamine use (adjusted OR 2.57, 95% CI 1.48-4.46). In Sepsis and Mean Arterial Pressure (SEPSISPAM), Asfar et al [25] found no overall between-group difference in creatinine doubling or RRT, but among patients with chronic hypertension, the high-MAP group had significantly less RRT use (31.7% vs 42.2%; *P*=.046) and less creatinine doubling (38.9% vs 52.0%; *P*=.02). In patients with cirrhosis with septic shock and AKI, Maiwall et al [20] found AKI reversal at day 5 was significantly greater with the high-MAP target in the per-protocol analysis (53% vs 31%; *P*=.02), and a high-MAP strategy independently predicted AKI recovery (OR 2.36 - 2.47). Kuragayala et al [28] reported similar, purely descriptive rates of creatinine doubling (82% vs 84%) and RRT (66% vs 70%) between arms, without inferential statistics. Finally, Dünser et al [30] found that MAP and mean perfusion pressure were both significantly correlated with RRT need (r^2=0.124 - 0.136; *P*≤.001) and peak creatinine (r^2=0.269 - 0.277), with MAP <75 mm Hg providing the best discrimination for subsequent RRT need (AUC=0.724).

Hemodynamic Parameters and Vasopressor Requirements

A consistent, dose-dependent relationship between MAP target and vasopressor exposure was observed across studies. In a within-patient crossover from 65 to 75 mm Hg to 85 mm Hg, LeDoux et al [26] demonstrated a stepwise linear increase in heart rate, cardiac index, left ventricular stroke work index, systemic vascular resistance index, and norepinephrine dose (from 23 to 31 µg/min to 47 µg/min; *P*=.02). Bourgoin et al similarly found that raising MAP from 65 to 85 mm Hg significantly increased cardiac index and systemic vascular resistance index without changing lactate or oxygen consumption [21]. Among the RCTs, higher MAP targets consistently required substantially greater vasopressor exposure: Asfar et al [25] reported higher day-1 norepinephrine dose (0.58 vs 0.45 µg/kg/min; *P*<.001) and longer catecholamine infusion (4.7 vs 3.7 days; *P*<.001) in the high-MAP arm, Endo et al [24] reported longer vasopressor duration (65 vs 42 h) and higher cumulative norepinephrine (15.6 vs 9.6 mg) and vasopressin doses in the high-target arm, and Kuragayala et al [28] noted the low-MAP arm undershot its 65- to 70-mm Hg target (achieved MAP 57.3±13.7 mm Hg), while the high-MAP arm approximated its 80- to 85-mm Hg target (78.5±17.2 mm Hg).

Organ Support, Mechanical Ventilation, and Length of Stay

Endo et al [24] reported significantly fewer RRT-free days (18 vs 20; *P*=.02), ventilator-free days (15 vs 18; *P*=.012), and catecholamine-free days (16 vs 19; *P*=.01) at 28 days with the high-target strategy, indicating a greater overall organ-support burden. In contrast, Asfar et al [25] found no significant difference in 28-day survival without organ support between arms (60.6% vs 62.1%; *P*=.66), and Maiwall et al [20] found no significant intention-to-treat differences in ICU length of stay or mechanical ventilation duration, although both trended longer in the high-MAP arm. In the FINNAKI substudy, patients with AKI progression had significantly longer ICU stays than those without (5.7 vs 3.8 d; *P*<.001) [23].

Adverse Events and Splanchnic or Ischemic Outcomes

None of the included studies directly reported splanchnic perfusion or ischemia as a discrete primary outcome; the closest available proxy was mesenteric ischemia as an adverse event, which occurred at similar, low rates between arms in both Asfar et al [25] (2.3% vs 2.3%) and Maiwall et al [20] (1.3% high-MAP vs 0% low-MAP). Cardiac arrhythmias were more frequent with higher MAP targets in several studies: Asfar et al [25] reported significantly more atrial fibrillation with high MAP (6.7% vs 2.8%, *P*=.02), and Endo et al [24] noted that all main safety outcomes—arrhythmia, ischemic events, and hemorrhagic events—trended more frequent in the high-target group, although none reached statistical significance individually. Maiwall et al [20] found significantly more adverse events requiring protocol discontinuation with high MAP (24% vs 11%; *P*=.03), but significantly less intradialytic hypotension (12% vs 48%; *P*<.001), suggesting a trade-off between systemic vasopressor-related harm and protection from dialysis-associated hypotension at higher MAP targets.

Discussion

Principal Findings

This systematic review synthesized evidence from 11 studies examining MAP targets during septic shock resuscitation, with particular attention to splanchnic perfusion and renal outcomes. Pooled analysis of 3 trials [20,24,25] showed a nonsignificant trend toward higher 90-day mortality with higher MAP targets (OR 1.31, 95% CI 0.97-1.77), a trend echoed in the pooled 28- or 30-day mortality estimate derived from Asfar et al [25], Endo et al [24], and, in sensitivity analysis, Kuragayala et al [28] (OR 1.25, 95% CI 0.98-1.61). Although neither estimate reached statistical significance, the consistency of direction across both time points, combined with the early termination of the OPTPRESS trial due to harm [24], raises genuine concern that targeting a higher MAP does not confer a survival benefit and may plausibly increase risk in some patients.

These findings diverge from the physiological rationale that historically supported higher MAP targets in septic shock. Early mechanistic work by LeDoux et al [26] and Bourgoin et al [21] showed that acutely raising MAP from 65 to 85 mm Hg increased cardiac index and systemic vascular resistance without improving lactate clearance, urine flow, or creatinine clearance, suggesting that macrocirculatory augmentation above 65 mm Hg does not reliably translate into organ-level perfusion benefit. This disconnect persisted into the RCT era: Asfar et al [25] found no overall mortality or organ support–free survival benefit with an 80 - to 85-mm Hg target, and Endo et al [11] found the higher target reduced RRT-free, ventilator-free, and catecholamine-free days at 28 days.

A recurring theme across the evidence base, however, is that the relationship between MAP and organ injury is not uniform across patients and that baseline physiology modifies both the direction and magnitude of treatment effect. The clearest example is chronic hypertension: within SEPSISPAM, Asfar et al [25] reported that patients with hypertension randomized to the higher MAP target had significantly less RRT use (31.7% vs 42.2%; *P*=.046) and less creatinine doubling (38.9% vs 52.0%; *P*=.02), an effect not observed in patients with normal blood pressure. This is consistent with a rightward-shifted renal autoregulatory curve in patients with chronic hypertension, whereby an MAP adequate for autoregulation in normotensive individuals may fall below the autoregulatory threshold in those with long-standing hypertension. A second example is cirrhosis: Maiwall et al [20] found that a higher MAP target improved AKI reversal at day 5 in patients with cirrhosis and septic shock and AKI (53% vs 31%; *P*=.02), a population characterized by splanchnic vasodilation, effective arterial underfilling, and impaired renal autoregulation distinct from the general septic shock population. These subgroup signals, alongside the broader trial-level null or harm findings, suggest that a single population-wide MAP target may obscure clinically important heterogeneity of treatment effect and that individualized, comorbidity-informed targets may be more physiologically appropriate than fixed thresholds.

The renal outcome data reinforce this picture of MAP as a threshold rather than a linear "higher is better" variable. Poukkanen et al [23] identified a time-adjusted MAP below 73 mm Hg as independently associated with AKI progression (adjusted OR 2.57, 95% CI 1.48-4.46), while Dünser et al [30] reported that time below an MAP of 60 mm Hg was the strongest discriminator of 28-day mortality (AUC=0.779), with no added benefit from thresholds between 60 and 75 mm Hg. Similarly, Badin et al [22] found that an MAP of 72 - 82 mm Hg best discriminated AKI progression only in patients with existing early renal impairment. Collectively, these data suggest a threshold effect in which avoiding hypotension below roughly 60 to 65 mm Hg is critical, but pushing MAP higher confers diminishing or absent renal benefit, consistent with the null or harmful mortality signals from Asfar et al [25] and Endo et al [24].

Notably, none of the included studies reported splanchnic perfusion or ischemia as a discrete primary outcome, despite this being a central rationale for the review. The only available proxy, mesenteric ischemia as an adverse event, occurred at low and similar rates between MAP arms in both Asfar et al [25] (2.3% vs 2.3%) and Maiwall et al [20] (1.3% vs 0%), providing some reassurance that higher MAP targets are not associated with excess overt bowel ischemia, but this outcome was underpowered and nonspecific and cannot be equated with subclinical splanchnic hypoperfusion [20,25]. This represents an important evidence gap rather than evidence of absence of effect.

The safety profile of higher MAP targets also warrants attention. Higher targets were consistently associated with greater vasopressor exposure, from the stepwise norepinephrine increases seen by LeDoux et al to the significantly higher day-1 and cumulative catecholamine doses reported by Asfar et al [25] and Endo et al [24,26]. This increased vasopressor burden was accompanied by a higher incidence of atrial fibrillation in Asfar et al [25] (6.7% vs 2.8%; *P*=.02) and a trend toward more arrhythmic, ischemic, and hemorrhagic events in Endo et al [24]. Maiwall et al [20] identified a clinically important trade-off in patients with cirrhosis, in whom higher MAP targets increased protocol-discontinuing adverse events (24% vs 11%; *P*=.03) but substantially reduced intradialytic hypotension (12% vs 48%; *P*<.001), illustrating that the net safety balance of a given MAP target may depend heavily on which complications are most relevant to a specific population.

Our findings both extend and refine the conclusions of prior reviews. Leone et al [8], synthesizing studies through July 2014, concluded that an MAP of 65 mm Hg was generally sufficient, although 75 to 85 mm Hg might reduce AKI in patients with chronic hypertension. Our review, incorporating a decade of additional evidence including SEPSISPAM, Targeted Mean Arterial Pressure in Cirrhosis with Septic Shock (TARGET-C), and OPTPRESS, corroborates this hypertension-specific renal signal but adds a caveat Leone et al [8] could not have anticipated: the subsequent OPTPRESS trial [24], conducted in older patients, was stopped early for harm, indicating that higher-MAP benefit in hypertensive or older populations is not generalizable and may reverse in advanced age. Dari et al [10], restricting their meta-analysis to 4 RCTs, similarly found no significant difference in mortality (RR 0.94, 95% CI 0.87-1.01), RRT use, or ICU stay between high- and low-normal MAP

XSL•FO
RenderX

targets. However, by excluding observational evidence entirely, Dari et al [10] could not capture the continuous, threshold-based MAP–outcome relationship shown in cohorts such as Poukkanen et al [23], Varpula et al [29], and Dünser et al [27,30], nor the cirrhosis-specific findings of Maiwall et al [20] that our broader inclusion criteria captured. Kattan et al [11], reviewing hemodynamic monitoring, argued for shifting away from fixed macrohemodynamic targets such as MAP toward multimodal, perfusion-based endpoints such as capillary refill time. Our findings lend indirect support: the absence of consistent mortality or renal benefit from higher MAP across heterogeneous populations, alongside dose-dependent escalation in vasopressor exposure and arrhythmic risk, suggests that a single macrohemodynamic number is an imprecise proxy for tissue perfusion, reinforcing the case for perfusion-guided, individualized resuscitation over uniform MAP thresholds.

Limitations

Several limitations should be considered. First, substantial clinical and methodological heterogeneity across included studies, spanning populations (general septic shock, cirrhosis, older adults-only cohorts), MAP comparison strategies (fixed targets vs continuous exposure), and outcome definitions, precluded meta-analysis for all outcomes except mortality. Second, the overall certainty of evidence for mortality and renal outcomes was rated as very low using GRADE, reflecting serious risk of bias, inconsistency, and imprecision. Third, several trials were open-label, and 2 RCTs [20,21] were rated as having some concerns on RoB 2. Fourth, this review was not prospectively registered on PROSPERO, and restriction to English-language, full-text-available studies may have introduced language bias. Fifth, reliance on Google Scholar screening limited to the first 400 relevance-ranked results may have missed additional eligible studies. Sixth, this review itself included only 4 RCTs, a limitation similar to those it critiques in prior reviews. Seventh, adverse events were systematically reported in only 3 of the included studies, and arrhythmia data derive from just 2 trials (Asfar et al [25], Endo et al [24]), limiting the generalizability of the safety findings. Finally, no included study directly measured splanchnic perfusion or ischemia, forcing reliance on an imprecise adverse-event proxy that cannot capture subclinical gut hypoperfusion.

Future Directions

Future research should prioritize direct, quantitative measurement of splanchnic and mesenteric perfusion, using gastric tonometry, sublingual microcirculatory imaging, near-infrared spectroscopy, or gut-barrier biomarkers, within randomized MAP-target comparisons. Given the signal of differential treatment effect by comorbidity, adequately powered trials or individual patient data meta-analyses stratified by chronic hypertension, cirrhosis, and age are needed to clarify which subgroups benefit from higher MAP targets, and to reconcile the hypertension-related benefit reported by Leone et al [8] and Asfar et al [25] with the harm signal in older patients seen in Endo et al [24]. Trials should incorporate standardized vasopressor and adverse-event reporting to enable pooled safety analyses and should consider individualized or perfusion-guided targets, as advocated by Kattan et al [11], rather than fixed population thresholds. Finally, prospective registration and consistent outcome definitions across future studies would improve the poolability of evidence in this field.

Conclusion

Overall, this review does not support routinely targeting a higher MAP in septic shock, as the available evidence points toward no meaningful survival benefit and, if anything, a possible increase in harm, alongside greater vasopressor exposure and cardiovascular risk. At the same time, the evidence suggests that MAP is not a truly one-size-fits-all target: certain patients, particularly those with chronic hypertension or underlying liver disease, may benefit from a somewhat higher pressure target to protect kidney function, reflecting differences in how these patients' bodies regulate blood flow. Importantly, none of the available studies directly examined gut perfusion, leaving the central question motivating this review unanswered. Given the overall low certainty of the current evidence, a standard MAP target remains the safest general approach for most patients with septic shock, while an individualized, slightly higher target may be reasonable in select high-risk subgroups. Future research should move beyond a single blood pressure number and instead focus on directly assessing tissue perfusion, tailoring resuscitation strategies to the individual patient rather than applying a uniform target to all.

Acknowledgments

An AI tool (Claude Opus 5.5) was used in data extraction, but statistics were cross-checked for all extractable characteristics and results of the studies. It was also used in making tables.

Abstract

Background: Emergency department (ED) overcrowding is a persistent global health issue associated with adverse patient outcomes, diminished staff performance, and compromised health-system efficiency. Despite widespread recognition of the problem, there is no universally accepted approach to monitoring ED overcrowding. The use of disparate, nonstandardized indicators hampers cross-country comparison and the development of effective policies. A comprehensive synthesis of indicators currently used is essential to guide the adoption of robust, evidence-based metrics across diverse health care settings.

Objective: This study aims to identify, consolidate, and categorize indicators that have been used internationally to assess ED overcrowding and to highlight gaps in their use.

Methods: A comprehensive scoping review was conducted from October to November 2023 using four databases: PubMed, Scopus, Emerald Insight, and Google Scholar. Studies were systematically searched using predefined eligibility criteria. Level 1 and 2 screening were independently conducted by 9 researchers (NNMN, KASIP, NFS, NJN, MK, ZL, NNRA, LKY, and ISS) to minimize bias and enhance reliability, and discrepancies were resolved by consensus. A third reviewer (ISS) performed a full-text review, synthesis, and descriptive analysis. Indicators were categorized into input, throughput, and output. Input refers to factors driving ED demand, throughput encompasses internal ED processes such as triage, diagnostics, and treatment, and output addresses challenges in transferring patients to inpatient beds, such as bed shortages or delays. Descriptive analyses were then used to consolidate these indicators and to establish their relative importance. They were ranked based on frequency of reporting across diverse countries and health care settings.

Results: Out of 1347 articles screened, 117 articles were included in the study. A total of 307 indicators were retrieved and then consolidated into 26 distinct indicators. The majority of indicators were classified within the throughput domain (209/307, 68%), followed by the output domain (62/307, 20%) and the input domain (36/307, 12%). The most common throughput indicator, which was frequently reported, was ED length of stay, cited 87 times, followed by left without being seen and waiting time, each reported 30 times. Length of stay consistently emerged as a primary marker of systemic bottlenecks and operational inefficiencies across health care systems.

Conclusions: This review indicates that throughput measures, particularly length of stay, dominate current approaches to assessing ED overcrowding, whereas input and output indicators remain comparatively underrepresented. By consolidating 26 distinct indicators from 117 studies, this study provides a comprehensive evidence base to support the standardization of metrics for monitoring ED overcrowding internationally. These findings offer practical guidance for policymakers and health care leaders seeking to refine performance indicators, enhance benchmarking, and evaluate interventions aimed at improving patient flow. Further research should prioritize validation of underused indicators and the development of composite measures that better capture the complexity of ED crowding across diverse health care settings.

Introduction

Background

Emergency department (ED) overcrowding is a significant challenge faced by health care systems globally [1]. Although various studies have proposed definitions, ED overcrowding fundamentally occurs when the department's capacity is insufficient to meet the urgent needs of patients, leading to delays in care due to congestion [2]. Overcrowding is characterized by a surge in patients seeking care that exceeds the department's capacity to provide timely and efficient services, which reflects a mismatch between patient demand and available resources [3]. Overcrowding in the ED can arise due to a variety of factors, including an increase in patient volume, staffing shortages, and inefficient workflows. The scenario of overcrowding often begins even before a patient sets foot in the ED, influenced by factors such as external medical systems, lack of timely access to primary care, or seasonal health surges [4].

It is also associated with a range of adverse outcomes, including longer treatment durations, preventable medical errors, and the proportion of patients who leave the ED without receiving a medical evaluation from a health care professional [5]. Addressing ED overcrowding effectively requires comprehensive monitoring of patient flow, guided by a well-structured system of performance indicators. Health care authorities rely on these quality indicators to assess ED performance during regular operations and identify opportunities for improvement. The selection of appropriate indicators is crucial, as they guide decision-making based on specific process factors and the outcomes they measure. Improper selection or implementation of these indicators can lead to unintended and detrimental effects [6].

Indicators are essential for addressing ED overcrowding by providing real-time, data-driven insights across the patient journey, from seeking care to discharge or admission, while also monitoring key quality metrics to ensure efficient care delivery [7]. Both operational and clinical indicators are vital for guiding decision-making at each level. Previsit indicators, such as emergency call volume trends, ambulance diversion rates, and regional health data, help predict demand surges. Once patients arrive, operational indicators like triage times, treatment delays, and bed availability ensure efficient resource allocation and timely care delivery. Monitoring these indicators is crucial for public health surveillance, as they provide a comprehensive understanding of overcrowding and inform evidence-based interventions [8]. By tracking specific indicators, health care authorities can identify emerging trends, proactively allocate resources, and implement strategies to prevent overcrowding, thereby improving patient outcomes and health care delivery. Similarly, an Australian ED is exploring the integration of patient flow indicators, including measures of patient acuity, length of stay, and the availability of beds, to improve patient care and manage overcrowding in the ED. The implementation of the "Emergency Department Throughout Time Indicator" in Australia has helped to streamline patient flow, reducing waiting times for critical care [9].

The need for appropriate ED overcrowding indicators is critical for enhancing the efficiency and effectiveness of emergency care systems [10]. By using these indicators, health care authorities can analyze key metrics, such as patient wait times, length of stay, and throughput rates, providing a more accurate understanding of patient flow dynamics and facilitating targeted interventions [11]. These indicators play a vital role in assessing resource use and availability, enhancing the understanding of overcrowding, and driving improvements in health care delivery, resource management, and patient outcomes in both global and local contexts [6].

Study Objective and Rationale

The primary objective of this study is to describe the indicators used to measure overcrowding at the EDs in hospitals using a scoping review. This objective helps to review the indicator used across a range of hospital settings globally. To achieve this, the study is guided by the central research question: what indicators are used to measure overcrowding in EDs in hospitals worldwide? This question forms the basis of the investigation, which aims to provide a comprehensive understanding of how overcrowding is measured and managed across different health care environments. The findings are expected to contribute to the development of more effective strategies for addressing ED overcrowding and improving health care delivery on a global scale.

Methods

Study Design

This scoping review was conducted in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Review and Meta-Analyses extension for Scoping Reviews) as presented in Checklist 1.

Protocol and Registration

The study protocol was registered with the National Medical Research Registry, Malaysia, under NMRR ID-23 - 01709-HDO. Data collection was carried out between May 2023 and April 2024. The content of this review adheres to the registered protocol and aligns with the stated study objectives. The authors are accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Eligibility Criteria

The search strategy was developed using the population, intervention, and outcome framework. The study population comprised health institutions with operational EDs, where service congestion and overcrowding are frequently reported. The intervention was defined as the implementation, application, or evaluation of institutional or hospital performance measures. The outcome focused on the primary indicators used to assess ED overcrowding within these emergency care settings. The comprehensive set of keywords related to ED overcrowding and the indicators used to evaluate or manage it was used to identify relevant studies. All records retrieved from the initial

XSL•FO
RenderX

search were screened and assessed for relevance according to predefined inclusion and exclusion criteria in the Textbox 1.

Textbox 1. Eligibility criteria.

Inclusion Criteria

Studies were included if they met the following criteria:

- **Population:** conducted in hospitals, health centers, health institutions, emergency departments (EDs), trauma centers, or accident and EDs.
- **Intervention:** investigated indicators, measures, indices, parameters, attributes, determinants, or metric indices related to ED performance.
- **Outcome:** reported outcomes associated with overcrowding, congestion, or service overload within ED settings.
- **Study design:** primary research studies of any design, including reports addressing ED overcrowding.
- **Publication type:** article published in peer-reviewed journals.
- **Language:** published in English.
- **Access:** full-text articles available for review.

Exclusion Criteria

Studies were excluded if they met any of the following criteria:

- **Population:** not focused on EDs or involved nonhuman populations or nonhealth care facilities (eg, veterinary hospitals).
- **Intervention:** did not include any indicators or measurements related to ED overcrowding.
- **Outcome:** did not address issues of overcrowding, congestion, or overload.
- **Study design:** nonprimary studies such as literature reviews, commentaries, study protocols, or ongoing research.
- **Publication type:** other publication types, including conference papers, dissertations, or abstract books.
- **Language:** published in languages other than English.
- **Access:** full-text article not available.

Information Sources

Articles were sourced from selected databases, including PubMed, Emerald Insight, Google Scholar, and Scopus. Google Scholar was included to capture gray literature, as the initial search yielded a substantial number of documents, particularly theses and technical reports. All retrieved records were assessed for eligibility.

Search Strategy

The search process was conducted by the principal investigator, KASIP, in June 2023. This process targeted studies published between 2013 and 2023 to ensure the inclusion of the most recent evidence, considering health care system advancements [12]. The inclusion timeframe was restricted to the past 10 years to capture the most recent evidence, considering the rapidly evolving health care landscape that may limit the applicability of older studies [13]. A research specialist reviewed and optimized the search strategy, focusing on Boolean operators and database-specific indexing terms. Keywords were combined into final search strings, such as (hospital OR health OR healthcare) AND (indicators OR measure OR index) AND (overcrowding OR congestion), which were applied across all databases. The number of records retrieved and the corresponding search strategies are summarized in Table S1 in Multimedia Appendix 1. All results were exported to Mendeley, and duplicates were removed manually. The final set of articles meeting the inclusion criteria was incorporated into the review.

Study Selection

Selected studies that capture literature on ED overcrowding and relevant indicators based on the eligibility criteria Textbox 1 were managed using Mendeley software by KASIP and LKY. The studies were evenly distributed among 4 pairs of researchers (Group 1: NJN and NNRA, Group 2: NNMN and ISS, Group 3: ZL and LKY, and Group 4: KASIP, NFS, and MK). Nine researchers (NNMN, KASIP, NFS, NJN, MK, ZL, NNRA, LKY, and ISS), working in pairs, independently reviewed the same articles to ensure accuracy and consistency. In most cases, each pair included at least 1 researcher with a clinical or public health background. Specifically, KASIP is a research officer, NNRA is a nurse researcher, and LKY is a pharmacist. During the level-1 screening process, researchers reviewed the titles and abstracts of the studies, and the required information was recorded using the Google Form. In level-2 screening, the process involved a detailed evaluation of the full texts of the studies that passed the first stage, with results recorded in a Google Sheet. Disagreements between paired reviewers at both stages were initially resolved through discussion and consensus. If the consensus was not achieved, a third independent reviewer (ISS) from a different screening pair, who had not previously screened the study, acted as the assessor to make the final decision.

Data Charting

During level-1 screening, data collected primarily included study characteristics such as focus on ED overcrowding, document type, study design, publication status, and the presence of reported indicators. Upon completion of this stage, findings

XSL•FO
RenderX

were mapped based on the presence of indicators or other measurements, and studies reporting relevant data were selected for level-2 screening. Level-2 screening focused on more detailed information, including year of publication, authorship, study setting, study design, study objectives, study acceptance, identified indicators, and the specific measurement tools used by 4 pairs. Findings from both screening levels were cross-checked, and any discrepancies were resolved through consensus discussions between reviewers to ensure rigor, validity, and trustworthiness. KASIP made the final determination, which was subsequently validated by ISS.

Data Items

A list of data items was developed by KASIP and subsequently validated by ISS. These items are presented in Table 1.

Table . Data items extracted at each screening level.

Level of screening	Data items
Level 1	• Focus on ED[a] overcrowding (yes, no, or unable to retrieve the abstract) • Document type (eg, articles in a journal: review, letters, editorial or comments, consensus statement, newsletter, original article, policy brief, thesis, or report) • Study design (eg, case control, case study, cohort, cross-sectional, mixed methods, qualitative study, quasi-experiment study, randomized controlled trial, reviews – scoping or systematic and literature) • Publication status - ongoing studies or protocols (yes or no) • The presence of reported indicator (yes or not applicable)
Level 2	• Article ID (code assigned to each selected study) • Year of publication • List of authors • Study setting (origin or site of the study implementation) • Study design • Study objectives • Acceptance of the study (accept or reject) • Identified indicators • Specific measurement tools (eg, National ED Overcrowding Study (NEDOCS) and Emergency Department Work Index (EDWIN)

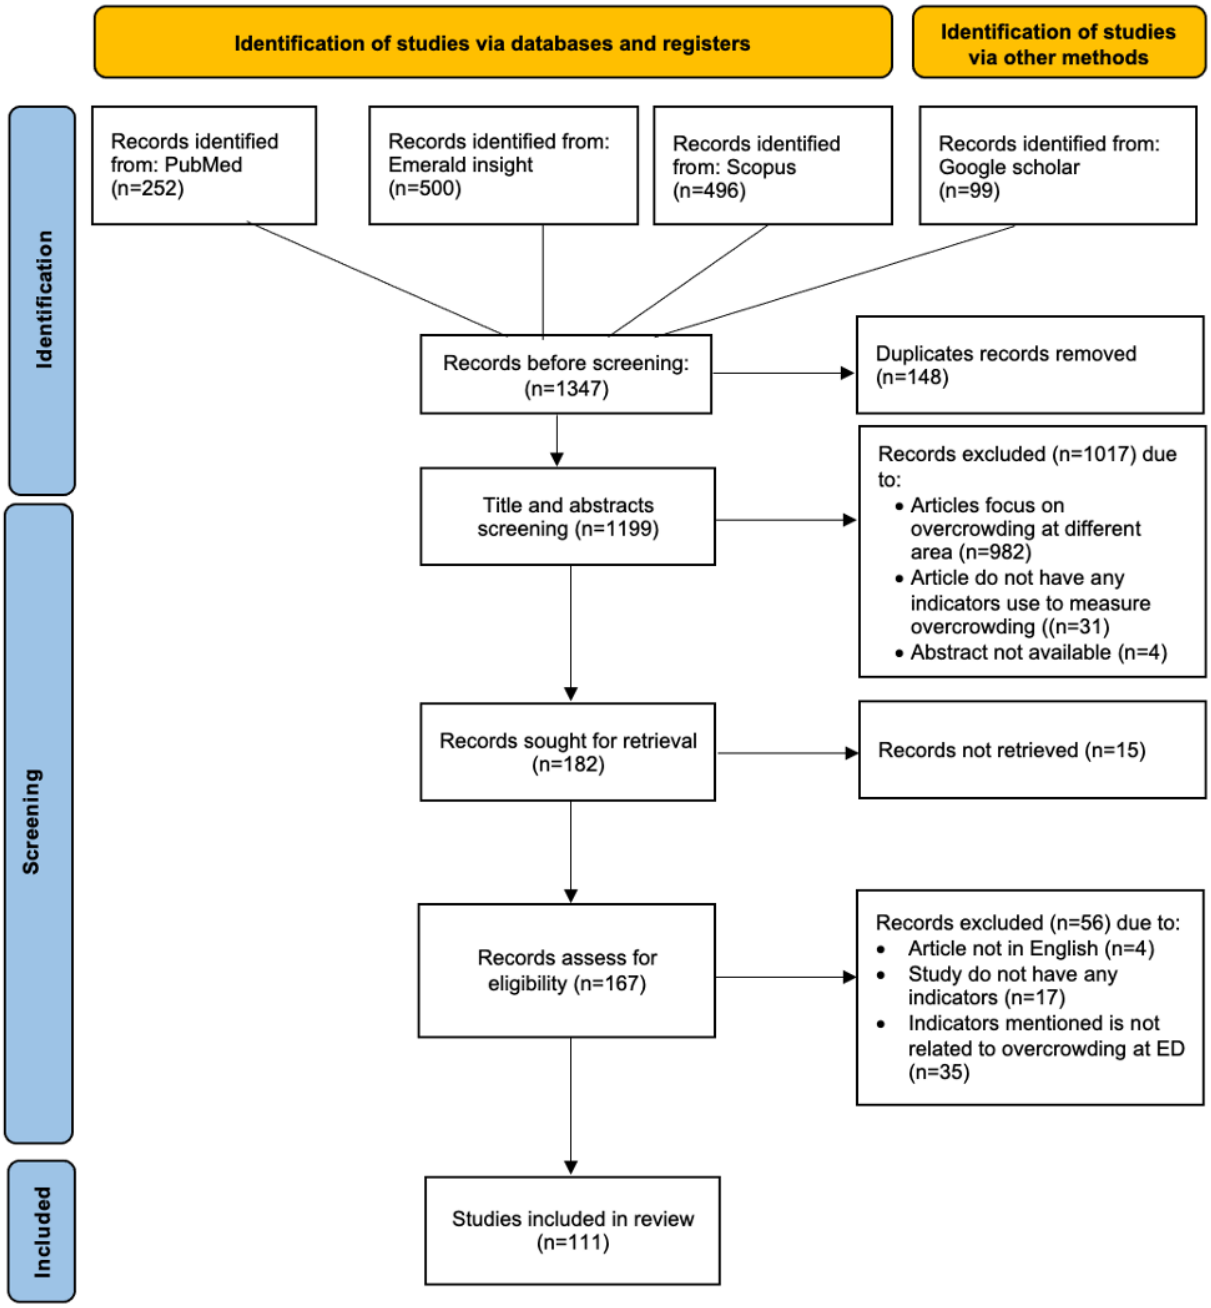
[a]ED: emergency department.

Critical Appraisal

Critical appraisal was not conducted and no risk of bias assessment of the included studies was undertaken in this study, as the purpose of a scoping review is to comprehensively gather and map existing evidence from the literature, summarize key concepts, and identify available findings across different contexts and countries that can inform and guide future strategies.

Data Synthesis

Data extracted from both screening levels were categorized into input, throughput, and output components by KASIP, LKY, MK, and NJN, based on Asplin et al [14]. Input refers to factors that drive demand for ED services, including emergency, unscheduled, and safety-net care. Throughput encompasses ED activities such as triage, diagnostic evaluation, treatment, and inpatient boarding, while output addresses challenges in transferring admitted patients to inpatient beds, including limited follow-up care, bed shortages, or transfer delays. Using this concept, specific indicators of ED overcrowding, such as waiting time, length of stay, bed occupancy rate, and patient flow, were systematically extracted and organized to identify the most frequently used measures globally. This approach helps identify the bottlenecks, allowing the appropriate indicators and the planning of targeted strategies to improve the affected areas.



Results

Study Selection

Figure 1 illustrates the process of identifying, screening, and inclusion of studies for the review. Initially, a total of 1347 records were identified from 4 databases: PubMed (n=252), Emerald Insight (n=500), Scopus (n=496), and Google Scholar (n=99). After removal of 148 duplicate records, 1199 titles and abstracts were screened. Of these, 1017 were excluded for the following reasons: focus on overcrowding in other areas (n=982), absence of indicators measuring overcrowding (n=31), or unavailability of abstract (n=4). Subsequently, 182 records were sought for retrieval, but 15 were unable to be retrieved. Next, 167 records were assessed for eligibility based on inclusion and exclusion criteria, of which 56 were excluded as the article was not in English (n=4), study did not report any indicators (n=17), or the indicators were not related to ED overcrowding (n=35). In the final level, 111 studies [3,7,11,15-121] as mentioned in the List of indicators in Multimedia Appendix 2, were included for data synthesis.

XSL•FO
RenderX

Figure 1. Flowchart of the article selection. ED: emergency department.

Characteristics of the Included Studies

The greatest number of studies examining indicators was published in 2014 (n=14) [15-27, 109] followed by 2019 and 2021 (n=14 each) [1,3,28-51,122], 2017 (n=13) [52-63,123], 2016 and 2018 (n= 9 each) [7,64-80], 2020 (n=11) [81-91], 2022 (n=9) [92-100], and 2013 (n=6) and 2015 (n=6) each) [11,101,103-108,110-113]. Studies mostly originated from the United States of America (n=32) [16-18,22,24,28,34,39,40,44,51-54,68,72,77,80,82,83,87,89,95,103,104,107,109,112,114-117] [27]. Additional articles included in this study came from countries such as Australia (n=12) [23,26,31,36,47,55,56,73,75,76,98,122], Canada (n=7) [20,32,45,57,58,78,85], Italy (n=6) [29,37,43,59,92,99], The Netherlands (n=6) [7,33,79,101,111,117], Taiwan (n=6) [3,60,69,88,94,106,118], Sweden (n=4) [35,38,49,100], South Korea (n=5) [25,81,86,105,113], France (n=4) [11,30,71,95], India (n=2) [1,41], Israel (n=3) [48,95,108], Turkey (n=2) [15,19], Brazil (n=2) [42,52], England (n=1) [70], Germany (n=2) [21,93], Saudi Arabia (n=2) [46,90], Switzerland (n=2) [119,120], Belgium (n=1) [123], Iran (n=1) [61], and Vietnam (n=1) [50]. In some studies, the country was not specifically mentioned or not applicable (n=9) [62-65,67,74,91,102,106].

The study designs of the articles primarily included quality improvement, case-control, case study, cohort study, simulation modeling, cross-sectional study, quantitative study, editorial, literature or systematic or scoping review, mixed methods,

XSL•FO
RenderX

retrospective study, quasi-experimental study, and time series. For the study design, most studies used a cross-sectional study design (n = 55) [1,5,7,9,11,12,15,17,19,21,23,26,28,30,33,35,38,41,44,46,48,52,55,57,58,61,63,66,67,70,73,77,78,81,83,86,89,91,93,96,98,100,101,103,105,107,110,114,118,121,123] followed by a cohort (n = 18) [7,11,20,28,31,32,45,46,48,53,54,56,60,69,79,89,112,116]. Detailed characteristics of the studies included in this review are shown in Multimedia Appendix 2.

Result of Indicator Retrieval

Overall, 111 studies [3,7,11,15-121] reported indicators for measuring overcrowding, either alone or in combination with other tools, while 6 studies used only specific tools without reporting indicators. The list of indicators mentioned in Multimedia Appendix 2, a total of 360 indicators were initially extracted. The minimum number of indicators reported in the studies was one, whereas the maximum number of indicators identified in a single study was 11. Indicators that conveyed similar information and descriptions were identified and merged. Following detailed discussions among the investigators, indicators that conveyed similar information or measured the same underlying concept were grouped together to minimize redundancy. This results in a reduced set of 307 indicators.

These indicators were subsequently analyzed and categorized according to Asplin et al [14] conceptual model of ED overcrowding. Overall, out of 307 indicators identified, the majority, 209 (68%), were classified within the throughput component, reflecting their central role in managing ED performance. In comparison, 62 (20%) indicators were categorized in the output component, while the least proportion, 36 (12%) indicators, were categorized as input. Among the 307 indicators, several of them convey and measured the same parameters. They were then consolidated once more in the final phase of the analysis and presented as a single description for clarity and easier stakeholder comprehension. This process produced 26 distinct indicators.

Synthesis of Results

The findings indicate that the widely used indicator to measure overcrowding was the strengthening of throughput processes, with ED length of stay (ED LOS) emerging as the most frequently used indicator. This was followed by waiting time and left without being seen (LWBS), each reported in 30 studies [19,20,22-24,28,30,34,43,54,57,65-67,70,73,85,102,104,110,114,115]. Within the input component, the average number of patients visiting the ED was the most commonly applied indicator. For output, ED boarding time was most frequently used. The results from the search strategy for indicators using PubMed, Emerald Insight, Google Scholar, and Scopus, and the frequency of indicator uses across studies, along with their classification according to ED components, are summarized in Table 2.

XSL•FO
RenderX

Table . List of indicators with frequency, and ED[a] components classification.

Indicators	Description	Frequency mentioned (n)	Study	ED components
Average number of patients visiting ED	Average total number of patients who attended ED [91,114]	23	[7,15,16,27-29,41-43,57,62,64,73,81,101-103,114]	Input
Representations to ED within 48 - 72 hours	Percentage of patients making an unplanned visit to ED within 48 - 72 hours after first visit for the same chief complaint [119]	7	[15,65,66,104]	Input
Ambulance diversion or turnover time	Period during which ED-requests ambulances that would normally bring patients to the hospital to instead proceed to other hospitals presumed to be less crowded [52,105]	6	[17,30,31,55,102,106]	Input
ED length of stay	Measured from first clinician contact in the ED (triage or ED reception) until the patient physically left the ED (admitted, transferred, or discharged) [2,11,44,61]	84	[2,11,12,17,18,20,22,23,25,26,28,30,31,33,34,36,38,39,41,42,44,46,48,49,51,52,54,55,57,58,60,61,63,64,66,68,69,71,72,74,75,77,78,80,82,83,85,87,89,90,92,94,95,97,98,100,101,104,105,107,108,110,112,113,115,116,118,120,121]	Throughput
Waiting time	Total time from initial registration or triage to first being seen by a doctor or clinician [20,111]	31	[2,10,12,14,17,20,24,25,27,28,30,32,33,35,36,38,40,42,43,45,47,48,50,52,53,55,56,58,59,61,63,64,66,67,69,70,72,73,75,76,78,79,81,83,84,86,87,89,91,93,96,97,99,100,102,103,106,109,111,117,119,120]	Throughput
Left without being seen	The number of patients who arrived, registered, and underwent the triage process but leave prior to being seen by a medical provider or physician [2,17,74,92]	30	[2,12,14,17,20,22,24,25,30,32,34,36,38,40,42,43,45,46,48,50,52,53,55,56,58,59,61,63,64,66,67,69,70,72,73,75,76,78,79,81,83,84,86,87,89,91,93,96,97,99,100,102,103,106,109,111,117,119,120]	Throughput
ED occupancy rate	The number of occupied beds divided by the total number of ED beds, expressed in percentage [15,24,88,92,112]	21	[2,5,6,8,9,11,13,14,16,19,21,24,26,27,29,31,33,35,37,39,41,44,46,47,49,50,53,54,56,57,59,60,62,65,66,68,70,71,74,76,77,79,80,82,85,86,88,91,93,94,96,99,100,104,105,109,113,115,118]	Throughput
Arrival to consultation	Time taken by patient from arrival at primary triage until patient sees a doctor or first consultation by physician [30,65]	11	[11,30,58,72,83,85,87,97,103,107,111]	Throughput
Time to admit and treat	Time interval spent by patient between arrival in the ED and his or her first consultation by a physician [23,49,80,89,92]	7	[16,18,29,39,44,51,55]	Throughput
Time to decision and referral	Time measured from patient arrival to decision of referral, discharge, or admission [20,23]	5	[11,48,55,60,121]	Throughput
Ratio of doctors/patient, nurse/patient	Number of patients each unique clinician is responsible for in a given time slot, presented for each profession [39]	5	[38,92]	Throughput

XSL•FO

Indicators	Description	Frequency mentioned (n)	Study	ED components
Mortality rate	Refers to a patient's death when that patient was still physically in ED or had been initially admitted to the hospital from ED, expressed in number [74]	4	[35,66,91,104]	Throughput
Patient satisfaction	Total percentage of patients ranked their overall ED care as very good or excellent [17,34]	4	[17,34]	Throughput
Diagnostic turnaround time and time after diagnostic test	Durations of the different diagnostics that a patient is subjected to during their stay in the ED. Defined as the time from order entry to the time the radiology and laboratory releases a report in the system [51]	3	[33,115]	Throughput
Percentage of patients left against medical advice	Patients who left without completion of medical care [15,111]	2	[41,83]	Throughput
Time to triage	Measured from patient's arrival to first encounter with triage nurse [11,23]	2	[11,48]	Throughput
Number of ED beds	Number of licensed ED beds, as presented to state health office [92,94]	1	[16]	Throughput
Patient throughput	Number of patients who are treated and discharged from a health care facility within a specific period [93]	1	[18]	Throughput
ED boarding time	Time duration between a patient's bed-request and admission to an inpatient bed [31,33,45,73,97,105]	25	[7,16,22,29,34,42,44,45,55,56,63,70,73,78,86,89,92,114,115]	Output
Number of admissions	Number of admissions from ED, represent workload level in ED [121].	18	[16,22,26,29,34,42-44,51,52,73,78,89,98,114]	Output
Discharge time	Time taken from decision to discharge by physician until patient leaves the bed [30]	9	[11,26,28,50,51,66,97]	Output
Percentage of patients exiting the ED within 4 - 8 hours	Proportion of all patients exiting ED within 4 - 8 hours, either discharged directly from ED or admitted to inpatient wards [5,119]	7	[11,18,23,56,62,91,111]	Output
Hospital Bed Occupancy Rate (BOR)	Ratio of occupied beds to census beds ratio [85,89] The number of patients in licensed bed and overflow locations over the number of licensed treatment beds [26]	5	[18,31,52,62,102]	Output
Bed turnover time	Time from when a patient is discharged until an inpatient bed is available for the next patient [3]	2	[52]	Output

Indicators	Description	Frequency mentioned (n)	Study	ED components
Bed waiting time	Time from decision by ED doctor for admission and referral to primary team until patient arrives at bed in ward [30]	2	[7,97]	Output
Number of hospital beds	Number of licensed hospital beds, as presented to state health office [92,94]	1	[16]	Output

[a]ED: emergency department.

These 26 indicators' descriptions were collated and summarized as seen in Table 2. Categorization into the 3 components of ED crowding showed that the largest proportion of these indicators was concentrated within the throughput component, comprising 15 indicators, followed by the output component with 8 indicators, while the input component accounted for only 3 indicators. These results highlight the predominant representation of throughput elements compared to input and output elements, underscoring their central importance within the framework.

Discussion

Principal Results and Comparison With Prior Work

In this review, the numerous indicators used to assess overcrowding in the EDs illustrated the complexities and diversity of the ED system around the world. The methods by which these indicators are categorized also revealed differences in the conceptualization of overcrowding in the literature. Based on the framework by Asplin et al [14], the indicators obtained from the review were mapped to the input, throughput, and output components. Most of the indicators obtained in this review measured the throughput component, highlighting the importance of examining internal ED work processes, including triaging, room placement, initial provider evaluation, diagnostic testing, and treatment [7].

Throughput indicators dominate the ED performance system largely due to regulatory mandates, policy initiatives, and their alignment with multiple stakeholder interests. The Centers for Medicare and Medicaid Services has specifically made their metrics related to throughput measures for compliance and reimbursement purposes [124]. Furthermore, these metrics are relatively easy to capture from administrative data and electronic health records without the need for resource-intensive data collection methods [1,125]. Hospital administrators find the throughput metrics relevant due to their interest in operational efficiency and capacity management. Patients and families experience visible evidence of emergency performance through waiting times and length of stay, which made throughput measures the dominant focus compared to other quality dimensions [2,125].

Throughput components are mainly involved in internal processes in the ED. The overcrowding causes are due to the need of the specialists or consultants, a lack of instrumental diagnostic support, and a high number of procedures conducted, which results in a burden in ED and compromises the patient flow [4]. The strength of the manpower and adding resources could help in overcoming the overcrowding issues and fulfill the demand. The strategies from micro-level and macro-level should be managed appropriately based on the local setting and the health care institution’s capability [3,4,126].

Among the 3 components, ED LOS from the throughput category emerged as the most commonly measured indicator across studies. Introduced as part of the National Health Service ED performance metrics in the United Kingdom, length of stay serves as a critical measure of throughput and overcrowding, reflecting delays in diagnostics and treatment. Research has shown that patients discharged during shifts with a mean Length of Stay ≥6 h face a 79% higher risk of 7-day mortality compared to those with a length of stay <1 hour [117]. Prolonged length of stay underscores systemic issues, such as diagnostic delays and bed shortages, highlighting its impact on patient outcomes. Reducing length of stay is vital for improving patient satisfaction and increasing the ED’s capacity to manage higher patient volumes. Prolonged length of stay is associated with higher patient dissatisfaction with ED care. This finding is supported by a study by Parker and Marco [127], which explored the correlation between length of stay and patient satisfaction. The authors discovered that patients were dissatisfied with ED services when the Length of Stay exceeded 195 minutes, whereas they were satisfied when the length of stay was less than 150 minutes.

The throughput indicators, often associated with regulatory and accreditation requirements, are integral to ensuring compliance and improving health care delivery standards [7]. Among these, waiting and boarding times have been recommended as routine quality measures. Waiting time, in particular, is a critical indicator with significant implications for patient satisfaction and perceived quality of care. A prospective cross-sectional study involving 644 patients found that increased waiting room time was associated with perceptions of compromised care (OR [odds ratio] 1.05, 95% CI 1.02 - 1.09 for each additional 10 minutes spent in the waiting room), as well as receiving care in hallways (OR 2.02, 95% CI 1.12 - 3.68) [41]. These perceptions can affect patient trust and the overall reputation of health care facilities [93]. Furthermore, prolonged waiting times can lead to dissatisfaction and health deterioration, potentially resulting in more severe complications. As a visible aspect of overcrowding, waiting time plays a pivotal role in shaping public perception and trust in health care services.

LWBS and ED occupancy rates are good proxies of patient satisfaction [11,18]. The LWBS rate reflects patient frustration and the ED’s inability to manage patient flow effectively.

XSL•FO
RenderX

Studies have consistently documented a positive correlation between ED overcrowding and LWBS rates [11,32,38,93,96]. The number of patients leaving without receiving care varied widely, ranging from 213 over an 18-day period [18] to 14,170 over 27 months [28]. This trend highlights systemic inefficiencies within EDs that compromise patient safety and satisfaction [16]. High LWBS rates indicate long wait times and overcrowded conditions, posing significant challenges to operational efficiency, patient safety, and care quality.

Given the impact of patient satisfaction, EDs are increasingly focusing on improving internal processes and addressing overcrowding. This shift has driven the measurement of additional throughput indicators to inform strategies for enhancing patient flow and overall service quality [19]. This explains why these indicators are frequently measured for overcrowding in this review. In contrast, only 12% (36/307) of the indicators fall under the input component, with the average number of patients visiting the ED being the most common. Likewise, 20% (62/307) of indicators were categorized as output like ED boarding time and number of admissions. Since input indicators are related to the demand for ED services, and output indicators are influenced by the inefficient disposition of ED patients, these processes are more challenging to control. Some studies have identified patient arrival characteristics as influences of input indicators, while the inability to transfer patients out of ED affects output indicators [65,92]. These factors are outside the control of the ED and involve other departments, thus requiring greater coordination.

While throughput measures are important, they must be balanced against input and output indicators to avoid a narrow assessment on the performance of ED overcrowding. Since throughput measures primarily emphasize speed, they risk incentivizing premature discharges to meet time targets. In systems dominated by throughput metrics, other critical dimensions such as clinical quality and patient safety indicators may be overlooked [5,128,129].

Limitations

This review has several limitations. First, the literature search was conducted in June 2023; additional studies may have been missed. Despite broad eligibility criteria, some relevant studies (eg, non-English or without full-text) may have been excluded. Nevertheless, the compilation and categorization of indicators remain relevant. Second, a key challenge was the lack of clear definitions for certain indicators, such as distinguishing between waiting time and the interval from arrival to consultation. However, the researchers have clearly defined the variables in the results to assist the reader in better understanding. Third, the heterogeneity of indicators across studies also made direct comparisons difficult. Fourth, as no single "perfect" indicator exists, hospital systems may benefit more from using a combination of measures, such as ED occupancy rate, length of stay, and ED volume, to obtain a comprehensive assessment. Fifth, the variability in indicator use across settings complicates efforts to establish universal benchmarks. Sixth, intergroup reliability was not assessed, as the primary objective in this study was to identify indicators and map the findings according to input, throughput, and output components. Methodological rigor was maintained through independent screening, structured consensus discussions, and resolution by a third reviewer. These limitations highlight the need for more standardized definitions and consensus on evidence-based indicators to support meaningful comparisons and guide public health policies.

Conclusions

In conclusion, the findings of this review highlight that throughput indicators were more prominently studied as key metrics in measuring ED overcrowding. The review provides further evidence that length of stay emerged as a critical indicator reflecting systemic bottlenecks and operational inefficiencies.

These findings underscore the importance of prioritizing throughput indicators, particularly ED LOS, as a benchmark for monitoring and addressing overcrowding. However, the lack of standardized definitions and variability in indicator use highlight a critical need for future research to develop a universally accepted framework for measuring ED overcrowding. Further studies should also explore the integration of input, throughput, and output indicators in predictive models to provide a more holistic understanding of patient flow dynamics.

From a policy perspective, the evidence suggests that interventions targeting diagnostic delays, staffing adequacy, and bed availability should be prioritized to reduce bottlenecks and improve patient outcomes. Policymakers and health care administrators may consider adopting composite measures, rather than relying on a single indicator, to guide resource allocation and performance evaluation. At the national level, embedding standardized overcrowding metrics into hospital accreditation and reporting systems could enhance comparability across institutions and support evidence-based policy development.

Overall, addressing ED overcrowding requires coordinated efforts at both institutional and policy levels. By strengthening measurement frameworks and aligning them with local contexts, health care systems can not only improve patient satisfaction and safety but also build greater resilience in responding to increasing health care demands.

Acknowledgments

The authors would like to thank the director of our institute for Health Management (IHM), Noraziani Khamis, for granting permission to conduct the study, providing guidance and support throughout, and assisting with the review of the manuscript. The study was conducted as part of our Institute's project which was registered with the National Medical Research Registry (NMRR), Malaysia, under NMRR ID-23-01709-HDO and not funded.

Abstract

Background: The increasing number of older adults living with chronic conditions has led to rapid growth in information and communication technologies (ICTs) designed to support chronic disease self-management. Although many technologies target behaviors such as medication adherence, physical activity, dietary management, and follow-up care, the breadth, characteristics, and design considerations of these tools for adults aged 65 years and older have not been comprehensively reported.

Objective: This scoping review aims to systematically map the existing literature describing ICTs developed to support chronic disease self-management among adults aged 65 years and older. Specifically, the review seeks to (1) identify the types of ICTs available; (2) characterize the self-management behaviors they target; and (3) examine the extent of older adults' involvement in the design, adaptation, or evaluation of these technologies.

Methods: This review followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. Seven databases (PubMed, CINAHL, Web of Science, Cochrane Library, Compendex, IEEE Xplore, and Computers & Applied Sciences Complete) were searched, with all searches completed on December 15, 2024. Inclusion criteria were peer-reviewed studies published in English between 2007 and 2025 that (1) included adults aged ≥65 years; (2) addressed one or more chronic diseases; and (3) evaluated, described, or tested an ICT intended to support at least 1 chronic disease self-management behavior. Two reviewers independently screened all titles and abstracts and full texts; disagreements were resolved by a third reviewer. Data were charted using a standardized extraction template and synthesized narratively by technology type and self-management domain.

Results: Nineteen studies met the inclusion criteria. Technologies were grouped into 4 broad categories: mobile apps, online platforms, wearable or sensor-based tools, and smart home or device-integrated systems. Physical activity and medication management were the most targeted self-management behaviors, whereas follow-up appointment adherence and dietary behaviors were less frequently addressed. Only a small number of studies explicitly involved older adults in the design or development process, and such involvement was often limited to usability testing rather than participatory co-design.

Conclusions: The current evidence base is fragmented, with substantial variability in technology types, targeted behaviors, and reported outcomes. Significant gaps remain regarding the participatory design of ICTs with older adults and the development of technologies that address multiple self-management needs simultaneously. Future ICT development should intentionally incorporate older adults and caregivers throughout the design cycle and expand beyond single-behavior interventions to reflect the multimorbidity common in this population.

Introduction

Most population projections estimate that by 2030, 1 in 6 people worldwide will be aged 60 years or older [1], compared with 1 in 10 at present [2]. The older adult population is expected to grow and eventually double by 2050, reaching 2.1 billion persons worldwide [1]. According to the US Centers for Disease Control and Prevention, 6 in 10 adults in the United States are living with 1 or more of the "big five" chronic conditions: diabetes mellitus, cardiovascular disease, chronic respiratory

XSL•FO
RenderX

disease, cancer, and stroke [3]. Older adults are at increased risk of having chronic conditions; two-thirds of Medicare beneficiaries have 2 or more chronic conditions [3]. This shifting demographic and the prevalence of chronic conditions result in an expanding number of older adults living with chronic conditions.

For individuals living with chronic diseases, effective self-management, wherein patients take an active role in their own care, is essential for improving physical health, emotional well-being, and overall quality of life [4]. Self-management typically involves patients consistently engaging in healthy lifestyle behaviors, including maintaining a balanced diet, participating in regular physical activity, adhering to prescribed medications, and attending follow-up medical appointments [5].

Rapid advancements in technology (ie, smartphones and applications), connectivity (ie, mobile broadband availability), and commercial potential have resulted in an explosion of numerous information and communications technology (ICT) tools designed to support chronic disease self-management behaviors [6-8]. For older adults in particular, technologies designed to support health care and chronic disease management are classified into four general areas, which are based upon location of use and platform: (1) mobile-based apps, (2) smart home–based technologies, (3) online-based technologies, and (4) personalized application-based technologies [9]. Mobile-based apps, typically accessed via smartphones and tablets, are widely used to support remote medical services and personalized care. Among these, mobile health and telehealth platforms are the most prevalent. Smart home technologies, which incorporate ICT-enabled tools within the home, such as digital reminders for medical appointments, are increasingly recognized for their role in chronic disease management. Online-based technologies mainly refer to web-based services, including access to podcasts, disease-specific forums, health care providers and product reviews, and other health-related content, all of which support informed decision-making and continuous engagement with care. Personalized application-based technologies refer to a wide range of assistive devices that are programmed to improve care outcomes for older adults. Examples include intelligent devices that monitor vital signs such as blood pressure.

However, using ICTs to support chronic disease self-management among older adults presents significant challenges due to age-related barriers to technology use and engagement [10]. These barriers include generally lower levels of digital literacy and skills; increased concerns about privacy; and physical or cognitive limitations such as impaired vision, hearing loss, and memory decline [11-14]. As a result, older adults often depend on caregivers to effectively use health technologies [15]. In response, the literature has consistently emphasized the need for more accessible and inclusive design, particularly for ICTs aimed at this population [16]. A widely endorsed approach is to involve both older adults and their caregivers in the design process [17,18]. This co-design strategy has been shown to enhance usability, increase patient satisfaction, improve disease management, boost health literacy, and reduce health care costs [18].

Despite substantial expansion of ICTs for chronic disease management, our search found that the literature specifically focused on adults aged 65 years and older remains fragmented and inconsistent. Prior reviews often examine younger populations, focus narrowly on single diseases (eg, diabetes), or aggregate technologies without distinguishing specific self-management behaviors. To date, no comprehensive review has mapped the breadth of ICTs supporting self-management behaviors uniquely for adults aged 65 years and older.

A scoping review is methodologically suited to (1) map broad and diverse bodies of literature, (2) clarify key concepts, (3) identify types of evidence, and (4) highlight gaps rather than evaluate intervention effectiveness or pool outcomes. Given the wide variation in study designs, technologies, and outcomes and the exploratory nature of the research questions, a scoping review is justified and aligns with PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidance.

Guided by this rationale, this scoping review aims to address the following research questions:

1. What types of ICTs have been developed to support chronic disease self-management among adults aged 65 years and older?
2. Which self-management behaviors (eg, medication adherence, physical activity, dietary management, and follow-up care) are targeted by these technologies?
3. To what extent are older adults involved in the design, adaptation, or evaluation of these technologies?

Methods

Protocol and Registration

This review followed the PRISMA-ScR guidelines. The protocol was not registered.

Eligibility Criteria

Consistent with scoping review methodology, eligibility criteria were developed to capture the breadth of literature describing ICTs that support chronic disease self-management among adults aged 65 years and older, rather than to evaluate intervention effectiveness.

The inclusion and exclusion criteria are summarized in Textbox 1.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Population—adults aged 65 years or older managing 1 or more chronic diseases
- Concept—information and communication technologies (ICTs) designed to support at least 1 chronic disease self-management behavior**,** including (but not limited to) medication adherence, physical activity, diet, or follow-up appointment attendance
- Context—any setting (eg, home, community, and clinical)
- Types of sources: peer-reviewed empirical studies (qualitative, quantitative, mixed methods, feasibility or pilot studies, observational studies, or trials) published in English between 2007 and 2025

Exclusion criteria

- Interventions targeting only health care providers
- Nondigital or nonpersonalized technologies
- Studies not focused on chronic disease self-management
- Reviews, editorials, protocols, conference abstracts, or dissertations

A pilot screening phase was conducted during the initial article selection, in which similar articles from target journals were reviewed to refine the scope and thematic alignment of this review. This process guided database selection and search strategy refinement but was not part of the formal eligibility criteria. Because the goal of a scoping review is to map existing evidence rather than restrict it based on study design or comparator groups, no comparator was required or used as part of the eligibility criteria.

Information Sources

A comprehensive search was conducted in 7 databases selected in collaboration with a health sciences librarian: PubMed, CINAHL, Web of Science, Cochrane Library, Compendex, IEEE Xplore, and Computers & Applied Sciences Complete. All searches were completed on December 15, 2024. Reference lists of included studies were hand searched for additional relevant articles.

Search Strategy

Search terms were developed to reflect the review's core aims: older adults, digital health technologies, and chronic disease self-management. Terms were adapted for each database using controlled vocabulary (eg, Medical Subject Headings [MeSH]) and keywords. Detailed search strings are included in Multimedia Appendix 1.

Study Selection

Titles and abstracts were independently screened by 2 reviewers (PM and CRS). Rayyan, an internet-based software package, was used to facilitate article screening [19]. The 2 authors independently completed the title and abstract screening and full-text screening. Full texts of potentially eligible studies were assessed using the defined inclusion and exclusion criteria. Disagreements were resolved through consensus with the third author (YW). A PRISMA-ScR flow diagram was used to outline the study identification and selection process.

Data Collection Process

In accordance with scoping review methodology, a standardized data charting form was developed and iteratively refined. Two reviewers (PM and CRS) independently extracted data from the included studies using a standardized data extraction form. Extracted data included study characteristics (author, year, and country), population demographics, technology description, targeted chronic diseases, self-management domain, outcomes related to technology use and acceptance, and reported effectiveness. The third reviewer (YW) resolved disagreements.

Data Items

Key data items included the following:

- Author, year, and country
- Study design
- Participant age and health status
- Type and functionality of technology
- Chronic diseases addressed
- Self-management behaviors targeted
- Setting (home based, clinical, and other)
- Extent and type of older adult involvement in design or evaluation
- Reported outcomes (clinical, behavioral, or usability related)

Data charting was iterative; reviewers updated the form as familiarity with the literature increased, in accordance with best practices for scoping reviews.

Synthesis of Results

Consistent with PRISMA-ScR, no risk of bias or formal quality assessment was conducted, as the goal was to describe the extent and nature of existing evidence rather than to evaluate or compare intervention effectiveness.

Because of substantial heterogeneity in study designs, outcomes, technologies, and measurement approaches, meta-analysis was neither planned nor appropriate. This aligns with the purpose of a scoping review.

Narrative and Thematic Synthesis

A descriptive, narrative synthesis was conducted. Studies were grouped according to the following categories:

- Technology type (mobile apps, web-based platforms, wearable or sensor technologies, and smart home systems)

XSL•FO
RenderX

- Targeted self-management behaviors
- Chronic disease or health focus
- Degree of older adult involvement in design or testing

To identify key themes across studies, we used a structured thematic analysis process. First, during initial coding, 2 reviewers independently reviewed charted data and coded recurring concepts related to technology use, usability, self-management support, and design involvement. Second, in code consolidation, codes were compared, merged, and refined through discussion. Third, we used theme development to group codes into preliminary categories and iteratively refined them to generate overarching themes reflecting patterns across studies. Fourth, in a final synthesis, themes were summarized and integrated into the narrative results. This analytic process enabled identification of major trends, gaps, and characteristics of the literature.

Effect Measures

Because this is a scoping review, no standardized effect measures were calculated. When available, quantitative outcomes (eg, percentages, use statistics, and self-reported behavior changes) were summarized descriptively based on the information reported in each study.

Results

Study Selection

The database search identified 897 records. After deduplication, 815 (90.9%) titles and abstracts were screened. Following full-text review, 19 (2.1%) studies met the inclusion criteria. The study identification and selection process is summarized in Figure 1 (the PRISMA-ScR flow diagram).

XSL•FO
RenderX

Characteristics of Included Studies

The 19 included studies were published between 2007 and 2025, with the majority (n=18, 94.7%) published after 2012. Studies were conducted across multiple disciplines, including rehabilitation, geriatrics, computer engineering, nursing, and digital health.

Sample sizes varied substantially, ranging from 10 to 803 participants, with most studies enrolling fewer than 120 participants. All studies included older adults aged 65 years and older, although several recruited broader adult populations and reported subgroup data for older adults.

Technologies described in the included studies (n=19) encompassed 4 primary categories: mobile apps and tablets (n=9, 47.4%), web-based platforms (n=5, 26.3%), wearable or sensor-based technologies (n=3, 15.8%), and smart home or device-integrated systems (n=2, 10.5%).

Self-management behaviors targeted most frequently included physical activity (n=11, 57.9%) and medication management (n=10, 52.6%). Dietary behavior (n=7, 36.8%) and follow-up appointment support (n=3, 15.8%) were less commonly addressed.

A detailed summary of charted study characteristics is provided in Table 1.

Table . Charted characteristics of included studies (n=19).

Study	Technology type	Self-Management focus	Age (years)	Sample size, n	Notes (major study features)
Nischelwitzer [20] 2007	Mobile medical app	Physiological tracking	36 - 84	15	Early mobile prototype; pilot feasibility
Ali et al [21] 2012	Touchscreen platform	Nutritional education	60 - 76	31	Education-focused dietary interface
Ammann et al [22] 2012	Web platform	Personalized physical activity	19 - 89	803	Large sample; tailored content

XSL•FO
RenderX

Mapping of Self-Management Behaviors

To describe the scope of self-management behaviors addressed by ICTs, the 19 included studies were categorized according to the primary behavior targeted.

Physical activity was addressed in 11 (57.9%) studies. These studies evaluated pedometers, activity monitoring mobile apps, wearable sensors, or web-based activity programs. Approaches included real-time step tracking, motivational prompts, and personalized exercise recommendations.

Medication management was targeted in 10 (52.6%) studies. Technologies included digital pillboxes, reminder systems, medication self-management apps, and SMS text messaging medication prompts. Most outcomes were descriptive, reporting perceived usefulness, adherence trends, or frequency of system use.

Dietary behavior was addressed in 7 (36.8%) studies. These ICTs focused on dietary logging, nutritional education through tablet or TV interfaces, and monitoring of self-reported dietary behaviors. Few studies provided objective dietary outcomes; most reported usability, satisfaction, or behavioral intentions.

Follow-up appointment support was addressed in 3 (15.8%) studies. Appointment reminders were delivered through SMS text messaging systems or integrated care platforms. Studies described improved perceived access to resources rather than clinical outcomes.

Older Adult Involvement in Technology Design

Of the 19 studies, only 4 (21.1%) explicitly described involving older adults or caregivers in technology design or refinement. Of these, 2 studies used usability testing only, which occurred late in the development cycle. Only 2 studies incorporated participatory or co-design approaches, allowing older adults to contribute to early-stage feature development.

This limited involvement highlights a critical gap between design practices and the needs of older adult users—a key theme in our narrative synthesis.

A summary of user involvement is presented in Table 2.

Table . Extent of older adult involvement in information and communication technology design, adaptation, or evaluation (n=19).

Study	Sample size, n	Older adult involvement during design	Type of involvement
Nischelwitzer et al [20]	15	No	Initial pilot testing only
Ali et al [21]	31	No	Usability testing after development
Ammann et al [22]	803	No	Not reported
Hess et al [23]	47	No	End user feedback only
Reeder et al [24]	96	No	Postdeployment evaluation
Jiménez-Fernández et al [25]	22	No	Usability evaluation
Ellis et al [26]	20	No	Usability or feasibility testing
Mira et al [27]	99	*Yes*[a]	*Co-design: medication routine insights*
Dasgupta et al [28]	16	No	Usability and performance testing
Costa et al [29]	62	No	Informal feedback
Georgsson and Staggers [30]	10	No	Satisfaction survey
Yan and Or [31]	119	No	Logging and perceived usefulness
Pariser et al [32]	76	No	Telemedicine use feedback
Lang et al [33]	116	No	Usability testing
Nambisan et al [34]	20	*Yes*	*Iterative prototyping*
Traviss-Turner et al [35]	22	No	Behavior tracking input
Shi et al [36]	64	No	Attitudes and satisfaction assessment
Valdeverona et al [37]	38	No	Acceptability evaluation
Spinean et al [38]	147	No	End user adoption data

[a]Italicized text denotes studies with meaningful (but limited) co-design or development-stage input.

Themes Identified in the Narrative Synthesis

Through thematic analysis of charted data, 3 overarching themes emerged.

Theme 1: ICTs Commonly Target Single Behaviors Rather Than Multidimensional Self-Management

Most technologies (14/19, 73.7%) focused on only one self-management behavior, despite the high prevalence of multimorbidity in older adults. Physical activity and medication

XSL•FO
RenderX

adherence dominated the intervention landscape, while diet and follow-up behaviors were underrepresented.

Theme 2: Limited Integration of Older Adults in Design and Development

Consistent with prior literature on participatory design, few studies included older adults in the design process, and involvement was often superficial. Studies that incorporated older adult or caregiver feedback reported improved usability, increased engagement, and greater perceived relevance. However, participatory co-design remains the exception rather than the norm.

Theme 3: Focus on Usability Over Effectiveness

Across studies, outcomes overwhelmingly emphasized usability, perceived usefulness, intention to use, and satisfaction. Few studies measured changes in actual self-management behavior or clinical outcomes, reflecting a broader trend toward feasibility or proof of concept research rather than rigorous evaluation.

Summary of Findings

The evidence base is diverse but fragmented. ICTs designed to support chronic disease self-management in older adults vary in purpose, technology type, and targeted behavior. Several key gaps were identified. These gaps included minimal involvement of older adults in technology design, scarcity of multidimensional or integrated self-management technologies, lack of objective outcome measures, and limited focus on follow-up appointment adherence and dietary behavior.

Additional Analyses: Qualitative Synthesis

Articles that reported technology interventions and included self-management aimed at improving chronic disease outcomes using either clinical or behavioral outcomes were eligible for systematic review inclusion (Table 3). We categorized the interventions into the following 4 self-management activities: medication behavior, physical activity, dietary behavior, and follow-up appointment attendance.

XSL•FO
RenderX

Table . Self-management behaviors targeted by information and communication technologies in the included studies (n=19).

Study	Medication behavior	Follow-up appointment attendance	Physical activity	Dietary behavior	Reported outcomes related to behavior
Nischelwitzer et al [20]	No	No	Yes	No	Measured user input data including blood pressure and glucose level
Ali et al [21]	No	No	No	Yes	Measured perceived usefulness and ease of use

Discussion

Principal Findings

Despite the extensive body of literature on technology use in chronic disease management, relatively few studies (n=19) have explicitly examined the role of ICTs in supporting self-management behaviors among adults aged 65 years and older. This finding underscores the relative underdevelopment of an evidence base that is both age specific and behaviorally grounded, despite the high burden of multimorbidity and chronic disease management demands in this population. Given the well-established link between the 4 key self-management behaviors (ie, medication adherence, attending medical appointments, engaging in physical activity, and maintaining a healthy diet) and chronic disease outcomes, future research on technology use in chronic disease management should specifically address these behaviors to ensure more concrete and actionable findings [18].

Importantly, the scoping nature of this review allows for identification of patterns and gaps across heterogeneous study designs rather than assessment of intervention effectiveness. Viewed through this lens, the limited number of studies focused explicitly on adults aged 65 years and older reflects not only a quantitative gap but also a conceptual one in how older adults are positioned within digital health research. Future studies should place particular emphasis on adults aged 65 years and older, a population with a high prevalence of multiple chronic conditions and a documented lower intention to use health information technologies designed for self-management [39,40].

The identified gap gains further significance in light of known predictors of technology use for disease management, particularly performance expectancy and social influence. Lower levels of these factors may contribute to suboptimal adoption and sustained use of ICTs among older adults with chronic diseases [41]. While several studies implicitly acknowledged these determinants, few explicitly incorporated them into intervention design or evaluation frameworks. Understanding these predictors is crucial for informing targeted interventions that address the specific needs, expectations, and social contexts of older adults.

An increasing body of literature highlights the importance of involving older adults in the design of technologies intended to support their health [9]. However, only a small subset of studies in this review reported meaningful involvement of older adults during early design or development phases, with most limiting engagement to late-stage usability testing. Emerging research further suggests that incorporating older adults' caregivers and support networks into the design process can improve communication, strengthen social relationships, and enhance sustained technology use [17,42]. The limited adoption of participatory and co-design approaches identified in this review therefore represents a missed opportunity to align ICT development with the lived realities of aging with chronic disease.

Regarding technology types, mobile technologies and personalized applications were the most frequently reported, surpassing web-based and home-based solutions. This pattern aligns with broader literature on technology acceptance among older adults, which suggests that tablets and smartphones are often perceived as more accessible and easier to use than desktop or laptop computers [43,44]. However, the predominance of mobile solutions should not be interpreted as evidence of optimal fit for all older adults, particularly those with sensory, cognitive, or socioeconomic barriers that may limit access or sustained use.

The included studies addressed self-management behaviors related to physical activity, medication management, diet and nutrition, and follow-up appointment attendance. While social services and social connectedness were rarely targeted, 1 study using an interactive TV-based platform demonstrated promising outcomes related to access to services and social engagement, suggesting a potential role for ICTs in addressing social isolation as a component of chronic disease self-management [45,46]. This finding highlights the need to broaden conceptualizations of self-management beyond biomedical behaviors to include social and contextual dimensions that influence health and well-being in later life.

Implications for Practice and Future Research

This scoping review reveals several important opportunities for improving the design and implementation of ICTs that support chronic disease self-management in older adults.

First, expand the range and integration of self-management behaviors addressed. Future technologies should move beyond single-behavior interventions to reflect the multidimensional nature of chronic disease in older adults. Attention should also be given to social services as a self-management behavior, and exploration of technologies targeting social isolation is warranted.

Second, integrate older adults and caregivers across all stages of technology development. Participatory and co-design methodologies should be prioritized to ensure that ICTs align with users' functional abilities, digital literacy, and everyday care contexts. Early-stage involvement, rather than post hoc usability testing alone, is particularly important for improving relevance and adoption.

Third, incorporate social and contextual determinants of technology use. Factors such as digital literacy, socioeconomic status, internet access, and social support networks are central to understanding ICT adoption and effectiveness among older adults. Future research should explicitly measure and report these contextual factors rather than treating them as background characteristics [43,47].

Fourth, adopt more robust evaluation approaches as technologies mature. While feasibility and usability studies remain appropriate at early stages, later-phase research should incorporate objective measures of behavior change, care processes, or health outcomes to better assess real-world impact.

XSL•FO
RenderX

Finally, develop technologies that support care continuity and follow-up. Appointment adherence and communication with health care providers remain underexplored yet highly relevant domains for older adults' health outcomes and health care use.

Collectively, these implications underscore the need for more holistic, user-centered, and contextually informed ICT development strategies tailored to older adults managing chronic disease.

Strengths and Limitations

This review's strengths include a comprehensive, librarian-assisted search strategy; adherence to PRISMA-ScR reporting guidelines; and a structured, iterative approach to data charting and thematic synthesis. By focusing on self-management behaviors rather than specific diseases or technologies alone, this review offers a behaviorally grounded map of the current evidence base that complements prior disease-specific reviews.

Several limitations should be noted. First, while this scoping review provides valuable insights into ICTs targeting older adults, it did not assess intervention effectiveness or quality, consistent with scoping review methodology. Second, the heterogeneity of study designs, populations, and outcome measures limited cross-study comparability. Third, gray literature was not included, which may have excluded emerging or non–peer-reviewed technologies relevant to older adults. Finally, although sociocultural and structural factors were identified as important gaps, these were infrequently reported in the included studies, limiting deeper analysis of their influence on ICT adoption and use [46,48].

Conclusions

This scoping review maps the current landscape of ICTs designed to support chronic disease self-management among adults aged 65 years and older, revealing a fragmented and uneven evidence base. Although a wide range of technologies has been developed, most focus on single self-management behaviors and provide limited evidence of meaningful older adult involvement in design or development.

The findings have important implications for aging researchers, health informatics scholars, and technology developers. Addressing the identified gaps, particularly the limited use of participatory design, the narrow focus on individual behaviors, and the lack of attention to social and contextual factors, will be essential for advancing more inclusive and effective ICT-based self-management support for older adults. As the population ages and the prevalence of multimorbidity increases, intentional, age-centered approaches to digital health design will be critical for improving chronic disease management and health equity in later life.

Abstract

Background: Neurodegenerative diseases are a major and growing global health burden. Their pathogenesis is complex, and effective therapies remain limited. Gene editing and stem cell–based strategies are reshaping the therapeutic landscape. However, the field has not been systematically examined through bibliometric analysis.

Objective: We aimed to define the intellectual landscape of global research on gene editing and stem cell therapy for neurodegenerative diseases from 2005 to 2024, highlight evolving hotspots, track the field's evolution, and identify major bottlenecks limiting clinical translation.

Methods: We retrieved 1821 publications from the Web of Science Core Collection (2005-2024). We performed a multidimensional bibliometric analysis using CiteSpace and VOSviewer. We assessed publication output, country and institutional contributions, key authors and journals, co-cited references, and keyword networks. These analyses were used to track the field's evolution and pinpoint emerging themes.

Results: In total, 9978 researchers from 90 countries and 2515 institutions contributed to this literature. Annual publications increased from 28 in 2005 to 179 in 2024, with stepwise growth over time. The United States ranked first in output (n=780) and in citation impact (total local citation score=2784; total global citation score=40,009). China and India ranked second and fifth in output, respectively, but their average citation impact was lower than that of the leading countries. The University of California, San Francisco, and Johns Hopkins University remained consistently influential. Boulis NM, Bankiewicz KS, and Feldman EL were among the most prominent contributors. *Molecular Therapy* was the leading journal in this area. Keyword analyses pointed to a growing intersection between genetics and immunology. Major topics included nanotechnology-based delivery, adeno-associated virus vectors, small interfering RNA, intrathecal microsphere injection, autophagy, blood-brain barrier (BBB) targeting, clustered regularly interspaced short palindromic repeats (CRISPR)/CRISPR-associated protein 9 (Cas9), and induced pluripotent stem cells. Burst detection highlighted "open label" as a recent hotspot. This likely reflects rising translational activity and early clinical testing.

Conclusions: The field is moving from technology development toward clinical translation. Anglo-American countries currently drive both productivity and influence. China and India contribute heavily to volume but need a stronger impact. CRISPR/induced pluripotent stem cell platforms and BBB-focused delivery remain central frontiers. The rise of "open-label" studies suggests accelerating clinical momentum. Future progress will require safer and more efficient delivery, clearer standards, and larger global consortia to harmonize protocols and speed translation.

Introduction

Neurodegenerative diseases (NDs) comprise a group of progressive disorders characterized by neuronal loss and functional decline, leading to worsening cognitive, behavioral, and/or motor impairments over time [1]. Common NDs include Alzheimer disease (AD), Parkinson disease (PD), amyotrophic lateral sclerosis (ALS), and Huntington disease (HD). Globally, more than 50 million individuals are affected, and the prevalence is rising with population aging, creating a growing public health and economic burden [2]. Although decades of research have clarified key pathological hallmarks, such as β-amyloid deposition, tau hyperphosphorylation, and α-synuclein aggregation [3,4], most available therapies remain largely symptomatic and do not reliably halt or reverse disease progression. Only a limited number of drugs, including donepezil and levodopa, are approved for clinical use, and their benefits are modest and often constrained by adverse effects. Accordingly, there remains a strong need for therapies that modify disease mechanisms rather than symptoms alone [5,6].

Recent advances in gene editing and stem cell technologies have created new therapeutic possibilities for NDs [7,8]. The clustered regularly interspaced short palindromic repeats (CRISPR)/CRISPR-associated protein 9 (Cas9) system enables precise perturbation of disease-relevant genes and can be used to correct pathogenic variants or modulate aberrant protein expression, including targets such as *APP*, *SNCA*, *SOD1*, and *C9orf72*. In parallel, induced pluripotent stem cells (iPSCs) can be differentiated into functional neuronal populations, providing a platform for cell replacement strategies. For example, CRISPR-based *SOD1* silencing delays motor neuron degeneration in ALS models, and transplantation of iPSC-derived dopaminergic neurons has shown potential to improve motor outcomes in clinical studies of PD [9]. Notably, the convergence of these approaches is becoming an active research direction. The Cas9nVQR editing tool can efficiently modulate gene dosage in human iPSCs and has been reported to ameliorate AD-related phenotypes, including amyloid-β (Aβ) secretion and tau hyperphosphorylation [10]. Gene editing may also be applied to improve graft survival and functional engraftment by reducing immune rejection after transplantation [11]. However, key challenges remain, including off-target editing, tumorigenic risk of stem cell–derived products, and safe and efficient delivery in vivo. Addressing these barriers will be essential for clinical translation.

Bibliometric analysis applies quantitative methods to published literature to map the knowledge structure and research dynamics within a field. Using tools, such as CiteSpace, VOSviewer, and HistCite, bibliometrics can identify influential contributors and core documents, track emerging topics, and evaluate scholarly impact. It can also reveal collaboration networks and cross-disciplinary opportunities, thereby informing more strategic allocation of research efforts and resources. In addition, bibliometric evidence can help policymakers understand field trajectories and support evidence-based decision-making [12-14]. In NDs, prior bibliometric studies have focused on selected diagnostic and therapeutic topics [15,16]. However, gene editing and stem cell therapy represent rapidly expanding and increasingly intersecting frontiers, and a systematic bibliometric assessment of their progress, technical barriers, and translational trajectories in NDs remains lacking. Therefore, we performed a bibliometric and visual analysis of global research on gene editing and stem cell therapy for NDs from 2005 to 2024. By integrating publication trends, institutional collaboration networks, co-citation clustering, and keyword burst detection, this study aims to define the field's intellectual landscape, highlight evolving hotspots, and identify major bottlenecks limiting clinical translation [17].

Methods

Data Sources and Search Strategies

This study systematically retrieved articles published between January 2005 and December 2024 based on the Web of Science Core Collection (WoSCC) database. The retrieval strategy revolved around 2 major themes: NDs (including AD, PD, HD, etc) and gene editing and stem cell therapy technologies (covering CRISPR/Cas9, base editing, stem cell transplantation, etc). The 2 groups of terms were connected by the Boolean operator "AND." For the ND group, an extended search formula was used as follows: TS=("Neurodegenerative Diseases" OR "Degenerative Neurologic Disorder" OR "Nervous System Degenerative Diseases" OR "Neurodegenerative Disorder" OR "Neurologic Degenerative Disease" OR "Neurologic Degenerative Condition" OR "Neurologic Degenerative Diseases" OR "Degenerative Neurologic Disease" OR "Alzheimer Disease" OR "Alzheimer Syndrome" OR "Alzheimer Type Dementia" OR "Senile Dementia" OR "Parkinson Disease" OR "Huntington Disease" OR "Chronic Progressive Hereditary Chorea" OR "Huntington Chorea" OR "Amyotrophic Lateral Sclerosis" OR "Frontotemporal Dementia" OR "Frontotemporal Lobe Dementia" OR "Multiple System Atrophy" OR "Spinocerebellar Ataxia" OR "Prion Diseases"). The gene editing and stem cell group integrated technical keywords as follows: TS= ("Gene Editing" OR "Genome Editing" OR "Base Editing" OR "Genetic Therapy" OR "Genetic Therapies" OR "DNA Therapy" OR "Gene Therapy" OR "Gene-Based Therapy" OR "Stem Cell Therapy" OR "Stem Cell Treatment" OR "Stem Cell Transplantation"). Moreover, the search terms made full use of the truncation symbol "*" to cover term variants (such as "therapy" and "therapies"). The literature screening was carried out in 2 stages: preliminary screening and manual screening. In the preliminary screening stage, nonresearch papers/review literature (such as conference abstracts and patents) and non-English literature were first excluded. In the manual screening stage, 2 researchers independently evaluated the literature, and they mainly excluded the literature that did not match the disease type and the degenerative lesions (such as stroke and epilepsy) and the literature that did not match the treatment methods (such as literature only involving traditional drugs or nongenetic intervention methods). When there were disagreements during the screening process, a consensus was reached through discussion to ensure that the finally included literature met both the relevance of the target disease and the consistency of the treatment methods. Finally, we exported the relevant data of

XSL•FO
RenderX

the literature (authors, institutions, keywords, references, etc) in plain text format.

Research Methods

We built a reproducible, multistep workflow and applied complementary software tools for descriptive statistics, collaboration mapping, and knowledge-structure mining. We first used HistCite (v12.03.17; developed by Eugene Garfield) to summarize annual publication output and overall growth of the field. To assess citation impact, we calculated the total local citation score (TLCS) and total global citation score (TGCS). The TLCS captures a paper's influence within the dataset, whereas the TGCS reflects its impact across the broader scientific literature. Together, these metrics provide a domain-specific and field-wide view of research influence.

Next, we used VOSviewer (v1.6.19; developed by Nees Jan van Eck and Ludo Waltman at Leiden University's Centre for Science and Technology Studies) to construct co-authorship networks at the country, institution, and author levels. To focus on core contributors, we applied minimum thresholds of 20 publications for countries and institutions and 10 publications for authors. In the resulting maps, node size is proportional to publication output, and edge thickness represents collaboration strength. Overlay visualizations encode the average publication year as a color gradient, allowing temporal shifts in activity to be viewed directly [18,19].

To characterize the intellectual structure and identify emerging fronts, we applied CiteSpace (v6.3.R1; developed by Chaomei Chen at Drexel University). We performed document co-citation clustering using 1-year time slices, selected nodes with the g-index (k=25), and pruned networks with the Pathfinder algorithm to emphasize the strongest connections. Cluster quality was evaluated using modularity (Q) and mean silhouette (S) values, with Q >0.3 indicating a meaningful modular structure and S >0.5 indicating acceptable internal consistency. All clustering analyses in this study met these criteria. We then used keyword co-occurrence and burst detection to define major themes and track rapidly rising topics. Finally, journal dual-map overlays were used to visualize cross-disciplinary citation flows [20].

Results

Annual Publication Trend Analysis

We identified 1821 publications (2005‐2024) (Figure 1), including 1083 original articles (59.5%) and 738 reviews (40.5%). Articles accumulated a TLCS of 3343 and a TGCS of 45,163, whereas reviews had a TLCS of 1443 and a TGCS of 34,729. The predominance of original articles is consistent with a technology-driven surge in primary discovery, while the substantial share of reviews suggests that multiple subareas have begun to consolidate into more mature themes. Citation patterns differed by publication type. Articles showed a lower TGCS-to-TLCS ratio than reviews (13.5 vs 24.1), indicating that original studies tended to concentrate influence within the core literature of this domain, while reviews more readily propagated across adjacent fields. Together, these data suggest a field still fueled by primary innovation but increasingly supported by integrative synthesis.

XSL•FO

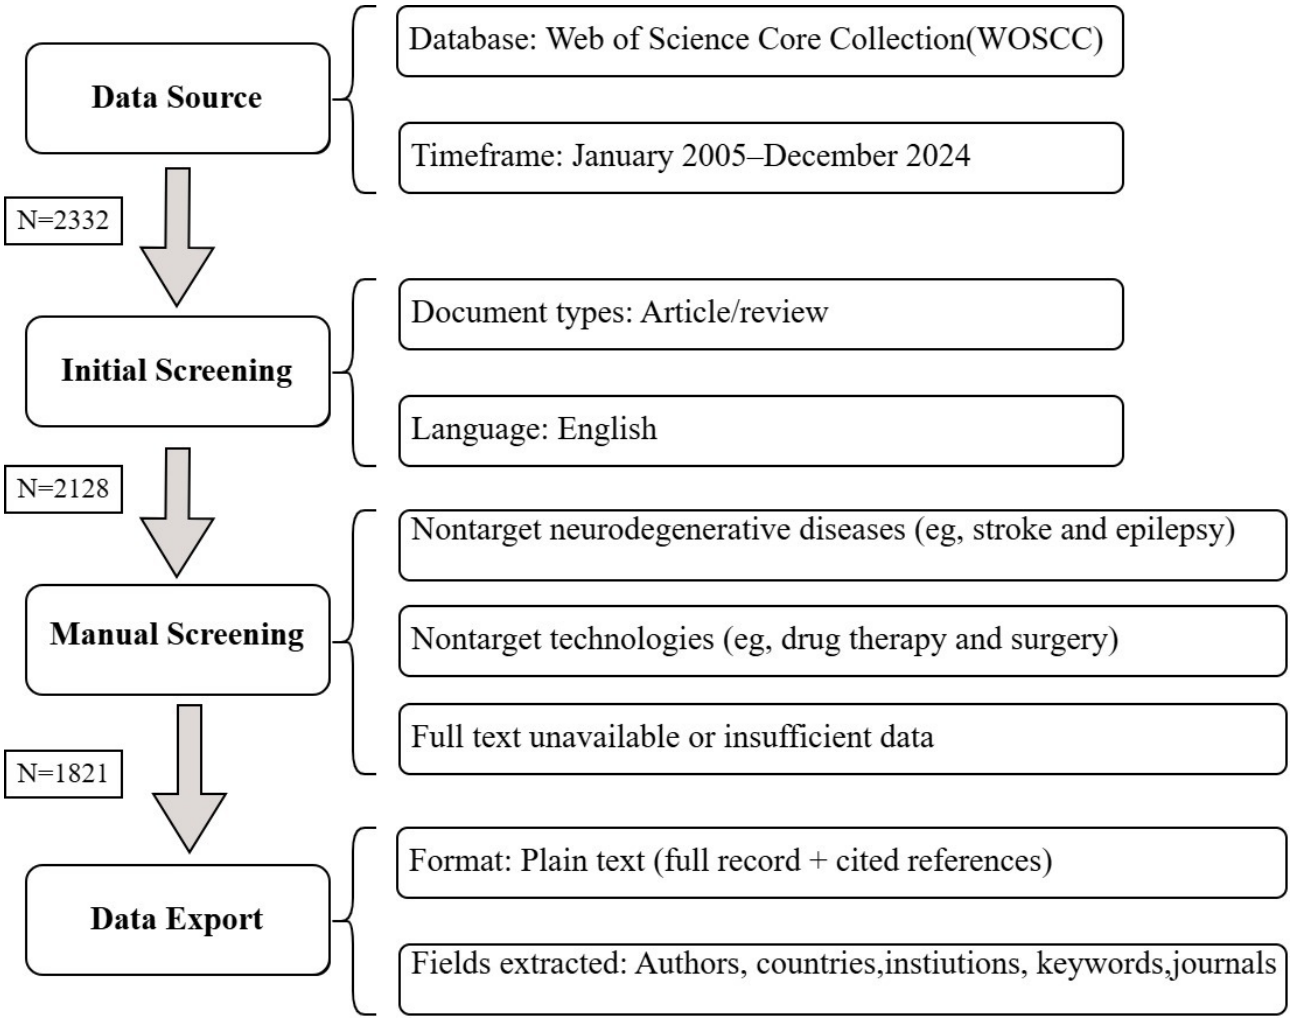
Figure 1. Flowchart of data collection in this study. The diagram illustrates the identification, screening, eligibility, and inclusion phases for records retrieved from the Web of Science Core Collection. The numbers of records identified, included, and excluded at each stage are shown, with specific reasons for exclusion provided in the corresponding boxes.



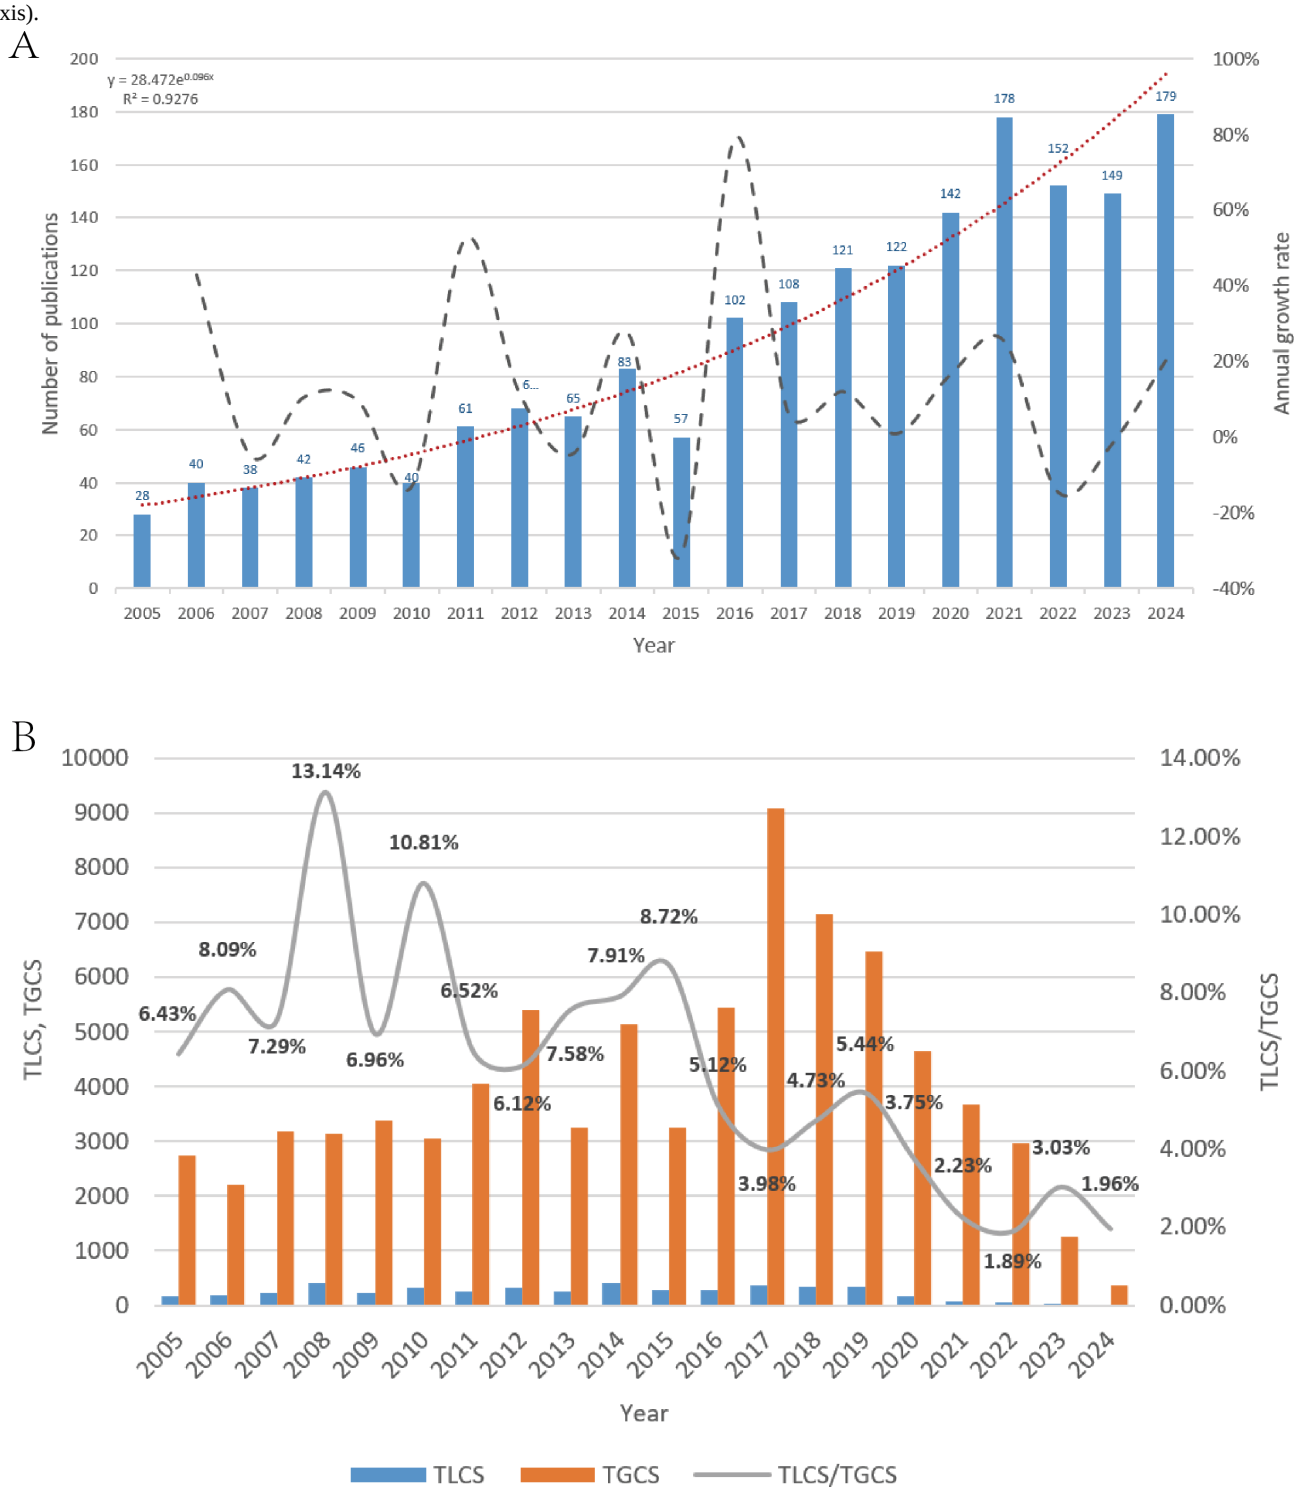


Figure 2A summarizes the annual publication output, fitted trend, and growth rate from 2005 to 2024. Output increased from 28 publications in 2005 to 179 in 2024, with a stepwise rise over time. This trajectory is separated into 2 phases: an exploratory period (2005 - 2015) with a mean of 57 publications per year, followed by an acceleration period (2016 - 2024) with a mean of 125 publications per year. Figure 2B shows the annual TLCS, annual TGCS, and TLCS/TGCS ratio over the same time window. The annual TLCS peaked in 2012 (TLCS=413), coinciding with the highest TLCS/TGCS ratio (13.14%). In contrast, the annual TGCS reached its maximum value in 2017 (TGCS=9092), reflecting a period in which publications from this field achieved particularly broad citation uptake.

XSL•FO
RenderX

Figure 2. Annual publication trend. (A) Annual publication output, trend line, and growth rate from 2005 to 2024. Line chart showing the number of publications per year (bars, left y-axis) and the calculated annual growth rate percentage (line, right y-axis). The dashed trend line is fitted to the publication count. (B) Temporal distribution of the total local citation score (TLCS), total global citation score (TGCS), and TLCS/TGCS ratio. Blue bars represent the annual TLCS (left y-axis), orange bars represent the annual TGCS (left y-axis), and the line represents the TLCS/TGCS ratio (right y-axis).

Country Analysis

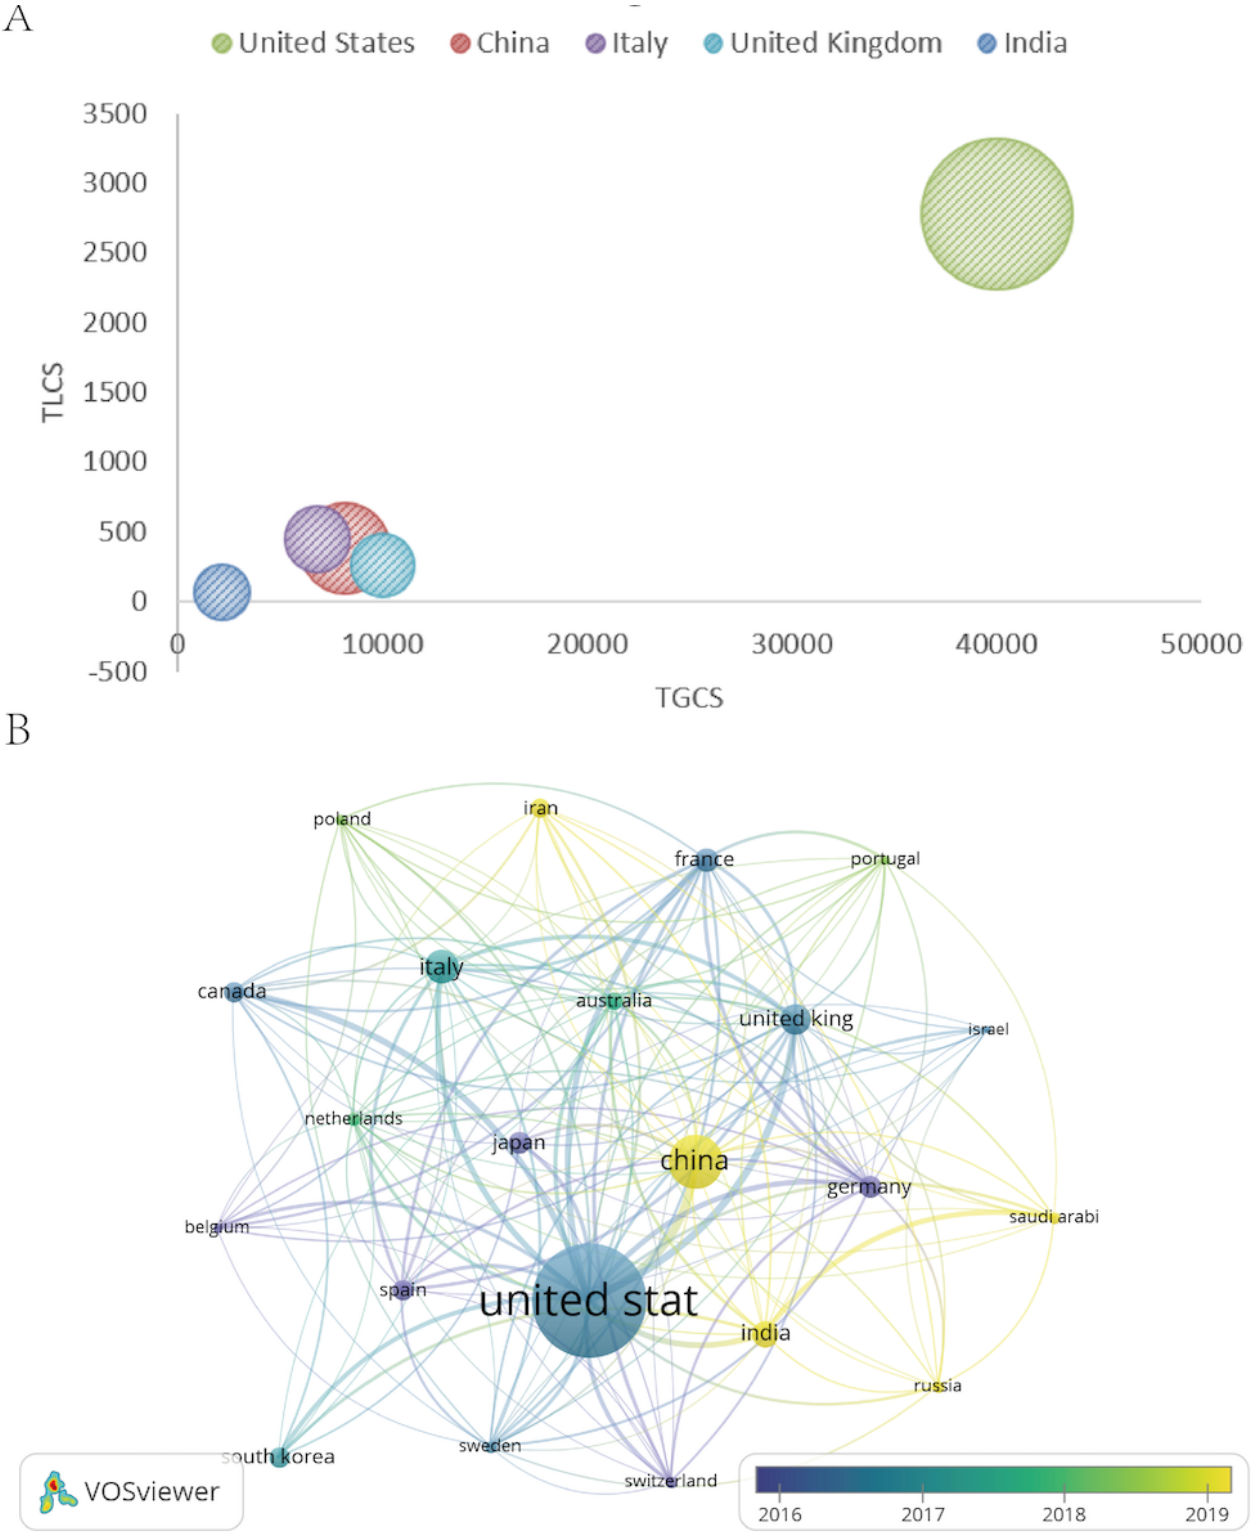
A total of 90 countries published work on gene editing and/or stem cell therapies for NDs. Table 1 summarizes the 10 most productive countries, including the publication count, share, TLCS, TGCS, and average number of citations per article. The United States ranked first by output (n=780) and by citation impact (TLCS=2784; TGCS=40,009), accounting for more than 40% of all publications in the dataset. Germany had the highest average number of citations per article (97.90). China and India ranked among the top 5 in publication volume but had the lowest average number of citations per article among leading countries, indicating high throughput but comparatively limited per-paper impact.

XSL•FO
RenderX

Table . Top 10 countries with the most publications.

Rank	Country	Documents (N=1821), n (%)	TLCS[a]	TGCS[b]	Average article citation
1	United States	780 (42.8)	2784	40,009	51.29
2	China	282 (15.5)	384	8180	29.01
3	Italy	146 (8.0)	448	6807	46.62
4	United Kingdom	138 (7.6)	262	9980	72.32
5	India	110 (6.0)	70	2159	19.63
6	France	91 (5.0)	214	4684	51.47
7	Japan	88 (4.8)	146	2462	27.98
8	Germany	80 (4.4)	102	7832	97.90
9	South Korea	79 (4.3)	257	2890	36.58
10	Canada	77 (4.2)	159	6690	86.88

[a]TLCS: total local citation score.



[b]TGCS: total global citation score.

Figure 3A visualizes the top 5 countries using a bubble plot in which the TGCS (cross-field reach) is shown on the x-axis and the TLCS (within-field influence) is shown on the y-axis; bubble size reflects publication volume. The United States clustered in the upper-right quadrant, consistent with strong performance across productivity and both citation dimensions. China ranked second by output but remained well below the United States in the TLCS and TGCS, suggesting that publication volume has outpaced citation influence. Italy and the United Kingdom produced similar numbers of papers but showed distinct citation profiles: the United Kingdom had a higher TGCS (9980 vs 6807), whereas Italy had a higher TLCS (448 vs 262), consistent with differences in how research from each country disseminates within versus beyond the core field. India showed a lower TLCS and TGCS overall, which may reflect differences in infrastructure, funding, and international visibility.

Country collaboration patterns are shown in the overlay visualization (Figure 3B). Nodes denote countries, edges indicate collaboration strength, node size represents publication volume, and node color reflects average publication year. The network reveals broad international connectivity, with the United States serving as a central hub. Several late-emerging contributors, including China, India, Iran, Saudi Arabia, and Russia, showed more recent activity, suggesting a gradual diversification of global participation in this area.

Figure 3. Country analysis. (A) Bubble chart of the top 5 countries by publication volume. The x-axis represents the total global citation score (TGCS) as a measure of cross-disciplinary reach, while the y-axis represents the total local citation score (TLCS), indicating field-specific recognition. The bubble size corresponds to the total publication count. (B) Country overlay visualization diagram. Nodes represent countries, with size proportional to the publication volume. Links indicate collaboration between countries. Node color denotes the average publication year.

Analysis of Research Institutions

A total of 2515 institutions contributed to research on gene editing and/or stem cell therapies for NDs. The 5 most productive institutions are listed in Table 2; all these are based in the United States, consistent with the country-level dominance observed above. Publication counts across these top institutions were closely clustered (32 - 41 papers), suggesting broad, parallel investment rather than concentration within a single "monopoly" center. Institution-level impact differed substantially. As shown in Figure 4A, the University of California, San Francisco, showed the highest average citations per paper (153.15), nearly threefold higher than Johns Hopkins University (55.73). This gap indicates that the University of

XSL•FO
RenderX

California, San Francisco, not only had a high-volume output but also contributed disproportionately influential work within the field. Collaboration patterns are shown in Figure 4B. The national network highlights several strong institutional pairings, including Emory University-University of Michigan, Harvard University-University of California, San Francisco, and Massachusetts General Hospital–associated nodes. Together, these connections suggest an ecosystem in which basic research, technology development, and clinical programs are interlinked, supporting a "bench-to-clinic" pipeline. The overlay map (Figure 4C) further indicates a shift toward broader participation over time, with institutions, such as the University of Massachusetts, Harvard Medical School, the University of Pennsylvania, University College London, and the Chinese Academy of Sciences, appearing as increasingly active contributors in more recent years.

Table . Top 5 institutions with the most publications.

Rank	Institution	Country	Documents, n	Average article citation	TLCS[a]	TGCS[b]
1	Emory University	United States	41	49.34	310	2023
2	University of Massachusetts	United States	41	34.51	159	1415
3	Johns Hopkins University	United States	33	55.73	129	1839

RenderX

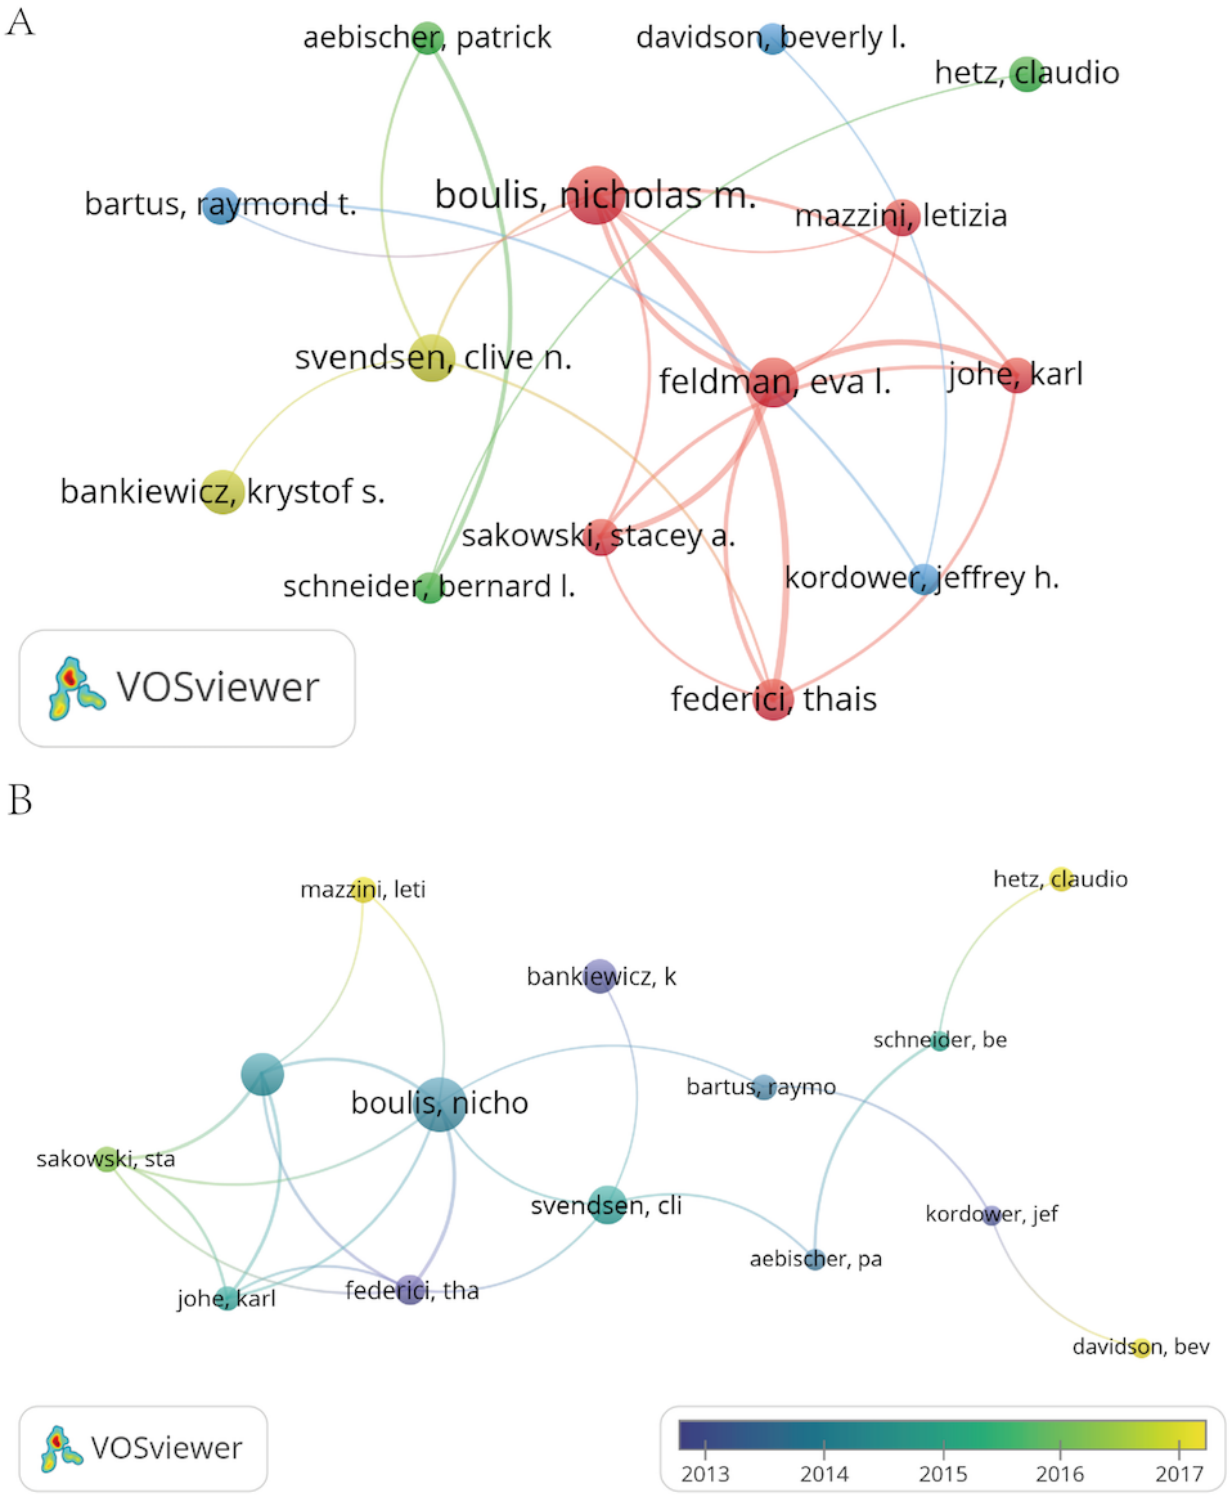
Analysis of Research Authors

Across the 1821 publications, 9978 authors contributed to this research area. The 5 most productive authors are listed in Table 3. Boulis NM ranked first by publication count (24 papers) and contributed a highly cited clinical study in the *Annals of Neurology* (TGCS=157), "Intraspinal neural stem cell transplantation in ALS: phase 1 trial outcomes," which established feasibility and safety for intraspinal neural stem cell delivery in ALS and helped shape subsequent translational efforts in the field [21]. Bankiewicz KS ranked second and showed the highest average number of citations per paper (124.07), consistent with sustained influence from work on aromatic L-amino acid decarboxylase (AADC) gene therapy for PD [22]. Feldman EL showed the highest H-index (104), reflecting broad and durable citation impact across multiple ND-related themes. Author collaboration is visualized in Figure 5A and B. Node sizes reflect publication volume, and the relatively small differences among the top authors point to a distributed authorship landscape rather than dominance by a single group. The overlay map further suggests increased activity around 2017, marked by the appearance of multiple highly active contributors (eg, Mazzini Leti, Davidson Bev, and Hetz Claudio), consistent with a period of accelerated field growth and diversification of research directions.

Table . Top 5 authors with the most publications.



Rank	Author	Documents, n	TLCS[a]	TGCS[b]	Average article citation	H-index	Organization
1	Boulis NM	24	223	1106	46.08	32	Emory University
2	Bankiewicz KS	14	267	1737	124.07	68	Ohio State University
3	Feldman EL	18	263	1064	59.11	104	University of Michigan
4	Svendsen CN	16	213	970	60.63	76	Cedars-Sinai Medical Center
5	Federici T	12	195	614	51.17	54	University of Milan

Journal Analysis

The 1821 publications were distributed across 649 journals. The 5 most productive journals are summarized in Table 4. Collectively, these data illustrate a stratified dissemination landscape in which publication volume and citation influence do not always align. The *International Journal of Molecular Sciences* published the highest number of papers (n=52), but showed a modest impact factor (4.9) relative to other core journals, alongside 1586 total citations and an H-index of 114. This pattern suggests high throughput with more variable per-paper influence. In contrast, *Molecular Therapy* combined substantial output (45 papers) with the strongest citation profile among the leading journals (4300 total citations; impact factor

XSL•FO
RenderX

of 12.1; H-index of 158), supporting its position as a central venue for high-impact work in this domain. *Neurobiology of Disease* ranked third (30 papers; impact factor of 5.1; 1327 citations; H-index of 151), consistent with sustained influence from mechanistic and disease-model studies. *PLOS One* ranked fourth (29 papers; impact factor of 2.9; 996 citations; H-index of 268), reflecting broad topical coverage and extensive long-term citation accumulation. *Gene Therapy* ranked fifth (27 papers; impact factor of 4.6; 1179 citations; H-index of 153), maintaining a stable niche within gene therapy research.

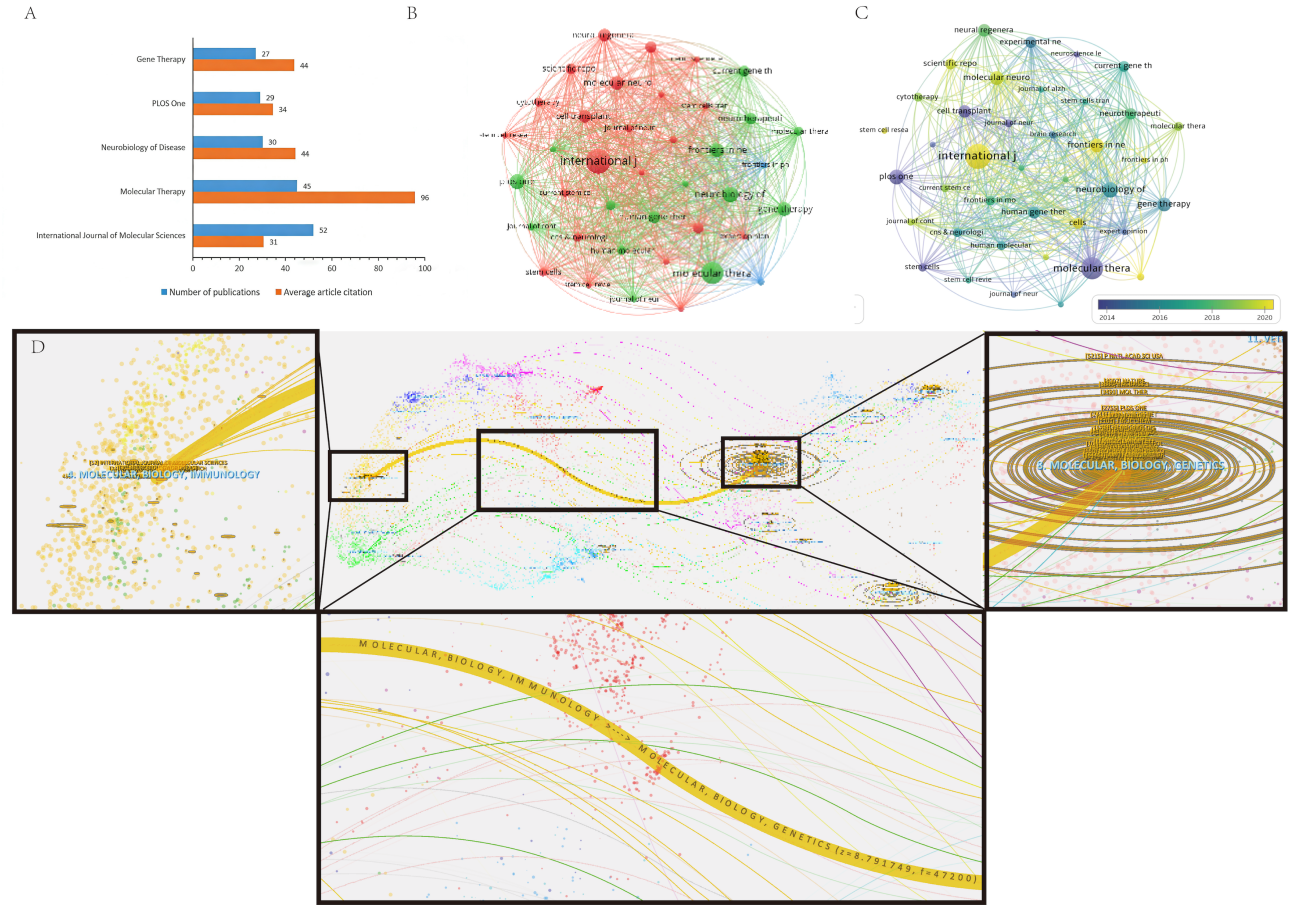

Table . Top 5 journals by publication volume.

Rank	Journal	Total publications, n	Total citations, n	Impact factor	H-index
1	*International Journal of Molecular Sciences*	52	1586	4.9	114
2	*Molecular Therapy*	45	4300	12.1	158
3	*Neurobiology of Disease*	30	1327	5.1	151
4	*PLOS One*	29	996	2.9	268
5	*Gene Therapy*	27	1179	4.6	153

Figure 6A compares publication volume and mean citations per paper for these journals and again highlights *Molecular Therapy* as a top contributor by both output and influence (45 papers; 95.56 citations per paper). Its most cited paper (226 citations), "Direct muscle delivery of glial cell line–derived neurotrophic factor (GDNF) via human mesenchymal stem cells (MSCs) improves motor neuron survival and function in a rat model of familial ALS," reported the therapeutic benefit of GDNF-expressing human MSCs in an ALS rat model and serves as a representative translational milestone in this space [23]. Figure 6B shows dense interjournal citation connectivity, consistent with rapid knowledge turnover and active cross-referencing across core venues. The dual-map overlay (Figure 6C) indicates directional citation flows from citing journals focused on molecular biology and immunology toward citing journals focused on molecular biology and genetics, supporting a convergence of delivery/immune considerations with genetic and mechanistic foundations.

XSL•FO
RenderX

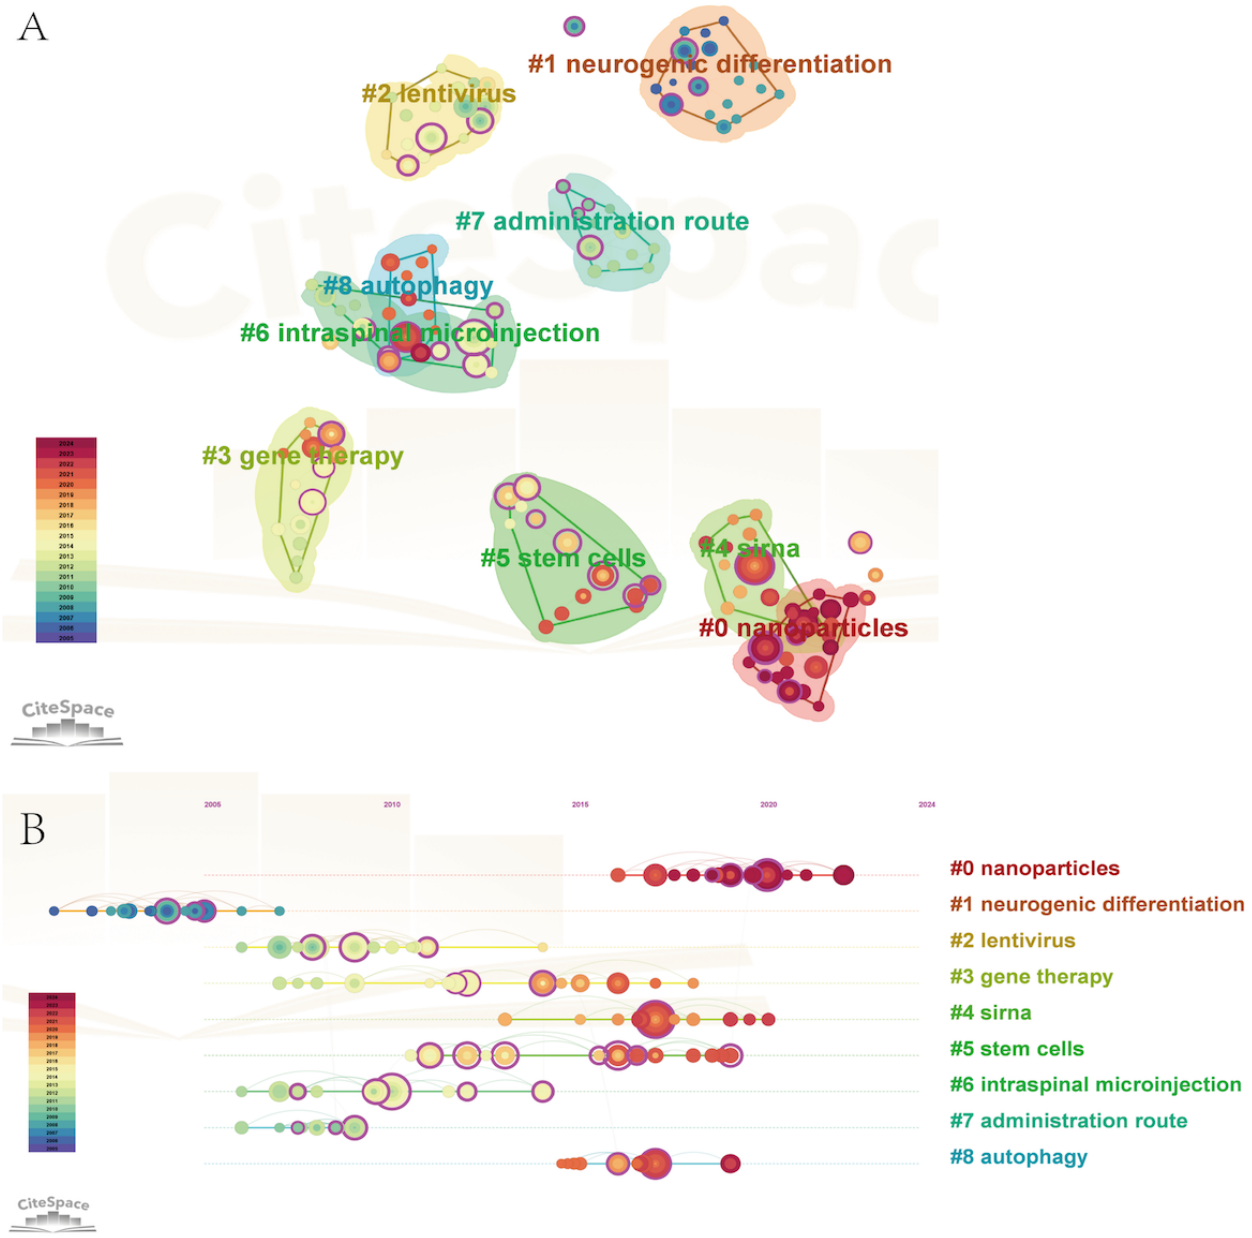
Figure 6. Journal analysis. (A) Top 5 journals by publication volume and field-weighted citation impact. Journal names are listed on the vertical axis. Blue bars represent the total number of publications per journal. Orange bars represent the average citations per article for that journal within the analyzed dataset. (B) Journal collaboration network visualization diagram. (C) Journal overlay visualization diagram. (D) Dual-map overlay of journals. Left-side clusters (citing journals) are concentrated in molecular biology/immunology and health/medicine, while right-side clusters (cited journals) are focused on molecular biology/genetics and clinical medicine. Colored curves indicate citation links, with curve thickness proportional to citation frequency (f). Key metrics: z=8.79, f=47,200.

Literature Co-Citation Analysis

To identify foundational studies shaping the field, we examined highly influential documents by the TLCS. Table 5 lists the 5 papers with the highest TLCS, which collectively span gene therapy approaches (including adeno-associated virus [AAV]–mediated glutamate decarboxylase [GAD]/AADC delivery) and stem cell–based strategies (including MSC transplantation). These studies also represent a range of administration routes (eg, intrathecal, intravenous, and intracerebral delivery) and translational stages from animal models to phase I clinical testing.

XSL•FO
RenderX

Table . Top 5 publications with the highest local total citation score.



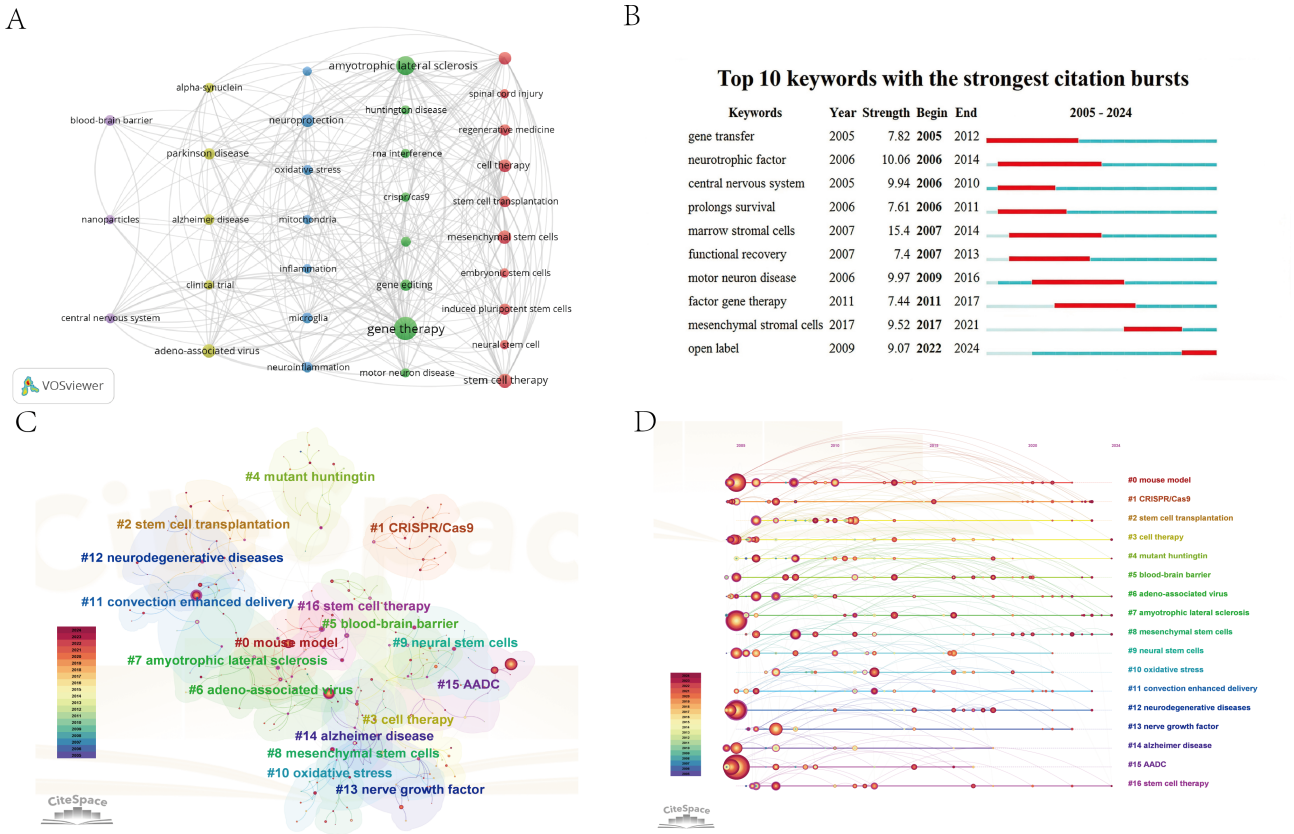
Rank	Title	Journal	First author	Year	TLCS[a]
1	A phase 1 clinical trial of nerve growth factor gene therapy for Alzheimer disease [24]	*Nature Medicine*	Tuszynski MH	2005	102
2	Safety and tolerability of gene therapy with an adeno-associated virus (AAV) borne GAD gene for Parkinson's disease: an open label, phase I trial [25]	*Lancet*	Kaplitt MG	2007	95
3	Mesenchymal stem cell transplantation in amyotrophic lateral sclerosis: a phase I clinical trial [26]	*Experimental Neurology*	Mazzini L	2010	86
4	Safety and immunological effects of mesenchymal stem cell transplantation in patients with multiple sclerosis and amyotrophic lateral sclerosis [27]	*Archives of Neurology*	Karussis D	2010	71
5	Safety and tolerability of putaminal AADC gene therapy for Parkinson disease [22]	*Neurology*	Christine CW	2009	65

[a]TLCS: total local citation score.

CiteSpace co-citation clustering revealed a strong network structure and cluster coherence (Q=0.8485; S=0.9513; Figure 7A). Nine major clusters were identified, including "nanoparticles," "neurogenic differentiation," "lentivirus," "gene therapy," "siRNA," "stem cells," "intraspinal microinjection," "administration route," and "autophagy," collectively outlining the core intellectual pillars of the field. The timeline view (Figure 7B) further suggests that "nanoparticles," "siRNA," and "autophagy" have become more prominent in recent years, consistent with increasing emphasis on delivery engineering and mechanistic modulation.

XSL•FO
RenderX

Figure 7. Co-citation analysis. (A) Clustering diagram of co-cited documents. Network of co-cited references clustered using CiteSpace. Nodes represent references, and links represent co-citation strength. Colors denote distinct thematic clusters (see cluster labels #0-#8). Clustering quality metrics: modularity Q=0.8485; mean silhouette S=0.9513. (B) Time evolution diagram of clustering of co-cited documents. Timeline visualization of the co-citation clusters shown in part A. The x-axis represents the publication year (2005-2024). Each horizontal band corresponds to a cluster, showing the timespan during which its constituent references were cited. Clusters are labeled #0-#8.



Keyword Analysis

Keywords provide a compact representation of study focus and are well-suited for tracking thematic evolution. Figure 8A shows 31 keywords occurring more than 20 times, highlighting recurring attention to AAV, autophagy, blood-brain barrier (BBB), CRISPR/Cas9, iPSCs, and nanoparticles. Keyword co-occurrence analysis yielded high clustering quality (Q=0.7813; S=0.9197), indicating that the identified keyword groups are both well separated and internally consistent.

XSL•FO
RenderX

Figure 8. Keyword analysis. (A) Keyword co-occurrence network diagram. Node size corresponds to keyword frequency. Keywords are grouped by color based on co-occurrence patterns. (B) Keyword burst diagram. Burst detection analysis performed in CiteSpace (γ=0.5). Each horizontal bar represents a keyword, with red segments indicating the period of significant frequency increase ("burst"). (C) Keyword clustering diagram. Network of co-occurring keywords clustered using CiteSpace. Colors denote 17 distinct thematic clusters (labeled #0-#16). Clustering quality metrics: modularity Q=0.7813; mean silhouette S=0.9197. (D) Keyword clustering time evolution diagram. Timeline view of the keyword clusters from part C, showing the activity period of each cluster from 2005 to 2024. The x-axis represents time, and each horizontal line corresponds to a cluster (#0-#16), visualizing the emergence and persistence of research themes.

Burst detection (Figure 8B) identified "marrow stromal cells" as the strongest burst term (strength=15.4), while "neurotrophic factor" showed the longest burst duration (2006 - 2014), consistent with an early wave of neuroprotection-focused strategies. Notably, "open label" emerged as a recent burst term, aligning with increasing attention to early-stage clinical translation.

Keyword clustering further resolved 17 clusters (Figure 8C), spanning disease entities and mechanisms (eg, NDs, ALS, AD, mutant huntingtin, and oxidative stress), gene editing and gene therapy platforms (eg, CRISPR/Cas9, AAV, and AADC), and stem cell or cell therapy strategies (eg, stem cell transplantation, MSCs, and neural stem cells). Additional clusters captured experimental models and neuroprotection-related themes (eg, mouse model and nerve growth factor) as well as delivery paradigms (eg, BBB and convection-enhanced delivery [CED]). The temporal map (Figure 8D) indicates sustained activity across multiple directions over the past 2 decades, with concurrent advances in delivery optimization, mechanistic deepening, and clinical translation. Together, these trends point to a field with not only strong foundational accumulation but also persistent bottlenecks that continue to motivate technological innovation and cross-disciplinary integration.

Discussion

The treatment of NDs is at a critical inflection point, with gene editing and stem cell therapy increasingly converging as translational strategies. To our knowledge, this study is the first bibliometric analysis to systematically map the global research landscape and emerging trends in this field. Over the past 2 decades, annual publication output increased in a stepwise fashion and entered a clear acceleration phase after 2016. This shift likely reflects several enabling advances in gene and cell therapy. For example, the rAAV2-retro variant, which has been generated through AAV capsid engineering, can efficiently access projection neurons via retrograde transport, improving gene delivery performance [28]. In parallel, iPSCs became essential for disease modeling, and MSCs engineered to overexpress brain-derived neurotrophic factor (BDNF) improved outcomes in HD mouse models [29]. Together, these developments likely contributed to sustained growth from 2016 onward. High-impact outputs in this area also show recognizable milestone patterns. The local citation peak in 2008 (TLCS=413; TLCS/TGCS=13.14%) may relate to studies reporting that MSC transplantation can prolong survival, reduce neuroinflammation, and improve motor neuron function in ALS mouse models [30,31]. In contrast, the global citation peak in 2017 (TGCS=9092) likely reflects broad uptake of the widely cited review "Parkinson disease" in *Nature Reviews Disease Primers*

XSL•FO
RenderX

(2017), which synthesized gene therapy targets and vectors as well as the trajectory and current status of stem cell–based strategies in PD [32]. These peaks appear to align with 2 key stages of field development: proof-of-concept experimental validation and consolidation of translational pathways.

At the country level, the United States maintains a dominant position in publication output as well as in the TLCS and TGCS, and the top 5 institutions are all based in the United States. The Boston area, anchored by Harvard University and Massachusetts General Hospital, exemplifies a "basic-to-clinical" collaborative ecosystem, where geographic proximity may facilitate high-frequency interaction and accelerate translation. The sustained US advantage likely reflects multiple reinforcing factors. Long-term and stable research and development investment provides resilience for high-risk, long-cycle research and supports continuity in key directions. In addition, policy and institutional infrastructure (eg, federal funding mechanisms, evaluation systems, open science practices, and industry-academia translation pathways) may improve efficiency across the pipeline—from project initiation to dissemination—thereby strengthening both output and impact. Finally, the centrality of US institutions within international collaboration networks increases access to high-impact consortia and may amplify visibility and downstream citation performance.

China and India contribute substantial publication volume, but their per-paper citation impact remains comparatively low (China: 248 articles; 29.01 citations per article; India: 110 articles; 19.63 citations per article). Collaboration structure may partly explain this gap. China's collaboration intensity with Western countries remains far below that of the United States (Figure 3B), and India appears more peripheral in the international network, potentially limiting exchange and dissemination. Journal distribution may also contribute. As shown in Table 4 and Figure 6A, outputs from these countries more often appear in high-volume journals with lower field-specific influence, whereas representation in specialty high-impact venues, such as *Molecular Therapy*, remains limited. In addition, keyword evolution (Figures 7 and 8) suggests that research from these countries may concentrate more heavily on applied and translational clusters, while fewer outputs appear to define foundational, concept-setting advances that often drive long-term citation accumulation. Collectively, these patterns suggest that increasing influence will require deeper integration into high-impact international networks and more sustained investment in originality and frontier research.

At the same time, our data suggest a complementary global innovation landscape. The United States shows broad leadership with strong representation in foundational and early-translational clusters, such as novel AAV engineering and first-in-human studies, consistent with its network position and presence in high-impact journals [33]. In contrast, publication growth from countries, such as China and India, aligns more strongly with applied technology clusters, including nanoparticle delivery systems and stem cell transplantation protocols [34]. European contributors, including Germany and the United Kingdom, show sustained depth in mechanistic clusters, such as oxidative stress and protein aggregation, reflecting enduring strengths in fundamental biomedical science [35]. These patterns argue for collaboration models that pair mechanistic depth, platform engineering, and clinical execution. Institutions seeking higher impact may benefit from long-term partnerships with leading laboratories through co-designed projects and joint publication strategies, alongside deliberate targeting of field-leading specialty journals and sustained investment in frontier directions.

Our co-citation and keyword analyses highlight recurring focal areas, including "adeno-associated virus," "nanoparticles," "blood-brain barrier," and "marrow stromal cells." AAV vectors remain central tools due to relatively low immunogenicity, broad tropism, and stable long-term transgene expression [36]. We also identified clusters, such as "lentivirus" and "siRNA." Lentiviral vectors can enable durable gene expression through genomic integration and provide relatively large cargo capacity for platforms such as CRISPR/Cas9 or neurotrophic factor genes [37,38]. Small interfering RNA (siRNA) can silence pathogenic genes through RNA interference and may also complement gene-editing strategies by modulating target expression or reducing unintended activity [39]. However, clinical translation remains constrained by 2 major bottlenecks [40]. First, BBB penetration is often insufficient in humans, despite robust performance in some animal studies. Second, neutralizing antibodies against AAV can reduce transduction efficiency and may contribute to treatment failure, while immune-evasion strategies remain comparatively underdeveloped. Recent progress in surface-modified and targeted nanoparticles has improved BBB delivery [41]. In our analyses, "nanoparticles" emerged as both a persistent focus and a growing frontier. Nanoparticles (1 - 100 nm) can be engineered (eg, using rabies virus glycoprotein peptides or lactoferrin) to facilitate BBB transport; protect payloads, such as AAV and siRNA; and potentially influence stem cell survival and differentiation [42,43]. Encapsulating AAV within lipid nanoparticles, for example, has been reported to enhance vector stability and in vivo penetration through optimization of lipid composition and structure [44]. These advances underscore the promise of integrating material science with vector biology to improve delivery and the therapeutic index.

Another prominent cluster was "autophagy," a cellular quality-control pathway that clears misfolded proteins and damaged organelles. Enhancing autophagy is an attractive therapeutic direction, but precise bidirectional control remains challenging because excessive activation risks degrading essential proteins [45]. MSCs and MSC-derived extracellular vesicles also remain highly visible in the literature. The burst term "marrow stromal cells" supports sustained attention to MSC-based strategies. Bone marrow–derived MSCs can support neural repair through the secretion of neurotrophic factors and immunomodulatory effects [46]. Human MSCs engineered to overexpress BDNF improved outcomes in HD mouse models [29,47]. Laromestrocel, an allogeneic bone marrow–derived MSC product from young healthy donors, has shown encouraging findings in AD, including reduced rates of whole-brain volume loss and hippocampal atrophy, without amyloid-related imaging abnormalities during treatment [48]. As a cell-free alternative, MSC-derived exosomes are emerging as nanoscale carriers capable of delivering therapeutics to the

XSL•FO
RenderX

brain, supporting Aβ clearance and neuroprotection [49]. MSC-derived exosomes have also been reported to localize to inflamed brain regions and to be taken up by neurons, suggesting potential for targeted delivery [50]. The recent emergence of "open label" indicates that clinical translation is advancing but still concentrated in early validation. Consistent with this, many highly cited clinical studies in this field are phase I open-label trials. While open-label designs are practical for early exploration, definitive efficacy requires subsequent confirmation in larger randomized, double-blind controlled studies [24-27]. Beyond vector-related barriers, translation also faces platform-wide challenges: nanoparticle safety and long-term stability in humans remain incompletely defined; MSC survival and integration after transplantation are often limited; gene editing carries the risk of off-target effects; and stem cell–based approaches raise concerns regarding tumorigenicity and immune reactions. Finally, many trials remain limited by a small sample size and a short follow-up, underscoring the need for larger cohorts and longer-term surveillance to establish durability and rare safety signals.

Our keyword clustering further resolved thematic dimensions beyond tools and cells. These included disease entities and mechanisms (eg, oxidative stress, mutant huntingtin, AD, and ALS), gene-editing and gene-therapy platforms (CRISPR/Cas9, AAV, and AADC), stem cell and cell therapy strategies (MSCs, neural stem cells, and transplantation), delivery paradigms (CED and BBB), and experimental models and neuroprotection-related themes (mouse models and nerve growth factor). Oxidative stress reflects cellular injury driven by excessive reactive oxygen and nitrogen species, and interventions that neutralize reactive oxygen species remain under active exploration, although deeper mechanistic work is still needed to guide therapeutic development. CRISPR/Cas9 enables precise genome manipulation [51], and AADC gene therapy has shown translational potential in PD, although dose optimization and immunogenicity remain important challenges. Stem cell therapy offers multitarget potential but continues to face constraints in standardized manufacturing, delivery efficiency, and long-term safety [52-56]. Delivery remains a central determinant of success: CED can improve distribution within the central nervous system and offers a strategy to address BBB-associated constraints [57,58]. Animal models remain essential, but differences between rodents and humans, particularly BBB properties and lifespan, can contribute to translational inconsistency. Clinical studies of neurotrophic factors, such as nerve growth factor, have generally shown safety but limited efficacy in late-stage disease, highlighting the complexity of these interventions [59]. Overall, progress will depend on improving delivery and efficiency, reducing immune barriers, and strengthening safety assessments to support reliable clinical benefit.

The integration of iPSC technology with CRISPR/Cas9 editing remains particularly promising for personalized approaches. Patient-derived iPSCs can mitigate immune rejection concerns while enabling gene correction or targeted modification. In HD, CRISPR/Cas9 correction of CAG-repeat expansions in *HTT* in patient-derived iPSCs yielded differentiated neurons with improved functional phenotypes [60]. Additionally, iPSCs can differentiate into diverse neural cell types, and when combined with CRISPR/Cas9 technology, they enable the generation of specialized cells tailored for multicell-type ND therapies. In PD treatment, researchers differentiated iPSCs into dopaminergic neurons, applied CRISPR-mediated gene correction, and observed symptom improvement in PD models following transplantation [61]. In AD, neurons or astrocytes can be obtained through differentiation of patient-derived iPSCs, and CRISPR/Cas9 can be used for precise knock-in/out or allele replacement of key risk genes, such as *APP*, *PSEN1/2*, and *APOE*, thereby reversing most phenotypes [62]. In ALS, pathogenic variants around *SOD1*, *C9ORF72*, *TARDBP*, and *FUS* can be investigated in motor neurons differentiated from iPSCs and their co-culture systems, observing key phenotypes such as RNA metabolism abnormalities, stress granules, axonal transport deficits, and cell nonautonomous damage, as well as using gene correction to validate the causal relationship between phenotypes and mutations [63]. Across multiple ND models, combined iPSC-CRISPR strategies have shown therapeutic benefit with acceptable tolerability and low immunogenicity in animal studies [64].

In the process of transitioning technologies from the laboratory to clinical and industrial applications, ethical considerations and regulatory frameworks often pose more immediate practical bottlenecks, impacting whether new technologies can gain approval, establish trust, and achieve large-scale implementation, in addition to scientific feasibility and engineering maturity. Ethically, it is essential to regulate informed consent, privacy, and data security while ensuring fairness in the risk-benefit balance. In the context of iPSCs and CRISPR, particular attention should be given to evaluating off-target or unintended effects, long-term safety, follow-up requirements, and the protection of vulnerable populations. On the regulatory front, this involves product attributes, quality systems, and the requirements for clinical evidence and risk management, including endpoint settings and long-term safety evaluations. These factors significantly influence research design, data availability, timelines, and costs, ultimately determining the efficiency of translation.

This study has several limitations. First, literature retrieval was restricted to the WoSCC, which may omit journals or regional contributions not indexed in this database. Second, although search terms were refined, omissions cannot be fully excluded. Third, we did not incorporate additional translational indicators, such as patent landscapes.

This study systematically reveals dynamic development trends and research hotspots in gene editing and stem cell therapy for NDs through bibliometric analysis. Global annual publications show stepwise growth, with countries like the United States and Germany making outstanding contributions. However, clinical translation faces challenges, such as low BBB penetration efficiency and immune responses, though emerging approaches like nanoparticle-rabies virus glycoprotein peptide modification and MSC exosomes demonstrate breakthrough potential. Additionally, combined applications of iPSCs and CRISPR/Cas9 gene editing show significant therapeutic promise. The "open label" keyword burst indicates that most studies remain in early validation phases, characterized by small clinical trial samples,

XSL•FO
RenderX

short observation periods, and weak evidence levels, necessitating urgent validation of long-term safety and efficacy. Future efforts should prioritize optimizing delivery systems, validating clinical translation, and fostering interdisciplinary research (eg, artificial intelligence–driven AAV capsid design) through dedicated ND funds. Strengthening "basic-clinical-industrial" collaborative networks, enhancing clinical evidence quality, and exploring CRISPR/Cas9-stem cell integration will provide critical pathways to overcoming therapeutic bottlenecks in NDs.

Abstract

Background: Recommender systems are pivotal in organizing information to enhance noticeability, reduce overload, and streamline decision-making. They can be even more effective if combined with digital nudges. Digital nudging is a subtle approach that combines design, information, and interaction elements to create a choice architecture that can guide user behavior in digital environments. While promising in many fields, there is a notable gap in health promotion, particularly because digital nudges and recommender systems can encourage and support sustained healthier choices in nutrition, physical activity (PA), and sedentary behavior reduction to prevent overweight and obesity.

Objective: This scoping review addresses these gaps by exploring how digital nudges and recommender systems are used in obesity prevention.

Methods: We prospectively published the scoping review protocol and adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. Eligibility was defined using the PCC (Population, Concept, Context) framework. We searched 7 bibliographic databases (MEDLINE and PsycINFO via Ovid, Web of Science, CINAHL via EBSCO, Scopus, ACM Digital Library, and IEEE Xplore) up to October 2023. Following a 2-stage screening by independent reviewers, we selected 68 articles that included 94 user evaluations.

Results: Most articles (36/68, 53%) report on recommender systems focused on nutrition, with fewer (16/68, 23%) aiming to promote PA. Most studies on digital nudges (11/68, 16%) targeted nutrition-related nudges for shopping and meal selection (8/68, 2%). Articles address PA and sedentary behavior less frequently (3/68, 4%). Three out of 68 (4%) articles report on recommender systems in combination with games, and 2 out of 68 (3%) articles report on recommender systems and digital nudges. Approaches to item retrieval vary widely, with 31 out of 68 (46%) articles failing to describe their methods. In the scoping review, we found a discrepancy between the target group for which the system was developed and the group with which the evaluation was conducted. Sixty-eight evaluations report positive results, while 26 studies report mixed, negative, or no-difference results.

Conclusions: Integrating digital nudges and recommender systems might hold potential in overweight and obesity prevention by subtly encouraging healthier lifestyle choices. However, the heterogeneity in study designs, outcome measures, and reporting quality limits the comparability of findings and makes it difficult to draw robust conclusions about effectiveness. Future work should include detailed definitions, mechanism descriptions, broader geographic representation, and rigorous intervention testing and user evaluations to fully leverage these systems for improved health outcomes and to support sustainability and well-being objectives.

KEYWORDS

recommender systems; lifestyle; physical activity; sedentary behavior; obesity prevention; digital health; digital intervention; digital nudges

Introduction

Background

Recommender systems are tools designed to predict and suggest items, services, or content that users might like based on their preferences, behavior, or other data. For instance, recommender systems can suggest recipes informed by the user's past experiences and dietary preferences, such as vegan or vegetarian options. These preferences are discerned by analyzing and comparing the search histories of different users [1,2]. Furthermore, these systems can remind users to increase their physical activity (PA), integrate tasks into daily schedules based on personal calendars and to-do lists, calculate caloric expenditure, and propose recipes based on that expenditure, while also suggesting suitable exercise methods [3]. In this process, recommender systems use sophisticated algorithms to analyze extensive datasets. This approach facilitates tailored suggestions by applying diverse filtering techniques [4-6]. Therefore, recommender systems are considered digital interventions that leverage nudging mechanisms in the digital environment [7]. Digital nudging is an approach grounded in behavioral economics that utilizes user interface design elements to influence user choices in digital environments. These elements encompass, for example, graphic design, coloring, specific content, wording, ranking, and other features, collectively serving as subtle tools to guide individuals toward decisions or behaviors [8]. In other words, they provide a choice architecture in the digital space intended to guide individual decisions. The digital environment is where users make decisions on screens, such as tablets, websites, or mobile apps [9]. Nudging mechanisms, according to the taxonomy developed by Münscher et al [10] and reflected in the functionality of recommender systems, can be categorized into:

- Decision information: This refers to techniques that target the presentation of decision-relevant information without altering the decision options. This category focuses on how information is perceived, represented, and framed, influencing the decision-making process. It includes methods such as translating information to make it clearer, reframing choices to alter perspectives, simplifying complex data to enhance comprehension, and making critical information or social norms visible to guide decision-makers without changing the underlying content.
- Decision structure: This involves altering the arrangement and presentation of decision options to influence decision-making strategies and outcomes. This approach includes modifying the decision environment by setting defaults, adjusting the range or composition of available options, changing the effort required to select an option, and altering the potential consequences associated with each choice. The goal of these techniques is to guide decision-makers toward more desirable outcomes by organizing and structuring the decision space in a way that impacts their selection process.
- Decision assistance: This encompasses techniques aimed at supporting individuals in following through with their intentions to bridge the intention-behavior gap. This category includes interventions such as reminders to bring desired options to the forefront of attention and facilitating commitment to reinforce adherence to chosen behaviors. These techniques are designed to enhance self-regulation and assist decision-makers in maintaining their resolve, thereby increasing the likelihood of consistent and intended actions.

Recommender systems automatically select information that influences information noticeability [10]. They sort information based on preferences and prompt as suggestions to elicit a reaction from users. In doing so, recommender systems can reduce information overload, help rank information, and streamline the decision-making process [1,2].

While recommender systems inherently possess features such as information selection, simplification, and reminders akin to digital nudges, they are rarely included in the category of digital nudges in the field of health promotion. They are designed with these principles in mind. Interactions within these systems, such as visual feedback on daily step counts, calorie tracking, messages, and reminders, are infrequently developed with the explicit framework of digital nudges as the guiding principle. By effectively using design, information, and interaction elements, digital nudges aim to steer decision-making processes. Combining digital nudges and recommender systems could increase their individual effectiveness, as demonstrated in various studies [8,11-13]. However, only a small number of nudges with recommender system mechanisms have been investigated until now [7], and large gaps exist [14]. Furthermore, the literature is characterized by expanding research activity, volume, and heterogeneity [15].

However, given the effects that digital nudges and recommender systems can exert, this potential should be leveraged for obesity prevention, a crucial aspect of modern lifestyle interventions. According to Hummel et al [16], 62% of nudging treatments have statistically significant effects, with a median effect size of 21%, which varies by category and context. Defaults emerge as the most effective strategy (number of included studies: 21, median effect size: 50%; average effect size: 87%), while precommitment strategies are the least effective (number of included studies: 2, median effect size: 7%; average effect size: 7%). Additionally, digital nudging demonstrates comparable effectiveness and presents opportunities for individualization, allowing for more tailored approaches to influencing healthy behaviors. Obesity prevention has become an important part of public health prevention due to the drastic increase in obesity in the past decades, with adult obesity rates as high as 34% in some European countries and even 40% in the United States [17]. As the trends continue almost unencumbered, novel approaches are required to prevent and reduce obesity, and digital tools have aimed to contribute to this. Utilizing

XSL•FO
RenderX

recommender technologies and nudging strategies aids users in navigating the extensive and often heterogeneous data landscape. This approach is instrumental in identifying accurate and relevant information essential for making informed health-related decisions [18-20]. By using a personalized digital choice architecture, the way information, services, and choices are presented to users on websites and other online services can be altered. This approach can subtly encourage desired behaviors such as improved dietary habits to prevent weight gain and enhance metabolic health. Additionally, it can promote more physically active lifestyles and support maintaining healthy weights. Research into digital nudging analyzed how users perceive choices and make decisions in digital environments [7,8]. Combining this knowledge with recommender systems allows for presenting tailored suggestions within a choice architecture that naturally guides users toward desirable decisions. For example, combining healthy food items based on user preferences with visual progress bars or social comparison features (eg, "90% of users chose this option") could encourage users to follow recommendations [21,22]. General challenges reported by individuals who are gaining weight, such as making poor choices when tired or hungry, focusing on budget constraints rather than a balanced diet, lacking time to gather information on healthy food items or exercise, or staying motivated over a more extended period, can be addressed by both approaches.

Bergman et al [13] described various types of digital nudges based on digital nudge patterns, outcomes, context, evaluation, personalization, interconnectivity, and mode of delivery. However, the context was broadly labeled as "health," without specifically addressing the behavior targeted by these nudges. Similarly, Jesse and Jannach [7] developed a taxonomy for coding digital nudges, integrating the work of others by categorizing nudges and their mechanisms [10,22-24]. However, their work did not focus on the health context of the systems. A similar pattern can be seen in the literature on recommender systems. De Santis et al [25] identified 10 reviews from 2017 to 2023, covering 308 primary studies on recommender systems and nudges for obesity prevention, primarily focusing on technical system properties and strengths and weaknesses [1,26-35]. While health domains related to obesity prevention were mentioned, system implementation and evaluation with users were rarely described. De Croon et al [28], for example, analyzed the use of recommender systems in health applications aimed at laypersons and identified 26 nutrition-related recommender systems, including meal plans, recipes, restaurant suggestions, and fruits. Further, 24 studies were included under lifestyle, encompassing PA and the combination of nutrition and PA, as well as other lifestyle behaviors such as smoking. Similarly, Pincay et al [6] classified various studies analyzing recommender systems under "wellness," which covered diets, exercise routines, and care recommendations for children and older people. Pincay et al [6] did not distinctly separate nutrition from PA behaviors. Cai et al [2] identified 24 health domains. The health domain (specific health conditions, issues, or diseases) identified ranges from general healthy lifestyle promotion to specific health domains such as diabetes and obesity. Bondevik et al [1] analysis focused on technical aspects of food recommender systems, such as methods and techniques used within the recommender system (eg, filtering, personalization) data processing techniques (eg, data used for calculation similarities, data used for training the system), evaluation, and reproducibility without considering specific target groups, topics, or the integration of approaches such as digital nudges. Sun et al [36] offered a broader perspective, mapping health recommender systems based on characteristics, techniques, interfaces, and user involvement. However, health behaviors were broadly categorized under "lifestyle." No review has explicitly focused on nutrition, PA, and sedentary behavior (SB) reduction. Furthermore, given the diversity of contexts in which health behaviors occur, it is crucial to consider socioeconomic and geographical disparities, as these can significantly impact mechanisms, norms, acceptance, effectiveness, and, in the end, the generalizability of digital intervention strategies. More information is needed on current research approaches, target audiences, and employed methods and techniques to efficiently use recommender systems, digital nudges, or a combination of both for overweight and obesity prevention.

Study Aims and Objectives

This paper addresses the gaps in mapping how digital nudges and recommender systems are currently used in research to target overweight and obesity by addressing nutrition, PA, and SB reduction.

The detailed objectives of this scoping review are as follows:

1. To identify digital nudges or recommender systems for overweight and obesity prevention that target diet, PA promotion, or SB reduction.
2. To map the digital nudges and recommender systems according to the target population, health behavior (diet, PA, or SB), and system classification (eg, mechanisms for developing recommendations, delivery channels, personalization, interconnection, and used combinations).

In doing so, our goal is to identify the current state of research, identify gaps, and identify the next steps in research. By understanding these gaps, researchers can better identify what needs to be addressed in the next steps and help avoid repeating approaches.

Methods

Study Design, Protocol, and Registration

A detailed description of the methods for this scoping review was previously published [37], and this scoping review follows the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [38]. We chose a scoping review because it allows us to map the key concepts and gaps within the area of interest. The work on this study began in July 2023, and the database searches were conducted in October 2023. Screening and study selection were conducted from October 2023 to March 2024, data extraction from April to October 2024, and data synthesis from November 2024 to February 2025.

Ethical Considerations

No ethical approval was required for this review, as the data were obtained from publicly available materials.

Eligibility

The eligibility criteria were based on the PCC (Population, Concept, Context) framework [39]. We included primary studies of any design (randomized or nonrandomized, with quantitative or qualitative data) (Table 1). We excluded all articles that tested the system using hypothetical or predefined datasets, focusing only on studies that tested it on a real-world sample.

Table . Eligibility for inclusion in the scoping review.

PCC[a]	Inclusion criteria	Exclusion criteria
Population	Any human population groups (children or adults; healthy, at risk for chronic diseases, or clinical samples)	Studies that do not test the systems or nudges with humans, and studies that only use hypothetical or predefined datasets.
Concept	Digital nudges or recommender systems (stated in the title, abstract, or full text of a study)	Digital nudges or recommender systems not used, or studies that use digital nudges or rely on recommender systems but do not name them in the title, abstract, or full text
Context	Any geographical setting; overweight and obesity prevention (eg, nutrition, food recipes, grocery stores, meal preparation, PA[b] promotion, SB[c] prevention)	Digital nudges or recommender systems used in fields, such as blockchain, finance, security, privacy, agriculture, service, and e-commerce rather than for overweight and obesity prevention

[a]PCC: Population, Concept, Context.

[b]PA: physical activity.

[c]SB: sedentary behavior.

As PA and SB are not opposites but complementary, we included studies targeting PA and SB. PA is defined as any bodily movement generated by skeletal muscle contraction that increases energy expenditure above the resting metabolic rate and is characterized by its modality, frequency, intensity, duration, and context of practice [40]. In contrast, SB includes any waking behaviors characterized by an energy expenditure of ≤1.5 metabolic equivalents while in a sitting, reclining, or lying posture [41]. In general, this means that one can be both physically active (eg, meeting the WHO recommendations for PA) and highly sedentary (eg, accumulating a high amount of sitting time), which significantly influences the choice of intervention elements to be utilized, depending on the targeted specific behavior [42].

Information Sources and Search Strategy

The search strategy was developed with the assistance of an information specialist, in collaboration with the involved experts (coauthors). We utilized the Joanna Briggs Institute (JBI) 3-step approach [43] to formulate the search strategy using keywords as well as index and MeSH terms [44]. The seven databases searched until October 2023 were MEDLINE and PsycINFO via Ovid, Web of Science, CINAHL via EBSCO, Scopus, ACM Digital Library, and IEEE Xplore. The full search strategy for Medline can be found in Multimedia Appendix 1.

Study Selection

Two reviewers independently screened the records using predefined eligibility criteria based on the PCC framework (Table 1) in a 2-stage process. Titles and abstracts were screened in Rayyan, followed by a full-text screening in Covidence. Any disagreements were resolved through discussion at each stage between the 2 reviewers or through the involvement of a third reviewer.

Data Charting and Data Items

A team of reviewers performed data extraction using a standardized, self-developed, and pilot-tested extraction form. After extraction, one researcher (SF) processed the data into predefined categories and verified the coding with a second team member (Table 2).

XSL•FO
RenderX

Table . Predefined categories.

Code	Operationalization	Explanation
Country/region	• Country: as indicated in the publication, if not indicated in the publication, the country of the first author's affiliation	• High-income, upper-middle-income, lower-middle-income, and lower-income countries based on the World Bank country classifications by income level (2022 - 2023)
Recommender system classification [45]	• Methods: approach that the recommender system uses to perform the retrieval of items [6]	• Content-based filtering, where recommendations are made by identifying items similar to those previously liked by the user or other users with similar profiles [46,47]. • Collaborative filtering, which relies on similarities between users to recommend items based on the preferences of other users with similar profiles [48]. • Hybrid recommendation combines multiple techniques to overcome the limitations of single approaches [45]. An example is the deep learning approach to item retrieval in recommender systems that refer to the application of deep neural networks (deep learning) to filter relevant items (eg, products, films, songs) for a user from a vast pool of options. Deep learning is used in this context to uncover complex patterns within data, thereby enabling more precise and personalized recommendations. • Knowledge-based recommendation is another approach based on user preferences and constraints [35]. Collecting the preferences of a user (preference elicitation) within the scope of a dialogue and then recommending items either (1) based on a predefined set of recommendation rules (constraints) or (2) using similarity metrics that help to identify items which are similar to the preferences of the user [35]. • Evolutionary approaches rely on optimization algorithms inspired by natural evolution to retrieve or rank items. These approaches are beneficial when the search space for items is vast, and the system needs to explore a variety of combinations to find the most optimal recommendations.
	• Techniques	• How the relationships between items are computed (eg, Rasch-tailoring, TOPIs[a], conversational agent, iALS[b] algorithm) [6].
Age	• Children (0 - 14), • 15 - 17, 18 - 40, 40 - 65, adults (18-65), ≥60, older adults (≥65), adults (18-65) and older adults (≥65), not reported	• Where possible, the mean age was used to report age data. If the mean age was not provided, age ranges were used, and the target group was assigned accordingly based on these age ranges.
Outcome	• Positive: only positive results are reported • Negative: only negative results are reported • Mixed: positive and negative results are reported • No difference	• A qualitative assessment of the results was chosen to consolidate the extremely varied reporting of outcomes (such as significance levels, descriptive statistics, content analyses, and log data).

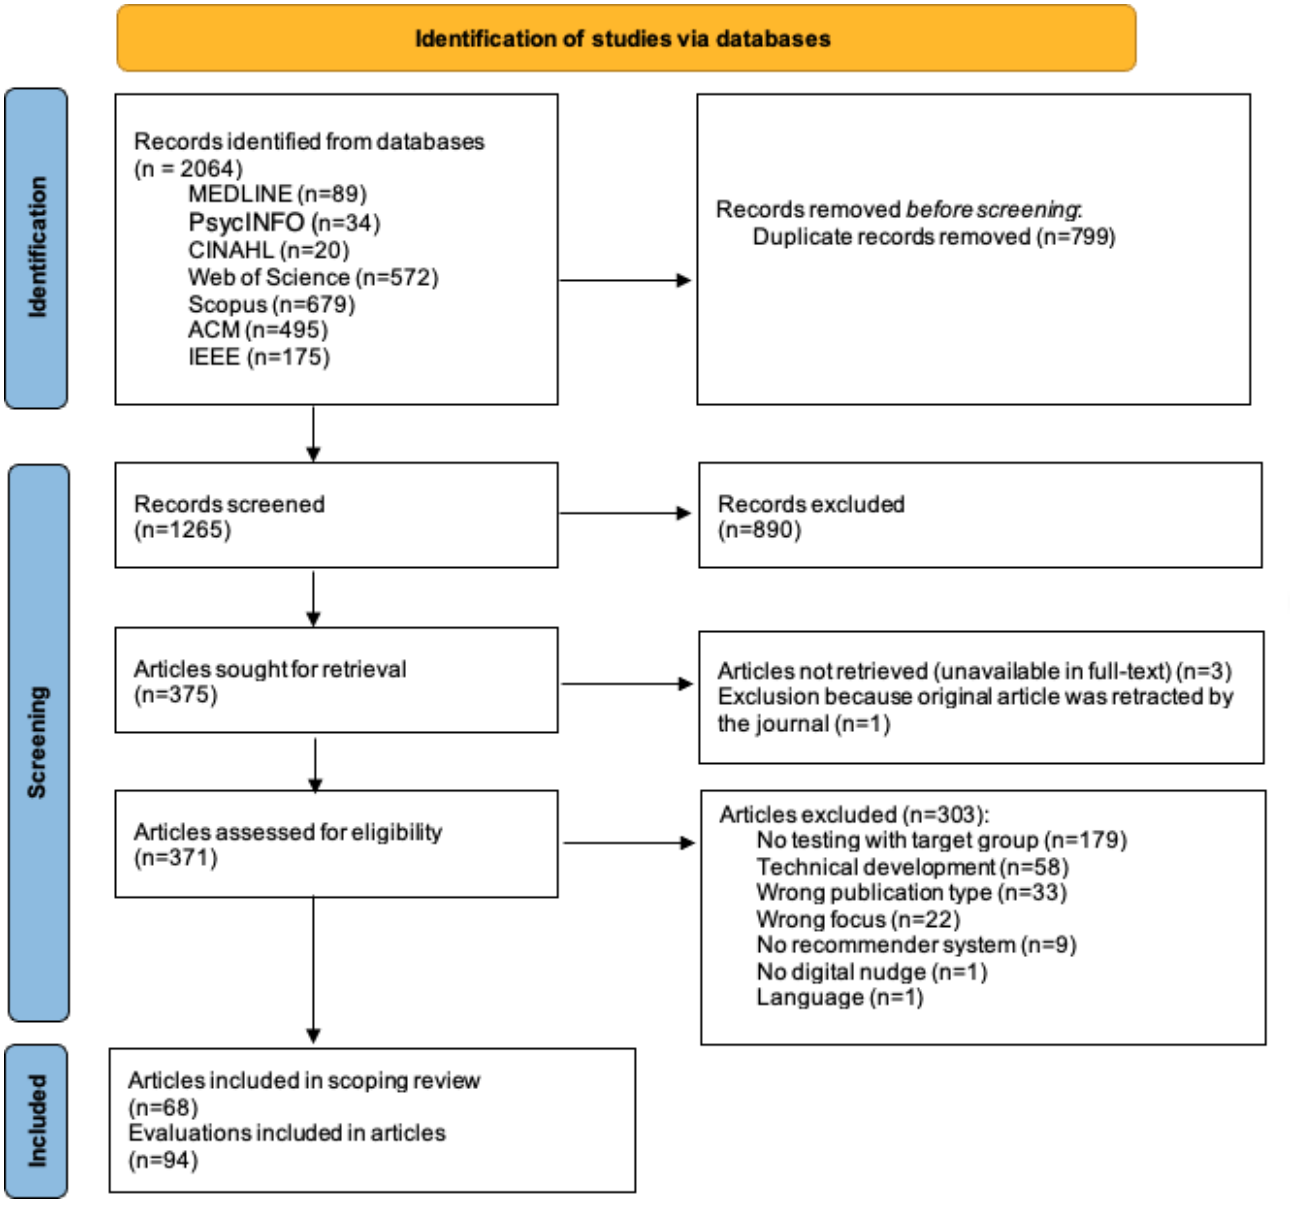
Critical Appraisal

No evidence appraisal was conducted. In a scoping review, the primary aim is to map the existing literature and provide an overview of the breadth and scope of research on a particular topic rather than to assess the quality of the evidence. This type of review typically includes a wide range of studies, often without applying strict inclusion criteria related to methodological rigor. As a result, scoping reviews do not appraise evidence quality, focusing instead on identifying and categorizing available evidence.

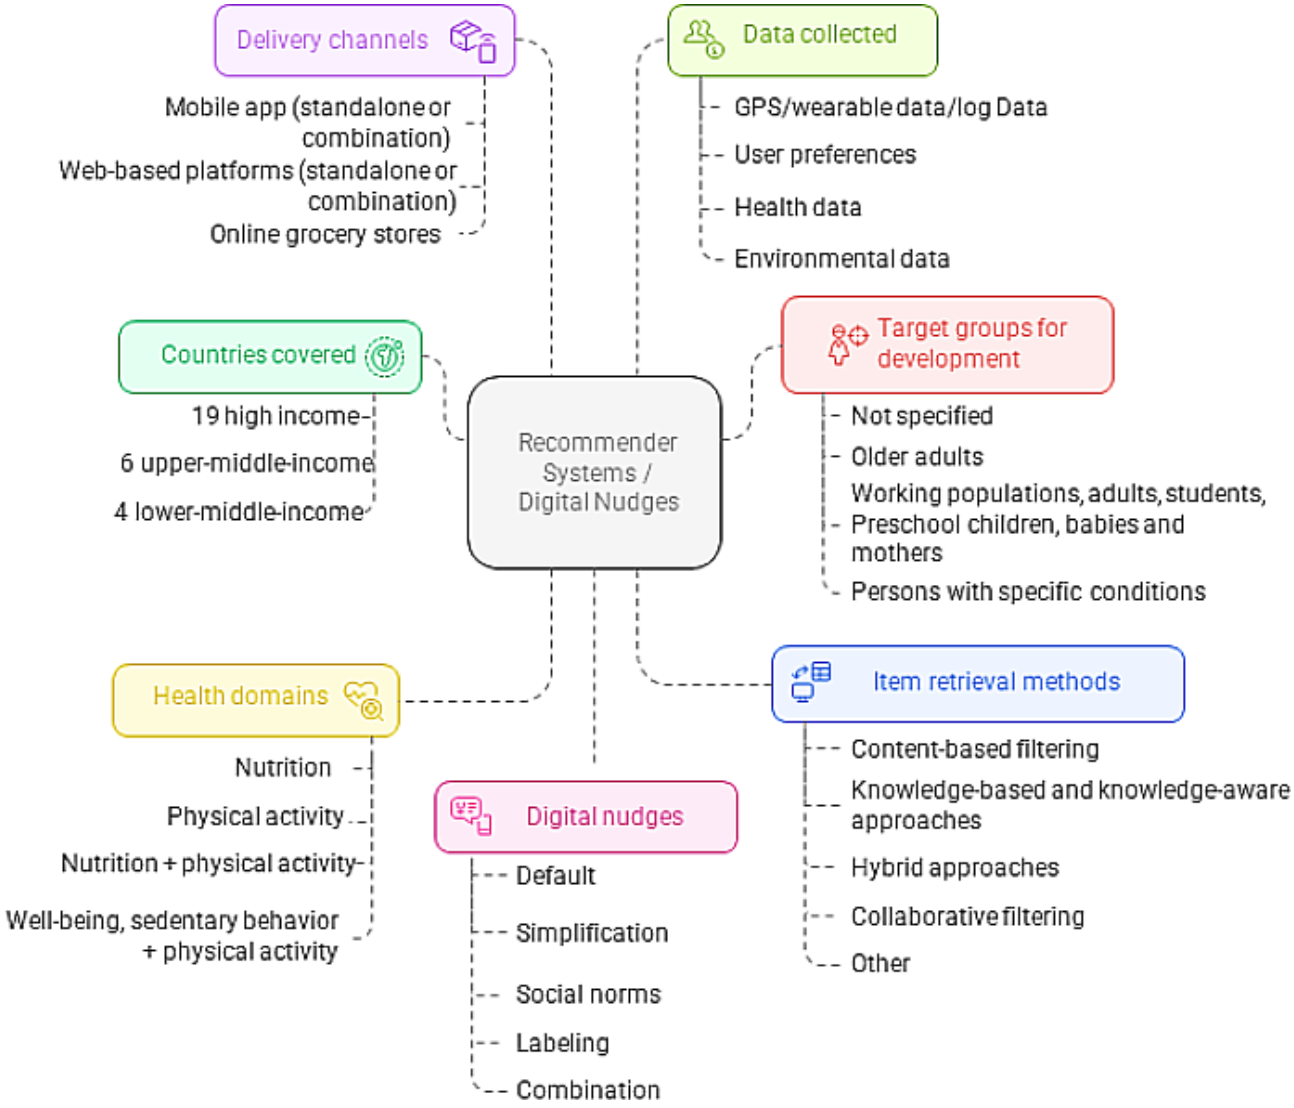
Overlap of Primary Studies Included in This Review and Other Reviews With Systematic Methodology



In addition to this scoping review of primary studies, we conducted a second scoping review of reviews identified in our search [49]. The scoping review of reviews included 10 reviews (n=8 systematic reviews and n=2 scoping reviews). The reviews addressed recommender systems for any human populations (n=6), described the systems (n=8), and focused on nutrition (n=6). The overlap between the primary studies included in the 10 reviews and those in this review was low. Specifically, of the 308 primary studies included in the 10 reviews, 10 primary studies were included in this scoping review.

Results

Characteristics of Included Studies



Of the 2064 records identified, 375 full-text articles were reviewed, and 68 articles covering 94 user evaluations were included (Figure 1). A detailed overview of the included studies is provided in Multimedia Appendix 2. Figure 2 provides an overview of the results.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

XSL•FO
RenderX

Figure 2. Overview of the results: study characteristics, behaviors addressed, item retrieval methods, and digital nudges used.

Countries or Regions

Based on the World Bank's country classifications by income level (2022 - 2023), the articles were published from 19 high-income countries (65%), 6 upper-middle-income countries (21%), and 4 lower-middle-income countries (14%). The United States was the most represented among the high-income countries [50-58], followed by Germany and the Netherlands [59-73], Belgium [74-79], Italy [80-84], and Portugal [85-88].

The study overview table in Multimedia Appendix 2 provides a detailed overview of the countries and regions covered, as well as the study characteristics.

Target Population Addressed for Whom the Digital Nudges or Recommender Systems Were Intended

Among the 68 articles, the majority did not specify the target group for which the digital nudges or recommender systems were intended (52/68, 76%). For those mentioning a target population, older adults (≥65 y) were the most frequently mentioned group (3/68, 4%, Table 3) [86-88]. All other target groups, such as mothers with babies [89], students [71], and persons with specific conditions, were each addressed once (Table 3). The addressed conditions in the articles included diabetes (2/68, 3%) [90,91], congenital [70] and coronary heart disease [57], and hypertensive patients [92] (except for diabetes, each mentioned once).

Coronary heart disease patients	1	[57]
Patients with congenital heart disease	1	[70]
Insufficiently active people	1	[75]

[a]Not applicable.

Behaviors Addressed by the Digital Nudges and Recommender Systems

The articles predominantly focused on dietary behaviors, with 54 out of 68 (79%) articles covering nutrition. PA was addressed in 22 out of 68 (32%) articles. One article explicitly included SB, in combination with PA and mental health [94]. Fifteen out of 68 (22%) articles reported on PA.

Eight out of 68 (12%) articles explored nutrition and PA together [53,56,85,93,96-99] (Table 4).

System Characteristics (Recommender Systems, Nudges, Personalization, Interconnection, Delivery Channels)

Fifty-two out of 68 (76%) articles reported on recommender systems, 11 out of 68 (16%) articles focused on nudges [55,59,65,69-71,73,77,94,108,114] and 2 out of 68 (3%) articles discussed a combined system incorporating both a recommender system and a nudge [63,110]. Additionally, 3 out of 68 (4%) articles explored recommender systems in combination with games [60,93,95]. An overview of the characteristics can be found in Figure 3.

Figure 3. Characteristics: comparison between recommender systems and digital nudges. PA: physical activity.

Recommender Systems

In the category of recommender systems (52/68, 76%), 36 out of 68 (53%) articles addressed recommender systems targeting nutrition (meal choice: 22/68, 32%; macronutrient composition: 11/68, 16%; shopping: 3/68, 4%). Additionally, 16 out of 68 (23%) articles reported recommender systems used to increase PA, 10 out of 68 (15%) articles purely targeting PA, and 5 out of 68 (7%) articles examined a combination of nutrition and PA, with 1 article also incorporating sleep behavior.

The approaches used by the recommender system to perform the retrieval of items [6] were collaborative filtering (2/68, 3%) [62,100], knowledge-based and knowledge-aware approaches (5/68, 7%) [64,67,84,89,90], content-based filtering (6/68, 9%) [64,66,79,87,92,105], hybrid approaches (6/68, 9%) [83,95,102,103,113,117], as well as, for example, deep-learning-based [107] and evolutionary [96] approaches (1/68 each) (definitions: Table 2) and various combinations of the systems. In 22 out of 68 (32%) articles, the methods used within the recommender systems were not further specified. In another 9 out of 68 (13%) articles, while the recommender system itself was not clearly defined, the accompanying techniques used were described, including rule-based reasoning, conversational agents, artificial intelligence (AI)–based personalization, or Rasch-based tailoring.

XSL•FO
RenderX

Digital Nudges

Within the nudge category (11/68, 16%), 4 articles focused on shopping behavior [55,59,77,114], and 3 out of 68 (4%) articles addressed meal choice [65,69,108]. One article focused on addressing macronutrient composition [73]. Additionally, 3 out of 68 (4%) articles targeted PA [70,71,94], with 1 placing PA within a broader context, including SB and physical and mental health [94].

In articles reporting on digital nudges targeting nutrition behavior, various nudges were tested: default rules (eg, automatic assignment to a category, default setting of the food group, or recipe class), simplification (eg, simplified representation using images, pictograms, or the display of labels), and social norms (information on the behavior of what most people have done) [59]; the combined use of scores such as Nutri-Score and Eco-Score (graphics) and social norms [77]; social norms alone [55]; ranking and personalization [65]; or a combination of different approaches (defaults, social norms, warnings, defaults, and social cues) [114]. Combinations of salience (stimuli that capture the attention and influence decision-making, such as attractive or unattractive looking unhealthy food products), transparency (adding a message about what the nudge is intended to do), self-nudging (giving individuals the opportunity to adjust the nudge according to their preferences or decide whether they want it to be instantiated) [69], social norms, hedonic goal nudges and positional nudges [108], and attentional bias [73] were also explored.

In the context of PA studies, the digital nudges tested included providing information [70] and motivational prompts [71].

Personalization and Interconnection

Forty-one out of 52 (79%) recommender articles reported using participant information for system personalization including partial personalization (eg, preferences, likes, GPS, health data, wearable data, survey data). Questionnaires for user preferences were commonly used, with some studies also incorporating wearable data for partial or full personalization. However, the descriptions were insufficient to clearly distinguish between partial personalization (where a study gathers user data—such as location, demographics, or user actions—to infer the potential influence of the nudge/recommender system on user behavior) and full personalization (where information is used to personalize the choice architecture of individual users dynamically).

None of the studies reported using this information to influence how information from other users affects the analyzed user behavior (partial interconnection). Similarly, none of the studies provided information on how the actions of one user, in turn, dynamically modify the choice architecture of other users (full interconnection).

Delivery Channels

Nineteen out of 68 (28%) articles did not provide information on the mode of delivery or the devices used to access the systems. Of these, 14 out of 68 (21%) were recommender system studies and 5 out of 68 (7%) were digital nudge studies. The most commonly reported delivery method was through a mobile app (27/68, 40%), either as a stand-alone application or in combination with a desktop application, a wearable, or a game. Web-based platforms, either as a standalone approach or in combination with an app, were reported in 11 out of 68 (16%) articles [50,55,68,79,84,102-104,106,111,114,118]. Online grocery stores were used in 3 out of 68 (4%) studies [59,69,77]. One study did not fit into these categories because it was conducted in fast-food restaurants using online menu boards [108].

Evaluations Reported

Population on Which the Digital Nudges/Recommender Systems Were Tested

In the 68 included papers, 94 evaluations were reported. Most systems were evaluated with individuals aged 18 to 40 years (28/94, 26%), followed by adults aged 18 to 65 years (17/94, 18%). Further evaluation groups included combinations of adults aged 18 to 65 years and ≥60, 18 to 65 and ≥65, 18 to 40 and ≥65, and 40 to 65 years (altogether 12/94, 13%). Other individuals included were those aged 15 to 17 years, alone and in combination with other age groups (2/94, 2%), and those aged 0 to 14 years (2/94, 2%). In 23 out of 94 (24%) evaluations, the age range of the evaluation group was not reported. Furthermore, 53 out of 94 (78%) evaluations reported the gender of the evaluation group, with 51 (54%) reporting mixed gender and 2 (2%) reporting exclusively on women [89,93].

The sample sizes used for the evaluation varied substantially (Table 5). In 5 evaluations, no sample size was provided.

XSL•FO

[a]Some articles contain several evaluations.

[b]RS: recommender system.

[c]PA: physical activity.

[d]Not available.

Twenty-five out of 94 (27%) evaluations reported intervention time. The shortest intervention time reported was 7 days [92,97], while the longest was 3 years [95].

Twenty-five out of 94 (27%) evaluations reported an evaluation design. These designs included randomized controlled trials (7/94, 7%) [53,69-71,75,77,94], 2×2 between-subject designs (4/94, 4%) [62-64,104], online experiments (4/94, 4%) [55,59,73,109], single-case experiments [56], 2×2 mixed research designs [64,72], and quasi-experimental designs [57] (2/94, 2% each). Further designs were, for example, pre-post surveys [50], field experiments [59], longitudinal between-subject designs [76], effect differences between groups and within subjects [66], and 2×2 within-subject experiments [65].

The instruments used for evaluation ranged from questionnaires [51,67,81,87-89,95] and online surveys [60,78,91,96,110,113], focus groups [78], and ratings [61,82,84,95] to combinations of these methods with task performance, observations, gameplay monitoring, or user data.

Evaluation Results

This scoping review includes 94 evaluations, of which 68 report positive results. There are 26 studies with mixed, negative, or no-difference results. In the domain of recommender systems related to nutrition, there were 8 studies with mixed results [45,67,79,84,87,89,92,109], 3 with negative outcomes [61] (2 evaluations in [64]), and 1 showing no difference [52], totaling 12 studies. For recommender systems targeting PA, 4 studies reported mixed outcomes [54,68,76,116]. In the case of recommender systems combined with nudges, 1 study reported mixed results [110]. Two studies reported mixed outcomes when combining recommender systems and games [60,95]. Studies involving nudges showed mixed results across 7 evaluations [55,59,70,77,94,108,118], with 1 showing no difference [71]. It is important to note that further comparison is not feasible due to the extreme heterogeneity of approaches, methods used, outcomes, and research questions, ranging from, for example, user and system evaluation, user satisfaction evaluation, system or chat performance, choice satisfaction, plausibility tests, or intervention validations across these studies (Multimedia Appendix 2).

Discussion

Principal Findings

Recommender systems help users avoid information overload and aid in decision-making by using filtering techniques to suggest relevant content. These systems typically present users with a curated list of items tailored to their preferences or needs, simplifying the process of finding and evaluating relevant information. By doing so, they streamline decision-making and make information searching more efficient [10]. These approaches can be classified as nudges, allowing recommender systems to be grouped under the category of digital nudges. This scoping review aimed to identify digital nudges or recommender systems for overweight and obesity prevention targeting diet, PA promotion, or SB reduction and to map the

XSL•FO
RenderX

digital nudges and recommender systems according to the target population, health behavior (diet, PA, or SB), and system classification (eg, mechanisms for developing recommendations, delivery channels, personalization, interconnection, and used combinations).

Recommender systems identified in this work predominantly focused on dietary behavior, with less emphasis on promoting PA. Additionally, the studies found that reporting on digital nudges primarily focused on nutrition, influencing shopping behavior and meal choices. Other health behaviors, such as PA and SB, are rarely reported. Only one study reported a combination of recommender systems and nudges. With this overview, the scoping review aligns with other reviews that reported that, in health promotion, the combination of recommender systems and nudges is underused. Jesse and Jannach [7] identified 9 domains in 18 articles that combined digital nudges and recommender systems. The domains were route planning, e-commerce, internet services, and social media, with route planning and e-commerce being the most popular ones.

This scoping review underscores the imbalance in the geographical distribution of research on recommender systems and digital nudges aimed at tackling overweight and obesity prevention [13]. High-income countries dominate the field, with the United States, Germany, the Netherlands, Belgium, Italy, and Portugal among the most represented. This distribution indicates that most research is focused in already technologically advanced regions, leaving middle- and low-income countries underrepresented. This discrepancy reflects broader socioeconomic disparities, including access to funding, infrastructure, and technology necessary to conduct such research. Expanding research efforts to include middle- and low-income countries would help to understand how digital interventions function across diverse socioeconomic contexts. Such inclusivity is crucial, as health behaviors such as diet and PA are global concerns, and solutions tailored to high-income settings may not be as effective in other contexts. In addition, overweight and obesity rates are high in many low- and middle-income countries [17]. A focus on a few countries hinders the adaptation of the identified digital nudges and recommender systems to other cultural, normative, and geographical contexts, thereby limiting the generalizability of the findings [1].

Regarding the second objective—classifying these systems based on the target population, behavior, personalization, and delivery—it was found that all recommender systems reported in the scoping review offered personalized recommendations. In this context, the findings of the scoping review differ from those reported in the literature. Bondevik et al [1], in their review of food recommender systems, state that 50.7% of the included recommender systems are not personalized. This discrepancy may be attributed to the slightly different scope of the scoping review. The present review only includes studies that explicitly evaluated the systems on users, which may result in a higher rate of personalization.

While many articles on recommender systems focus primarily on technical features [1,2,28,36], a central challenge identified in this scoping review is the lack of a clear and consistent definition of recommender systems, particularly in their application to health behaviors. Defining what constitutes an "actual system" can be ambiguous. Many studies describe systems that support users in selecting from a large pool of options without explicitly naming the system's mechanisms for item retrieval. This difficulty in identifying recommender systems stems from insufficient descriptions in the literature, limiting the reproducibility and understanding of how these systems function. Future research should aim for more transparent reporting, providing clear system descriptions and code access [1]. This would also enable research to transition the tested systems into user studies—a gap also identified in this work. Currently, systems are developed and evaluated for accuracy, user-friendliness, and applicability [1,2]. However, real-world intervention and implementation evaluation with repeated measurement over a longer time and larger sample sizes are needed [2]. Also, studies testing the same recommender systems in different target groups are missing. Both would increase the generalizability of the results. This is consistent with the result that 54 articles did not mention the intended target group. The evaluations, however, were reported very heterogeneously, often with small sample sizes of adults (18-65) or younger persons (18-40). Further studies are needed to combine explicitly and test recommender systems and nudging interventions in robust user studies (including trials, mixed methods approaches, and interdisciplinary research) to identify approaches with the potential for a long-term positive impact also requested by El Majjodi et al [119].

Despite the potential for digital nudges to enhance adherence to recommender systems, this scoping review reveals that many systems fail to capitalize fully on nudges, which aligns with Jesse et al [7], who reported that 69 of 87 nudging mechanisms identified in the literature have not yet been tested. Visualizations of behaviors, such as calorie consumption or activity levels, are commonly used; however, they are often disconnected from established nudging strategies. More explicitly, integrating nudges into these systems allows users to be more effectively influenced toward healthier behaviors. For instance, intuitive graphics, personalized comparisons, and progress summaries can serve as subtle nudges that reinforce positive behavior change. However, these approaches often lack a connection to digital nudging research [7,120]. By leveraging these approaches more purposefully within design feedback tools, these systems could achieve greater user engagement and more impactful behavior change [121]. Future research should focus on developing methods that incorporate these insights to maximize the impact of recommender systems in health interventions. Furthermore, beyond health behaviors, recommender systems have a broad potential to contribute to sustainability and well-being goals, as noted in recent studies [122,123]. For example, recommender systems could help optimize energy consumption in light of sustainability and environmentally friendly lifestyle choices [124,125]. More research is needed to harness this potential to fully integrate behavioral insights into recommender systems and increase the selection share of sustainable and healthy items and to support behavior [126-129]. This must be accompanied by qualitative research addressing accessibility questions, balance (eg, healthy

XSL•FO
RenderX

choices vs occasional indulgences), when the systems become intrusive, and how to balance taste preferences with health and environmental considerations—this may require perhaps options to preselect the main foci. El Majjodi et al [110] highlighted a crucial point that has often been overlooked in many system developments: the inherent capacity of these systems to learn. This could result in learning effects that deviate in undesirable directions. For example, systems might learn users' tastes and recipe preferences, which, over time, may no longer align with healthy options. As the systems evolve based on the prioritization of past preferences, their parameters shift accordingly. Currently, there is no research or discussion on how such developments are monitored or compared against the initial preferences entered by users and what the user accepts.

Traditional evaluations of recommender systems have primarily focused on prediction quality and user satisfaction, utilizing a combination of online and offline evaluations, as also found in the included studies [1]. However, as Atas et al [130,131] point out, there are other critical dimensions to consider, such as how users perceive the recommended items or the visibility of certain items in recommendation lists. Atas et al [130] argue that preferences are unstable and subject to change during the recommendation process. These factors directly influence user behavior and the effectiveness of the systems in guiding healthier choices. Future evaluations should adopt a more holistic approach that includes these additional metrics, ensuring that recommender systems are accurate and effective in shaping user behavior toward positive outcomes.

Implications for Research

This paper presents the current state of research on digital nudges and recommender systems for obesity prevention, highlighting important gaps in evidence and practice. While both approaches might be effective, the current evidence is mixed. Provided that methodology and evaluation standards are harmonized, and stronger interdisciplinary collaboration between intervention experts, user experience scientists, ethicists, and implementation researchers is established, these technologies can be applied in a more targeted and sustainable manner. This would also enable comparative effectiveness trials to provide stronger evidence on the effectiveness of these approaches in this field. Knowing about these gaps is crucial because it enables researchers to target their efforts where they can make the greatest impact and helps avoid repeating ineffective approaches or overlooking promising new directions. This scoping review identified various points that should be targeted in the future:

First, there is a pressing need to harmonize the definitions of recommender systems, interventions, digital nudges, and evaluation methodologies used in obesity prevention research. Clearer definitions and standards for system properties, targets, and evaluation foci will make studies more comparable and cumulative [126,132].

Second, advancing this field will require genuine interdisciplinarity, integrating research and expertise from intervention development, user experience (UX) science, ethics and data governance, implementation, and behavioral science. The collaboration can enhance the design and effectiveness of digital nudges and recommender systems and ensure that interventions are contextually appropriate, user-centered, and scalable in real-world settings. Combining intervention development and UX research addresses usability, engagement, satisfaction, and adaptation of systems for diverse populations based on rigorous behavioral theory and empirical testing. Implementation science frameworks help to evaluate how well these interventions are adopted, reach their intended audiences, and sustain their impact beyond pilot trials. Insights from behavioral science, such as optimal design, timing, and frequency of triggers, reminders, labels, and nudges, are indispensable for the technical aspects. By systematically connecting these disciplines, future research can address not only technological and efficacy questions but also barriers to adoption, ethical data use, and the real-world conditions necessary for population-level obesity prevention [132].

Third, current systems frequently use static user preferences but rarely leverage the learning capability and dynamic adjustment demonstrated in commercial products. Real-time personalization, adaptation, and interconnection among users remain underutilized in research interventions, though they are increasingly utilized commercially. A critical discussion must also address how commercial products that already integrate these advanced features could be leveraged for research purposes without compromising personal data ownership, trust, transparency, and adherence to ethical standards. Balancing the use of commercially developed technologies with robust protections for user privacy and data governance is crucial to maintaining public trust and meeting high ethical standards in health research and intervention.

Fourth, data governance, privacy, and user ownership of data were largely absent from the reviewed studies. Yet, these are central to building trust in future health technologies and ensuring ethical and legal compliance in the dissemination of expanded systems. This includes establishing clear standards and best practices for the transparent use of data, informed consent, secure data storage, and providing users with meaningful control over their personal information. Collaborations among ethicists, legal experts, technology developers, and end-users are essential to co-create solutions that foster trust, comply with evolving regulations, and enable responsible innovation and research. It is essential to highlight the positive aspects of the systems but also to address areas of risk, such as developers' underlying assumptions, backward learning, and echo chambers. Such discussions are rarely included in current work.

Fifth, the scoping review predominantly focused on individual-level interventions. However, individual prevention alone cannot realize its full potential without supportive environments and population-level policy frameworks that enable healthy choices and prevent weight gain at scale. Population-level approaches are essential because they create the social, economic, and physical contexts necessary for sustainable behavior change. Integrating individual-level digital interventions, such as nudges and recommender systems, within broader population health policy approaches might be a long-term goal. This integration requires developing and evaluating multilevel interventions that consider policy, environmental, community, and health care system factors

XSL•FO
RenderX

alongside personalized behavior change tools. By bridging individual and population approaches, research can better address the complex determinants of obesity and enable impactful, equitable prevention strategies at scale. This approach is a very complex one and needs, as a starting point, evidence-based and effective interventions.

Limitations

Several limitations emerged during this review. First, many studies were excluded because they did not test their recommender systems in real-world settings, focusing instead on hypothetical scenarios or predefined datasets. This exclusion limits the generalizability of the findings, as it is unclear how these systems would perform in practical applications. Additionally, we excluded studies that did not label their nudging approach as digital nudges. This decision likely led to the exclusion of some studies that might have been relevant to our analysis. For instance, studies focusing on shopping behaviors or the use of labels in online stores may have used digital nudging techniques or interventions in the digital environment but were not explicitly categorized as such. Consequently, these studies might have been overlooked in our scoping review. This limitation underscores the importance of how nudging interventions are described and classified in research, as it impacts the comprehensiveness of evaluations in the field. A potential limitation of our scoping review is the identification of SB within the broader context of PA. In our scoping review, we directly searched for SB to identify and include studies addressing SB. We only found one study that specifically addressed SB. While SB can be considered part of a continuum of movement behavior, some studies may have indirectly included it without explicitly mentioning or assessing it as a distinct factor. Many studies likely focused solely on moderate to vigorous PA and consequently overlooked SB, one of the continuum's extremities. This oversight is significant in light of ongoing debates regarding whether SB should be viewed as part of the movement behavior spectrum or as a separate entity [41,133]. Many publications fail to address SB independently, which can lead to a lack of emphasis on understanding its uniqueness and implications. Therefore, future research should explicitly consider and differentiate SB from other forms of PA to ensure a comprehensive understanding of movement behaviors and their impacts.

Another limitation is that we did not conduct a formal quality assessment. Scoping reviews are designed to map the extent and nature of available research rather than critically appraise the quality of the evidence, as would be the focus of a systematic review. Given the significant heterogeneity in methodologies, outcomes, and study designs, applying a uniform quality appraisal would not have been feasible without the risk of oversimplifying the diverse research landscape. Consequently, while this scoping review highlights the breadth of existing literature and its current gaps, the lack of quality assessment may affect the generalizability of the findings.

In line with the nature of scoping reviews as outlined above, this scoping review aims to provide a comprehensive overview of the existing literature in a particular research area, without focusing on specific outcome effects. The diverse range of topics and breadth of evidence precluded a detailed methodological quality assessment, which, as stated, might not have been feasible or appropriate given the exploratory aims of this scoping review. The broad scope and diversity of included studies make it challenging to report effect sizes or significances, leading to a qualitative categorization of outcomes as positive, negative, or mixed. This categorization choice is aligned with the scoping review's objective to include studies presenting both qualitative and quantitative findings, further emphasizing potential limitations in generalizability and effect estimation. The primary focus remains on identifying key concepts and knowledge gaps rather than evaluating the effectiveness of specific interventions, thus necessitating caution when applying these findings to specific contexts or populations.

Additionally, the review revealed that many studies do not report essential system details, such as how they personalize recommendations or use user data, making it challenging to assess the full scope of their effectiveness. Future research should prioritize real-world testing and comprehensively describe system design, personalization, and interconnection mechanisms to enhance transparency and reproducibility.

A final consideration concerns the timing of our database search, which was completed in October 2023 and may, therefore, not fully reflect the most recent developments in the field, particularly regarding AI and machine learning. While generative AI and large language models have attracted increasing attention during this period, our search strategy focused on applications evaluated in human populations rather than on studies using predefined datasets. Consequently, some of the most recent innovations may not yet be represented among the studies identified. Future reviews could incorporate emerging research on generative AI and large language models to capture these dynamic developments more fully.

Conclusion

Combining digital nudges and recommender systems can play a crucial role in overweight and obesity prevention by encouraging healthier lifestyle choices and subtly, nonintrusively guiding users toward better nutrition, PA, and SB habits. However, their effectiveness and, in particular, which mechanisms may be helpful have not yet been fully explored. More details on definitions and mechanisms, as well as more inclusive geographical representation, intervention and implementation tests, and user evaluation studies, are essential for advancing the field. Previous research has often focused on individual-level interventions; however, for a tangible impact at the population level, integration into multilevel approaches, including policy and environmental strategies, is essential. The personalized, dynamic adjustment of nudges in combination with recommender systems, alongside assurances of data privacy and user trust, offers promising avenues for future investigation. This underlines that the contribution of this review is not merely descriptive but emphasizes the advancement of interdisciplinary methodology, evaluation frameworks, and scalability of digital interventions as critical priorities for ongoing research. By addressing these challenges, future studies can better harness the potential of these systems to improve health outcomes and contribute to broader goals such as sustainability and well-being.

Funding

This study was conducted within the HealthyW8 project, which was funded by a European Union grant from the European Health and Digital Executive Agency (HaDEA), project number 1010806. The funder did not influence the content of this study.

Authors' Contributions

SF conceptualized the study. SF, LAR, PVG, ALL, LM, KKDS, TDM, and TB developed the methodology and critically reviewed the manuscript. LC conducted the literature searches. SF, CS, TDM, JH, CL, CAO, and LM screened the studies. SF, CL, and CAO extracted and processed the data. SF analyzed the data, visualized the results, and wrote the first draft of the manuscript. All authors reviewed and edited the manuscript.

Abstract

Background: Aged care has recently undergone major transformations due to demographic aging and the concomitant need to manage health care costs. New emerging technologies (ETs) have started to play central roles in the daily management of older adults. For these transformations to effectively promote successful and active aging, it is essential to understand the opinions of older adults on the impact that technology can have on their vulnerabilities and aging process.

Objective: This work aims to study the ethically related impact of ETs on cognitively healthy older adults' vulnerabilities.

Methods: Using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, we conducted a systematic review of empirical (qualitative) evidence exploring the relationship between ETs and older adults' vulnerabilities as perceived by older adults (older than 65 years) without cognitive impairments. Five major databases (PubMed, Web of Science, Embase, CINAHL, and Philosopher's Index) were queried on March 1, 2022. After eliminating duplicates, titles, abstracts, and full texts were screened for relevance. Data analysis and synthesis followed the preparatory steps of the coding process detailed in the Qualitative Analysis Guide of Leuven methodology, which involved carefully reading the publications included, identifying significant themes, and constructing conceptual schemes for each paper. The quality of the publications was evaluated by using the Critical Appraisal Skills Program.

Results: A total of 11,631 results were obtained. Eventually, 70 articles were included, and of these, 46 articles had a high level of methodological quality. The remaining 24 articles had moderate quality. ETs appeared to have an ambivalent effect, mitigating some already existing vulnerabilities, and at the same time, worsening already existing vulnerabilities or creating new vulnerabilities. For example, unconventional monitoring techniques (eg, wearables) often mitigated relational vulnerability, helping to maintain independence and remain at home and in one's community. Conversely, these same devices may negatively affect moral vulnerability, threatening older adults' privacy linked to data confidentiality.

Conclusions: This systematic review, which focused on the perceptions of older adults without cognitive impairments, enriches the vast literature about the everyday management and care of seniors by exploring the ethical implications of ETs. This research is complementary to another systematic review of qualitative evidence, which analyzed the views of older people with cognitive disorders on the same topic. Although a certain ambivalence in the use of ETs was identified by both population groups, it is interesting how cognitively healthy older adults give more importance to some dimensions of vulnerability, such as the moral and relational ones, which, in the case of cognitively impaired older adults, are not as significant. Two important aspects identified were the respect of privacy and data security, and the perceived risk of control and surveillance linked to the use of monitoring technologies.

Introduction

Background

On December 14, 2020, the United Nations General Assembly declared 2021 - 2023 the decade of healthy aging [1]. Healthy aging, as described by the World Health Organization (WHO), aims to improve older adults' lives globally [2,3] by focusing on not only individuals' functional capacities and residual abilities but also the broader environmental context.

XSL•FO
RenderX

The world population is aging rapidly, with 9% of the global population being older than 64 years [4], and in Europe, 19% of people are older than 65 years [4]. By 2050, these figures will rise to 16% and 28%, respectively. This demographic shift reflects major improvements in public and individual health [5]. However, aging is often associated with increased vulnerability, frailty, psychophysical decline, reduced functional capacity and autonomy, and the onset of chronic conditions or major disabilities. These challenges require health care systems, communities, and individuals to adopt innovative tools and care models to ensure sustainability and long-term manageability [5].

In this context, technology has become a key resource, being increasingly pervasive in society and having a particular significance for aged care. Various terms, for example, AgeTech, ElderTech, SilverTech, and GeronTech [5,6], refer to the health-related industrial sector developing devices that support older adults and formal or informal caregivers. Many emerging technologies (ETs) have entered the market, defined as "radically novel and relatively fast-growing" technologies "characterized by a certain degree of coherence persisting over time and with the potential to exert a considerable impact on the socioeconomic domain(s)" [7]. Some examples considered in this work include wearables (smartwatches, smart bands, and emergency pendants), smart home technologies, assistive robots, and virtual reality [8]. Purely mechanical devices, such as ramps and rails, mobility aids like wheelchairs, and toilet modifications (shower chairs and bath seats), fall outside the scope of this work.

When used in aged care, these technologies are sometimes referred to as "welfare technologies" or "assistive technologies" [9]. Welfare technologies, a subgroup of ETs, can be applied across various social domains (health care, education, work, art, etc) and include technologies intended to enable older adults to remain at home, support independent living, compensate for staff shortages in health care sectors, reduce costs, and enhance self-reliance [9]. Similarly, assistive technologies promote individual functioning and social participation [10]. These technologies support not only healthy aging but also *active aging* [11,12], fostering patient engagement [13], empowerment, and shared decision-making in health care and self-management [14,15]. Such initiatives, by encouraging older adults to actively participate in their own care and preserve their physical, psychological, relational, and emotional capacities, may also reduce health care costs [8] and ease the burden on informal caregivers. Promoting active aging also supports a shift from reactive care to health promotion and disease prevention, aligned with a "salutogenic perspective" [16,17], which emphasizes individuals' holistic reflection on managing the vulnerabilities and stressors of old age and prioritizes well-being [12]. ETs can thus contribute substantially to *ageing-in-place* initiatives [5,18-22] and, for cognitively healthy older adults, to *successful aging* [21], which is understood as maintaining a life within one's own community [18].

As aged care evolves, the home may increasingly become the primary setting for care, delaying institutionalization and helping older adults in maintaining routines consistent with their identity. This transition is supported by ETs and do-it-yourself tools, that is, devices that can be managed autonomously by older adults themselves.

The growing integration of ETs in aged care has led to *gerontechnology*, which studies how advances in technology address older people's needs [23]. Substantial literature has since examined ETs conceptually and philosophically, focusing on their ethical implications in the everyday care of older adults [9,24-28]. Among them, some studies have also explored the perspectives of older adults and carers on the desirable features of ETs [29,30], and numerous quantitative and qualitative studies have analyzed the impact of ETs, especially the ethical challenges they raise [30-34]. Within this body of research, older adult populations are heterogeneous and often categorized based on cognitive functioning. Some studies have focused on individuals with cognitive impairments (eg, mild cognitive impairment, Alzheimer dementia, vascular dementia, Lewy body dementia, and frontotemporal lobar dementia) [35,36], while others have considered cognitively healthy older adults who remain relatively independent [37]. To ensure that transformations in aged care driven by the spread of ETs truly support the well-being and successful aging of all older adults, it is essential to understand how both population groups perceive the impact of ETs on their vulnerabilities and aging more broadly.

Working Hypothesis

To the best of our knowledge, no study currently provides a systematic overview of the qualitative evidence regarding the perceptions of older adults without cognitive impairments toward ETs in general (across all the different forms, from robots to monitoring technologies), their use, and their ethically related impact, particularly the relationship between ETs and older adults' vulnerabilities. The novelty of this work lies both in its systematic mapping of all available qualitative evidence in an aging population and its attention to the intersection between ETs and older adults' vulnerabilities, a narrow and largely undertheorized area within the broader bioethical debate.

Vulnerability in aged care has been analyzed in multiple facets [38]. Six key types of vulnerabilities have been identified: (1) physical vulnerability (PHV), referring to physiological and pathological bodily decline; (2) psychological vulnerability (PV), encompassing emotional, cognitive, and experiential factors affecting mental health; (3) relational or interpersonal vulnerability (RV), rooted in human ontological interdependence and dependence in real-life contexts; (4) moral vulnerability (MV), which positively fosters dignity, respect, and moral preferences, but may also lead to infantilization, depersonalization, and stigmatization if negatively interpreted; (5) sociocultural, political, and economic vulnerability (SPEV), caused by unfair situational factors; and (6) existential or spiritual vulnerability (ESV), relating to intrinsic existential and spiritual conditions that intensify with aging.

However, a gap remains regarding how ETs influence these vulnerabilities. Using these 6 dimensions of vulnerability as a reference and considering their potential interactions with ETs, this study aims to fill this literature gap by analyzing how ETs may affect older adults' vulnerabilities and by assessing their ethically related impact, understood as contents relating to

XSL•FO
RenderX

ethical issues within well-known ethical approaches (eg, principlism and relational care ethics) [39].

Methods

Systematic Review Procedure

We carried out a systematic review of qualitative evidence to gain a deeper understanding of the perceptions and experiences of older adults without cognitive impairments with respect to their vulnerabilities in relation to the use of ETs. Systematic reviews of qualitative evidence are methodologically rigorous reviews presenting an up-to-date, comprehensive overview of qualitative studies, that is, semistructured interviews, focus groups, and informal observations [40].

The analysis followed several steps. First, we formulated the research questions. Second, we conducted a systematic search of the literature, consisting of an electronic database search and a "snowballing" process. Third, we identified relevant publications on the basis of well-defined inclusion and exclusion criteria. Lastly, published research results, which met the inclusion criteria, were analyzed and synthesized, creating conceptual schemes in order to identify and define the ethical arguments in response to our research questions.

Research Questions

We formulated the following interrelated research questions:

1. What is the ethically related impact of ETs on cognitively healthy older adults' vulnerabilities?
2. What suggestions or strategies do cognitively healthy older adults provide for addressing vulnerabilities related to ETs?

Literature Search

We developed 3 groups of search terms that guided us in formulating the aforementioned research questions (Multimedia Appendix 1). Group 1 consisted of terms that refer to the type of participant, namely, cognitively healthy older adults. Group 2 consisted of terms that pertain to technology and more specifically to ETs. The terms reported in Groups 1 and 2 were identified on the basis of two previous works [8,41]. We used the expressions "social robots" and "assistive robots" (instead of "social and assistive robots") to intercept as many results as possible. Group 3 consisted of terms that refer to the concept of vulnerability or similar concepts (ie, frailty, fragility, frailness, acceptance, attitude, concerns, discomfort, distress, ethical issues, and ethics). Indeed, as already stated, when associated with the aging population, the concept of vulnerability has a specific connotation, represented in the 6 dimensions presented earlier in the text. However, since there may be some papers that refer, in the content of their reflections, to 1 of the 6 dimensions of vulnerability while nonetheless using a different framing or different expression to refer to it, other terms (eg, distress and discomfort) were added. The keywords "acceptance," "attitude," and "concerns" were used for similar reasons. In qualitative studies involving older adults, ethical issues are often not explicitly presented to participants during interviews, focus groups, or other types of approaches. At the most, these issues may be inferred from the broad questions posed to seniors, who are typically asked simpler questions about their adoption of ETs, their concerns, the perceived benefits and drawbacks, the usability, and similar topics.

The 3 groups of concepts were gathered and expressed according to the properties of each major database (Multimedia Appendix 2). The terms and the search strings were chosen and devised by the first author (AF) in consultation with the other authors (VS and CG). The following 5 electronic databases were queried: PubMed, Web of Science, Embase, CINAHL, and Philosopher's Index. These databases cover the literature in biomedicine, bioethics, philosophy, and (medical) anthropology.

Database queries were conducted on March 1, 2022, and studies not available in English were excluded. Multimedia Appendix 2 presents the number of results returned using the search terms. We used EndNote (version X9; Clarivate Analytics) reference library software to organize the citations of the identified papers, and duplicates were manually deleted.

Inclusion and Exclusion Criteria

For publications to be included in our systematic review and appraisal, they had to meet a predetermined set of inclusion and exclusion criteria (Multimedia Appendix 3). Screening of the articles was not limited by publication date.

As for the population under study, we included two categories of contributions in our selection of papers: (1) studies using standardized tests to assess cognitive function (eg, Mini Mental State Examination and Montreal Cognitive Assessment) and (2) studies that, while not using formal cognitive assessments, explicitly stated that participants were capable of understanding the study and providing informed consent. In these cases, participants were considered to be not only legally competent (ie, able to consent) but also cognitively competent, as explicitly stated or implied by the authors of selected contributions.

The first (AF) and last (VS) authors screened the titles, abstracts, and full texts of identified papers according to these criteria. The abstract screening was performed separately by the first (AF) and last (VS) authors to make sure that the selection criteria were applied consistently. For 87.3% (3077/3526) of the abstracts, the authors agreed on the items to be included or excluded. For questionable abstracts (449/3526, 12.7%), the first 2 authors (AF and MDL) discussed the candidate abstracts until an agreement was reached.

If the full text of an article was not available, the first author or corresponding author of that article was contacted via email to request a PDF copy. To ensure the search was exhaustive, the "snowball technique" was applied to the reference lists of eligible publications to identify additional potentially relevant publications. The search process was performed according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [42]. The PRISMA checklist is provided in Checklist 1.

All the included publications were from the qualitative research literature; thus, they provided insights on the concept of vulnerability and/or related concepts (ie, frailty, frailness, and fragility) in relation to ETs, as expressed by older adults without cognitive impairments during semistructured interviews or focus groups, or in other settings (eg, informal observations).

XSL•FO
RenderX

The final list of included publications and the descriptions of the characteristics of the included publications are presented in Multimedia Appendices 4 and 5, respectively.

Quality Appraisal

The quality of the included publications was evaluated by using the Critical Appraisal Skills Program (see the Methodological Quality section). The second author (MDL) assessed each full-text article and constantly discussed the assessments with the first author (AF), who also carefully read and assessed the full texts. When doubts arose, discussions were held until a consensus was reached. This appraisal tool allowed the identification of studies with a high, medium, or low methodological quality. None of the studies were excluded based on methodological quality, because after careful verification, they were all found to be sufficiently adequate.

Data Extraction and Synthesis

Procedure

For data extraction and synthesis, we decided to follow the 5 preparatory stages of the coding process detailed in the Qualitative Analysis Guide of Leuven (QUAGOL) [43]. In the first stage, the second author (MDL) thoroughly read and reread all the included publications to familiarize herself with the data and to identify the significant themes described. Ethically related content was identified based on themes and concepts present in a previously completed review of argument-based ethics literature [39] and those stemming from the relational care ethics approach as operationalized in the dignity-enhancing care model of bioethics [44]. In the second stage, the first (AF), second (MDL), and last (VS) authors developed a narrative summary of the highlighted parts. In the third stage, for each publication, a conceptual scheme was created. This scheme summarized the various concepts that are important to answer the research questions. An example of a conceptual scheme is illustrated in Multimedia Appendix 6. Each conceptual scheme was examined separately by the authors (AF, MDL, and VS) to verify that it corresponded to each selected publication. The authors discussed conceptual schemes until they agreed on adequate content. In the fourth stage, these individual conceptual schemes were compared to verify that the content of the conceptual schemes reflected the most important concepts to answer the research questions. All conceptual schemes were transformed into a global scheme that showed the ethics-related impact of ETs on the dimensions of aged care vulnerabilities (Multimedia Appendix 7), as gleaned from the perceptions and experiences of older adults. An iterative analysis and a check between this scheme and the previous stages of QUAGOL were conducted to ensure that the scheme was consistent with the included papers. In the last stage, as reported in this review, we prepared a description of the results.

Categories of ETs

The ETs used in the qualitative studies under review were organized in this work according to the categories proposed in a previous publication [8]. Conventional monitoring techniques (CMTs) are those technologies that rely on traditional devices, such as oximeters or blood pressure monitors, to continuously observe older adults' physiological and physical parameters and keep track of their condition through technological platforms [8,45-47]. On the other hand, unconventional monitoring techniques (UNMTs) introduce innovative technology components, such as body or environmental sensors, that allow more pervasive monitoring, and they comprise, for instance, smart home technologies or ambient intelligence [48,49]. Virtual reality techniques (VRTs) refer to headsets that create 3D environments in which older adults are "immersed" [50,51]. Finally, socially assistive robots (SARs) are robots that are able to interact with older adults and provide physical or cognitive assistance [52,53].

Conceptual Framework

In conducting data extraction and synthesis, we adopted a 2-fold strategy (top-down and bottom-up) to assess the ethically related impact of ETs on vulnerabilities. The top-down approach, a deductive and theory-driven method, helped guide and focus our research questions. The approach originally set out was relational care ethics, which emphasizes the moral significance of care relationships and human dependencies. This approach was operationalized in a dignity-enhancing model of care [44] where both dignity and vulnerability played central roles. We also relied on a framework of macro-themes and key issues derived from the relevant literature [8,24,26,39]. This interpretative lens, encompassing several sensitive ethical concerns, such as security, privacy, and autonomy, was applied, refined, and adapted to analyze the selected studies and to assess their ethical impact in relation to older adults' vulnerabilities.

The concept of vulnerability itself was informed by a recent systematic review of argument-based literature [38], which proposed a taxonomy we adopted to present ethically related findings. This allowed for a more analytical understanding of how ETs interact with both existing and potential vulnerabilities in cognitively healthy older adults.

The bottom-up approach relied on an inductive, data-driven method, seeking to infer underlying meaning directly from participants' words and expressions.

Results

General Descriptions of Included Publications

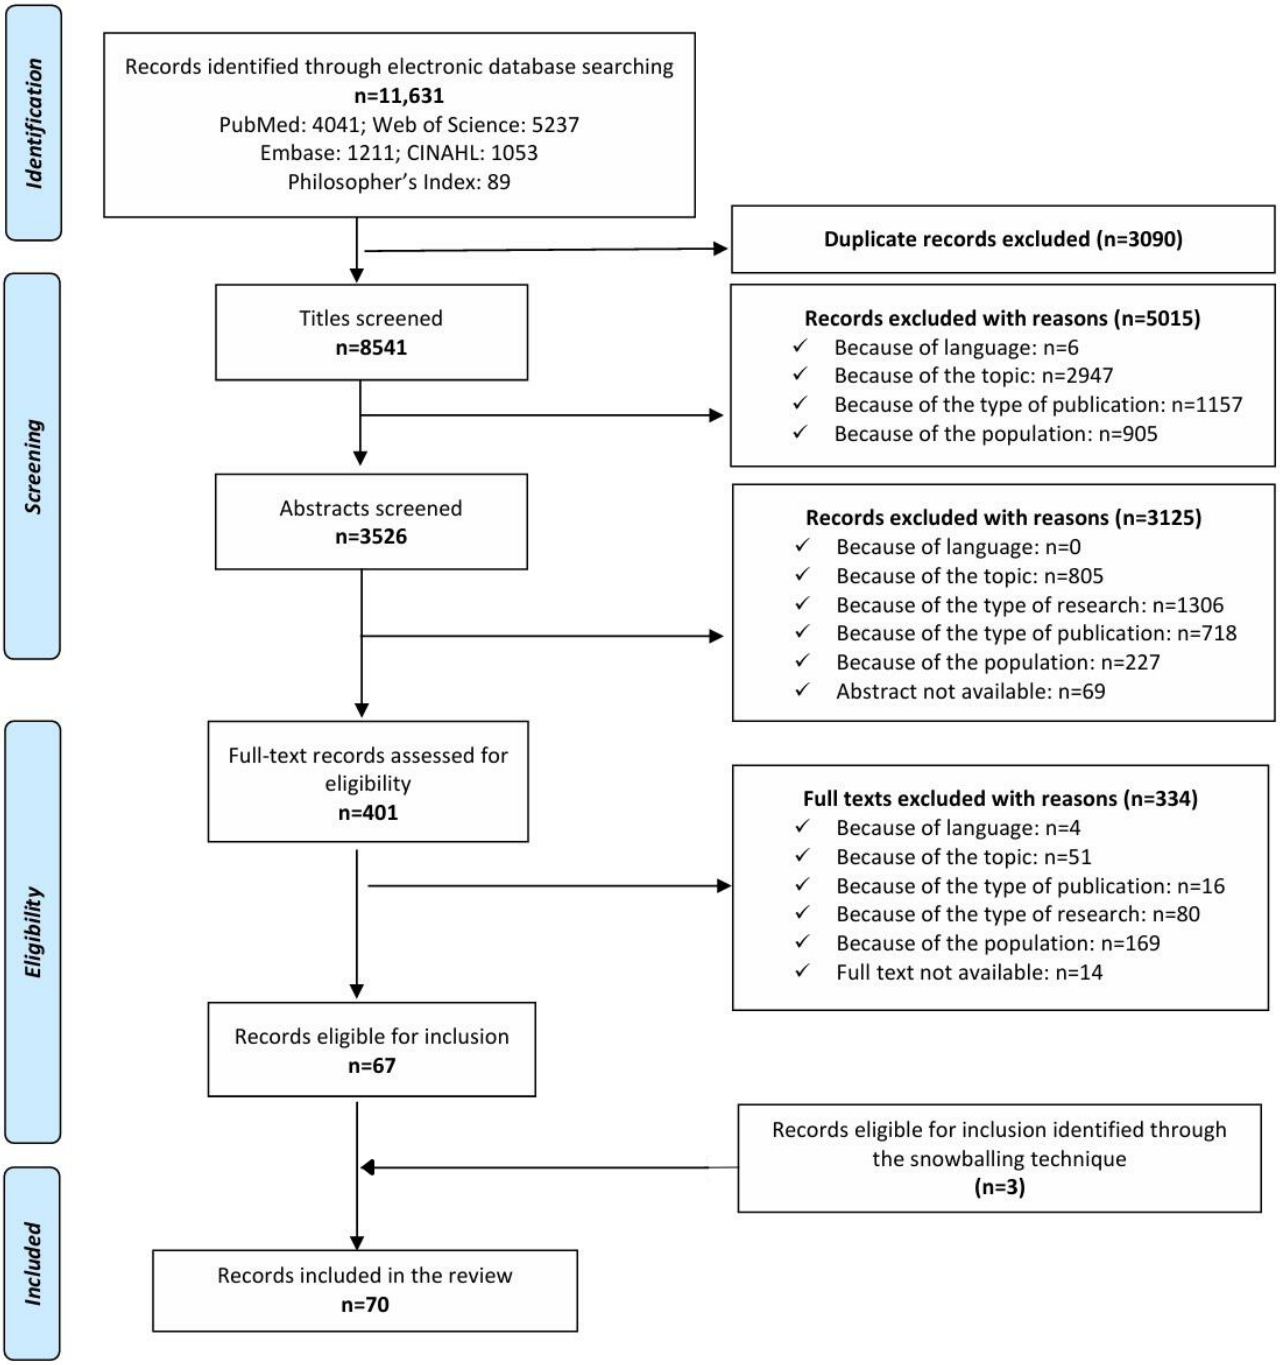
A total of 70 publications (Multimedia Appendix 4) met our inclusion criteria: 67 were identified from the research queries and 3 were identified through the snowball technique. For a detailed description of the general characteristics of the included papers, see Multimedia Appendix 5. The PRISMA flowchart is provided in Figure 1.

All the included publications were from the qualitative research literature; thus, they provided insights on the concept of vulnerability and/or related concepts (ie, frailty, frailness, and fragility) in relation to ETs (Multimedia Appendix 3), as expressed by older adults without cognitive impairments during semistructured interviews or focus groups and in other qualitative research settings (eg, informal observations) (Multimedia Appendix 5). With respect to the method used to obtain the qualitative data, 61 (87%) studies used semistructured or general interviews (38/70, 54%) or focus groups (23/70, 33%), and 5 (7%) studies used a combination of semistructured

XSL•FO
RenderX

interviews and focus groups. Other methods included observations (7/70, 10%), usually in combination with interviews or focus groups, and self-report diaries (1/70, 1%).

Publication years ranged from 2004 to 2022, with 53 (76%) articles published between 2015 and 2022. The Americas, Europe, Australia-Oceania, and Asia are represented in this systematic review, meaning that the included studies had first authors from all these different continents. However, most studies were conducted in Europe (36/70, 51%) and the Americas (22/70, 31%). Within Europe and the Americas, the authors' affiliations varied widely. For authors based in Europe, the affiliation for 16 (23%) publications was an institution in Britain or Sweden. For authors based in the Americas, the affiliation for 19 (27%) publications was an institution in the United States.



For inclusion in this review, papers had to involve older adults without cognitive impairments in the context of aged care. All the included papers featured older adults aged 65 years or older. More specifically, 20 (28%) studies included older adults aged 70 years or older, and 2 (3%) included older adults aged 80 years or older. Among the included studies, 47 (67%) were unclear about or did not mention the health status of the participants. Moreover, 26 (37%) studies reported the participants' pathological conditions and/or physical impairments, and 11 (16%) studies indicated cardiovascular pathologies or not-specified chronic conditions.

With regard to technologies, all previously mentioned categories of ETs, except for VRTs, were used in the included publications. The most studied category was that of UNMT, which was reported in 41 (58%) publications. Moreover, 29 (41%) studies focused on the use of environmental sensors (eg, chair and bed sensors, motion sensors, and fall detection sensors) [37,54-81]. In the papers, the authors often referred to these monitoring tools using the term "smart home," and they less frequently used "ambient intelligence" or "Internet of Things." In 14 (20%) studies [54-56,67,69-71,78,82-87], the focus was on the use of wearable sensors, such as smartwatches and smart bands, which can collect a variety of information regarding physical activity or vital signs. For example, in 1 study [84], participants used Fitbit, a wearable device that monitors some aspects of the user's behavior and vital parameters (eg, number of steps, distance covered, calories burned, heart rate, and blood pressure).

CMT was the second most studied category, which was noted in 25 (36%) publications. More traditional and common information and communication technologies, such as mobile phones, smartphones, tablets, and computers, were used to provide health-related services (eg, televisits; teleconsultations; and tips for self-management and self-monitoring of one's health, well-being, and/or illness) through the use of so-called mHealth apps [88,89]. The use of such ETs in health care is referred to as "telehealth" [80,90,91].

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart showing the electronic database search, publication identification, and selection process for the included articles.

Finally, the least studied category was SAR, which was noted in 16 (23%) publications. These robots, which were described in detail in 9 (13%) studies [30,92-99], can be divided into 3 groups: nonanthropomorphic [92,93,95,98,99], anthropomorphic [30,95], and zoomorphic [95-97]. An example of the first type of SAR is the robotic platform Hobbit [92,99], which is connected to an ambient assisted living environment and provides entertainment, reminders, fall and emergency detection, and prevention services. Regarding the second group, NAO [95] and Alice [30] are humanoid robots, which are mostly used as companion-type robots to interact and communicate with older adults. Among robots with animal features, the most famous one is PARO [95-97], a baby seal robot that can elicit positive emotions. PARO was originally designed for older adults with dementia, but it has also proven to be a valid tool for older adults without cognitive disorders, as noted in 3 (4%) studies included in this review.

The fourth category of ETs, VRT, was not present in any of the included studies, and the possible reason is that it is still a state-of-the-art technology and has a high cost.

Methodological Quality

The quality assessment results of all included publications are summarized in Multimedia Appendix 8. According to the evaluation carried out, 46 (66%) studies had a high level of methodological quality. On the other hand, the remaining 24 (34%) studies were classified as having moderate quality.

XSL•FO
RenderX

All the papers had a clear statement of the aims of the research, explained the relevance, clarified the methodology followed, and presented the findings explicitly and clearly. In 66 (94%) studies, the researchers also discussed the contribution of the study to existing knowledge and identified new areas of research.

With regard to data collection and recruitment strategies, 61 (87%) studies took appropriate measures, paying adequate attention to ethical issues, such as obtaining ethical approval from ethics committees and informed consent from participants. On the other hand, with regard to data analysis, 22 (31%) studies did not provide an in-depth description of the analysis process.

Finally, the quality appraisal revealed 2 important limitations. First, in 56 (80%) studies, researchers failed to justify the research design and describe how they decided which method to use. Second, in 64 (91%) studies, researchers did not take into consideration the influence they would have on participants and the research project, thereby presenting a potential risk for bias.

Ethics-Related Analysis

The included articles were analyzed using a 2-fold strategy (top-down and bottom-up; see the Conceptual Framework section).

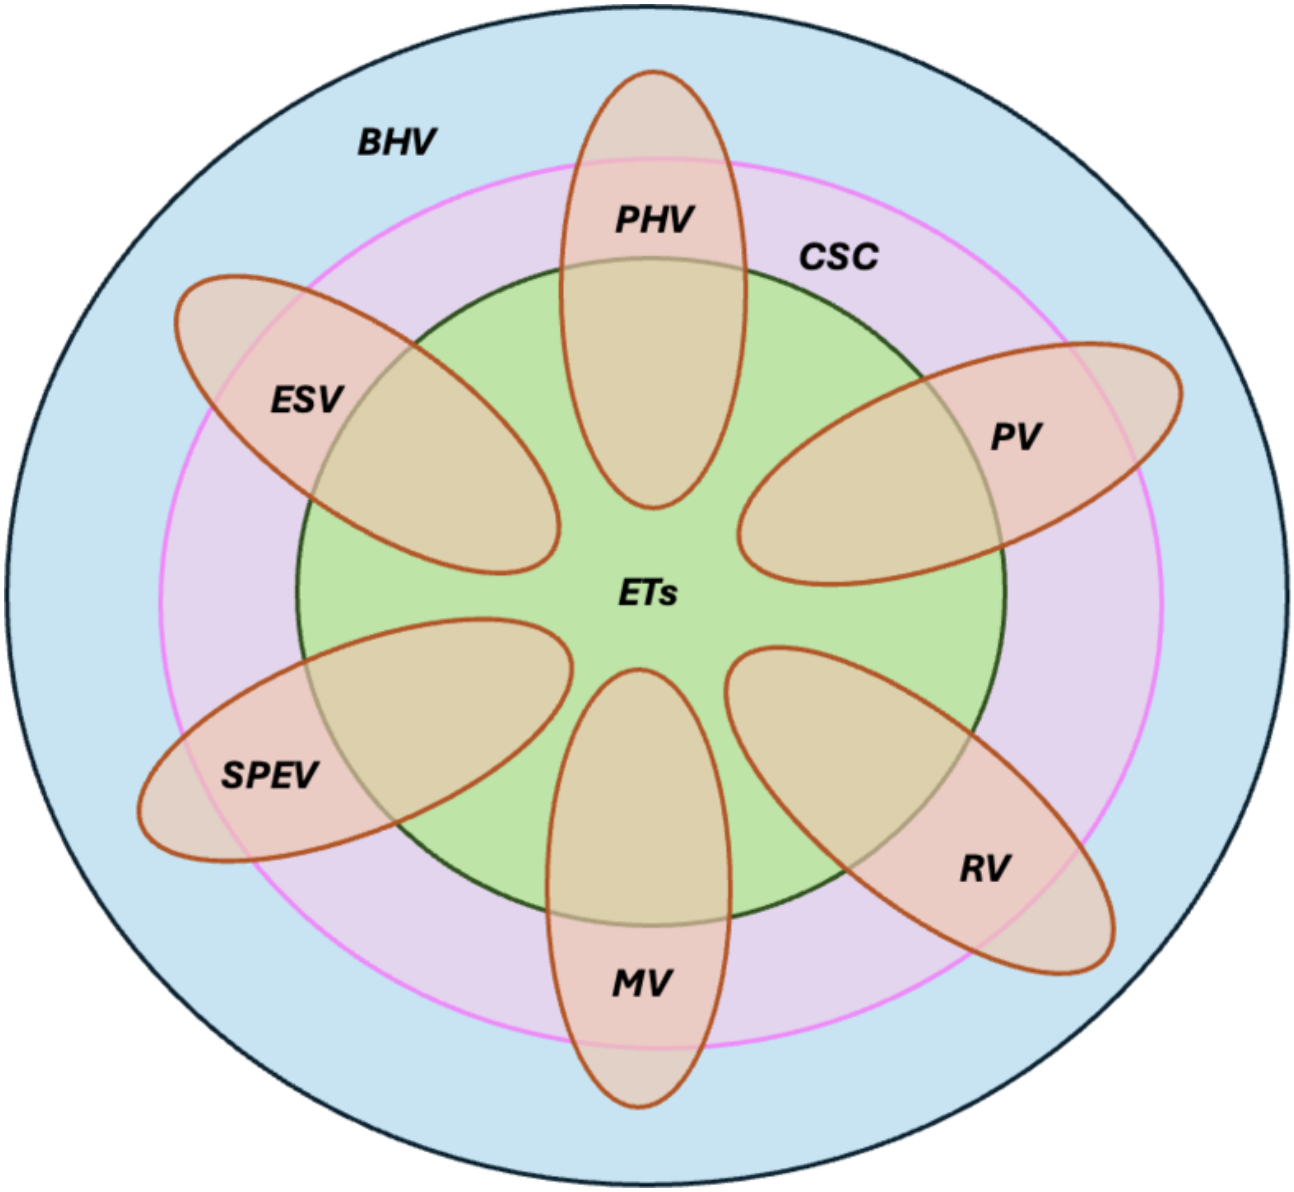


Figure 2 provides an illustration to help understand the results of our systematic review in relation to the broader debate surrounding vulnerability in aged care.

Basic human vulnerability refers to the inherent fragility and finitude of human existence, which cannot be eliminated by technological or other means. In response, humanity has developed various cultural and social constructs, including art, health care, social services, education, politics, economics, and technology, to manage both basic and situational vulnerabilities. These constructs are particularly relevant to the 6 dimensions of vulnerability in aging populations. Among them, ETs may impact both basic and situational vulnerabilities; however, some situational vulnerabilities may resist intervention due to their complexity or deep existential roots.

As summarized in Multimedia Appendix 7, the next sections will present the ethically relevant results of the review, analyzing the impact of ETs on the vulnerabilities of older adults, based on what was reported by study participants. Each of the following paragraphs explores 1 of the 6 dimensions of vulnerability, and they are ordered from the most frequently mentioned dimension to the least frequently mentioned one. Finally, the emerging theme of usability, which was not originally present in the taxonomy, has also been presented.

XSL•FO
RenderX

Figure 2. Illustration of the relationship among emerging technologies (ETs), vulnerabilities of older adults, and cultural and social constructs. BHV: basic human vulnerability; CSC: cultural and social constructs; ESV: existential or spiritual vulnerability; MV: moral vulnerability; PHV: physical vulnerability; PV: psychological vulnerability; RV: relational or interpersonal vulnerability; SPEV: sociocultural, political, and economic vulnerability.

MV Dimension

MV was the dimension of vulnerability most cited by the qualitative studies in this review, with 43 out of the 70 publications addressing it in its different nuances and meanings.

After analyzing the included papers, we further organized this dimension into the following subcategories: *decisional autonomy and/or self-determination* (noted in 14 studies), privacy linked to *confidentiality* (noted in 24 studies), privacy linked to *control and surveillance* (noted in 19 studies), privacy meant as respect for *integrity and identity* (noted in 9 studies), and *stigmatization and infantilization* (noted in 13 studies).

Older people participating in the studies included in this review emphasized the impacts that ETs have on privacy linked to *confidentiality* and more specifically to the management of personal data collected by devices and their disclosure to third parties (ranging from caregivers to health professionals and to potential strangers). This aspect was consistently framed in negative terms by the interviewees. In fact, in all the 24 studies in which the theme of confidentiality emerged, ETs were believed to have a negative impact, as most participants felt that ETs violated their sensitive and personal data. This was especially true for UNMTs, which were studied in 19 out of 24 publications. In particular, two functions of monitoring technologies seemed to be of great concern for older adults: (1) the recording of images and sounds [54,57,58,60,62,64,70] and (2) the collection of personal data [29-58,59-66,67,71,73,74,77,85,86]. For example, in 1 study [54], older adults felt that the use of a camera was intrusive and violating. One participant said, “I wouldn’t want to feel that somebody was watching my activities.” In another study [57], talking about an IP web camera, participants said that it was “too invasive and would make them feel uncomfortable in their own home.” With regard to a smart speaker, a few participants “expressed concerns it would be used to listen into private conversations.” Considering data collection, storage, and transfer, older adults were concerned about data security and

XSL•FO
RenderX

expressed the desire to be protected from possible privacy breaches and from the possible misuse and abuse of their personal data [29,58,59,66,67,71,73,74,77,85,86]. For example, in 1 study [58] that addressed home monitoring techniques, such as wireless motion sensors, in-kitchen temperature sensors, and door contact sensors, a participant stated:

> *I might be concerned about confidentiality issues, such as a breach of my personal information or potential harms due to my information being exposed to others.…There could be a possibility that a burglar could see my data accidentally and come along after I go out.*

In another study [29], in relation to the use of different kinds of technologies based on artificial intelligence, the following statement was made:

> *If they're [the technologies] so sensitive, they know three weeks before we know what's going wrong with our bodies. It seems to me that that kind of information could really be compromised, and seniors could, uh, who are very vulnerable, could really be hoodwinked more easily.*

Participants were also concerned about the transfer of data, which they would like to keep confidential and share only with their relatives and/or caregivers [59,63]. In 1 study [59], a participant said:

> *When you get older, you don't feel that safe on your feet…and you mean – is it – I have to announce that to everybody?…I think that's the most private thing that you're really interfering with.*

In another study [63], older adults had concerns even "about family members potentially 'knowing too much' and some were concerned that data could be used by families to the detriment of the older adults."

The second most recurrent topic concerning MV was privacy linked to *control and surveillance*, which was noted in 19 studies. Among these studies, 16 reported that ETs had a mostly negative impact, 2 [77,83] reported that devices had an ambivalent effect on MV, and 1 [100] mentioned that ETs appeared to mitigate MV.

Among the critical issues identified, the most prominent concern associated with ETs in general (CMTs [101] and SARs [30,102]), but especially UNMTs [54,55,59,62,65,70,73,78,79,84]) is surveillance. For example, in 1 study [55], a participant associated this negative feeling of constant monitoring with past traumatizing experiences, when "there were 'folkpolice' everywhere watching everyone, and everyone watched everyone else in East Germany… and we don't want that system here. And, at least not here in our home." In another study [59], a participant said that "you'd feel like a puppet on a string…I don't want to be – something watching me." Finally, in another study [79], participants linked surveillance to the Big Brother Syndrome [103], and the following statement was made:

> *While they do not mind having the system monitoring them 24/7, the incorporation of a camera into such system would be "too intrusive." "No, definitely no photos. It's like big brother, and i'm not having that."*

In 2 studies, UNMTs were reported to have both positive and negative effects. In 1 study [83], which examined a wrist-worn monitoring device, the positive aspect highlighted was the increased sense of safety, resulting from the awareness of being constantly monitored. For example, a participant said:

> *I feel safe. It must be safer.…In this way they can keep a track of me even when they are not here, which is good because I'm alone here in my house.*

This perception of protection, linked to surveillance, was particularly emphasized in relation to falls, as also stated in another study [100]. On the other hand, in these studies, a strong discomfort also emerged, resulting from the feeling of being "watched," which was perceived as a violation of personal and private space.

Among the included studies, 14 reported that older adults felt that ETs had either a positive or negative impact on their decisional autonomy and/or self-determination. In a positive way, CMTs and UNMTs improved older adults' decisional autonomy and minimized their loss of control, as they enabled older adults to control certain elements of their house or their life [61,76,104-106]. For example, in some studies [61,76], smart home technologies were really appreciated because these devices provided the possibility to remotely control the environment (eg, lights, television, and doors). With regard to GatorTech Smart Home [61], an older woman liked above all "the ability to command the house to open blinds, doors, lights" and "the ability to see who was at the front door and make the choice to see if wanted to respond rather than having to go over and look through the peephole."

However, despite this benefit, ETs (CMTs, UNMTs, and SARs) can also interfere in a negative way with older adults' decisional autonomy, as they direct the life of older adults and make them lose control of their daily activities and decision-making capacity [29,30,55,59,77,94,101,107]. This fear emerges not only in relation to monitoring technologies [29,55,59,77,101,107] but also in relation to the use of SARs [30,94]. Talking about Alice [30], a robot with a small humanoid body and a human-like face, a study mentioned about "negative feelings related to feeling powerless in stopping the perceived technological imperative. Participants felt as if they had no choice but to comply with the evolution of SAR." One participant said that SARs "cannot take over," and another claimed that "not everything can just happen because it [the SAR] says it."

Other frequently mentioned themes in relation to MV were stigmatization and infantilization, which appeared in 13 publications. Twelve publications highlighted how ETs exacerbate feelings of stigmatization and infantilization because older adults associate the use of these devices (mostly UNMTs) with aging and dependency [30,47,55,62,64,74,76,79,80,94,95,104]. For instance, both CMTs and UNMTs [47,62,64,74,76,79,80,104], especially smart home technologies, were despised because the participants believed that these are tools for more vulnerable people with serious disability problems and not devices for healthy

XSL•FO
RenderX

individuals like them. Two studies specifically pointed out the phenomenon of depersonalization, as monitoring techniques like sensors [55] and SARs [30] gave older adults the idea of being seen as an *object* rather than a person with individual needs. With respect to the infantilization phenomenon, the issue emerged negatively in relation to the use of SARs. In particular, in 1 study [94], it was stated:

> *Some participants found the concept of interaction with companion robots demeaning.…Craig was similarly condemnatory of ElliQ: "Crazy. I do think I'm a bit more intelligent than that."*

Likewise, in some studies [30,95], the use of robots was described as childish and dehumanizing.

Only 1 publication showed that ETs could have a positive impact on MV, as, according to the participants of the study, Interaktor, an interactive app for regular reporting of health concerns, allowed health care personnel to take care of older adults as people, reducing depersonalization [46]. Older adults reported a "feeling of being appreciated" and a "feeling of being acknowledged as a valued person."

Shifting the perspective on privacy again, the last 2 connected themes were integrity and identity. In 9 studies where these themes were mentioned, the negative impact of ETs was emphasized, mostly with reference to UNMTs [54,55,57,59,62,71,77], such as smartwatches, health trackers, chair and bed sensors, motion sensors, and home energy sensors. In 8 publications [54,55,57,59,62,71,94,101], the problem was the perceptions of obtrusion, intrusion, and invasion, which were interpreted as violations of personal space, a kind of "attack," compromising personal integrity and identity. In addition, in 1 study [60], a participant was very concerned about the potential misuse of her identity, which was caused by the use of "welfare technology" (ie, ambient assisted living).

RV Dimension

The second most frequently cited dimension of vulnerability was RV, which appeared in 40 out of the 70 publications. These 40 studies focused on interdependence in real-world settings, and none of them reported an impact on the ontological interdependence characterizing human nature, that is, the intrinsic relational and social nature of human beings.

The relationships among older adults, caregivers, personnel, and/or family members appeared in 36 publications. In 19 studies, older adults highlighted only the positive impacts of ETs on RV. In 7 studies, on the other hand, some disadvantages concerning RV emerged. Finally, in 10 studies, participants emphasized the ambivalent effects of ETs on RV.

Most publications showed that ETs can positively influence RV as participants saw ETs as a support to maintain their independence and remain at home and in their own community [57,65,75,81,94,108,109]. This was especially true for UNMTs like smart home technologies. For example, in 1 study [75], with regard to a sensor monitoring system, which included passive infrared motion sensors, magnetic contact sensors on doors and cabinets, and a flush sensor in the toilet, a participant said:

> *It may be useful for the future.…People can stay at home longer with the help of sensors because there is more supervision.…It is always nice to stay in your own neighborhood, especially for elderly people who have neighbors and friends in their neighborhood.*

Another important benefit with regard to RV was the relief from loneliness [61,65,92,94,106,108,110,111]. SARs, in particular, were seen by older adults as pleasant companions to spend time with. In 1 study [94], ElliQ, a nonmobile home assistant robot with moving parts, conversation functions, and a female-sounding voice, was praised by respondents, and it was stated:

> *…would be comforting in a quiet and lonely household: "It breaks the silence of the day." For Sarah, the more linguistically sophisticated presence of ElliQ had a positive side, because it was like having a person in the house.*

CMTs, such as tablets, smartphones, and laptops, which enable remote communication and video conferencing, were also highly appreciated as ways to connect with members of one's network and receive practical and emotional support from them [37,89,91,98,106,107,112]. In 1 study [89], a participant's point of view on the use of mHealth apps was reported:

> *You'll [the doctor] assist me in keeping an eye on it [the remedy] and reporting back through the app and then I can connect with a trusted advisor just through the app – that would be great. Convenient.*

In another study [112], an interviewee made the following statement about tablets (such as iPad and Kindle Fire): "I feel more informed; I feel I'm in more contact with my family."

In other publications, however, ETs were reported to have a negative impact on the relationships among older adults, caregivers, personnel, and/or family members. According to 1 study [73], UNMTs like ambient assisted living might reduce the independence of older adults, and a female participant stated:

> *I think it's very intrusive and I think people who are over 70 as I am would find it just one step down from you making dependent on somebody…If you feel you've got your independence…you know…I think it would be own step down…yes I didn't like it.*

Sometimes ETs were despised because they can replace human interaction and reduce "face-to-face care" [80,90,100,101], increasing the sense of loneliness [101,113]. Interestingly, ETs were considered problematic because they might generate misunderstandings and mistrust among people [113,114]. For example, in 1 study [113], with regard to the use of a tablet-based communication app allowing asynchronous multimedia communication, it was stated:

> *Six participants verbalized that the technology created family tensions.…Our older people preferred asynchronous communication, to send audio messages, and to receive text messages, but family preferred synchronous communication and video and photo messages. Participants were "disappointed" with relatives that instead of replying to their messages via the app called them on the telephone.*

XSL•FO
RenderX

Finally, as anticipated, in 10 studies with regard to RV, older adults expressed their opinions on ETs in ambivalent terms. ETs appeared to enable older adults to maintain and improve their autonomy and independence in daily activities [30,67,72,77,104,105], but the use of these same tools raised their fear of losing residual autonomy and abilities [76,95,104], that is, the set of psychophysical capacities and functions that are not (for the time being) affected by the deterioration that normally characterizes human aging. Moreover, while ETs appeared to improve contact and provide support [30,46,66], which can reduce feelings of loneliness [30,76,95], they may exacerbate this same loneliness [105] and raise fears of a gradual loss of human interaction [30,46,66,67,72,77].

With regard to human-robot interaction, in 4 studies [93,97,108,115], older adults only emphasized the positive aspects of using ETs. In 4 other studies [71,91,92,100], however, only critical issues emerged. In 3 studies [30,94,95], older adults' opinions were ambivalent. Paradoxically, the use of SARs was appreciated for contradictory reasons. On the one hand, participants appreciated the resemblance of robots to living beings (human beings [95] or animals [94]). For example, in 1 study [94], talking about Biscuit, an animal-like robot, an interviewee said that it showed compassion and "a dog-like affection," and the interviewee made the following comment:

> *You could touch Biscuit.…It's got eyes you can look in. So, you get some sort of empathy back, or feeling back, the way it tilts his head when you talk to him.…More like a real dog.*

In 1 study [95], with regard to home robotic devices, it was mentioned that "participants reacted to the nonverbal communication capabilities of some robots, stating: It's like having another person in the flat that would communicate with me." However, other older adults held the opposite view, and it was stated that robots are more appreciable because they do not have the "defects" of living beings, both human [30,108] and animal [97]. For instance, in 1 study [108], the following statement was made: "the fact that the robot could not 'speak, offend, or get angry like a human being' was mentioned as an advantage of this special companion by one participant." Likewise, in another study [97], PARO, a baby seal robot, was appreciated because, as a participant stated, "you don't have to feed him or clean his litter box or sweep up his hair from rugs." In another study [30], the humanoid robot Alice was described as follows:

> *Very accurate. They will not be hasty, or they will not have a bad mood.…They won't forget anything.…They will not be distracted, will not have a headache. I think it is positive that they will always be 100%.…Available.…Concentrated.…Trustworthy.*

In addition, other emphasized aspects were features like a nice physical appearance [93,97], inviting and "unintimidating" attitudes and cuteness [97], and relational support [115].

These results, however, were mirrored by criticism. While some older adults appreciated SARs for their "roboticism" and "nonsimilarity" to living beings, others despised the fact that they are programmed to "pretend" to be what they are not. Indeed, some older adults refused their inauthenticity and lack of spontaneity [30,92,94,95,100]. Their simulation of living beings' capabilities (affective, social, etc) was strongly rejected as phony. For example, in 1 study [94], ElliQ, a nonmobile robot, and Vector, a toy-like robot, were described as follows:

> *…lacking feeling and being "cold."…Stephanie said: …I don't' like the sort of seeming humanizing of the whole thing. It's ridiculous.*

Even Biscuit [94], which was praised for its "dog-like affection" by 1 older adult, was criticized by another:

> *…the simulation of a living dog and the reactions it prompts are phony.…A live dog is "not programmed to be joyous when it sees you" (Sarah).…Gwen…found Biscuit repellent because, "It's false. It's something that I'm trying to be happy or I'm trying to be something that I'm not."*

This criticism was reiterated in another study [95], where an older adult said that "the only thing that a robot could do to me or respond to me would be a response that's been built in, it's not spontaneous." The critique of the lack of authenticity was connected to the rejection of the robot-provided mode of care, as stated in a study [30], in response to the use of Alice:

> *…only could interact in a preprogrammed manner.…According to most participants the care SARs provide to older adults would lack a fundamental quality of human care: "empathy," "care for the hearth" and so forth.*

In 2 papers [71,91], the issue of human-robot interaction emerged in connection with the use of CMTs and UNMTs. In particular, older people complained about a sense of anxiety and doubt. In the first study [71], talking about some digital services, such as Amazon and Google, activity trackers like Fitbit, and home energy sensors like Nest, a participant said:

> *Although I use the computer, I do find it quite frightening. The reason is that I don't understand it. And I don't know how to put things right.*

In the second study [91], it was mentioned that telehealth technologies, such as videoconferencing, elicited anxiety for various reasons: "(1) receiving spam, (2) experiencing system updates, (3) losing written text, (4) damaging a device, (5) fearing the use of technology in general, (6) fearing microwave radiation, (7) fearing inadequate privacy protection, (8) feeling unsafe using the internet, and (9) fearing online scams or cyber criminals."

PHV Dimension

PHV was reported in 36 out of 70 publications, thus constituting the third most frequently cited dimension by participants in qualitative studies. An analysis of these 36 studies showed that in most cases, ETs appeared to have a positive impact on PHV.

Indeed, 33 studies revealed that ETs mitigated PHV, which was interpreted as nonpathological physical or physiological bodily deterioration related to aging. Participants appreciated ETs, particularly UNMTs, for different reasons. ETs with monitoring functions can detect emergencies like accidents and falls [30,37,46,58,62,64,66,75,79,81,87,99,100,116] and can monitor health conditions, daily habits, therapy compliance, and health

XSL•FO
RenderX

changes [54,56,57,70,75,77,81,83,85,99,101,104]. They were also useful in some cases to monitor the environment and the opening of doors and windows [61,65,70,74,92,100]. These factors, according to older adults, increased the sense of safety and security [37,46,55,65,66,70,72,74,75,77,79,81,83,85,92,100,101,104]. This positive impact was associated with the possibility of remaining in one's own home and avoiding institutionalization in a nursing home [66,77,83,101]. For example, in 1 study [75], the importance of environmental sensors for both fall detection and detection of physical decline was emphasized:

> *Mrs. D explained this as follows: "Well, you are on your own, so something can happen, like when you fall and can't get up.…I had the idea that this should be watched by someone somewhere."…Mrs. A expressed this as follows: "if there should be a slow change in my daily pattern, I certainly wouldn't report it. I wouldn't notice, and therefore, I find it important that the nurse's station gets a signal like: keep an eye on that"*

Similarly, in 1 study [100], the robot Jibo was admired for the home security it provides:

> *P12 told a story of how the robot could help them…"It seems like a useful idea that if I'm sleeping, and I could have a robot that detects something unusual that I would like to be alerted to…You could program the thing and say if I have a sound like somebody trying to get through the window, please wake me up."*

Other participants highlighted how the use of ETs, above all wearable activity trackers, such as Garmin Vivofit 2, Fitbit, Apple Watch, Jawbone, Misfit Nike, and Gear Fit, which automatically track and monitor various indicators of physical activity (eg, steps taken, pulse or heart rate, calories consumed, etc), could motivate them to be more physically active and improve their health status [30,57,75,82,84,86]. For instance, in 1 study [86], it was stated:

> *Participants agreed that tracker use motivated them to walk more, driven by quantifying activity (counting steps) and continuously making users "more conscious of extra walking" (female participant, non-user).*

Finally, the last important positive aspect concerning PHV in terms of nonpathological deterioration was the physical support and assistance SARs can provide [99,115], assisting older adults in house chores and picking up and transporting objects.

Some studies [30,58,61,77,81,88,117] showed that ETs can also mitigate PHV linked to pathological physical age-related conditions. Some participants perceived ETs, mostly UNMTs, as useful tools to prevent diseases and manage illnesses, such as diabetes, heart failure, dementia, and Alzheimer disease [58,77,81,88,117], and physical impairments, such as vision deficits [30,61]. In 2 studies [79,91], however, participants reported that ETs could exacerbate PHV. They were concerned about the possibility of CMTs and UNMTs negatively impacting a person's health, causing diseases (eg, cancer). For example, in 1 study [79], a participant asked:

> *Could the sensor radio waves give you cancer? I think this is what I would be worried about.*

In another study [91], the use of telehealth technologies, such as videoconferencing, elicited similar comments, and older adults expressed their fear of microwave radiation.

PV Dimension

PV was the fourth most frequently mentioned dimension by older adults, appearing in 33 out of 70 studies. These 33 papers dealt only with strictly psychological dimensions (cognitive, emotional, or both).

The emotional aspects were those most often mentioned by older people, and they appeared in 23 out of 33 publications. Of these studies, 21 showed how ETs could mitigate PV. In only 8 studies, older adults highlighted the negative aspects.

Focusing on the positive comments, according to participants, the use of ETs could have a positive influence on older adults' emotions and improve their mood: CMTs and UNMTs could provide a sense of safety, security, and reassurance [37,61-64,69,74,80,101,107]. With their monitoring functions, these devices not only contribute to improving PHV but also provide peace of mind. For example, in 1 study [62], a participant commented on the use of smart home technologies, saying that "his friend has decided to use such a device to have 'peace of mind.'" ETs in general, but especially SARs, are stimulating tools that older people enjoy using [46,82,86,92-94,97,112]. Hobbit [92], a robotic platform with personal and social functionalities, raised the following comments:

> *He's interesting and amusing.*
>
> *It is great fun when he is working well.*
>
> *When he moves and his head moves, I get happy and compassionate.…He's charming.*

Another SAR, PARO [69,110], was really appreciated because of its calming effect and its positive influence on emotions. The use of other technologies [46,86,106,112] conveyed a sense of achievement and appreciation. Finally, the appearance of the technology, especially in the case of robots that look like living creatures, aroused positive feelings in users (eg, empathy, compassion, and tenderness) [93-95].

On the other hand, 8 studies revealed how ETs, mostly UNMTs, could have a negative effect on PV, generating adverse emotions and negative attitudes, such as irritation, frustration and annoyance [68,94,95,106], fear [55,56,107], reduced sense of safety [37], and self-doubt and lack of self-worth [106]. For instance, the robot ElliQ was criticized for its cold manners and its disturbing intrusiveness. Participants said:

> *It talks all the time.*
>
> *I don't know whether that would drive me mental if it kept interrupting me and telling me what to do…I might want to get an ax and cut it up.*

In 1 study [107], older adults, reflecting on the use of UNMTs and CMTs, stated that they evoked the fear of "not being able

XSL•FO
RenderX

to manage the technology, making a fool of oneself, and having to ask for help." Moreover, the following statement was made: "Also, fear of being forced into something unwanted and of ruining something was described." Finally, another study [106] stated that even the use of more common technologies, such as tablets, smartphones, and laptops, has challenged older adults, who feel incompetent when they are unable to use the devices, experiencing a sense of inadequacy:

> *Jennifer (female, 71, tablet) demonstrate how her frustration with online activity leads to self-doubt: …"Is it me doing something wrong?"*

With regard to the cognitive level, 8 studies [30,57,67,82,99,102,108,118] showed how ETs could have a positive effect, compensating for memory deficits through the reminder function [30,57,67,99,102,108], influencing motivation and awareness [82], or improving intellectual functions [118]. For example, in 1 study [67] analyzing CMTs and UNMTs like smartwatches, an older adult said:

> *I think it's good because there's some people who as time goes by lose certain of their faculties as time goes by, and memory beginning to fade and so on.*

In another study [82], the Jawbone bracelet, an UNMT that monitors daily activity, was described as follows:

> *I was motivated by the technology, that I freely admit.…I have walked a little more while being monitored.*

In another study [118], participants said:

> *It [the tablet] keeps the brain active.*
>
> *Learning any new skill, surely is helping the cognitive function.*

At the same time, paradoxically, 5 studies [56,76,95,113,118] revealed that ETs could have a negative impact on the cognitive aspects of PV, because they could make older adults more aware of their cognitive decline [56,113] or they could cause a loss of intellectual functioning [76,95,118].

SPEV Dimension

SPEV appeared in 25 publications. According to 1 study [38], sociocultural vulnerability (SCV) arises when older adults experience social exclusion, isolation, marginalization, or stigma, exacerbated by gender discrimination, educational disparities, and low social support. Economic vulnerability (EV) and political vulnerability (POV) include discrimination in health care access and exposure to unjust judicial systems. These 3 SPEV subdimensions will be analyzed separately.

SCV was identified in 13 studies. Most of these focused on the isolation of older adults and their exclusion from social life, highlighting the positive [58,80,104,106,109,111,112,115] or negative [72,77,101,118] impact of ETs (CMTs and UNMTs for the most part) on SCV.

In 8 studies addressing the advantages of ETs, older adults said that these devices can help them integrate into society and reduce the sense of isolation. For example, in 1 study [115], the SAR was appreciated because it could provide company for older adults, in addition to performing house chores: "Robots will be welcome if I can return to my home, where they can bring me water and live and play with me… (Male, participant 13)." CMTs, such as tablets (eg, iPad) [112], were seen as tools to stay connected to not only family and friends, mitigating RV, but also society and the outside world at large:

> *Harold stated: "I feel more informed; I feel I'm in more contact with my family."…Connie said, "I feel like I'm connected to the world."…"Well, I feel like I've come up in the world."…Carol, 80-years-old, said she felt more "modern…I'm up par with other people." Mary, who is 89-years-old, mentioned that she felt like she was "coming into the 21st century."*

However, some studies indicated that ETs may exacerbate SCV by increasing isolation and social exclusion. Specifically, older adults expressed concerns about losing human contact, abandonment, and isolation linked to the growing use of monitoring technologies [72,77]. In 1 study [77], participants said that ambient assisted living technologies "should not replace human care…'Nothing can replace human contact. The more helpless you are, the more you need for people to come and check on you once in a while.'" In another study [101], the use of CMTs (ie, assistive technology services) made older adults fear being "neglected by the official health care system and society." In another study [118], the concern was different, as the cause of isolation was not the excessive use of monitoring technology, but rather older adults' lack of access to it or inability to use it, which prevented them from keeping in touch with others and the society as a whole:

> *"I'd really like to be in the modern world and to be able to manage these things and to be able to access more. I just feel very limited in what I'm doing.…" (G2, P6). Participants in the no computer experience group also stated: G3, P6: "I think we're missing out a lot, because all the information is at hand and we don't know how to collect that information."…G3, P5: "I just think we're like a forgotten generation, that's what I feel like. You want to go in and you want to be able to talk with your family and your grandchildren and not look vacant when they say, I'm going to do this."*

In 2 studies, older people focused on the barriers to ET use. Participants in the first study [104] expressed concerns about access to CMTs and about their inexperience with these devices. In the second study [114], older adults stressed how different understanding and use of technology between young and older people expose intergenerational differences, and the paper stated:

> *Grandchildren preferred to send videos and receive video/images, while participants mostly sent audio and preferred to receive text messages. Additionally, grandchildren would not receive replies within a day and thought it was frustrating. Grandparents showed surprise and confusion when we told them that grandchildren were expecting quicker replies, as they wanted to "take time and think about what to say back."*

XSL•FO
RenderX

A study on home monitoring techniques (wireless motion sensors, in-kitchen temperature sensors, door contact sensors, and pressure mats) considered SCV by examining older adults' living situations [58]. It highlighted the positive contribution of ETs in reducing abandonment [58], as these technologies compensate for the lack of support from children.

EV was addressed in 13 studies. All of them, except for 1 study [89], highlighted how ETs exacerbate this vulnerability. Most older adults' comments indicated that ETs have a strong financial impact on their income. Many participants expressed concerns about the high costs of these devices and their maintenance, which they could not afford [30,57,62,65,66,72,79,83,88,90,105,118]. This criticality emerged for all 3 types of ETs, but especially in relation to UNMTs, such as smart home technologies. Only 1 study reported how mHealth apps mitigate EV, as they could allow older adults to save money on health management [89]:

> *I mean one of the things I think is terrific that we can email our doctors and get an answer quickly. I'm all for it. It makes good sense. Participant 11.*

Finally, POV was discussed in only 1 study [111], and older adults found that the use of CMTs had a negative impact on this vulnerability. The study showed that ETs exacerbate POV because the lack of skills and knowledge on ETs could complicate older adults' participation in political life and decrease their possibility to be informed and obtain economic benefits [111].

ESV Dimension

Lastly, ESV was by far the least cited, as it appeared in only 1 publication [113]. In this study [113], according to the participants, a CMT, such as a tablet-based communication app, which allows asynchronous multimedia communication, can exacerbate ESV because it makes older adults aware of their existential limitations and of their finitude:

> *They reported how "inadequate" and "limited" they felt. For Ike (aged 74), the technology made his "Parkinson's battles" more noticeable, from eyesight problems to "losing cognitive abilities" when he forgot about some app's "features." The technology emphasized his health status and a compromised sense of personhood and identity: "I was not like this before," he told us.*

Usability

Beyond the ethical impact of ETs on older adults' vulnerabilities examined through a top-down approach, adopting a bottom-up perspective revealed significant findings regarding usability. Usability issues were addressed in 36 of the 70 publications reviewed. According to the International Organization for Standardization (ISO), usability is "the extent to which a system, product, or service can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" (ISO 9241-11:2018) [119]. Usability was reported to significantly shape users' perceptions of a technology's usefulness and acceptability [120].

Regarding this topic, we observed that participants' perceptions related to the usability of ETs could be both positive and negative. A total of 18 publications highlighted the advantages of all types of ETs (CMTs, UNMTs, and SARs). However, critical issues were emphasized more often in 25 publications.

The first usability issue identified was the design or the interface of the devices, which raised many concerns among older adults. It was described by participants as uncomfortable or cumbersome [47,61,69,70,80,86,105,114,116,118]. For example, in 1 study [69], with regard to UNMTs (ie, motion and door sensors, smoke detectors, and fall detectors), the following information was provided:

> *Several older adults remarked on the light flashes coming from sensors.…She did not see its benefits and was also bothered by the light emitted from the sensors: "The watch kept falling out of her hand. It bothered her when she slept. She asked why the sensor light was flashing, why it was red, why this, and why that. It really drove me crazy. Then she said she did not want to wear it anymore, that it was useless" (Carer 5).*

Similarly, in another study [86], wearable activity trackers, in particular Garmin Vivofit2, elicited the following critique:

> *Nonusers described the band as plastic (ie, cheap and of bad quality), clunky, annoying, rigid, and uncomfortable: "It's very rigid. The design is poor. It collects water underneath. I end up having a really loose bracelet. Which could have some effect on accuracy. I don't know. I found it totally uncomfortable. It's really ugly."*

With regard to SARs, in 1 study [92], Hobbit was deemed "too big," and it was mentioned that "he gets very hot" and generates too much noise. In another study [116], the concern was about the excessive bulkiness of SARs, which could be dangerous if the older person lives in a small house with "potential presence of architectonic barriers." Moreover, the following statement was made: "Older adults' worries were also expressed in relation to the furniture or ornaments located inside their houses that could be damaged by robot movements." Other critical remarks were made about ETs, which were not user-friendly [84,91,106,121] and hard to understand [70,71,79,84,88,89,95]. In 1 study [84], older adults showed reluctance to use the wearable device Fitbit, which can monitor physical activity and vital signs:

> *…doubted their ability to manage the "complex" system.…For example, one senior said that "It sure takes a long time to use this Fitbit, I'm not sure it's worth it."…After using the devices,…seniors were more concerned with the output complexity of the wearable device, ie, the complexity of the measurements provided, expressed in incomprehensible data for them.*

Another type of UNMT, an integrated smart home system [70], was criticized in similar terms:

> *One participant…perceived the usability of an ISHS very complicated and was very hesitant to continue*

XSL•FO
RenderX

> *using an ISHS, "I find it difficult to use this technology, so I am not very confident I could properly use them in my life."*

Moreover, the interaction with technology evoked in the older adults feelings of frustration [29,70,82,84,89,90,95,99,111], disappointment [86], doubts about their efficacy and anxiety [82,86,91], fear [80], and apprehension [79]. These feelings sometimes emerged because of the device's inaccuracy and/or errors [84,86,99].

Participants also complained about their lack of knowledge and experience with the technologies and mentioned that this is a barrier preventing them from using the technologies [29,82,88,89,118]. For example, in 1 study [88], interviewees believed that "not knowing how to operate" mHealth technologies, such as mobile phones, tablet computers, patient monitoring devices, and mobile apps, "kept older adults from using such technology." Some interviewees commented:

> *I think they're good, but I just don't know how to use, to work it. I just don't have the knowledge on how to work it.*

> *I think the first thing is the lack of technical know-how is one of the barriers.*

Another barrier posed by some kinds of ETs was their inaccessibility to users with disabilities, such as reduced visual acuity [105].

Lastly, participants reported a sense of annoyance because the technology use was dependent on power supply and the need to charge the battery (and not simply replace it with a new one) [70,91,106].

Shifting the focus to publications that reported the benefits of ETs in terms of usability, many participants judged the different types of ETs as easy to use, user-friendly [46,54,61,75,82,87,88,92,98,109,112,114], and intuitive to operate and understand [57,87,107]. In other cases, the technology was appreciated because it was comfortable [70,90], versatile [118], and accessible, as it was designed with and for older people [114]. One paper showed how participants appreciated the communication service of SARs, enjoying the cooperation with the robots (ORO, DORO, and CORO) [93]. In 1 study [68], the reassuring features that indicated the technology was working were found to be important by older adults.

Analysis of several publications revealed that older adults have identified strategies to address 2 key usability issues: inadequate design/interface and lack of knowledge/experience. First, to improve the design of some technologies, participants were pragmatic in their recommendations [54,81,87]. For example, they asked for simple instructions, fewer buttons, larger fonts, manageable sizes, and speech-activated tools [81]. Second, to compensate for the lack of knowledge about technology, some participants suggested adequate and practical training on how to use it [79,88], while others highlighted the importance of support, encouragement, and education, considering that older adults need slow and individual guidance while using technology [111]. Other participants suggested receiving tailored instructions through readable and understandable manuals or handouts that accompany technology devices [79,81,118].

Means to Address Vulnerabilities

Our analysis showed that older adults' suggestions for addressing vulnerability were closely tied to the specific technologies examined. Four publications [66,79,88,113] described strategies to mitigate particular vulnerability dimensions, including PHV [79]; RV [113]; MV understood as privacy/confidentiality [66] and decisional autonomy/self-determination [66,79,113]; SCV, particularly regarding isolation/exclusion from social life [113]; and EV [88].

In 1 study [79], which involved UNMTs (wireless sensor network-based systems that collect a range of environmental and structural sensory information such as weight and blood sugar), participants expressed 2 contrasting views. Some participants prioritized autonomy and independence, arguing that "users should be allowed to turn the system off when desired," thereby emphasizing MV mitigation related to decision-making. Others prioritized safety, proposing time limits on deactivation or preventing users from turning the system off entirely, given its purpose of enabling prompt medical assistance. PHV containment took precedence, even at the cost of reducing individual autonomy.

In another study [66], which was also focused on UNMTs, older adults suggested mitigating privacy-related MV by "processing the information before it is transferred." To further address MV interpreted as decisional autonomy, older adults emphasized that they "should decide what information is collected and transferred and to whom" and that technologies should be tailored to self-determined needs.

Regarding RV, participants in 1 study [113], which reflected on the use of a CMT (tablet-based communication app), stressed the need to "destigmatize loneliness, making it 'OK to talk about it' (Elsie, 86)" and avoid exacerbating reduced agency or compromised personhood. For this purpose, they recommended to "(1) understand interests and backgrounds to identify interventions, (2) provide a list of options for people to choose from and experiment with, and (3) ensure activities that entail active involvement and afford opportunities for meaningful interaction within and across generations." These suggestions support decisional autonomy and call for the improvement of SCV, understood in a broad sense as the possibility of connection and interaction with others and specifically as the reduction of isolation and exclusion from social life, by fostering intergenerational relations.

Finally, in 1 study [88], to address EV, participants recommended providing mHealth tools free of charge:

> *I would consider this kind of technology only if it were given to me.*

> *Well, I tell you like this, if they are going to pay for me to use one, then I will use one for my health…*

XSL•FO
RenderX

Discussion

Main Findings

This review aimed to systematically examine the perceptions and experiences of healthy older adults exposed to CMTs, UNMTs, VRTs, and SARs, and to investigate the ethically related impact of such technologies on the vulnerabilities of these older adults.

MV emerged as the most frequent concern. Many older adults emphasized the potential negative impact of ETs, especially monitoring technologies (wearables and environmental sensors), on privacy in terms of confidentiality, data handling, and disclosure to third parties. Others noted positive implications for autonomy and self-determination, as these devices provide greater control over oneself and one's living environment.

RV was identified as the second most frequently mentioned vulnerability. ETs positively influenced relationships among older adults, care staff, caregivers, and family members by supporting independence and community living while also facilitating practical and emotional support. Concerns remained that technologies might replace human interaction, reduce face-to-face care, increase misunderstanding and mistrust, or exacerbate loneliness, and this is consistent with prior literature, particularly regarding SARs [23,122-125].

Comparing these findings with those of another systematic review on older adults with cognitive impairments [126], we observed similar ambivalence. ETs can mitigate existing vulnerabilities but can also create new and/or worse (already existing) vulnerabilities. This depends on both the specific type of technology used and the dimension of vulnerability considered.

Both cognitively impaired older adults and healthy older adults recognized the positive impact of ETs on PHV, particularly through the ability of UNMTs to monitor health changes, detect falls and emergencies, and identify intruders, confirming previous findings [41].

A similar ambivalence emerged with RV. Yet, unlike cognitively impaired individuals (who focused on PV, RV, and PHV), cognitively healthy older adults emphasized the negative impact of ETs on MV. UNMTs, in particular, appeared to interfere with decisional autonomy, jeopardize privacy (confidentiality), compromise privacy through control and surveillance, undermine integrity and identity, and cause stigmatization and infantilization. This aligns with concerns described in the so-called *Big Brother Syndrome* [23], that is, the perception of being constantly observed by monitoring systems and feeling bewildered by the presence of numerous devices, which invade personal space [125]. In general, the literature shows that older adults are often willing to accept some privacy infringements in favor of safety and other benefits provided [127], but they nonetheless expect ETs to be reliable and trustworthy [128] and often react negatively to the invasiveness, intrusiveness, and obtrusiveness of ETs [122].

In conclusion, older adults with cognitive impairments tend to accept more tradeoffs in exchange for even modest physical or psychological benefits, due to greater psychophysical fragility, whereas cognitively healthy older adults tend to prioritize general, age-independent values, most notably privacy and autonomy.

Strengths and Limitations

The main strength of this work is that our study design is unique in that there are no other systematic reviews examining the relationship among ETs (taken as a whole), cognitively healthy older adults, and ethically related content, with a focus on vulnerability. Second, this review allows both a broader overview of the impact of ETs on older adults' vulnerabilities and a detailed analysis of how *specific types* of ETs affect *distinct* vulnerability dimensions. In other words, our research is highly informative with regard to both its *breadth* (ie, the number of ETs included) and *depth* (ie, the fine-grained scrutiny it enables on the specific challenges that every single family of ETs raises on distinct dimensions of older adults' vulnerabilities). Third, as a complement to another systematic review of qualitative studies [126], this review contributes to advancing a broader research agenda on aging that includes both cognitively healthy and cognitively impaired populations. Finally, by reviewing qualitative studies conducted with older adults, this research foregrounds their perspectives, including needs, desires, and concerns.

There are some limitations. First, the search was conducted 2 years ago and included only English-language articles, potentially limiting its temporal and linguistic scope. Second, some included studies may have inadvertently involved participants with cognitive disorders (eg, Alzheimer disease), as screening for such conditions was not always explicitly reported in the primary research. Third, as this is a systematic review rather than a trial, the findings are not generalizable. Nonetheless, by synthesizing all available translated studies on the topic, this work offers a broad overview and highlights the conceptual trends of potential relevance.

Conclusions and Future Directions

This study offers a solid theoretical foundation for future research, especially on strategies for addressing vulnerability in the context of aged care. Understanding older adults' vulnerabilities, especially in relation to ETs, is essential for identifying areas that demand greater sensitivity and tailored care approaches. Privacy and data confidentiality concerns (risks of breaches and data misuse or abuse) are crucial when deploying monitoring technologies, especially those involving audio or video recording in intimate settings. Cost also remains a significant barrier. Many older adults express interest in adopting ETs, but financial constraints may hinder their ability to do so. Equally important are the psychological impacts that such technologies may provoke, including anxiety, frustration, irritation, and feelings of inadequacy. Both ethics-by-design solutions and psychosocial interventions may help mitigate these effects.

Future research would benefit from complementing this theoretical framework with empirical studies aimed at identifying domains where psychological, sociopolitical, and economic interventions are most needed. Qualitative

methodologies would be particularly useful to capture the perspectives of key stakeholders, including formal and informal caregivers, health care professionals, and policymakers.

Acknowledgments

The authors attest that there was no use of generative artificial intelligence technology in the generation of text, figures, or other informational content of this manuscript.

Funding

This research is part of the project “Emerging Technologies and Vulnerabilities in Aged Care” (ElderTech), funded by Fondazione Cariplo (Social Research: Science, Technology and Society; grant number: 2020 - 1322).

Data Availability

Additional data are provided in Multimedia Appendix 4. The conceptual schemes generated during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

CG and VS originated the idea of conducting a systematic review of qualitative evidence exploring the relationship between emerging technologies and vulnerabilities in older adults without cognitive impairments. CG assisted in devising the search algorithms, cross-checked publication selection, analyzed the material, and revised the final manuscript. AF, VS, and MDL conducted the literature search, worked out most of the search and analysis methods used, and analyzed and synthesized the material. AF wrote most of the paper. MDL, GB, and VS contributed to the writing of parts of the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Postnatal depression (PND) is a clinical sign of sadness in certain individuals after childbirth. PND affects the mother, the baby, and the whole family. PND is now recognized as a public health concern worldwide. The global prevalence of PND is approximately 17.22%. However, less than half of those affected seek help, which means over 50% of PND cases are left untreated. Current reviews lack focus on digital interventions targeting parents in late pregnancy or postnatal stages. Existing studies prioritize symptom relief over fostering help-seeking behaviors.

Objective: This study aims to identify what serious games have been applied to support the treatment or help-seeking of PND and what gaps are still left.

Methods: Eligibility criteria for this review included full-text papers from 2015 to 2024 from conferences or peer-reviewed journals that were relevant to serious games to support help-seeking behaviors for individuals with depression. Seven research databases and publisher repositories were used. The final search was conducted in March 2025, and a thematic analysis was used to identify and organize recurring themes. As this review adopts a narrative approach, predefined eligibility criteria, a structured search strategy, and review by an interprofessional team were used to reduce selection bias.

Results: Only 2 studies related to PND were identified. After expanding the search string to depression, 13 studies were included in this review, and the studied games were divided into 3 help-seeking categories: promoting knowledge, reducing stigma, and raising awareness. This review identified that gamification, educational messages, and supportive character interactions could enhance engagement, build coping skills, and promote help-seeking in a practical, parent-friendly format. Nonetheless, this paper is limited by the reliance on depression literature due to scarce PND-specific studies, the quality of included studies, the exclusion of non-English language publications, and the use of common but select academic databases. These factors may affect generalizability but also serve to highlight critical gaps for future research and targeted intervention design.

Conclusions: There is a dearth of studies directly related to PND. Existing games commonly use narrative storytelling and interactive scenarios to promote empathy, correct misconceptions, and encourage help-seeking in broad depression. However, few are designed specifically for new parents, whose unique needs—such as time constraints—make mobile platforms the most suitable format for effective engagement. The authors propose that the future interprofessional codevelopment of a mobile serious game tailored to new parents would address the intervention and literature gaps identified in this review. It is argued that key design elements should include an emotionally engaging narrative, meaningful player choices, real-life parenting scenarios, calming visuals, and accessible, low-pressure gameplay. This review contributes to the progression of serious game research, with a focus on addressing the needs of an often underserved and undertreated PND population.

Introduction

Postnatal Depression: Definition, Consequences, and Treatment

Postnatal depression (PND) is a clinical diagnosis characterized by sadness after the birth of a child [1]. Most cases of PND start between 4 and 8 weeks after childbirth [2]. However, some research suggests that health care providers should screen for PND for up to 3 years after giving birth. This finding is in light of evidence that PND can develop after the traditional 6-month mark in some cases [3]. PND can result in various adverse maternal outcomes, impacting physical health, psychological well-being, interpersonal relationships, and risky behaviors [4]. Moreover, women who experience PND face an increased likelihood of experiencing clinical depression in the future, not just following repeated pregnancies but also throughout other periods of their lives [5].

PND affects not only the mother but the baby and family as a whole [6]. A mother experiencing PND may have difficulty bonding with her infant, providing proper care such as breastfeeding, and playing other maternal roles [1]. The potential consequences of this situation may extend to the child's physical, cognitive, language, emotional, social, and behavioral development and even impact the dynamic within the family unit over an extended period of time [7].

Perinatal mental health issues are now recognized as a significant public health concern all over the world. The global prevalence of PND was found to be approximately 17.22% in the largest meta-analysis of PND to date [8]. It is estimated that perinatal mental health disorders cost the Australian economy Aus $877 million per year (a currency exchange rate of Aus $1=US $0.66 was applicable) [9], the United States economy US $14.20 billion per year [10], and the United Kingdom £8.10 billion each year (a currency exchange rate of UK £1=US $1.34 was applicable) [11].

Health-Seeking Behaviors and PND

However, less than half of those affected seek help, which means over 50% of PND is left untreated [12]. The barriers to help-seeking for PND are various, including social and cultural stigma, lack of knowledge and awareness, and lack of accessibility to the health care system [13]. As highlighted, PND can have a detrimental effect on the entire family. Thus, further research is needed on the most effective ways to empower expectant new parents to seek help earlier and maintain positive mental health, ensuring this condition does not remain a silent struggle.

Digital Interventions and Management of PND

Digital games are interactive, computer-based experiences in which players interact with a virtual environment through input devices such as keyboards, controllers, or touchscreens. They range from simple, text-based applications to complex, immersive worlds powered by advanced graphics and artificial intelligence. Digital games can be played on multiple platforms, including personal computers, gaming consoles, smartphones, and virtual reality (VR) systems.

Game development is a complex process that often leverages specialized tools to streamline workflows and enhance functionality. Two critical components in this ecosystem are middleware solutions and game engines. Middleware provides developers with prebuilt modules to handle specific functionalities, while game engines offer comprehensive frameworks for building games.

Serious games play a crucial role in various domains by blending entertainment with purposeful outcomes, making them valuable tools for education, training, health care, and social awareness [14]. Unlike traditional video games designed solely for recreation, serious games leverage interactive and immersive elements to enhance learning, skill development, and behavioral change. Engaging users in simulated environments provides a risk-free space for experimentation and decision-making, leading to deeper comprehension and improved information retention. This kind of approach makes them particularly effective in fields such as education, where gamified learning experiences can make complex subjects more accessible and engaging for students. In professional training, serious games are widely adopted for skill development and simulation-based learning [15]. Industries such as health care, aviation, and military training use serious games to replicate real-world scenarios, allowing trainees to practice in a controlled setting. For example, medical simulation games help doctors and nurses refine surgical techniques and patient care by providing a safe space rather than performing procedures on real patients [16]. Similarly, corporate training programs integrate serious games to make the traditional learning experience more engaging and dynamic, thereby improving employee knowledge retention and job performance [17].

Beyond education and training, serious games significantly impact mental health and social awareness. Games designed to address depression can provide therapeutic benefits and be valuable and effective in reducing symptoms of depressive disorders [18,19]. Additionally, serious games are used to promote awareness about global challenges, such as climate change and poverty, by immersing players in experiences that foster empathy and drive real-world action [20]. By engaging storytelling, decision-making challenges, and interactive problem-solving, serious games go beyond traditional education and advocacy methods, making complex issues more relatable and actionable for diverse audiences.

In conclusion, serious games are an essential innovation in digital technology, bridging the gap between entertainment and meaningful engagement. Their ability to educate, train, and raise awareness while keeping users involved makes them a powerful tool across various industries. As technology continues to evolve, the potential for serious games to drive positive change in education, health care, and social development will only continue to grow. This narrative review aims to provide a comprehensive and interpretative narrative synthesis of the existing literature on serious games and digital interventions for PND. The goal is to critically evaluate current trends and gaps to explain the need for targeted research in this essential but often overlooked area.

Knowledge Gap and Objective

There is literature from the past 10 years reviewing digital interventions for symptoms of PND. In 2018, van den Heuvel et al [21] published a systematic review of the current literature on eHealth developments in pregnancy to assess this new generation of perinatal care. Studies that reported using eHealth during prenatal, perinatal, and postnatal timeframes include 71 studies covering 6 domains. These domains are information and eHealth use (eg, patients' use of the internet for pregnancy information [22]), lifestyle factors such as gestational weight gain, exercise, and smoking cessation (eg, technology-supported diet and lifestyle interventions [23]), gestational diabetes (eg, telemedicine for diabetes in pregnancy [24]), mental health (eg, therapist-supported internet-based cognitive behavior therapy among postnatal women [25]), low- and middle-income countries (eg, mobile health [mHealth] interventions for prenatal, birth, and postnatal period in low- and middle-income countries [26]), and telemonitoring and teleconsulting (eg, wireless antepartum maternal-fetal monitoring [27]). There were 16 studies related to screening and treatment for PND (van den Heuvel et al [21], 2018).

Hussain-Shamsy et al [28], 2020, aimed to understand the extent, range, and nature of mHealth tools for prevention, screening, and treatment of perinatal depression and anxiety in order to identify gaps and inform opportunities for future work. Compared to the van den Heuvel et al [21] review, it targeted interventions delivered through mobile phones, including apps and text message–based interventions with prevention, screening, and treatment purposes. Tools were for prevention (10/22, 45%), screening (6/22, 27%), and treatment (6/22, 27%). Interventions delivered included psycho-education (16/22, 73%), peer support (4/22, 18%), and psychological therapy (4/22, 18%); however, interventions that started in pregnancy and continued into the postnatal period were rare (2/22, 9%).

In the same year, Dosani et al [29] investigated existing uses of mobile phone technologies for perinatal depression in low- and middle-income countries, finding improved depressive symptoms after the interventions. Similarly, Wan Mohd Yunus et al [30], 2022, found positive outcomes for digitalized cognitive behavioral therapy (CBT) interventions for depression symptoms during pregnancy. However, it should be noted that the studies within this systematic review demonstrated relatively high risks of bias and some missing outcome data. Lau et al [31] (2022) also conducted a review synthesizing 18 randomized controlled trials and demonstrating support for the effectiveness of digital CBT for perinatal psychology symptoms (ie, depression, anxiety, and stress symptoms) in high-income countries; however, again, the included studies were found to be of limited quality. It is argued that the literature is promising in its indicative efficacy for digital and mobile interventions for perinatal mental health; however, further robust, high-quality, larger sample size, and interprofessionally co-designed randomized controlled trial research between health care professionals and application developers is required in this field.

Beyond the more common digital and mobile interventions, VR has been explored for its utility in this field. In 2024, Fallon et al [32] conducted a scoping review on the use of VR to support parents during birth and in the first year postbirth in different settings, finding that across these studies, VR was found to be effective in improving both physiological and psychological outcomes. Furthermore, mothers reported positive experiences of using VR, which could indicate VR's acceptability in this population.

Literature has looked not only at interventions targeting symptoms but also at prevention. Some have assessed web- and mobile-based psychological interventions' role in preventing depression during the perinatal period [33], as well as reviews on the current state of diagnostic and screening apps for perinatal mental health [34]. These review studies highlight important considerations for future research, including the need for comprehensive digital assessment tools, ensuring data protection and safety of the intended app use, and improving data sharing features between users and health care professionals for timely support.

Other prevention-focused research has aimed at increasing partner support (Pilkington et al [35], 2015). Several prevention studies that include a partner component have demonstrated some benefits [35]. However, not all of these interventions were delivered to both mothers and fathers, and research evaluating their effects on paternal mental health is lacking. Thus, it is argued that future research needs to focus more on developing active interventions for both partners.

In the past decade, numerous reviews have focused on digital interventions for perinatal mental health, particularly PND. Each of these reviews had distinct aims, ranging from examining eHealth developments during pregnancy [21] to evaluating the effectiveness of mHealth tools [28] and digital CBT interventions [30]. Others, such as Fallon et al [32], explored emerging technologies such as VR for supporting parents during the postnatal period. These reviews covered a variety of tools and populations, including both high- and low-income countries, and targeted different stages of perinatal care. Efficacious tools are important. However, those with perinatal mental health symptoms have demonstrated delays in seeking those interventions [36]. To the best of the authors' knowledge, there are limited review papers focused on how digital interventions can improve help-seeking behaviors in perinatal depression, highlighting a significant literature gap with important clinical and economic implications for undertreatment.

There is a paucity of research that explores how the games are designed for PND. However, there is a game-specific exploration of depression symptoms more generally, which is of relevance given that PND and major depression share identical symptoms except for onset [37]. In 2014, there were 2 relevant review papers. One is the systematic review by Fleming et al [38] of the evidence for serious games in the treatment or prevention of depression. The current data suggest that it is possible to develop serious games for depression, that young people are willing to try them, and that available adherence and impact data, whilst limited, are promising. The other systematic review is Li et al [39] systematically examining the effectiveness of game-based digital interventions for depression, investigating psycho-education and training, VR Exposure Therapy, exercise, and entertainment.

XSL•FO
RenderX

Psycho-education and training and VR Exposure Therapy were identified as the most popular types of game applications for depression. Given the demonstrated potential gains for global access, it becomes even more crucial to meet the needs of those reluctant to seek help through current methods.

To the best knowledge of the authors, there is only one relevant review from 2018 (Dias et al [40]). Dias et al [40] aimed to identify through a systematic review how gamification and serious games support depression treatment and identified two significant literature gaps, including the limited study of (1) the effectiveness of gamification and serious games for depression and (2) hazard assessment of the side effects of using gamification and serious games in depression treatment. The technologies identified in this review included mobile, computer, wearable, and web applications that were applied in gamification, serious games, VR, and speech analysis. This area has not been revisited since this 2018 review, as far as the authors are aware, yet in recent years, there has been an increasing interest in serious games for depression and health problems more broadly [41].

A systematic review of casual video games (CVGs) by Pine et al [42] provided a systematic review of the effects of CVGs on treating anxiety, depression, stress, and low mood. This work includes 9 CVGs, of which 6 studies aimed at reducing anxiety, 2 studies examined effects for depression, and 4 studies investigated the impact of CVGs on treating stress or low mood. CVGs are becoming increasingly popular, and people report playing them for various reasons, such as relieving stress and relaxing, which may provide some initial benefit for those who need additional support or are waiting to access more comprehensive treatment.

In 2021, a total of 4 relevant works on games for depression and border mental health concerns were published in Australia, Ireland, Austria, and Taiwan. King et al [43] narratively reviewed indie—or independent—games that address mental health, trauma, and grief, highlighting developers' difficulties due to insufficient game design and research studies when creating, developing, and evaluating serious games. Indie games were initially defined as games made on low budgets by small teams that were published outside more mainstream channels and used by larger companies. There are many challenges when developing serious games, including limited funding, small teams, a need for broad expertise, and limited examples for developing both games and studies. Serious mental health games that target those with mental illness directly face additional challenges, such as mental health disorder symptoms that can affect the present ability to engage with content. This challenge means developing mental health serious games presents unique challenges to developers, who must decide how to best address their intended audience.

Differing from previous work that targeted independent games, Kowal et al [41] focused on the mental health benefits associated with playing commercial video games to address symptoms of depression and anxiety. In light of the current research, we conclude that commercial video games show great promise as inexpensive, readily accessible, internationally available, practical, and stigma-free resources for mitigating some mental health issues in the absence of, or in addition to, traditional therapeutic treatments. Aside from the game target general public, Martinez et al [44] investigated serious games published between 2015 and 2020 for depression and anxiety in children and adolescents, with a new approach focusing on their applications: awareness, prevention, detection, and therapy. The results of this systematic review show that more awareness and detection games and games with awareness, prevention, detection, and therapy applications are needed. In addition, games for depression and anxiety should equally target all age ranges. For future research, developing and evaluating serious games should be standardized, and the games should always offer support while playing. Meanwhile, Yen and Chiu [45] conducted a review to explore the effectiveness of VR exergames in improving older adults' cognition and ameliorating depressive outcomes. This study suggests that VR exergames can potentially positively influence cognition, memory, and depression in older adults. VR exergames could be an interesting strategy for active aging and a good mental health status.

In 2022, there were 5 key sources. First, Abd-Alrazaq et al [46] aimed to assess the effectiveness of serious games in alleviating depression by summarizing and pooling the results of previous studies. Their findings indicate that exergames are as effective as active interventions, which are usually delivered and supervised by health care providers. Meanwhile, Ruiz et al [18] systematically reviewed the evidence and found video game-based interventions were valuable and effective in reducing symptoms of depressive disorders. Additionally, Kim et al [47] conducted a systematic review, finding that serious games were beneficial in reducing depression in older adults. Regardless of the study setting, serious games appeared to reduce depression. Particularly, serious games, including physical activities, had a significant impact on reducing depression.

Concerning combined depression and anxiety-related symptoms, Townsend et al [19] conducted a review into the effectiveness of gaming interventions for treating either depression or anxiety in individuals aged 12 - 25 years. Preliminary evidence suggests that gaming interventions may be an effective treatment for youth depression but not anxiety. Further research is warranted to establish the utility, acceptability, and effectiveness of gaming interventions in treating mental health problems in young people.

The fifth relevant work of this year was published by Chitale et al [48], reviewing the viability of games and VR for the assessment of anxiety and depression, finding that possible digital correlates or biomarkers of depression and anxiety could help researchers with their design. It is important to emphasize that to ensure safety, efficacy, and privacy at a health care standard. It is argued that game developers and researchers must collaborate interprofessionally with qualified mental health specialists. More clinical data is necessary to further evidence the effective use of video games or VR in assessment methods for anxiety and depression.

In 2023, Gliosci et al [49] systematically reviewed the current array of scientific research on video games used as a therapeutic intervention tool for depression. The latest research on the use of video games as depression treatment methods shows that

XSL•FO
RenderX

there are significant gaps in the sector, particularly across generations. The age group that is most affected by the condition and now consumes the most video games—adults aged 18 - 40 years—has had limited focus in the game and mental health literature. Given that depressed people tend to be more isolated, there may be untapped possibilities, such as the unique way that games can bring people together, that could be used in different types of interventions.

Most recently, in 2025, Gómez-León [50] systematically reviewed the current serious games designed to train emotional regulation skills in children and adolescents, finding that serious games can be effective, acceptable, and feasible for learning emotional regulation strategies and reducing symptoms related to depression, anxiety, and lack of impulse control.

As highlighted, the current reviews have several limitations and clinically significant research gaps that need to be addressed. Existing reviews rarely address digital interventions specifically targeting parents in late pregnancy or postnatal stages. Most studies focus on adolescents, older people, or the general population with depression. Given the unique physiological and psychological needs of a perinatal mental health group and the common reluctance to seek help, it is crucial to develop targeted digital games and help-seeking interventions for new parents, especially during late pregnancy and the postnatal period.

Current reviews focus primarily on symptom relief rather than fostering help-seeking behaviors. For new parents, it is essential to explore how digital games can educate and provide psychological support to help them recognize symptoms of depression and empower them to seek professional help. Crucially, the physiological and psychological changes that occur during pregnancy and the postnatal period differ from those experienced by the general population with depression, often influenced by hormonal shifts and changes in life roles [1]. Existing reviews lack a deep exploration of how these specific mechanisms impact the effectiveness of gamified interventions, and therefore, this will be a particular aim of this review. Game design must consider these unique psychological and physiological changes to support the mental health of new parents effectively.

Although serious games have shown promise in supporting mental health, few have been tailored to the unique needs of new parents facing PND. Existing interventions often overlook practical constraints such as time limitations and emotional vulnerability. Given this need, the current review aims to explore how game-based tools can be thoughtfully designed to provide emotional support, foster help-seeking, and offer accessible education during this critical period.

There is growing recognition that serious games could offer an accessible, flexible, and emotionally supportive solution for broad mental health problems. This narrative review provides a comprehensive and interpretative narrative synthesis of the existing literature on serious games and digital interventions for PND and, where data is limited, extends its review to related literature on depression, given its almost identical diagnostic profile with PND. The aim is to critically assess prevailing trends and gaps and to inform the need for targeted research in key, often overlooked, areas. By addressing these aspects, we aim to make future direction recommendations for research and game developments that could cater to the unique needs of parents in late pregnancy and postnatal stages, particularly in raising awareness of help-seeking behaviors toward PND. This review aims to highlight how digital games can be more effective in supporting this specific underserved population.

Methods

Search Strategy and Study Selection

The literature search was conducted across 7 research databases and publisher repositories: PubMed Central, the ACM Digital Library, Google Scholar, the IEEE Xplore Digital Library, Science Direct, the Springer Library, and Wiley. Keywords included combinations of major terms such as “serious games,” “digital games,” “postnatal depression,” and “help-seeking.”

The resulting search string is as follows and shown in Table 1: ((serious game OR serious games OR gamification OR gamified OR game design OR game based OR game-based OR gaming) AND (postnatal depression OR postnatal depression OR perinatal depression OR maternal depression OR post-birth depression)). For the detailed search strategy, please refer to Multimedia Appendix 1.

Table . Search string.

Major terms	Synonyms
Postnatal depression	postnatal depression OR perinatal depression OR maternal depression OR post-birth depression
Serious game	serious games OR gamification OR gamified OR game design OR game based OR game-based OR gaming

The search covered literature published between 2015 and 2024 and was limited to studies published in English. We chose to only include articles published after 2015, considering relevance and time efficiency.

Given the only 2 game research specific to PND, we also chose to include depression as an analogous disorder for inclusion because, according to the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition) [51], major depressive disorder and PND share core diagnostic symptoms. Thus, the broadened search string is as follows: ((serious game OR serious games OR gamification OR gamified OR game design OR game based OR game-based OR gaming) AND (depression OR sadness OR depressive))

Initial search results were screened based on titles and abstracts by author WW. Then, full-text reviews were conducted by author WW and decided across the team, EP and JG, to

XSL•FO
RenderX

determine their relevance to the research objectives. Reference lists of key articles were also reviewed to identify additional sources. The screening process is shown in the Results section.

Studies were included if they discussed the design, application, or evaluation of serious games related to promoting help-seeking behaviors toward depression or perinatal mental health. Articles focusing solely on maternal health without mention of game-based interventions were excluded.

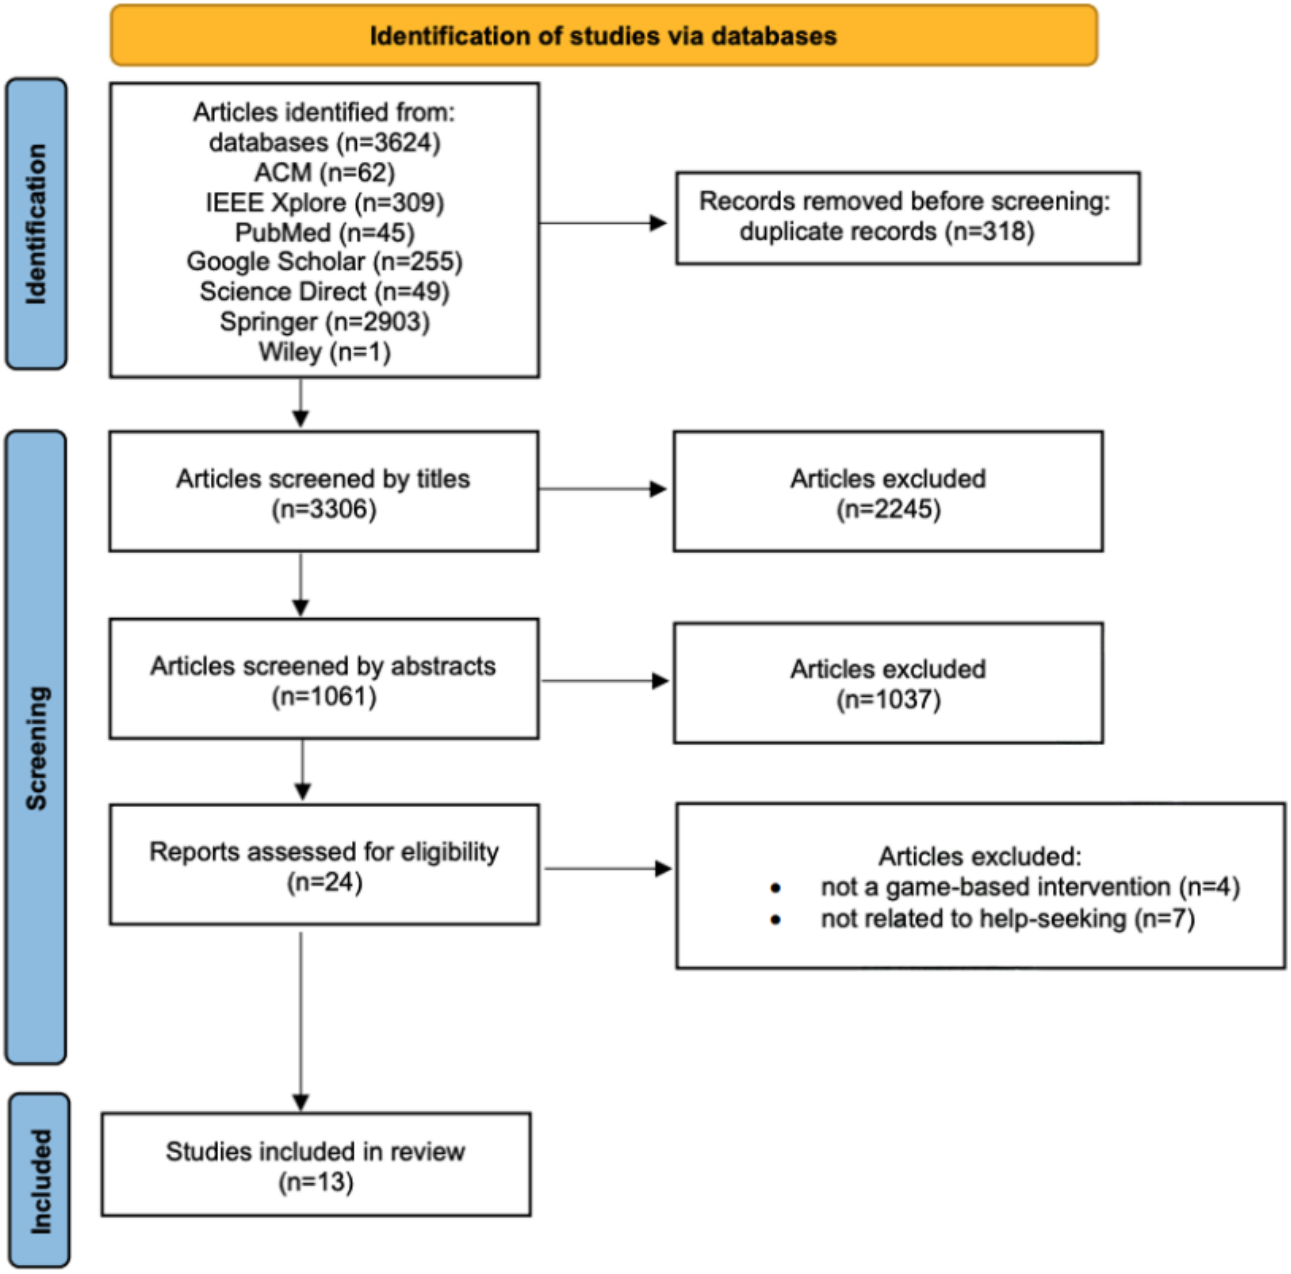
Sufficiency Statement

The authors acknowledge that their disciplinary backgrounds and research interests in digital mental health and game design may have influenced the interpretation and prioritization of specific themes during the analysis. Author WW is a PhD candidate who has experience in interaction design, data analysis, and software development. Author EP is a senior lecturer in the faculty of health. She has published reviews and empirical research in the field of mental health. She is also a clinical psychologist practitioner working with vulnerable and mentally unwell clients and families, including clients with PND. Author JG is a senior lecturer in games development, an experienced software engineer, and a serious game designer working with diverse clients. A particular emphasis was placed on design elements that support emotional engagement and help-seeking behaviors, which aligns with the authors' focus on developing interventions for new parents experiencing PND. Additionally, the narrative nature of the review allows for interpretive flexibility, which, while beneficial for exploring emerging ideas, may introduce subjective bias in theme identification and synthesis. The selection of literature in English only and a focus on peer-reviewed sources may have also limited the inclusion of culturally diverse perspectives and nontraditional forms of evidence.

Analysis Approach

To guide the synthesis and interpretation of findings across the selected literature, this review adopted a thematic analysis approach. Commonly used in qualitative research, thematic analysis is a systematic method for identifying, analyzing, and interpreting patterns of meaning—referred to as themes—within textual data [52]. It is particularly appropriate for narrative reviews, as it allows for the integration of diverse sources and offers a deeper understanding of complex issues across varied contexts. The analysis followed the 6-step process [53]. Initially, all included texts were read thoroughly by author WW to ensure familiarity with the content. From there, initial codes were generated inductively by author WW to capture recurring ideas, concepts, and relevant patterns. These codes were then reviewed by the team (EP and JG) and grouped into broader themes that reflected meaningful trends across the dataset. Each theme was refined and decided across the team (WW, EP, and JG) to ensure clarity, distinctiveness, and relevance to the review's aims. The final step was author WW weaving the themes into a cohesive narrative that highlighted their significance in relation to the central research questions.

By using thematic analysis, this review was able to go beyond a simple summary, offering a structured yet flexible framework to interpret findings. A thematic narrative approach was considered appropriate due to the heterogeneity of the sources, which varied in methodology, population focus, and design strategy. This flexibility allowed for a deeper exploration of how serious games function as educational and emotional tools, especially in the context of PND.



Results

Overview

There are 2 studies identified specifically from the search string PND, and 11 studies included from the search with depression. In total, 13 eligible studies were included in this review. There were 9 games published in academic articles, and the other 4 are from market research. In the past 5 years, there were 5/9 (55.6%) studies published. The screening process is shown in Figure 1. An overview of their characters is shown in Table 2.

Table . Summary of included studies.

Name	Year	Country	Study design	Sample size	Intervention length
Above Water	2016	Canada	N/A[a]	N/A	N/A
Stigma-Stop	2017	Spain	Comparison study	552	N/A
Leadership Training in Mental Health Promotion (LMHP)	2017	Germany	Quasi-experimental study	48	3 months
Moving Stories	2019	Netherlands	Cluster randomized controlled trial	185	6 months
MindMax	2020	Australia	Participatory design	40	N/A
MANTRA	2020	United Kingdom	Cocreation process	60	N/A
Hellblade: Senua's Sacrifice	2020	United States	Two-condition, randomized design	198	45 minutes
COEX-IST	2022	Brazil	N/A	N/A	N/A
PPDHero	2024	Bangladesh	Requirement elicitation study	108	N/A

[a]N/A: the data were not clear or not mentioned in the original paper.

This section divides the 13 studied games included into 3 categories based on their perspectives on improving help-seeking behaviors: promoting knowledge, reducing stigma, and raising awareness.

Promoting Knowledge

Overview

An overview of the games that focus on promoting knowledge to help improve depression can be seen in Table 3.

XSL•FO
RenderX

Table . Games focused on promoting knowledge.

Name	Year	Category	Aim	Audience	Game engine	Player mode
Above Water [54]	2016	Strategy games	This game informs people about the available strategies to cope with 2 types of anxiety disorders—generalized anxiety disorder and panic disorder. The game teaches players about existing treatments.	Game players	Physical cards and a mobile application	Multiple players
Moving Stories [55]	2019	RPGs[a]	This game aims to make adolescents have better mental health literacy and endorse fewer stigmatizing attitudes regarding depression.	Adolescents	Not specified	Single player
MindMax [56]	2018	Casual games	This game is to deliver psycho-educational modules and create a web-based community centering on well-being, AFL[b].	Men aged 16 to 35 years who are interested in AFL or video games	Mobile phone	Single player
MANTRA [57]	2020	Casual games	This game is to increase maternal and child health resilience before, during, and after disasters.	Vulnerable low-literacy female audiences in rural Nepal	Mobile phone	Single player
PPDHero [58]	2023	Serious games	This game aims to screen PND[c] and provide education and support to new mothers to identify and manage symptoms and connect with health professionals.	New mothers	Mobile gamification app	Single player

[a]RPG: role playing game.

[b]AFL: Australian Football League.

[c]PND: postnatal depression.

Above Water

In 2016, Wehbe et al [54] released the educational game *Above Water* for anxiety. It is a digital or physical hybrid game to inform people about the available strategies to cope with 2 types of anxiety disorders, which are Generalized Anxiety Disorder and Panic Disorder. It is designed to inspire players to share their experiences and develop their narratives by teaching them existing treatments. *Above Water* is a game that players play with physical cards and digital devices, such as tablets and smartphones. The game is designed to be played with 4 players. They are required to achieve all 6 categories of life goals, including career, education, health, self-improvement, financial stability, and relationships, while managing anxiety. They need to select 4 life goals on their smartphone, which cannot be changed during the play session. On each player's turn, they will draw 1 card to face up, play, or discard. Anxiety cards can be discarded by using treatment cards. They can be taught deep breathing skills, yoga, and stretching poses using mobile applications. The digital implementation does not require downloading an app. It uses a simple HTML5-enabled website. This game has several strengths, particularly in raising awareness and encouraging social support through collaborative gameplay. Its focus on educating players about anxiety and introducing treatment options makes it helpful in fostering an open dialogue about mental health. However, the game falls short in targeting specific populations and providing tailored

XSL•FO
RenderX

interventions. Additionally, it lacks mechanisms for improving long-term behavior change and cultural adaptation, which are critical elements for effectively addressing the unique challenges faced by parents dealing with PND. It could be improved by incorporating specific content for new parents and addressing unique social and cultural barriers.

Moving Stories

Moving Stories is a game-based school program for mental health literacy and stigma regarding depression published by Tuijnman et al [54] in 2019. It is developed by a professional game design company in collaboration with researchers and relevant stakeholders. Moving Stories includes three parts: (1) an introduction lesson, (2) a single-player, mobile, 3D video game, and (3) a contact session with someone with lived experience with a depressive disorder. The program focuses on three perspectives of mental health literacy: (1) recognizing the disorder, (2) having knowledge of help-seeking options and treatment available, and (3) first aid skills to support others who are developing or in a mental health disorder. The video game asks players to help a girl named Lisa, who has almost lost interest in everything. The players can do multiple things for Lisa to accumulate or decrease their relationship scores. As a bridge, the players are guided to share messages and discuss the reflection in a contact session with the school welfare coordinator or school counselor. This game demonstrates several strengths as a mental health intervention tool, particularly in improving mental health literacy, reducing stigma, and promoting help-seeking behaviors. By empowering players with knowledge, its approach to directly confronting myths through gameplay helps break down stigma. It encourages a more open conversation about mental health issues, which sets the foundation for increased understanding and empathy. It is crucial to tackle the stigma that new parents might face regarding PND. A key strength of the game lies in its focus on promoting help-seeking behavior. Through interactive scenarios that involve assisting the character Lisa and guiding her toward appropriate support, *Moving Stories* emphasizes the importance of recognizing mental health issues and seeking help. This game aligns well with the need to address the avoidance of help-seeking behaviors seen in PND, where new parents often struggle to ask for support due to stigma or lack of awareness. Incorporating role-playing elements demonstrates how and when to seek help, which is critical for empowering individuals to take action in real-life situations.

MindMax

MindMax is an app that incorporates gamification, mini-games, and social connection to improve men's mental health and well-being, published by Cheng et al [56] in 2018. This game is based on the original well-being training program that the Australian Football League Players' Association offered players. Thanks to the collaboration with the University of Sydney and the University of Technology Queensland, it aims to deliver a portable, digital version of Australian Football League Players' Association's existing program. The design process includes 3 phases. The first phase is 6 participatory design workshops consisting of 3 stages: discovery, evaluation, and prototype to identify how best to frame the well-being concept discussed in *MindMax* and, more broadly, how to structure a mental health and well-being app for the intended audience. The second phase is knowledge translation. The third phase is user experience testing interviews. This work explained well why and how they implement the participatory design process. The core components of *MindMax* include two parts: (1) multiple educational modules, each around 10 minutes, and (2) a web-based community centering on well-being, sports, and video games. The good point in an educational context is that the audience does not care about what context is presented, but how it was presented. The tone of expression is very important. Regarding the social element, it suggested the app should enable rather than emulate, and sharing personal experiences with potential groups they are conscious of may need careful consideration.

One of the key strengths of *MindMax* is its incorporation of psycho-educational modules that provide users with mental health information in a clear and accessible manner. Each module is designed to be short (approximately 10 min), making it feasible for users with limited time, such as new parents with demanding schedules. These modules cover foundational topics such as mindfulness, emotional well-being, and basic coping skills. For new parents experiencing PND, such content can be particularly beneficial as it provides them with the tools they need to understand their emotional state and learn practical strategies for managing stress. Making these modules easily digestible helps ensure that even those unfamiliar with mental health concepts can engage with the material effectively. Besides, the mini-games and reward-based mechanics used in *MindMax* are particularly useful in maintaining user engagement, which might be a crucial factor for individuals who may be overwhelmed with responsibilities or have limited energy to devote to self-care. Using games as rewards helps create positive reinforcement for completing educational tasks, encouraging continued learning and interaction. For new parents, especially those struggling to make time for themselves, gamification can transform mental health support into something enjoyable and less intimidating, thus promoting consistent use of the intervention. The light-hearted games and achievement-based systems can provide much-needed moments of relaxation and enjoyment, breaking up the often stressful and exhausting routines of caring for a newborn.

MANTRA

MANTRA is a serious mobile game that aims to reach a low-literacy audience in a low-resource setting with knowledge of maternal health, neonatal health, and geohazards. This work was published by Mueller et al [57] in 2020. The game mechanic is relatively simple in this game: picture matching with audio and visual feedback. The project's core goal is to tailor the knowledge to a local cultural context to fit specific settings with low literacy and resources. Throughout the design process, co-design and cocreation were guiding principles. The game design methodology builds on these principles and typical software development processes. The "drag-and-drop" is the only mechanism needed in the game. There is a touchscreen tutorial at first to help users who are not familiar with the screen interface. There are 3 modules in total, each containing 3 levels of complexity. The unsuccessfully answered question will be

XSL•FO
RenderX

pulled into an error pool and repeated up to 3 times throughout the level. The player will fail this level if all 3 times are answered incorrectly. *MANTRA* demonstrates several notable strengths in health education, particularly its accessibility for low-literacy users, cultural localization, and reinforcement of knowledge through repetition. It is designed for low-literacy users. It uses pictograms, audio prompts, and simple, intuitive interactions to ensure that even those with limited literacy skills can engage with and benefit from the game. This setting is particularly valuable for new parents from underserved communities who may lack access to formal health education, effectively addressing knowledge gaps. Second, the game's cocreation and cultural localization enhance its relevance and acceptance. Given that cultural context plays a significant role in the understanding and treatment of PND, incorporating cultural elements into the game helps to establish a deeper connection with users, reduce stigma, and increase engagement. Lastly, *MANTRA* uses repeated learning modules and immediate feedback, which helps reinforce knowledge retention. For new parents needing to master coping strategies and understand when to seek help, this method of repetition is crucial for effectively supporting their mental health outcomes. However, *MANTRA* also has some limitations. First, while using simple mechanics (such as drag-and-drop) makes the game accessible, it may not provide the depth of engagement needed for users facing significant mental health challenges. Second, the game lacks features that actively promote help-seeking behavior. For a digital game aimed at addressing PND, it is essential to include explicit pathways to professional support, such as information on local health care services or in-game guidance on seeking help, to bridge the gap between awareness and action. Lastly, the content of *MANTRA* primarily focuses on mothers without sufficient consideration of the role of fathers or nonbirthing parents in supporting maternal mental health.

PPDHero

PPDHero is a novel web-based system published by Sara et al [58] in 2024 for new mothers to screen PND and provide them education and support to identify and manage symptoms and connect with health professionals if needed. The design process starts with an elicitation study, which involved 6 senior doctors, who were incorporated with surveys from the broader public. The system was developed based on interview and survey data analysis. It includes three modules: (1) relevant content management; (2) screening, assessment, and gamification; and (3) a treatment and support module to enable users to share resources, enroll in screening procedures and treatment plans, register for gamified activities, and involve trusted professionals in their postnatal journey. The gamification tasks, such as quizzes and exercises, are implemented in the screening and assessment session to enhance the assessment process. Its strengths lie in its comprehensive approach, integrating education, screening, and treatment in a single platform. Using gamification elements, such as quizzes and interactive activities, enhances user engagement and makes learning about PND more attractive. Additionally, the platform provides a personalized experience through tailored treatment plans based on screening results, ensuring that users receive targeted support to manage their mental health. However, while the platform provides education and support, it lacks features specifically aimed at reducing stigma, which is an important factor in encouraging new mothers to seek help.

Reducing Stigma

Overview

In Table 4, there is an overview of game-related components that contribute to depression and broad mental health illness by reducing stigma to the game players.

Table . Games focusing on reducing stigma.

Name	Year	Category	Aim	Audience	Game engine	Player mode
Stigma-Stop [59]	2017	Simulation games	This game aims to reduce the stigma toward mental illnesses.	High school students	Unity3D	Single player
Leadership Training in Mental Health Promotion (LMHP) [60]	2017	Serious games	This game is to promote employee mental health and reduce mental illness stigma at work.	Managers	Digital game-based training program	Single player
Hellblade: Senua's Sacrifice [61]	2020	RPGs[a]	This game aiming to let players play video games featuring characters enduring mental illness may ultimately reduce stigma through transportation and identification.	Game players	Unreal Engine 4	Single player

[a]RPG: role playing game.

XSL•FO
RenderX

Stigma-Stop

Stigma-Stop is a 3D serious game to reduce the stigma toward mental illness among high school students, published by Cangas et al [59] in 2017. It is specifically designed to reduce the stigma associated with mental health disorders by educating players about different mental health conditions, such as depression, schizophrenia, bipolar disorder, and panic disorder with agoraphobia. The game provides information about these disorders through interactive dialogues and scenarios where players must choose how to react to individuals with mental health issues. This kind of approach is effective in challenging and correcting misconceptions about mental illness, particularly among young people. The game presents players with scenarios of interacting with characters representing different mental health conditions. Players are asked how they perceive the characters' psychological state, whether they have experienced similar emotions, and how they can help the character. These choices, along with the feedback provided for correct and incorrect responses, allow players to learn more about mental health hands-on, engagingly. However, the game also has notable limitations. Its primary focus on adolescents and broader mental health disorders may make it less directly relevant for new parents dealing specifically with PND. Additionally, the game lacks practical coping strategies or therapeutic guidance, which limits its effectiveness as a support tool aimed at improving the help-seeking behaviors of PND.

Leadership Training in Mental Health Promotion (LMHP)

Leadership Training in Mental Health Promotion (LMHP) is a digital game-based training program for managers to promote employee mental health and reduce mental illness stigma at work, published by Hanisch et al [60] in 2017. It applied various gamification components, such as providing a storyline and clear goals, including the capacity to overcome challenges by learning, giving feedback on performance, showing progress, and reinforcing learning by allocating points rather than simply providing badges for achievements and enabling competition between players, to facilitate an innovative and engaging learning experience. *LMHP* demonstrates several strengths that make it an effective tool for supporting mental health in the workplace and reducing stigma. The program's focus on mental health literacy, reducing stigma, and improving self-efficacy among managers makes it well-suited to foster a supportive work environment. The interactive simulation-based approach helps participants practice these skills in a safe environment, leading to higher engagement and better skill retention. While *LMHP* has strengths in terms of mental health literacy and stigma reduction, it focuses on the workplace environment and specifically targets managers. The scenarios and skills taught are tailored to workplace situations, which may not fully address new parents' specific emotional and psychological challenges in their home environment.

Hellblade: Senua's Sacrifice

Hellblade: Senua's Sacrifice is an action-adventure game accurately portraying psychosis to reduce public mental health stigma, developed and published by Ninja Theory [61] in 2017. It aims to reduce the mental health stigma in 2 ways: by lowering stereotyping and limiting participants' desire for social distance. *Hellblade: Senua's Sacrifice* is set in an age of Vikings. Its story is about Senua's battles for the soul of her departed lover, Hela. Senua endures psychosis and must contend with her mental illness along with the challenges presented by her quest. The game blends gameplay mechanics and concepts such as puzzle solving, psychological horror, and melee combat. Voice acting is an integral part of the game, while its cut scenes combine motion capture by Melina Juergens and live-action performances by other actors.

The game's powerful and immersive portrayal of mental health struggles provides players with a unique opportunity to experience the emotional complexities associated with conditions such as psychosis. Through this kind of realistic depiction, new parents experiencing PND can see their struggles mirrored in the protagonist's experiences, helping them feel validated and understood. Second, the game's high-quality audio design plays a crucial role in enhancing the emotional depth of the experience. Using binaural audio to simulate auditory hallucinations, *Hellblade: Senua's Sacrifice* creates a profoundly immersive atmosphere that draws players into Senua's inner world. This kind of powerful audio experience can help new parents connect more profoundly with the emotional struggles portrayed, fostering empathy and offering a unique perspective on mental health challenges. Lastly, the game's development process involved collaboration with mental health experts and individuals with lived experience of psychosis. This process makes the portrayal of Senua's mental health struggles both vivid and respectful, adding credibility to the game's narrative.

Raising Awareness

Overview

In Table 5, there is an overview of how game-related components contribute to depression and broad mental health illnesses by raising awareness among game players.

XSL•FO
RenderX

Table . Games focused on raising awareness.

Name	Year	Category	Aim	Audience	Game engine	Player mode
Depression Quest [62]	2013	RPGs[a]	This game aims to show other people with depression that they are not alone in their feelings and to illustrate to people who may not understand the illness the depths of what it can do to people.	Game players	Twine engine	Single player
Keep in Mind: Remastered [63]	2018	Simulation games	This game is meant to be a therapeutic experience for those who struggle with mental illness on a journey of reflection and emotional healing.	Those who struggle with mental illness or those who find themselves lost in the dark	Unity	Single player
Before I Forget [64]	2020	Simulation games	This game aims to raise awareness about mental health and communicate to the audience the struggles of people experiencing dementia.	Game players	Unity	Single player
Sea of Solitude [65]	2021	Simulation games	This game aims to reveal the themes of depression, loneliness, and hopelessness, how we unwittingly push people away, and how our actions can negatively affect others.	Game players	Unity	Single player
COEX-IST [66]	2022	Strategy games	This game is meant to increase mental health awareness and focus on self-care as a form of prevention.	People with a wide age range, from teenagers to adults	Not specified	Single player

[a]RPG: role playing game.

Depression Quest

Depression Quest is an interactive fiction game dealing with depression. It was developed by Zoe Quinn [62] using Twine (Interactive Fiction Technology Foundation) and published in 2013. This game aims to spread awareness by showing other people with depression that they are not alone in their feelings. *Depression Quest* is not an easy gaming experience because its goal is precisely to let you experience the difficulties of depressed people. It is a text-based game, and your choice will impact your ending. *Depression Quest* has a straightforward game structure. There are no animations or complex controls. As the story progresses, the player chooses different options to move the story in different directions. The part that *Depression Quest* comes closest to reality is that it tries to make people who do not have experience with depression understand that there are choices that do not exist for people who have depression. In the game, as the depressive condition deepens, the optimistic options are crossed out by the system with a red line—the player can only choose the closed, pessimistic options, and the depressive condition further deepens. There are fewer and fewer options to choose from in the game. It is a vicious circle and one that many people with depressive tendencies face.

This game has several strengths in its design elements. First, the game's narrative-driven depiction of depression provides a deeply empathetic look into the daily struggles of a person experiencing mental health challenges. Second, the game uses a unique mechanic where certain positive choices become restricted based on the protagonist's mental health status. This mechanic reflects the real-life constraints imposed by depression, such as the difficulty in making proactive decisions when feeling overwhelmed. For new parents experiencing PND,

XSL•FO
RenderX

this feature can help explain why even seemingly simple actions might feel impossible. It encourages self-compassion by showing that these limitations are part of the condition, not personal failings. Furthermore, as players engage with the narrative and take actions such as seeking help, they unlock new options, which effectively illustrate the empowerment that can come from actively addressing mental health challenges. Third, *Depression Quest* is also effective in raising awareness and fostering empathy among those who may not have firsthand experience with depression. By taking players through scenarios involving hopelessness, lack of motivation, and interpersonal struggles, this game mechanic could help partners and family members of new parents better understand the challenges their loved ones face. This improved understanding can lead to more supportive relationships and foster a compassionate environment. Finally, the game places a strong emphasis on encouraging help-seeking behavior. Players can pursue therapy or medication throughout the match, impacting the protagonist's situation and improving the choices. By showcasing how seeking help can positively affect mental health, *Depression Quest* actively promotes the idea that professional support is valuable and effective. New parents, who may feel hesitant to seek help due to stigma or uncertainty, could see the benefits of reaching out in this kind of game, which can help motivate them to pursue the support they need.

However, despite these significant strengths, the game has a key limitation. The intense focus on the struggles of depression, combined with the dark and sometimes overwhelming themes, may risk leaving players feeling disheartened without enough positive reinforcement or hope to balance the experience.

Keep in Mind: Remastered

Keep in Mind: Remastered [63] is a heavy story-driven psychological indie game that follows Jonas, a man who struggles with grief, depression, and alcoholism, on a journey of reflection and emotional healing. One night, he awakens to a shadowy mirror world where beasts lurk, and stars do not shine. Lost and scared, Jonas must face the twisted beasts if he ever wishes to return home and learn the truth about his darkness. It was released by Little Moth Games and Akupara Games in March 2018. This game was created for those who struggle with mental illness or those who find themselves lost in the dark. This game is meant to be a therapeutic experience. *Keep in Mind: Remastered* has notable strengths that make it a compelling game for raising awareness about mental health challenges. For new parents, especially those experiencing PND, the portrayal of such internal struggles can help them feel seen and understood. This level of emotional storytelling can help reduce the stigma around PND by showing that struggling with mental health issues is not uncommon and that others share the negative thoughts and emotions they may be experiencing. Besides, the game uses symbolism effectively to represent the different facets of the protagonist's mental health challenges, such as dark creatures and eerie settings. This symbolism allows players to externalize their internal emotional struggles, making them more tangible and easier to understand. However, the game's focus on heavy and potentially triggering themes, lack of practical coping strategies, and absence of integrated help-seeking features might limit its effectiveness as a supportive intervention.

Before I Forget

Before I Forget is a single-player exploration game developed and published by 3-Fold Games [64] in 2020. It is a short game that draws the player to a character experiencing dementia. She is housebound and unable to leave the flat. Only the windows could offer a view of the outside world, with its letterboxes and birdbaths. Otherwise, the exploration all happened in the mind as the character scrabbles to dredge artifacts from her past. In this game, players guide Sunita Appleby, who is a scientist with early-onset Alzheimer disease. As she interacts with now-unfamiliar objects in her house, some of her memories return. The game features puzzle-like elements, such as recalling where mementos have been left and asking players to guide Sunita to the bathroom when she perceives her house as a shifting maze. The game's use of empathetic storytelling and emotional depth provides a powerful connection to the struggles faced by those with mental health challenges. The game fosters understanding and reduces stigma around vulnerability and emotional struggle by allowing players to see the world through the protagonist's perspective. Additionally, the emphasis on relationships and emotional connections highlights the importance of support networks, encouraging players to lean on their loved ones during difficult times. However, the game also has notable limitations; the lack of practical coping strategies limits its effectiveness as a tool for managing day-to-day mental health issues, such as PND.

Sea of Solitude

Sea of Solitude is an adventure video game developed by Jo-Mei Games and published by Electronic Arts [65]. The player controls a young woman named Kay, who endures such strong loneliness that her inner feelings of hopelessness, anger, and worthlessness turn to the outside, and she becomes a monster. As Kay, the player explores a seemingly empty flooded city and interacts with its scaly red-eyed creatures to reveal why she turned into a monster. Her emotions manifest into giant monsters standing in her way, trying to help but also destroy her. She needs to interact with and understand their underlying intentions to overcome the negative effects of those emotions. The game is an inner dialogue of a person trying to reconcile her shortcomings. It provides an insightful look at how mental illness devastates the lives of not just those it affects but also loved ones on the outside. Kay learns a lot about herself by understanding the value of listening, coming to terms with her flaws, and not just empathizing with her family but also accepting that a simple fix is not always possible. The game's powerful narrative effectively depicts the emotional struggles of loneliness, depression, and anxiety, allowing players to relate deeply to the protagonist's journey. Referring to this representation can help new parents normalize their emotions and reduce the stigma around experiencing mental health challenges during the postnatal period. The exploration mechanics and emotional expression throughout the game provide a meaningful way for players to reflect on their experiences. Additionally, the game's focus on empathy and understanding different characters' struggles helps to foster a

XSL•FO
RenderX

deeper connection between players and the themes of mental health. For new parents, this emphasis on empathy can reduce feelings of isolation and highlight the importance of reaching out for support, both for themselves and others. However, *Sea of Solitude* also has notable limitations in addressing PND effectively. The game lacks practical coping strategies that can be directly applied to real-life challenges. For new parents, having evidence-based tools and actionable advice would be instrumental in managing the day-to-day reality around PND. Without such strategies, the game may fail to deliver tangible help beyond emotional understanding. Moreover, the heavy themes of depression, anxiety, and loneliness may be overwhelming for some new parents, particularly those who are already vulnerable. Without sufficient pacing options or content warnings, the game risks triggering or intensifying negative emotions rather than alleviating them.

COEX-IST

COEX-IST is a 3D interactive story decision-making game that aims to grow awareness about depression and social isolation after a pandemic. In 2022, Rodrigues et al [66] developed and published it. The game story is based on 25 undergraduate students' personal experiences. It is a third-person short game based on narratives and point-and-click to interact with the scene's objects and make decisions. The end of the narrative has 2 possible actions for game over: victory over depression or victory of depression. The story's resolution also involves tying up the loose ends of the climax and falling action. Each choice has impact consequences. Both possible ending scenes allow the player to experience and think about depression, growing awareness of this illness. The game's interactive decision-making process, emphasis on empathy, and reflective storytelling structure offer a deep and meaningful engagement that helps players connect with the content and understand the complexities of mental health challenges. First, the interactive decision-making feature allows players to experience the consequences of their actions realistically. This level of interactivity encourages new parents to see the potential impact of small, positive actions in their own lives, thereby fostering a sense of control over their mental well-being. This sense of agency is particularly important for new parents, who may often feel overwhelmed by the responsibilities and pressures of caring for a newborn. Second, the game's emphasis on mental health awareness and emotional empathy is effectively conveyed through storytelling. By representing depression as "Mr. Shadow," *COEX-IST* provides a powerful visualization of the weight and burden of mental illness. This representation helps players externalize and better understand their own struggles. It also reduces the stigma associated with these emotions by demonstrating that they are a shared experience that can be overcome with the right actions. This empathetic storytelling can provide comfort and connection for those who may feel isolated in their struggles. Lastly, the structured storytelling approach gives the narrative a clear and engaging emotional experience that mirrors the journey of dealing with mental health challenges. For new parents, seeing the protagonist's ups and downs depicted in a structured way can help normalize their own experiences. The 2 possible endings—either overcoming depression or being overtaken by it—underscore the importance of the player's choices and illustrate the ongoing nature of mental health management. This setting highlights that while setbacks may occur, progress is possible, which can provide hope and motivation to players during difficult times.

Many of the reviewed games (eg, *Depression Quest* and *Before I Forget*) aimed to raise awareness and build empathy through immersive experiences that replicate the emotional realities of those affected. These games often use narrative-driven storytelling to allow players to live through the struggles of a character facing depression. Through experiencing the emotional highs and lows, players are encouraged to empathize with the character's struggles. This emotional journey is argued to be crucial not only for players who are personally dealing with mental health challenges but also for their support networks—such as partners, family members, and colleagues—who may benefit from a better understanding of what their loved ones are going through. This approach can externalize internal emotional struggles, providing validation for players dealing with similar issues. The intention here is to not only entertain but offer a profound and empathetic experience that helps players feel less isolated.

Some reviewed games (eg, *MindMax* and *Stigma-Stop*) encouraged players to seek professional help for mental health concerns. By embedding choices in the game where players can seek therapy, use support resources, or talk to someone, these games guide players toward understanding the importance of professional help in managing mental health conditions.

Six games targeted adolescents and youth from 15 to 25 years, and one targeted younger children. Six games do not specifically target an age group, but board game players. Examples of these groups include 1 study for men who are interested in AFL games and 1 study for company managers.

Among these games, only 2 games targeted new mothers with a game intervention focused on promoting knowledge. Although few studies directly target new parents, there is arguably some overlap with the depressive symptoms faced by the other groups discussed above. However, new parents are often in a unique and vulnerable position, facing a combination of physical, emotional, and psychological challenges. They usually experience heightened vulnerability, exhaustion, and lack of time [67], which requires an intervention that is not only effective but also easily accessible and low-pressure. Many of the games targeting adults with depression do an excellent job of portraying the emotional complexities of mental health issues. Still, their intensity and focus on complex gameplay may not be suitable for new parents who are experiencing severe fatigue. It is argued that the new parent target audience would benefit more from short, accessible gameplay that can be easily integrated into their busy routines, and casual yet meaningful experiences that provide emotional validation and support.

Given the needs of the new parent target audience, mobile platforms are likely the most suitable choice. Mobile games can be played in short bursts, require minimal setup, and are highly accessible because most people carry smartphones. Mobile accessibility also allows parents to engage with the game whenever they find spare moments, which is crucial given their unpredictable and fatiguing schedules. However, a hybrid

XSL•FO
RenderX

solution that combines mobile and web-based access to ensure that new parents have multiple ways to engage with the game based on their convenience may also be valuable. A web-based version could provide a larger screen and more detail for those moments when new parents can access a computer, while the mobile version allows instant play. WebGL technology further reduces minimum system requirements and will enable games to be accessed from any electronic device. Hybrid accessibility also increases reach, as it accommodates different user preferences and ensures that players have multiple ways to interact with the content.

Console and VR platforms, while highly immersive, are arguably not ideal for most new parents. While VR today is widely "plug and play" and often requires little more than a connection ID to get started, the transition to becoming a parent, particularly in the early months, is marked by extreme time constraints, chronic sleep deprivation, and a constant state of divided attention [68]. New parents often navigate caring for an infant, are adjusting to unpredictable routines, and manage both emotional and physical exhaustion. Therefore, it is proposed that even simple steps such as clearing space, troubleshooting hardware, or remaining engaged in a virtual environment for more than a few minutes can become overwhelming for parents who might be at risk of cognitive and emotional overload.

Discussion

Overview

There is a dearth of evidence directly related to PND, which is only 2 studies in the past 10 years. After expanding the search to depression, we included 11 more. The included studies predominantly aligned with 3 overarching themes: the promotion of knowledge, the reduction of stigma, and the raising of awareness. A core intention of several of the reviewed games (eg, *Above Water* and *Moving Stories*) is to educate players about mental health and reduce the associated stigma. This is achieved by exposing players to the symptoms, challenges, and lived experiences of individuals who are dealing with various mental health conditions. The games use different approaches, such as presenting players with scenarios that require them to make supportive decisions, simulating real-life interactions with people facing mental health challenges, and providing informative feedback. The ultimate goal is to educate the players on mental health literacy, that is, what different symptoms mean, why they matter, and how to effectively respond. This type of education, delivered in an interactive, engaging way, generally helped to demystify mental health issues, correct misconceptions, and encourage empathetic attitudes. This is argued to play a crucial role in reducing stigma by promoting understanding and highlighting the commonality of these experiences, breaking down the barriers that often prevent open conversations about mental health.

Game Mechanics

For depression management in general, several mechanisms are argued to be particularly impactful. Narrative storytelling, as seen in games such as *Hellblade: Senua's Sacrifice* and *Depression Quest*, may provide emotional engagement that helps players feel understood and validated by illustrating shared experiences of mental health struggles. Given the evidence that the recognition and acceptance of an individual's feelings and experiences promote mental well-being, seeing their experiences reflected in the storyline may create an emotional connection that could combat isolation. Choice-based interaction, where players make decisions that affect the storyline, may offer a sense of agency and sense of control, which is often decreased in those experiencing depression [69]. These decisions can illustrate how positive actions, such as seeking help or practicing self-care, might lead to better outcomes, potentially reinforcing a sense of empowerment for new parents. Simulated real-life scenarios could also play a role in helping players practice practical coping skills, such as managing stress or communicating with loved ones in a safe and controlled environment. Combined with resilience mechanics that highlight small wins, these mechanics may help maintain motivation during challenging times. Additionally, low-pressure gameplay is likely important to this target group, as it may reduce the cognitive and emotional needs of interaction, making the game more accessible to new parents who are experiencing fatigue and time constraints.

For educational purposes and stigma reduction, specific game mechanics may help build knowledge and empathy in accessible ways and minimally overwhelm the player. For example, educational micromessaging, as seen in "Match Emoji" and "Stigma-Stop," delivers brief and embedded content that increases awareness about mental health conditions. This mode of delivery may be especially valuable for new parents, who often benefit from concise, low-effort learning formats. Empathy-building mechanisms could also contribute to stigma reduction, an important function within PND given its high association with stigma [13]. Interactive elements that allow players to make supportive choices during character interactions may foster greater understanding and compassion. Role-playing as characters facing mental health challenges may help players consider these issues more personally, potentially encouraging self-compassion and empathy for others. Additionally, real-life scenario simulations may offer players opportunities to engage in realistic support-seeking situations, which could enhance a better understanding of seeking and receiving support.

Given the cultural, social, and personal barriers to seeking help for people with PND [13], certain game mechanics could play a valuable role in improving help-seeking behavior by reducing hesitancy and encouraging engagement with professional help. Choice-based interactions that include options for seeking therapy or speaking to a health care professional can illustrate the potential positive impact of these decisions and may help normalize the idea of reaching out. In-game scenarios that model conversations with health care professionals or trusted family members could also reduce anxiety by providing players with low-risk opportunities to observe or practice supportive dialogue. Additionally, incorporating positive reinforcement, such as visual or narrative cues that reflect improvements in well-being or relationships following help-seeking, may highlight the value of accessing help. For expectant parents who may experience PND after their baby is born, these mechanics may offer gentle encouragement and promote greater confidence

XSL•FO
RenderX

in taking the first step. As shown in Table 6, here is a comparison of game mechanics and different aims.

Table . Comparison of game mechanics and different aims.

	Build knowledge	Build empathy	Build awareness	Reduce stigma

Choice-based interaction		✓		✓
Educational micromessage	✓		✓	
Character interaction	✓	✓		
Real-life scenarios	✓		✓	
Resilience mechanics			✓	

Principal Findings

To effectively support new parents coping with PND and to address the gaps identified in this review, the authors argue that future research should focus on the interprofessional co-development of a serious game with the following important design elements. First, we argue that a relatable and engaging story is important and should reflect both the struggles and victories that new parents face, helping them see their own experiences mirrored in the game. By doing this, the game can foster a deep sense of understanding, connection, and emotional validation, which may be crucial for reducing the isolation [13] often felt during PND. Allowing players to make meaningful choices that influence the direction of the game could give them a sense of agency and control to combat the low sense of agency [69] frequently found in the experience of depression. These decisions should reflect real-life challenges, and the consequences should demonstrate how positive actions, such as seeking help or practicing self-care, can improve well-being. This interactive element can empower new parents to feel more in control of their own mental health journey. Incorporating real-life scenarios is also a key element. These scenarios should include common parenting challenges, such as communicating effectively with a partner, managing stress, or seeking support. Practicing these skills in a safe, controlled game environment can help players build confidence, making it easier to apply what they have learned to real life.

Gamification elements such as badges, progress tracking, and daily challenges should be used to keep players motivated and committed, in line with a positive reinforcement approach to learning and improving intrinsic motivation [70]. These features add an element of fun and reward, encouraging players to engage consistently with the game. The game should also include educational messages that provide important information about PND. These messages could cover recognizing symptoms, understanding when to seek help, and learning practical self-care techniques. Delivering these messages in small, easily digestible portions ensures that players can learn without feeling overwhelmed, and it is in line with research findings that show benefits for adult learners who engage in mobile-based microlearning steps [71].

Character interactions are another essential design element. Players should have opportunities to interact with supportive characters, which can help build empathy and promote positive communication skills. These interactions can model supportive relationships and reinforce behaviors that new parents can use in their own lives to improve their support networks. Celebrating small wins is also important; highlighting moments such as taking time for self-care or successfully reaching out for help can reinforce resilience and make players feel that each positive step, no matter how small, is a significant achievement. Lastly, the game should be designed to be accessible and easy to engage with in short sessions. Low-pressure gameplay is important, as new parents often face exhaustion and have limited time [68]. The game should be flexible, allowing players to pick it up and put it down whenever they have a few moments, ensuring it serves as a helpful, nonstressful tool in their daily lives. This balance of emotional engagement, practical learning, and ease of access is proposed to create a supportive experience that can make a meaningful difference for new parents coping with PND.

Recommendations

Overview

Serving the aim of our proposed project, we recommend focusing on the following subset of game types and mechanics.

Narrative-Driven Storytelling

Incorporate an engaging storyline that reflects the real-life experiences of new parents, including both struggles and successes. This mechanic helps players feel understood and connected, reducing feelings of isolation. The narrative should also include resilience themes to promote hope and perseverance.

Choice-Based Interactions

Implement choices that directly influence the game's storyline, allowing players to make decisions that affect their mental health journey. This empowers players by giving them a sense of control, emphasizing the positive outcomes of seeking help or practicing self-care.

Real-Life Scenario Simulations

Include scenarios that simulate everyday parenting challenges, such as communicating with a partner, managing stress, or seeking professional support. Practicing these skills in a game setting builds players' confidence and provides them with practical tools for real-life application.

Low-Pressure, Casual Gameplay

Design the game for short, manageable sessions that can be played on a mobile device. This mechanic ensures accessibility

XSL•FO
RenderX

for new parents, allowing them to engage with the game without added pressure or stress. Casual mechanics make the game easier to pick up and play whenever parents have a few free moments.

Educational Micromessaging

Integrate educational content subtly throughout the game to provide important information about PND, such as recognizing symptoms and self-care tips. Delivering these messages in a digestible format helps fill knowledge gaps without overwhelming the player.

Character Interactions and Empathy-Building

Allow players to interact with characters representing supportive individuals, such as partners, family members, or health care professionals. These interactions help model healthy communication and build empathy, both for oneself and others.

Gamification Elements

Add elements such as badges, progress tracking, and daily challenges to encourage ongoing engagement. Gamification makes the experience more rewarding and helps players stay motivated, which is especially important for building positive habits.

Celebrating Small Wins

Highlight small victories in the game, such as successfully reaching out for support or completing a relaxation exercise. Positive reinforcement builds resilience and emphasizes that progress, no matter how small, is meaningful.

Strengths and Limitations

This review draws strength from its interdisciplinary synthesis of literature spanning digital mental health interventions and serious games, offering a comprehensive overview that bridges technological and psychological perspectives. Examining a novel and emerging approach to PND care contributes to a growing area of interest that remains underexplored in current research. In instances where PND-specific evidence is limited, the review draws from broader depression literature to extract relevant insights while maintaining awareness of contextual differences. Importantly, it also provides a forward-looking perspective by identifying clear gaps in the existing literature and outlining specific directions for future research. These include the development and tailoring of serious games for PND populations, informed by existing evidence on effective game mechanics in comparable mental health contexts.

However, this review also has several limitations. First, the limited number of studies specifically focused on PND constrained the depth of analysis and made it necessary to draw from broader depression literature. While this allowed for the extraction of relevant insights, it may affect the generalizability of findings to the unique psychological and social experience of individuals with PND. Second, there is a potential for selection bias in the inclusion of literature; however, attempts to reduce this included using a structured search process and adhering to the preagreed scope. Future reviews might consider incorporating elements of systematic review methodology, such as dual screening or formal bias appraisal, to enhance rigor. Third, the review was limited to English-language publications, which may have excluded relevant studies from culturally and linguistically diverse populations, potentially narrowing the applicability of findings across global contexts. Expanding the language scope in future reviews could provide a more inclusive understanding of how serious games may support help-seeking across varied cultural settings. Finally, while a narrative review design can lack a systematic or quantitative appraisal of study quality and findings, in this case, given the heterogeneity of the studies reviewed, it did allow for a comprehensive synthesis of the available literature to better pinpoint specific targeted areas needing additional research with recommendations for targeted and novel game design to address that identified gap.

Future Directions

Based on the findings of this review, the authors plan to develop a game design prototype that selectively incorporates these recommended game mechanics, which will allow for an empirical investigation of utility and efficacy. The game design will have a particular focus on the accessibility and usability needs of new parents. We will begin by conducting user research, including interviews with new parents, to further understand their challenges and preferences. This process will ensure that the game design aligns well with their experiences and provides meaningful support. We will also collaborate interprofessionally with mental health professionals to ensure that the educational content is accurate and that the overall gameplay promotes mental well-being.

Additionally, we aim to develop a hybrid solution that allows for both mobile and web-based accessibility, ensuring that new parents have multiple ways to engage with the game based on their convenience. Once the prototype is ready, we will conduct usability testing and content value testing to assess its possibility and feasibility in engaging new parents and providing mental health support. Feedback from this testing phase will guide further refinements to make the game as supportive and accessible as possible for new parents to improve help-seeking behavior for PND.

Conclusions

The evidence base for PND-related interventions is currently limited and emerging, highlighting a notable gap in future research. Based on the analysis of existing games, many of them aim to educate players on mental health topics, using engaging scenarios that require players to make supportive decisions and learn about the lived experiences of people with mental health issues. This approach encourages players to understand mental health, corrects misconceptions, and promotes empathy, ultimately reducing stigma. Narrative storytelling also plays a significant role, allowing players to experience the emotional highs and lows of a character's journey, fostering a deep connection and validation for players facing similar struggles. Empowering players was also found to be valuable in seeking professional help by embedding scenarios that encourage reaching out to health care professionals and practicing coping skills in a low-risk, game-based environment. It is argued that these mechanics help players feel more comfortable about seeking support and build their confidence in managing their own mental health.

XSL•FO
RenderX

The included games target a range of audiences, including adolescents, adults, and the general public, identifying a literature gap that only a small number are specifically designed for new parents. New parents face unique challenges, such as exhaustion and time constraints, suggesting the ideal game platform is likely to be mobile—rather than immersive—platforms as they offer the flexibility and ease of use necessary for new parents. Finally, this review underscores the importance of expanding serious game research to more effectively reach and support those experiencing PND, a population that remains inadequately treated and frequently stigmatized in modern culture.

Abstract

Background: Postacute care (PAC) services are important to ensure functional recovery and provide adequate care for geriatric inpatients in acute care. The choice between different PAC options can be challenging, and predictors for the most appropriate among diverse discharge options are warranted.

Objective: We conducted a scoping review to identify predictors of appropriate discharge destinations for older adults (≥65 y) in acute care transitioning to different PAC settings and extract the most relevant predictors for different PAC settings as well as a generalizable set of predictor domains.

Methods: The databases of Medline, Embase, Cochrane Central Register of Controlled Trials, PsycINFO, CINAHL, and Emcare were systematically searched for English or German literature published until February 25, 2022. A total of 3 researchers screened, extracted, and categorized the data according to domains, discharge destinations, mean age, and health care systems origin, focusing on predictors that increase the likelihood of a discharge destination (positive predictors). The Jaccard index was calculated to compare the similarity between different possible domain combinations and existing literature.

Results: Of 22,382 records screened, 171 quantitative and 10 qualitative studies were included. After separating combined discharge destinations, we found 1047 predictors for different discharge destinations including nursing home (n=297, 28%), skilled nursing facility (n=223, 21%), inpatient rehabilitation (n=206, 20%), home with (n=97, 9%) or without (n=74, 7%) support, assisted living (n=63, 6%), and early inpatient rehabilitation (n=21, 2%). Of all positive predictors (n=723), age was the most frequently reported predictor (80/723, 11%). Geriatric syndromes were found more often in patients 80 years or older (121/192, 63%) and in non-US studies (174/285, 61%). The top reported predictors for discharge to nursing homes were diagnosed dementia (9/297, 3%) and deficits in instrumental activities of daily living (ADL; 10/297, 3%); for discharge to rehabilitation, the top predictors were longer length of stay (11/205, 5%) and existent cardiopulmonary disease (10/205, 5%); and for back home without support, the top predictors were good ADL (10/74, 14%) and mobility assessments (9/74, 12%). Among 20 predictor domains, 8 were most concordant with the literature: cognitive impairment, ADL, demographics, social support, hospitalization data, multimorbidity, mobility, and primary diagnosis.

Conclusions: This scoping review provides a comprehensive overview of predictors for appropriate discharge decisions in older adults in acute care, stratified by destination, age, study origin, and the predictor domains most concordant with the literature. The results will be valuable to inform the choice of features for clinical decision support systems, including the training of machine learning algorithms.

Introduction

Geriatric inpatients are at a high risk of functional decline during acute care treatment, and post-acute care (PAC) services are needed to ensure recovery [1]. Effective discharge planning has been shown to mitigate readmission rates, reduce hospital stays, lower associated costs, and enhance patient satisfaction [2]. Thus, choosing the most appropriate discharge destination is vital within geriatric comanagement, guaranteeing alignment with individualized rehabilitation and care needs. Modern health care systems present diverse PAC options, making selection challenging and highlighting the need for predictors of appropriate discharge destinations [3-6].

The World Health Organization defines continuity of care (COC) as the degree to which health care events are perceived as connected and coherent over time, aligning with patients' health necessities and preferences [7]. COC can be further categorized into relational continuity (patient-provider relationship), informational continuity (communication), and management continuity (coordination) [8]. In the context of geriatric comanagement in acute inpatient care, the choice of the most appropriate discharge destination refers to the management continuity aspect. In addition to COC and discharge planning, various terms encompass this dimension, including integrated care, case management, or transitional care [9,10].

Existing research has focused on predictors differentiating binary outcomes [11-13]. However, there remains a need for predictors supporting decisions among multiple discharge options to not miss relevant features.

To address this gap, we conducted a scoping review to identify potential predictors for the most appropriate discharge destination for older inpatients in acute care transitioning to different PAC options such as outpatient, inpatient or early rehabilitation, skilled nursing facility (SNF), nursing home, assisted living, or home-based care with or without support. As different health care systems offer different discharge destinations and funding options, we also planned to stratify according to the different health care system origins. Our scoping review will inform the feature selection for the development of a machine learning−driven clinical decision support system (CDSS) within the "Supporting Surgery with Geriatric Co-Management and AI" (SURGE-Ahead) project by providing a broad overview of predictive measures for different discharge options [14].

Methods

Conceptualization

We conducted a scoping review adhering to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Scoping Review extension guidelines; Checklist 1) and the Joanna Briggs Institute guidance [15,16]. A review protocol was registered on Open Science Framework and was adapted after a piloting phase to focus on "predictors" instead of "predictors and outcome measures" due to a lack of specific outcome measures for COC identified [17].

Eligibility Criteria

Using the Joanna Briggs Institute's population-concept-context framework, our focus was on older adult inpatients 65 years and older treated in acute surgical or medical hospital departments [18]. We included only participants 65 years and older, verifying this by examining the inclusion criteria and the reported age structure of each study population. Studies were included if they reported an age range with a lower limit of 65 years or above or at least provided a mean or median of 65 years or more. Publications with unclear age demographics were conservatively excluded. We aimed to identify predictors utilized by health care professionals to determine the most appropriate PAC setting. Predictors were defined as discrete, separable parameters associated with a specific discharge destination. When faced with complex models combining multiple parameters, we included the individual parameters whenever feasible but not the complex model itself. In quantitative analyses, we further required evidence of a statistically significant effect ($P \leq .05$). Studies had to involve transitions from acute care to different PAC options. German- or English-language publications were considered, excluding letters, comments, case studies, editorials, and studies primarily addressing health economic issues or involving psychiatry or rehabilitation departments for older adults. We excluded studies that chose to report composite discharge options like "discharge to nursing home or death," as these outcomes should not be combined. Similarly, studies including palliative care services like hospice as part of a composite discharge destination were excluded, as we consider individualized decision-making essential for palliative care.

Search Strategy

Comprehensive search strategies were developed that included different concepts for the successful choice of discharge destinations, including continuity of care, coordination of care, transition of care, integrated health care, case management, discharge planning, or rehabilitation eligibility determination. On February 25, 2022, the databases Medline (OVID interface), Embase (OVID), Cochrane Central Register of Controlled Trials (Wiley), PsycINFO (EBSCOhost), CINAHL (EBSCOhost), and Emcare (OVID) were systematically searched, guided by an experienced information specialist (KG). Search strategies for all databases searched are shown in Multimedia Appendix 1.

Study Selection and Data Extraction

Records obtained through the database search were imported into the Covidence systematic review software (Veritas Health Innovation). Additionally, the primary publications of all reviews identified in the literature search were imported into Covidence. Duplicates were removed using the deduplication functionality of the software, followed by manual verification in unclear cases marked by the software (MLF and CL). Two out of the 4 reviewers (MLF, CL, LB, and JW) independently screened all titles and abstracts for eligibility, followed by full-text screening. Any discrepancies were resolved through adjudication by a third author. Data extraction for each article was conducted by 2 of the 3 authors independently (MLF, CL, and JW) and consolidated by the team. The extracted data

XSL•FO
RenderX

encompassed study and population characteristics, health care systems origin, discharge destination, statistical analysis type, predictor, and quantitative measures of predictive strength (odds ratio, relative risk, confidence interval, *P* value) if available. The identified predictors were categorized into different domains after discussion in the review team. Data extraction for qualitative studies was conducted separately using a thematic evidence synthesis, assigning all qualitative and quantitative predictors, including representative quotes, to the predefined domains [19].

Data Analysis

Predictive directions indicating an increased (positive) or reduced (negative) probability of discharge to a specific environment were determined from odds ratios, relative risks, or manual labeling and joint consensus when necessary (MLF and CL). The negative predictors reported in the included studies often used double negations or lacked a differentiation of discharge alternatives. To avoid misdirected results, we focused our analyses on the positive predictors.

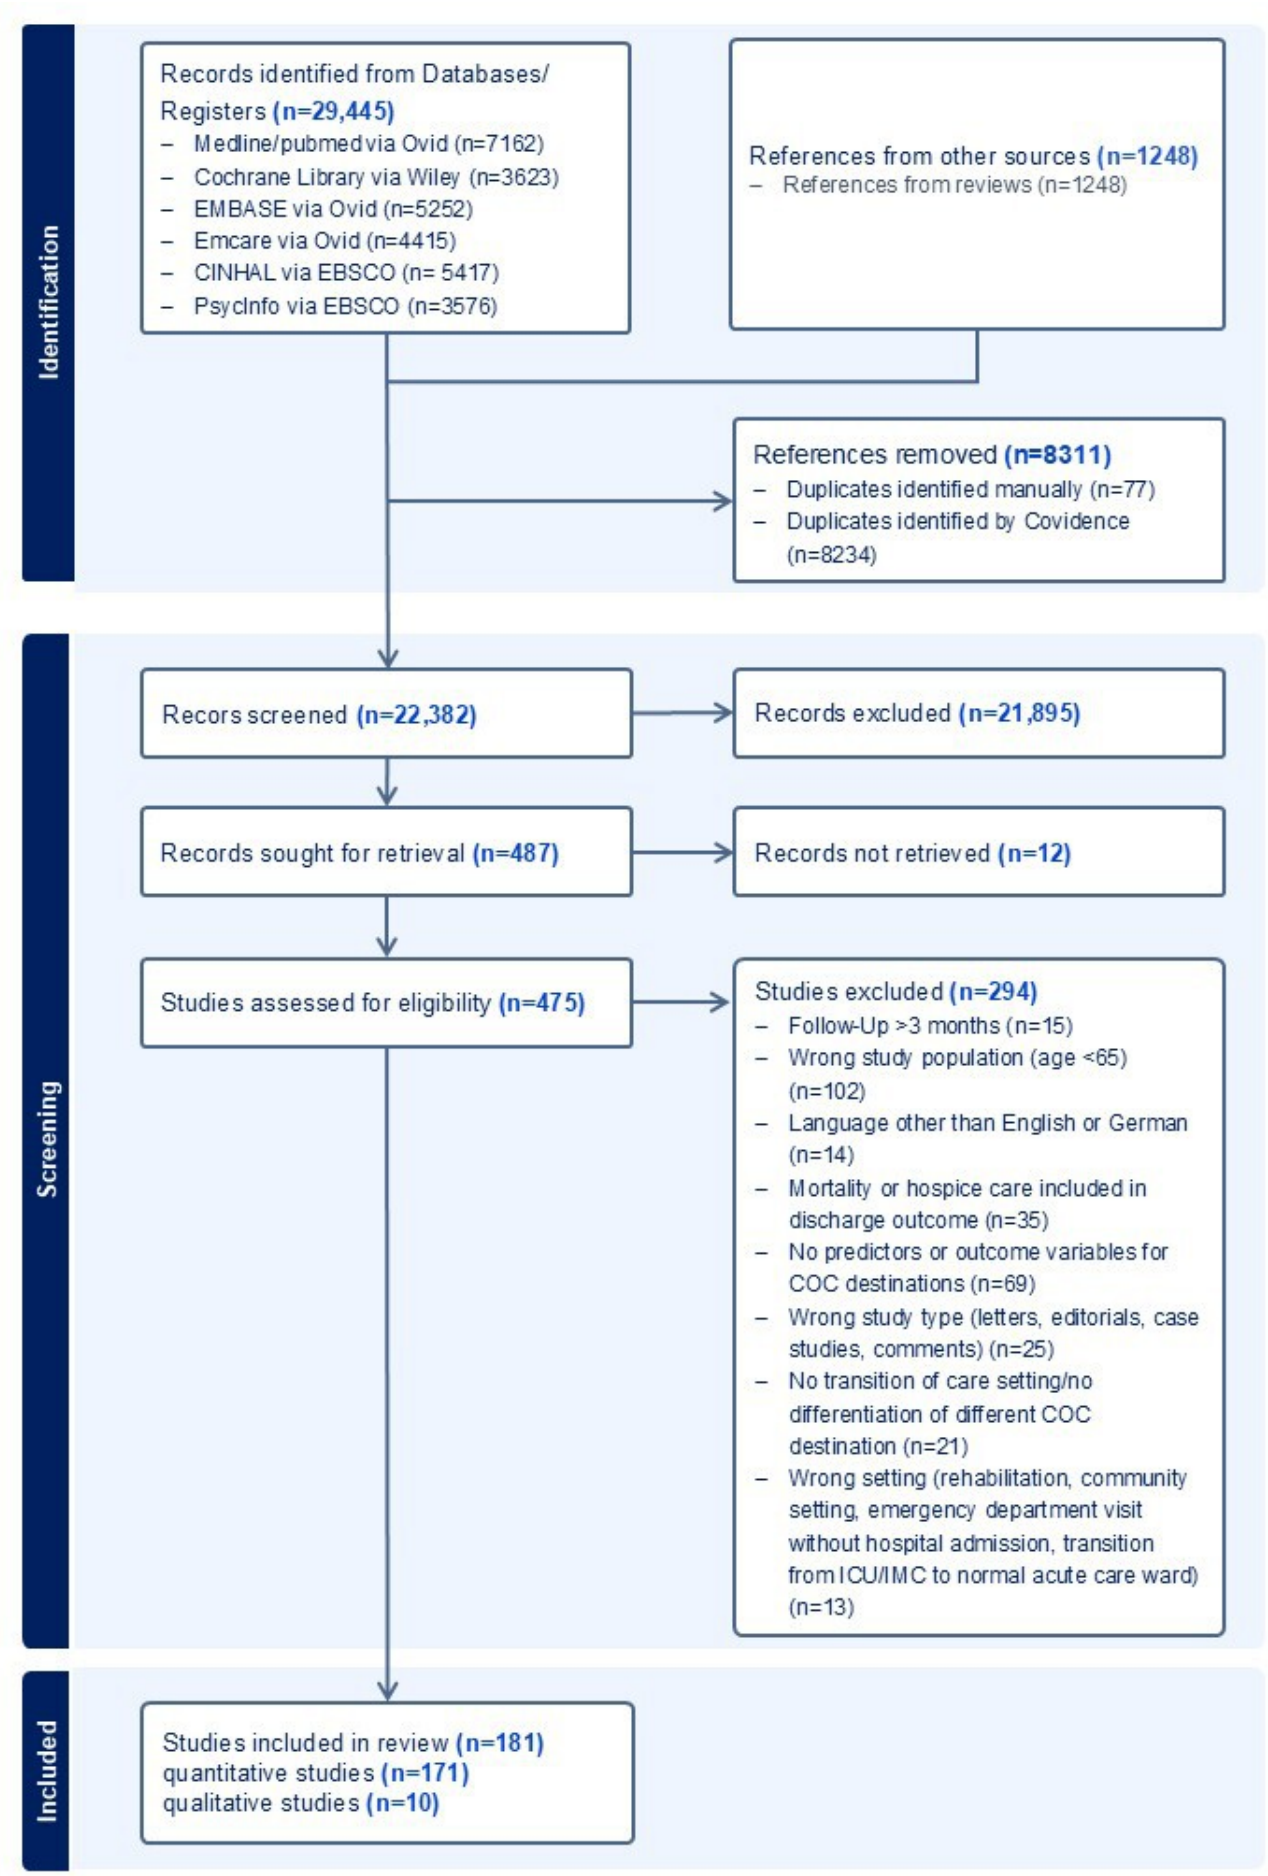
Predictors were also stratified based on discharge destinations (outpatient, inpatient or early rehabilitation, SNF, nursing home, assisted living, or home-based care with or without support, long-term acute care setting, or other acute care setting). In studies that consolidated multiple discharge destinations into a single outcome, these were extracted separately. The direction of effect was added to the top 5 predictors per discharge destination via manual extraction from the literature and joint consensus labeling (MLF and CL). Additionally, we stratified by mean population age (<80 y or ≥80 y) and health care systems origin: predictors from Anglo-European studies with mostly publicly funded health care systems (Europe, Canada, Australia) were also analyzed separately from studies from the United States of America with a relevant proportion of pay-for-service health services [20-22].

Similar predictive factors identified across multiple studies were consolidated, whereas validated assessment tools were treated independently. In some studies, data on predictive measures were reported without using a validated assessment instrument. In these cases, we categorized the results as “no specific score.” As an example, in the activities of daily living (ADL) domain, many studies reported “decreased ADL” or similar but did not use an established assessment like the Barthel index (BI). In these cases, we categorized the reported predictors as “ADL no specific score.”

The Jaccard Index can be used to measure similarity and diversity of sample sets [23]. It was used to determine the concordance between different potential domain combinations and those reported in the reviewed studies. A higher index value signifies better agreement. Based on the 20 defined domains, we juxtaposed approximately 1 million potential combination sets (all possible combinations) to be compared with those found in the literature. The domain set with the highest average Jaccard index value was identified as a potentially generalizable combination of key predictor domains most commonly associated with each other and existing literature.

Descriptive statistics and data manipulation were carried out using Microsoft Excel 2019 (Microsoft). We used Python 3.12.2 for the analysis, using the itertools standard library for generating combinations and set class methods for calculating the Jaccard index. For loading the data from Excel, the pandas 2.2.1 library was used.

Results



Overview

Our search yielded 22,382 database entries after removing duplicates. After title or abstract screening, we assessed the full texts of 475 studies for eligibility and included 181 studies (n=171 quantitative studies, n=10 qualitative studies). Figure 1 shows the PRISMA flow chart of the scoping review. All included studies are listed in Multimedia Appendix 2.

The included studies were published between 1984 and 2022. Most of the 181 studies originated from North America (USA: n=84, 46%; Canada: n=14, 8%). Europe accounted for approximately one-third (n=60, 33%), including studies from the United Kingdom (n=11, 6%), the Netherlands (n=11, 6%), Switzerland (n=8, 4%), Germany (n=7, 4%), Italy (n=5, 3%), and Spain (n=3, 2%). The remaining 15% were conducted in other parts of the world, including Australia (n=14, 8%) and Japan (n=7, 4%).

A total of 275 (in part combined) settings were described, and most studies (n=161, 58.5%) were conducted in surgical settings such as trauma or orthogeriatrics (n=75, 27%) and general or visceral surgery (n=28, 10%). Other prevalent settings were geriatrics (n=29, 11%) and general or internal medicine (n=27, 10%). In 7% (n=19) of settings, no clinical department was specified. The included studies encompass data from 6,357,026 participants with a mean age of 77.42 years.

Quantitative Studies

In the 171 quantitative studies, a total of 856 predictors for various discharge destinations were identified. More than half of these studies were prospective (88/171, 51.5%), while the remaining utilized a retrospective (78/171, 46%) or mixed approach (5/171, 3%). Most reported predictors were positive predictors (723/856, 84.5%). About two-thirds of the studies (116/171, 68%) reported the participants' mean age, with 55 of 171 (32%) studies having a mean age of 80 years or older and 61 (36%) having a mean age younger than 80 years.

Predictors

Age emerged as the most prevalent predictor across all categories. The 10 most frequent positive predictors are listed in Table 1 for all studies, and stratified by mean age <80 years, ≥80 years, US and Anglo-European studies.

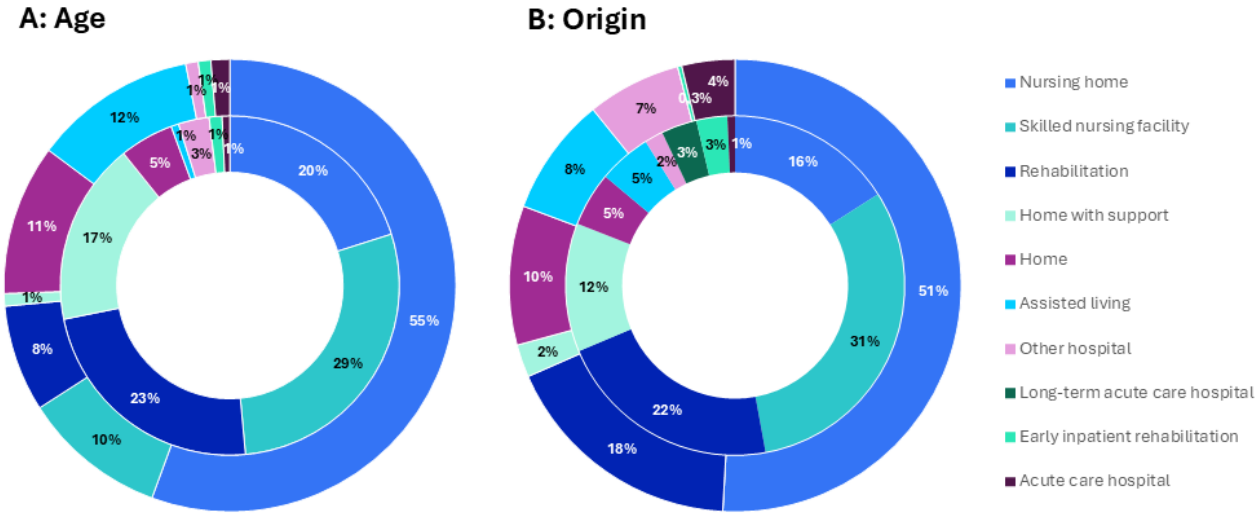
Discharge Destinations



We analyzed predictor-destination sets (n=1047) across 10 different discharge options. A discharge to nursing homes emerged as the most common option (n=297, 28%), followed by SNF (n=223, 21%), inpatient rehabilitation (n=206, 20%), discharge home with support (n=97, 9%) and without support (n=74, 7%), and assisted living (n=63, 6%). Less frequently

XSL•FO
RenderX

found were predictors related to early inpatient geriatric rehabilitation (n=21, 2%), long-term acute care hospitals (n=23, 2%), and other acute care hospitals (n=18, 2%).

Nursing homes were the predominant destination in the oldest old category (≥80 y: 124/223, 55% vs <80 y: 82/408, 20%), and inpatient rehabilitation (<80 y: 95/408, 23% vs. ≥80 y: 17/223, 8%) and SNF (<80 y: 116/408, 29% vs ≥80 y: 23/223, 10%) were the main destination in the younger old category (see Figure 2A). In Anglo-European studies, the most frequently reported discharge destination was nursing home (174/342, 51%) compared to SNFs (221/677, 31%) in US studies (see Figure 2B).

Figure 2. Predictors stratified by discharge destination. (A) Proportion of discharge destinations of studies stratified with mean age <80 years (inner circle, n=408) and ≥80 years (outer circle, n=223). (B) Proportion of discharge destinations of studies originating from the United States (inner circle, n=677) and Anglo-European countries (outer circle, n=342).

Predictors for Different Discharge Destinations

Age emerged as the predominant positive predictor for most discharge options (Table 2). Nevertheless, for a discharge home, the BI was found more often. Because of the scarcity of predictors in the categories early inpatient rehabilitation, acute care hospital, long-term acute care hospital, and other hospitals, no further stratified analysis was done for these destinations.

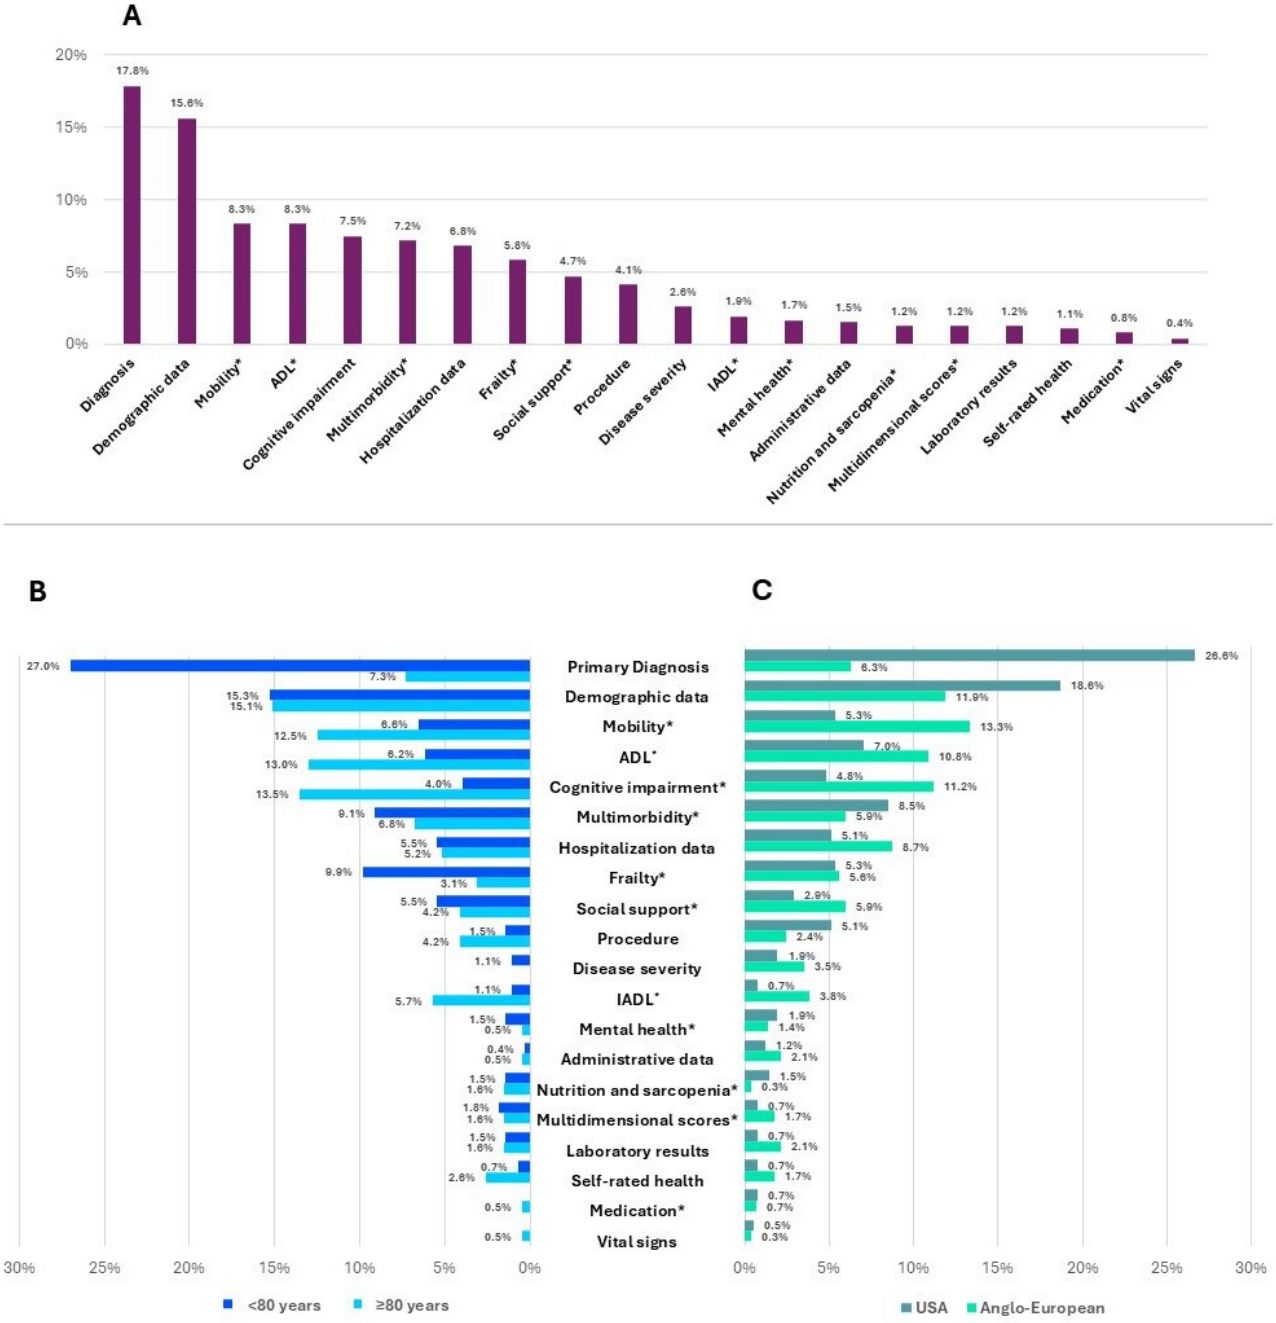
Negative predictors were a minority (133/856, 15.5%) and very heterogeneous, and often seemed not useful for the identification of the most appropriate discharge destinations, such as ethnicity or male sex for discharge to rehabilitation. More relevant predictors were the unavailability of caregivers for discharge to a nursing home, a hip fracture diagnosis, or a higher frailty index, not allowing for discharge home.



A detailed overview of the extracted evidence stratified by mean age, study type, study origin, and discharge destination is shown in Multimedia Appendix 3 and, according to the domains, positive as well as negative predictors, predictive strength indicators, and corresponding literature references in Multimedia Appendix 4.

Predictor Domains

After initial data inspection, 20 predictor domains representing common health care data and geriatric syndromes were defined, and all the extracted predictors were categorized accordingly. Diagnoses (129/723, 17.8%) and demographic data (113/723, 15.6%) formed the largest proportion. The assessment domains of geriatric syndromes, such as mobility (60/723, 8%), ADL (60/723, 8%), cognitive impairment (54/723, 8%), and frailty (42/723, 6%), were commonly represented as well (Figure 3A). Geriatric syndromes were more often predictive in the oldest old category (all: 352/723, 48.7%; <80 y: 129/274, 47.1%; ≥80 y: 121/192, 63%). In contrast, the frailty domain was a more frequent predictor in the younger old category (<80 y: 27/274, 10% vs ≥80 y: 6/192, 3%), as shown in Figure 3B.

XSL•FO
RenderX

Figure 3. Predictor domains. (A) Dark red columns: proportion of predictors across predictor domains (n=723). (B) Proportion of predictors across all predictor domains stratified by age. Dark blue bars: mean age <80 years (n=274); light blue bars: mean age ≥80 years (n=192). (C) Proportion of predictors across all predictor domains stratified by study origin. Dark green bars: US origin (n=413); light green bars: Anglo-European origin (n=286). ADL: activities of daily living, IADL: instrumental activities of daily living. *Geriatric syndromes.

Geriatric syndromes were more often extracted from Anglo-European compared to US studies (USA: 163/413, 39.5%; Anglo-European: 174/286, 60.8%). Among these, mobility (38/286, 13%), demographic data (34/286, 12%), along with cognitive impairment (32/286, 11%), and ADL (31/286, 11%) emerged as the predominant predictor domains (Figure 3C).

In total, 93 combinations of domain sets could be identified in the literature in our review. Contrasting these sets with all potential predictor combinations of the 20 domains, the greatest concordance with the highest average Jaccard Index score of 0.28 was found for the 8 elements shown in the upper part of Table 3 as a potentially generalizable domain set. As many literature-derived sets comprise solely 1 element, based on an 8-element set, the best Jaccard Index of 2 one-element sets could be 0.125. Thus, achieving a higher index value of 0.28 with an 8-element set across all literature represents a favorable outcome.

XSL•FO
RenderX

Table . Predictor domains most concordant with the literature and potentially generalizable. Upper part: Domain set with the highest mean Jaccard index in comparison to all sets found in the literature, in alphabetical order, including the top 3 predictors of each domain. Lower part: Other domains recognized in the review, in alphabetical order, including the top 3 predictors of each domain.

Domain	Predictor examples
Domain set most concordant with the literature	
ADL[a]	ADL NSS[b], Barthel index [27], Katz score [25]
Cognitive impairment	Dementia diagnosis, confusion assessment method [33], short portable mental status questionnaire [34]
Demographic data	Age, sex (female), ethnicity
Hospitalization data	Length of stay, ICU[c] treatment, source of admission
Primary diagnosis	Wound problems, cardiopulmonary disease, infectious disease
Mobility	Falls, De Morton Mobility Index [30], pre-fracture mobility score [35]
Multimorbidity	American Society of Anesthesiologists score [24], number of comorbidities, Charlson comorbidity index [26]
Social support	Living alone or with companion, preadmission professional support, caregiver support
Other domains	
Administrative data	Level of care hospital, prior hospitalizations, prior ICU admission
Disease severity	Glasgow coma scale [36], injury severity score [28], injury severity NSS
IADL[d]	IADL no specific score, Lawton index [37], InterRAI Acute Care (finances) [38]
Frailty	Frailty index[e], clinical frailty scale [39], Fried frailty scale [40]
Laboratory results	Anemia, fluid and electrolyte disorder, hypoalbuminemia
Medication	Number of medication, vitamin K antagonist therapy, therapeutic anticoagulation
Mental health	Geriatric depression scale [41], depression diagnosis, 8-item Patient Health Questionnaire [42]
Multidimensional scores	Hospital Admission Risk Profile [43], ISAR[f] (≥2) [44] and CGA[g] normal, multidimensional prognostic index (every 0.1 increase) [45]
Nutrition and sarcopenia	BMI [46], Mini Nutrition Assessment short form [47], sarcopenia diagnosis
Procedures	Orthopedic or trauma surgery, anesthesia or ICU treatment procedure, gastrointestinal surgery
Self-rated health	Older people's quality of life questionnaire [32], 3-item brief health literacy screen, Short Form-12 physical component summary [48]
Vital signs	Vital capacity, respiratory rate, systolic blood pressure

[a]ADL: activities of daily living.

[g]CGA: comprehensive geriatric assessment.

Qualitative Studies

A total of 10 studies were found that mostly utilized semistructured interviews complemented by observational techniques and reviews of patients' clinical records. Participants encompassed patients (n=8, 80%), health care professionals (n=8, 80%), and informal caregivers or relatives (n=2, 20%).

All study characteristics can be found in Multimedia Appendix 2.

A total of 98 predictors supporting an appropriate discharge decision were extracted. Predictors spanned various discharge destinations, namely discharge in general (n=36, 37%), return to home (n=25, 26%), transfer to rehabilitation (n=15, 15%), SNF (n=14, 14%), nursing home (n=5, 5%), and home with support (n=3, 3%).

XSL•FO
RenderX

These 98 predictors were categorized into 10 domains aligning partially with those identified in the quantitative studies: patient or caregiver involvement (n=27, 28%), organizational structures (n=16, 16%), health status or morbidity (n=16, 16%), communication among health care professionals or providers (n=9, 9%), social support (n=7, 7%), staff education (n=7, 7%), regional aspects (n=6, 6%), administrative health care data (n=4, 4%), hospitalization data (n=4, 4%), and home assessment (n=2, 2%).

Within the domain of patient or caregiver involvement, effective strategies emphasize communication and respect. Notable recurring themes include discussing discharge plans with patients and caregivers in a timely manner, addressing their capability to self-manage post-discharge, providing detailed medication schedules, and honoring patient preferences. As highlighted in 1 study, "Patients reported receiving contradictory information, especially with respect to medications and how to manage their care following discharge" [49], whereas another underscored that "...elders who thought they received enough information about how to manage their care after they left the hospital reported feeling satisfied" [50].

Regarding organizational structures, clear responsibilities, including staff continuity, geriatric comanagement, and standardized discharge procedures, emerged as significant components facilitating discharge decisions. A recent study emphasized the "...lack of recognized decision-making tools or algorithms as a critical issue in practice" [51].

The domain health status or morbidity includes parameters akin to those observed in quantitative studies, including ADL and cognitive impairment due to dementia or delirium. In 1 study, it was cited that "... clinicians noted the clinical challenges of managing delirium and the need for development of patient pathways for those with delirium" [52].

Discussion

Principal Findings

This scoping review identified and synthesized predictors of appropriate PAC destinations for older adults (≥65 y), transitioning from acute care to specific discharge destinations. Based on the analysis of 181 studies (171 quantitative, 10 qualitative), key predictors varied by discharge destination. Diagnosed dementia and deficits in instrumental activities of daily living were frequently associated with discharge to nursing homes, while longer length of stay and cardiopulmonary disease predicted discharge to rehabilitation, and good performance in activities of daily living and mobility assessments favored discharge home without support. Furthermore, the review highlighted the influence of age and geographical origin, with geriatric syndromes being more prominent in those aged 80 years and older and in non-US studies. The 8 predictor domains—cognitive impairment, activities of daily living, demographics, social support, hospitalization data, multimorbidity, mobility, and primary diagnosis—demonstrated the highest concordance with existing literature. These findings provide a comprehensive overview to inform clinical decision-making and the development of clinical decision support systems, including machine learning apps, aimed at optimizing PAC planning for older adults.

Comparison to Prior Work

Age emerged as the most frequent predictor over nearly all subgroups. Older adults ≥80 years tend to be more often discharged to nursing homes rather than rehabilitation facilities [53]. This could be due to the reduced availability and accessibility of facilities as well as misconceptions regarding their potential for improvement through these services. Investigations involving populations with a mean age of ≥80 years demonstrate an increased use of geriatric syndromes as predictors for discharge destinations, identifiable by a comprehensive geriatric assessment (CGA) [54]. Notably, frailty appears more frequently as a predictive factor in studies encompassing individuals with a mean age of <80 years. This could be because frailty was not assessed in these studies or because frailty has been mediated by age or functional parameters such as the BI [55,56]. Qualitative analysis revealed that patient or caregiver involvement was another important predictor for appropriate discharge destination, although hardly used in quantitative studies.

To address the observed heterogeneity in predictors, our review presents a higher-level categorization based on predictor domains. This provides a more standardized and manageable framework for analysis. A CGA is another established method for capturing the heterogeneity of potential limitations across geriatric domains, thereby improving the likelihood of living at home after 3 months [57]. Comparing the predictor domains most concordant with existing literature with a CGA, it stands out that 5 of the 8 predictor domains (mobility, ADL, multimorbidity, social support, and cognitive impairment) are also core elements of a CGA [54]. Therefore, a CGA supplemented by routine measurements such as current hospitalization, primary diagnosis, and demographic data forms a solid foundation for enhancing prediction accuracy of the most appropriate discharge setting and is probably one reason why it ultimately reduces discharge to higher levels of care [58].

Discharge destination choices are inherently contingent upon local health care infrastructure and accessible resources. Therefore, our analysis distinguishes between Anglo-European studies, predominantly characterized by publicly funded health care systems, and US studies with a higher proportion of pay-per-service options. Anglo-European research tends to prioritize geriatric syndromes and length of hospital stay as key predictors, whereas US studies place greater emphasis on diagnostic factors. Variations in health care systems result in disparate PAC options whose definitions diverge across settings [59,60]. For example, we found many predictors for discharge to SNF, uniquely offered in the United States, combining skilled nursing care with rehabilitative interventions, even though similar initiatives are emerging in European countries such as Germany [3,61]. Despite regional differences, parallel options exist for clinically stable yet functionally declined older patients requiring both nursing care and rehabilitation within other health care frameworks, illustrated by examples like the Australian respite residential aged care or early inpatient geriatric rehabilitation in Germany [6,62]. Regrettably, we did not find

XSL•FO
RenderX

any comparative analyses examining various PAC alternatives across countries.

A lack of standardized decision support tools assisting health care professionals when deciding on the best discharge option is one of the issues that were raised in the qualitative studies [51,63,64]. This was also supported by a recent scoping review by Singh et al [65] focusing on digital health solutions facilitating transitions in care. In a systematic review on 35 CDSSs for PAC referral that included mainly studies of non-geriatric adults, Kennedy et al [13] revealed that merely 14% have been integrated into regular clinical practice, potentially hindered by constraints in time resources. Conversely, positive outcomes have emerged from specific implementations, such as a pre- or post-implementation study of a CDSS with a 2-step approach that showed a significant reduction of readmission rates [66]. Also, other binomial prediction models for discharge destinations, for example, for routine versus nonroutine discharge as in Karhade et al [67], showed promising results with an area under the curve of 0.823 in a machine learning model. However, when comparing these findings to one of the few CDSS developed for multinomial differentiation across 6 discharge destinations involving over 14,000 participants, it achieved a lower overall area under the curve of 0.685 [68]. The findings presented in this review will help to develop future multinomial COC or discharge prediction models by identifying eligible features.

Strengths and Limitations

A key strength of our scoping review lies in the detailed differentiation of discrete prediction parameters, which enabled us to identify and statistically analyze a robust set of core predictor domains. However, our review is not without limitations, which can be categorized as pertaining to the included studies themselves and our review methodology.

We acknowledge the following limitations. The first limitation was the predominance of studies conducted in the US health care system with its specific PAC options and at least partially unmet health care needs due to some patients' lack of insurance coverage [69,70]. To address this limitation, we compared US studies with studies from Europe, Canada, and Australia with more similarly conceptualized health care systems, even though we are aware that this simplifies the complex differences between countries in the Anglo-European group that also exist.

The second limitation was the frequent use of nonstandardized assessments that we addressed by summarizing these measures into a "no specific score" predictor. For example, the predictors "problems with personal hygiene" or "ADL no specific score" are included in both the Katz Score and BI that again report comparable information. This indicates a need for a wider use of validated assessment instruments to capture the functional status in older patients in a uniform way. When selecting assessments for the future development of a CDSS tool or compiling assessments for a CGA, these validated and established assessments should be used.

Third, many of the included studies presented composite end points of different discharge destinations with unknown proportions among the different destinations as well as different populations concerning investigated diseases and clinical settings, which limits the validity of the extracted predictors for generalizable discharge destination options. Wherever possible, we tried to extract the singular discharge destination.

Fourth, focusing on the older geriatric population might have led to an omission of other studies mainly including nongeriatric adults that might also have included valuable information on the topic. For example, a review by Kennedy et al [13] found 33 studies presenting CDSS for optimizing discharge destinations, but only 6 studies were conducted in older age populations.

Fifth, our focus on positive predictors to avoid often confusing directions of effect among the negative predictors may have resulted in an undercapture of relevant predictors. With the negative predictors representing only 15.5% of the predictors, we consider the bias of this approach to be low.

Sixth, there is a lack of further details on the extracted predictors, for example, concerning the timepoint of the assessment or the direction of effect of the predictor. These parameters have been found relevant in other studies [66]. We partially addressed this lack of detail by manually extracting the direction of effect of the most frequent predictors stratified according to different discharge destinations. The aim of a scoping review is to cover a broader topic. This approach, however, results in a large heterogeneity among the included studies and a lack of details. Thus, the analysis provided here remains on a descriptive level and offers the opportunity for future research.

Seventh, only 10 studies were included in the qualitative analysis, with most studies from the 1990s and early 2000s, limiting the informative value of the qualitative evidence synthesis.

Eighth, the broad scope of studies screened and the comprehensive analysis undertaken resulted in a literature search limited to publications up to 2022. Nevertheless, we are confident that our review of this relevant, yet relatively stable, topic remains current.

Conclusion and Implications

This scoping review synthesized evidence on predictors of appropriate discharge destinations for older adults, highlighting the heterogeneity of factors influencing care transitions. The identified 8-domain set—including demographic data, activities of daily living, social support, hospitalization data, primary diagnosis, cognitive impairment, mobility, and multimorbidity—underscores the value of comprehensive geriatric assessment in guiding discharge planning. This work will directly inform the feature selection process for a machine learning algorithm within the SURGE-Ahead project, designed to improve discharge recommendations. Recognizing the limitations of existing data and the need for system-specific adaptation, we advocate for continued research and the implementation of evidence-based discharge planning strategies.

Abstract

Background: First Nations people in Australia experience inequitable mental health outcomes and service access. Digital mental health (DMH) services, which refer to offering mental health services through digital platforms, are considered potential solutions to address such mental health service inequities and improve the mental health outcomes of First Nations Australians. However, evidence on the effectiveness of DMH services for First Nations people in Australia is yet to be synthesized.

Objective: This systematic scoping review aims to fill this gap and to identify the facilitators and barriers that influence the implementation of DMH services among First Nations people in Australia.

Methods: A systematic search was conducted across 6 academic databases to search for studies related to DMH services for First Nations people in Australia. Search terms relating to First Nations people, geographic terminologies of Australia, mental health, and DMH services were used. Studies were included if they assessed the effectiveness of DMH services or the determinants of the facilitators and barriers of implementing DMH interventions among First Nations people in Australia. Data were extracted based on study design, targeted services, and research findings, and were then synthesized using a thematic analysis framework.

Results: In total, 22 studies met the inclusion criteria. DMH services were used to support and treat First Nations Australians and conduct psychological assessments in these individuals. Evidence of effectiveness was stronger for nonsevere mental health conditions. The determinants of the facilitators and barriers of the implementation of DMH services included the following: (1) organizational and administrative factors; (2) cultural appropriateness; (3) accessibility; (4) integration of DMH services in the existing health system; (5) engagement between clients and service providers; (6) coverage of different conditions and clients; (7) acceptability to DMH services; (8) digital literacy; and (9) efficiency.

Conclusions: Evidence on the use of DMH services for First Nations Australians remains heterogeneous in terms of study design and outcome measurement. DMH services appear to be most effective for managing nonsevere mental health conditions. Successful implementation requires multilevel structural support, including policy and organizational commitment, enhanced digital infrastructure, workforce training and engagement, and the design of culturally responsive DMH models to improve uptake and equitable access to mental health care among First Nations Australians.

Introduction

Aboriginal and Torres Strait Islander people in Australia ("First Nations" people used hereafter) view mental health as a part of a holistic view of health across all life stages [1,2]. Maintaining a personal connection to traditional culture, health views, and community serves as an important protective factor for the mental health of First Nations people [1,3-6]. Therefore, reinforcing cultural strength and resilience would foster personal resilience and self-esteem, thereby protecting their individual mental health [7] and reducing the likelihood of developing mental illness [5,8,9]. Moreover, mental health services that acknowledge the right of self-determination and the need for cultural understanding of First Nations people [10], provide culturally appropriate care [11], or employ First Nations health workers [12] are also more likely to reinforce protective factors and achieve better treatment outcomes.

However, First Nations people are facing more complex mental health challenges than the general population in Australia due to external historical and social determinants [13]. Historically, colonization led to intergenerational trauma that worsened their mental health [14]. Currently, First Nations people continue to face daily discrimination [15], along with social inequity in areas such as education and employment [9]. These structural inequities increase the likelihood of mental health issues within these communities [16] and create mental health outcome gaps between First Nations people and the general population. For instance, although the national health survey showed that the prevalence of any mental illness among First Nations people dropped from 29.3% in 2014 - 2015 [8] to 24% in 2018 - 2019, it was still considered high [17]. Additionally, a survey conducted in regional Australia that applied structured clinical interviews in 2014 - 2016 showed that the prevalence of any mental illness was 42.2% (4.2-fold higher than the prevalence in the general population) [5]. The prevalence of anxiety and mood disorders among First Nations people was estimated to be 1.6 - 3.3 times the national prevalence in Australia [18]. Furthermore, 16% of deaths of First Nations people were related to suicide in 2001 - 2005, which is 10% higher than the proportion in the general population [4].

Despite significant mental health needs and gaps, First Nations people experience barriers to accessing mental health services. First, structural racism, stigma toward mental health conditions, low health literacy, and less comfort in seeking help from health professionals prevent First Nations people from using more mental health services [11,12,19]. Second, a lack of local services and service providers creates barriers to travel for First Nations people [11,20], especially in areas with higher geographical remoteness that have a higher proportion of First Nations populations [21] but lower service access [22]. Moreover, community-controlled, culturally safe services may be unavailable for some First Nations people [23], and non-First Nations health workers who do not receive appropriate cultural safety training also contribute to service access barriers [20,24-26]. In 2018 - 2019, only 31% of First Nations adults with high or very high levels of psychological distress received professional mental health services [27]. Moreover, mental health service gaps were mostly reported by First Nations primary health organizations (134 out of 198 organizations) [28]. Furthermore, among suicide cases, First Nations populations were approximately 2 times less likely than non-First Nations populations to have received mental health support (23.8% vs 43.3%) [29]. In the Northern Territory, mental health service utilization of First Nations youth is nearly half that of non-First Nations youth (1.9% vs 4.1%) [30].

Digital mental health (DMH) services refer to providing mental health services through digital technologies [31-33]. DMH services have been implemented for the prevention, screening, intervention, and rehabilitation of mental health conditions [34] with or without mental health professionals' guidance or support [35], and they demonstrate promising results for managing various mental health conditions, including anxiety disorders [36], depressive disorders [37], posttraumatic stress disorder [38], and alcohol and other drug-related mental disorders [39]. Moreover, DMH services have been evaluated among different populations, including children and young people [40], adults [41], and older populations [42].

DMH services have been evaluated among First Nations people worldwide [43-46] and have shown the potential to address the current health outcome gaps faced by them. Evidence from Canada, New Zealand, and the United States indicates that DMH services support improvements in psychological assessment [47-50] comparable to existing face-to-face services. DMH services were also found to improve clinical outcomes [49,51] and continuity in mental health care [52], both as stand-alone and blended care. International evidence also suggests that DMH services can reduce mental health gaps by improving the accessibility and availability of mental health services among First Nations people [23,34-36].

In Australia, evidence on DMH services among First Nations people is mixed. Although digital gaps remain a barrier to DMH implementation [53], government funding has enabled the provision of digital infrastructure in rural and remote First Nations communities [54]. Another service gap is the need for culturally appropriate services [23]. Evidence suggests that DMH services may fail to deliver culturally safe services [55,56] due to the preference of First Nations people for the familiarity and safety of face-to-face services [50]. However, some studies have indicated that digital health may support cultural safety by increasing the involvement of First Nations health workers [43,57] and community-led design services [58], and by allowing patients to see familiar faces via video conferencing [54]. DMH services also enable First Nations people with mental health needs to include family and community members in decision-making, without the need for travel [54].

Currently, most systematic reviews have focused on international evidence regarding the application of DMH services to First Nations people [43-46]. Existing Australian evidence is more likely to review broad and general health conditions rather than focus on mental health [47,54,57,59] or to solely focus on the design and assessment of DMH services for First Nations people rather than the implementation [58]. There is a paucity of evidence on the effectiveness of DMH services and the facilitators and barriers of implementing these services among First Nations people in Australia. Our study

XSL•FO
RenderX

aims to address this research gap by exploring the following research questions: (1) What is the effectiveness of DMH services for First Nations people in Australia? (2) What are the determinants of the facilitators and barriers of implementing DMH services among First Nations people in Australia? Such evidence is critical for policymakers, health providers, and First Nations users to make evidence-informed decisions while funding, implementing, prescribing, and choosing DMH services.

Methods

Reporting and Registration

The reporting of this study followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines (Checklist 1) and was registered through PROSPERO (CRD42024612517).

Acknowledgment to Indigenous Data Sovereignty

This study follows the Maiam Nayri Wingara principles [60]. The authors acknowledge that First Nations people have control of the data ecosystem; all data are available to First Nations people; and this study pays respect to First Nations communities, will be accountable to these communities, and empowers the sustainable self-determination of these communities.

Outcome Definition

Our study outcomes include the effectiveness of DMH services and the determinants of facilitators and barriers. The effectiveness of DMH services is defined as the extent to which DMH services obtain the desired mental health outcomes. For example, for DMH services that are related to psychological diagnosis and assessment [49], the accuracy of diagnosis is considered as effectiveness. For treatments provided through DMH services [51,52,61], effectiveness is defined as the degree to which a treatment service improves mental health symptoms. The determinants of facilitators and barriers are defined as the determinants that can promote and impede, respectively, the implementation of DMH services for First Nations people in Australia.

Eligibility Criteria

Based on the PICO (population, intervention, comparison, outcome) protocol, this review considered studies that (1) included participants who were First Nations Australians; (2) included interventions that were DMH services with various functions; (3) included comparisons that were typical mental health services or did not include comparisons; and (4) targeted outcomes that involved changes in mental health conditions. In addition, studies written in English were included. Studies that were irrelevant to our PICO criteria and those that did not have full text available were excluded. Moreover, there was no eligibility criterion relating to First Nations groups, date of publication, or age of participants. See Multimedia Appendix 1 for detailed inclusion and exclusion criteria and the PICO protocol.

Search Strategy

A systematic search was conducted from September 9, 2024, to September 15, 2024, across 6 online databases: PsycINFO, PubMed, MEDLINE, Embase, Web of Science, and Google Scholar. Considering that more than 10,000 search results were obtained from Google Scholar, searching on this database was limited to the first 30 pages.

The search strategy was developed after consultation among 3 authors (SZ, XZ, and SD). Boolean operators, truncations, and search terms were tailored to each database. The search terms were organized around the following themes: First Nations people, geographic terminologies of Australia, mental health (including specific mental health conditions), and DMH services. Considering that DMH is a relatively new research area, there was no limitation on the publication date of the searched studies. See Multimedia Appendix 2 for details of the search strategy.

Study Selection

Selected studies were imported into EndNote 20 and Covidence, and duplicates were removed at this stage. Afterwards, the titles and abstracts were screened. Studies found to be irrelevant to the review topic based on an assessment of the title and/or abstract were excluded. Studies that had insufficient information in the title and abstract were moved to full-text screening. During full-text screening, studies that met the exclusion criteria were excluded.

One reviewer (SZ) conducted the title and abstract screening. Uncertainty in this process was solved through discussion with another reviewer (XZ), and any disagreements were resolved by involving the third reviewer (SD). Two reviewers completed the full-text screening, where one reviewer (SZ) made initial decisions and the other reviewer (XZ) checked the findings. Therefore, the selection process was not blinded. Disagreements were resolved through discussion or by involving the third reviewer (SD).

Data Extraction

Extracted data were tabulated based on author, year of publication, study design (qualitative, quantitative, or mixed methods), study aim, study population, research setting, type of DMH intervention, outcome (effectiveness, facilitators, and barriers), and key research findings. See Multimedia Appendix 3 for details of the extracted data.

For missing data, if the authors did not specify the reason, the reviewers tried to contact the authors to obtain relevant information. If such information was unavailable or no response was received, the missing data were excluded from the analysis process.

Strategy of Data Synthesis

The synthesis of data followed the thematic analysis method introduced by Thomas and Harden [62] and was guided by the SWiM (Synthesis Without Meta-Analysis) guideline [63].

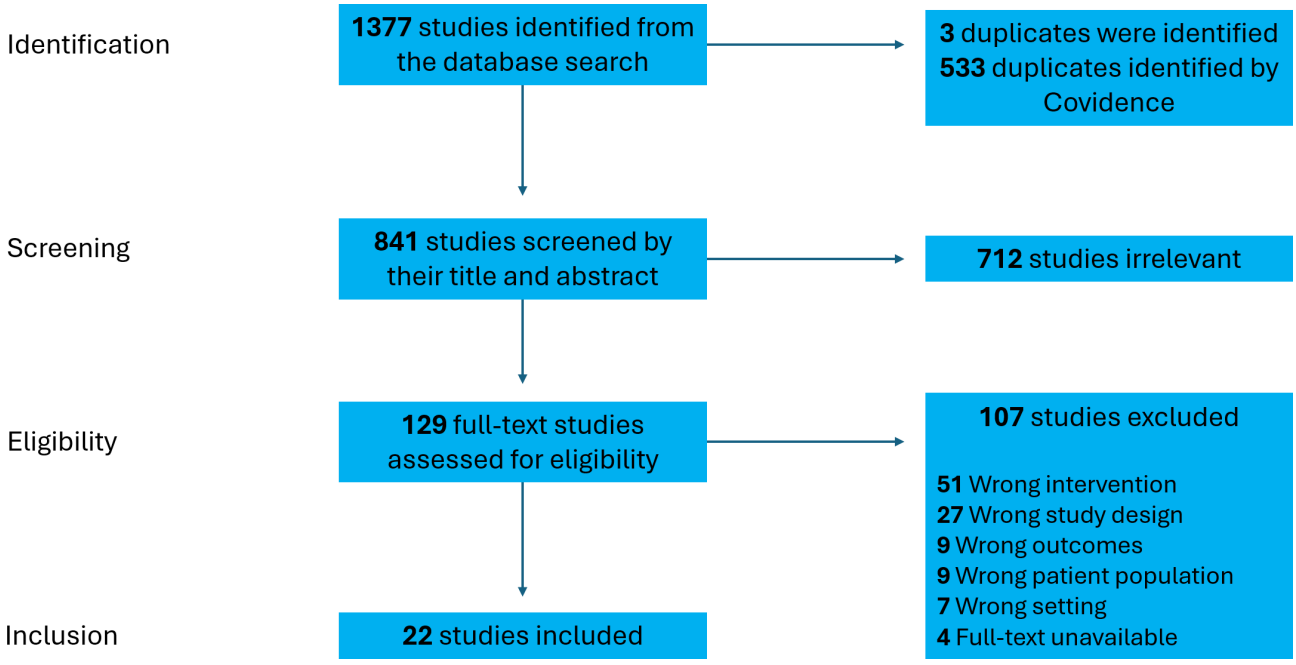
Reviewer SZ read selected studies completely and focused on the results section of those studies. Results relevant to the targeted outcomes of this review, such as the effect size of interventions or reported user experiences related to these

XSL•FO
RenderX

determinants, were summarized and coded into descriptive themes. Descriptive themes were categorized into subgroups and synthesized based on the type of data (qualitative or quantitative), research design (with or without a control group), and relevant determinants (facilitators, barriers, or effectiveness). Afterwards, reviewers standardized themes using the direction of the effect. Vote counting was conducted based on the direction of the effect. Then, the commonality among descriptive themes was found based on the direction of the effect or the different determinants they related to, which were used to formulate the analytical themes that summarized multiple similar descriptive themes. Analytical themes interpreted the primary results to fit the objectives of this review. To ensure the trustworthiness and validity of thematic analysis, during the generation of themes, reviewer SZ consulted reviewers XZ and SD to resolve any uncertainty. Once reviewer SZ completed generating themes, reviewer XZ checked all themes. Any disagreements were resolved by consulting the third analyst, SD.

Quality Assessment

This study applied the Aboriginal and Torres Strait Islander Quality Appraisal Tool [64] to assess the quality of health research from a cultural sensitivity perspective. Reviewer SZ carefully reviewed the included studies and answered the 14 questions in the Aboriginal and Torres Strait Islander Quality Appraisal Tool based on the content of all selected studies. Moreover, as the instructions for this quality assessment tool suggested, the numbers of studies assessed as "yes," "partially," "no," and "unclear" have been reported. Reviewer SZ applied the Mixed Methods Appraisal Tool (MMAT) [65] for assessing the methodological quality of the included studies. Only the relevant part of the included study was assessed. For instance, if the qualitative part of a mixed-methods study was the only part relevant to this review, the study was appraised as a qualitative study. The MMAT does not recommend scoring each study; hence, this review only reports the performance of the included studies on each criterion and the overall trend of the design of the included studies. All quality assessment results were checked by reviewers XZ and SD. See Multimedia Appendices 4 and 5 and the Results section for the quality assessment results.



In this systematic scoping review, all studies were included regardless of quality rating. However, the quality appraisal results informed the interpretation of the searched studies. Considering this study was a narrative synthesis and did not include a meta-analysis, no statistical weighting or sensitivity analysis was performed.

Results

General Characteristics of the Studies

A total of 22 articles were included in this review [66-87]. The PRISMA flowchart is presented in Figure 1. See Multimedia Appendix 3 for detailed characteristics. Except for 1 study that solely reported barriers [73] and 4 studies that solely reported effectiveness [72,82,85,87], the rest of the studies reported more than one targeted outcome (ie, facilitators, barriers, and effectiveness). Moreover, 16 studies [67,68,71-74,76,77,79-84,86,87] were published within 5 years, and all included studies were published between 2015 and 2023.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of article screening and inclusion.

Among the included studies, there were 8 qualitative studies [66,67,69,74,75,78,79,83], 8 mixed-method studies [68,70,71,76,77,80,81,84], and 6 quantitative studies [72,73,82,85-87]. Among the quantitative studies, 3 adopted a cross-sectional research design [72,73,87], 1 was a crossover study [82], 1 was a randomized controlled trial [85], and 1 was a prospective cohort study [86].

All studies involved First Nations people as the clients of DMH services. There were 5 studies involving health care providers who provided DMH services to First Nations people

XSL•FO
RenderX

[66,69,78-80], 2 studies involving both clients and service providers [67,74], 12 studies involving adult clients or clients whose ages were unspecified [68,70-73,75,81,82,84-87], and 3 studies involving youth or student clients [76,77,83].

Regarding the types of DMH services, 5 studies were related to general perspectives on DMH services [66,77-80]. Among the studies, 2 involved DMH services delivered through web pages [70,86], 12 involved DMH services delivered through mobile apps [67-69,71,72,74-76,79,80,84,85], 5 involved DMH services delivered through telehealth methods (text or voice-only phone call) [70,73,86,87], 1 involved DMH services delivered through video conferencing [82], and 2 involved DMH services containing both online and offline activities [81,83]. See Table 1 and Multimedia Appendix 3 for the details of DMH service types.

Table . Overview of the findings in relation to the effectiveness of digital mental health services.

Evidence type and study (author, year)	Data collection method	Data analysis method	Digital mental health service type	Major findings
Qualitative evidence				
Dingwall et al [68], 2023	Qualitative interviews at the end of the 4-week intervention	• Deductive approach for qualitative analysis	Aboriginal and Islander Mental Health Initiative for Youth (AIMhi-Y) app	• Participants had mental health improvements or gained help during tough times by using this app, which suggested its effectiveness.
Perdacher et al [74], 2022	Semistructured interviews	• Thematic analysis under the framework provided by the constant comparison method	Stay Strong app (custodial version)	• Both clients and practitioners reported that the app improved the abilities of self-insight and self-reflection of clients and guided the positive thinking of clients. • Both clients and practitioners reported that the app could enhance clients' confidence, view of self, and empowerment.
Povey et al [75], 2016	Three focus groups	• Thematic analysis	AIMhi Stay Strong iPad app and the iBobbly suicide prevention app	• Both apps have the potential to help people with minor mental health conditions overcome difficulties. • For the suicide prevention function, participants thought the app is useful for nonsevere conditions but may not be helpful in preventing suicide due to it being a severe condition.
Raphiphatthana et al [80], 2020	Semistructured interviews	• Thematic analysis that oscillated between deductive and inductive approaches	General digital mental health services (but many of the responses were related to the use of the Stay Strong app)	• Electronic mental health was perceived as potentially beneficial and useful for First Nations communities.
Routledge et al [81], 2022	Paper-and-pen test in classes or an online questionnaire	• Thematic analysis	Web-based lesson package, Strong & Deadly Futures	• Some facilitators reported that students learned the knowledge that the lesson planned to deliver, while students reported that the substance-related knowledge had been learned and understood.

XSL•FO
RenderX

Evidence type and study (author, year)	Data collection method	Data analysis method	Digital mental health service type	Major findings
Tighe et al [84], 2020	Semistructured interview	• Thematic analysis	iBobbly program	• Participants indicated that an app may not be able to provide enough support for vulnerable people who have severe mental health conditions. • The improved mental health literacy helped participants feel distracted from their thoughts and reduced their distress. • Some participants reported that the program has the effect of suicide prevention.
Quantitative evidence with comparison to typical mental health services or no intervention groups				

XSL•FO
RenderX

Evidence type and study (author, year)	Data collection method	Data analysis method	Digital mental health service type	Major findings
Lee et al [72], 2019	Intervention group: data from the Grog Survey app; Control group: clinical interview	• Triangulating the Finnish method to compare drinking status and average consumption between 2 groups using descriptive statistics. • Agreement between consumption data/daily alcohol consumption and withdrawal tremors was assessed through the Spearman rank correlation coefficient. • Sensitivity and specificity analyses (unspecified) were used to compare how well the app and clinical interview agreed when classifying drinkers' risk.	Grog Survey app	• The app can accurately test participants' drinking status (n=157), with 94.7% agreement with the clinical interview results. • The alcohol consumption level recorded by the app was usually higher than clinical interviews (drinks per drinking occasion: median 17.0, IQR [10.5, 27.9] vs median 15.4, IQR [9.6, 23.2]). • The app tended to categorize more participants at risk. The app identified 76.7% of drinking males and 69.7% of females as being at risk, while the interview identified 74.4% of males and 65.2% of females as being at risk. • The app appeared to be highly sensitive (92.7% - 97.5% sensitivity) in detecting at-risk drinkers, and when using matched and unmatched reference periods, the app could detect 10 and 37 more risky drinkers, respectively, than clinical interviews. • The average daily consumption recorded by the app and by the interview was moderately correlated (r=.52). Correlations were greater when only data from matched time periods were used (r=.62). Correlations were all statistically significant. • Participants were more likely to report the presence of tremors when using the app than when responding to the interview (17.0% and 7.2%, respectively; r_s=0.48). • There was high test-retest reliability for the app (r_s=0.81 for both participants and drinkers).

Evidence type and study (author, year)	Data collection method	Data analysis method	Digital mental health service type	Major findings
	Test results of the face-to-face and telehealth versions of both the MMSE[a] and the KICA-screen[b] tests	• The MMSE and KICA-screen test version total scores were compared using Spearman correlations. • Agreement between test versions was examined using Bland-Altman analyses. • Telephone test scores were prorated to equivalent in-person total scores to examine overall performance discrepancies directly.	Telehealth versions of the MMSE (TMMSE) and KICA-screen (TKICA-screen)	• Despite a reduction in effectiveness, the accuracy of the TMMSE was generally acceptable. The median TMMSE results were slightly lower than the MMSE results (24 vs 28.5, IQR 2 for both). There was a moderate correlation and a reasonable agreement between MMSE versions (r_s=0.33; *P*=.20), although the limits of agreement were unacceptably wide (−4.1 and 4.8 point differences). • The TKICA-screen was significantly less effective than the KICA-screen. There was a significant mean difference of 2.17 (95% CI 1.39 - 2.95), with wide limits of agreement (−1.09 and 5.43 point differences) and evidence of proportional bias (B=−1.03, SE=0.32; *P*=.005), with a tendency for poorer agreement at the lower end of the performance.
Tighe et al [85], 2017	Test results from the following psychological instruments: Depressive Symptom Index-Suicidality Subscale (DSI-SS), Patient Health Questionnaire-9 (PHQ-9), Kessler Psychological Distress Scale-10 (K-10), and Barratt Impulsivity Scale-11 (BIS-11)	• Paired *t* test	iBobbly program	

XSL•FO
RenderX

Evidence type and study (author, year)	Data collection method	Data analysis method	Digital mental health service type	Major findings
				• The effectiveness of the iBobbly app on suicide prevention was insignificant. The pre- and postintervention changes in the DSI-SS score were significant in the iBobbly arm (t=2.40, df=58.1; P=.02), but these differences were not significant compared with the waitlist arm (t=1.05, df=57.8; P=.30). • The iBobbly app was effective in reducing depression. The iBobbly arm showed a statistically significant decrease in PHQ-9 scores compared with waitlist controls. The interaction of the iBobbly arm by time was significant (t=2.79, df=56.9; P=.007; Cohen d=0.71, 95% CI 0.17-1.23), reflecting a substantial effect. • The iBobbly app was effective in reducing general psychological distress measured by the K-10. The interaction of the intervention arm by time was significant (t=2.44, df=57.5; P=.02; Cohen d=0.65, 95% CI 0.12-1.17), reflecting a substantial effect. • However, the PHQ-9 and K-10 scores for the control group (comparing baseline and receiving the iBobbly intervention afterwards) were insignificant. • The iBobbly app was not effective in reducing impulsivity, as measured by the BIS-11. The preintervention scores for the waitlist group were significantly lower than those for the iBobbly group (t=2.05, df=59.2; P=.045). Postintervention means were identical. However, after applying the iBobbly app to the waitlist group, the score reduction was insignificant (t=−1.82, df=29.1; P=.08).

Evidence type and study (author, year)	Data collection method	Data analysis method	Digital mental health service type	Major findings
Russell et al [82], 2021	KICA-screen results obtained from both face-to-face and online tests	• Liner correlation	KICA-screen delivered via telehealth	• The KICA-screen test delivered through digital platforms did not cause a decrease in effectiveness compared to the face-to-face version, owing to good correlation (Pearson r=0.851; P<.01) and good agreement (intraclass correlation coefficient=0.85; P<.01).
Titov et al [86], 2019	Health records measured by the K-10, PHQ-9, and Generalized Anxiety Disorder Scale-7 (GAD-7)	• A generalized estimation equation (GEE) modeling technique was used to examine the significance of changes in symptom measures over time. The main effects of course and Indigenous status were also examined.	MindSpot service	• For First Nations patients, the MindSpot service was effective at causing a significant decrease in the K-10 score (χ^2=5933.1; P<.001), PHQ-9 score (χ^2=5938.8; P<.001), and GAD-7 score (χ^2=5658.8; P<.001). • There were no differences in treatment outcomes between Indigenous and non-Indigenous patients (K-10: χ^2=0.1; P=.75; PHQ-9: χ^2=0.5; P=.49; GAD-7: χ^2=0.6; P=.44). • There was no difference in the outcome between Indigenous patients who chose the general wellbeing course and those who chose the Indigenous wellbeing course (K-10: χ^2=1.2; P=.27; PHQ-9: χ^2=0.5; P=.48; GAD-7: χ^2=2.9; P=.09).
Quantitative evidence with no comparison

Evidence type and study (author, year)	Data collection method	Data analysis method	Digital mental health service type	Major findings
Dingwall et al [68], 2023	Comparing participants' scores of psychosocial instruments at baseline and after the 4-week intervention: K-10, Patient Health Questionnaire-2 (PHQ-2), Generalized Anxiety Disorder-short form (GAD-2), Alcohol Use Disorders Identification Test (AUDIT-C), Drug Use Disorders Test (DUDIT), and Parent-rated Strengths and Difficulties Questionnaire (SDQ-parent rated)	• Paired sample 2-tailed *t* tests for psychological test results with within-group effect sizes (Cohen *d*)	AIMhi-Y app	• The app was significantly effective in reducing psychological distress (t_{29}=4.63; *P*<.001; Cohen *d*=0.85, 95% CI 2.79-7.21) and depressive symptoms (t_{29}=4.09; *P*<.001; Cohen *d*=0.75, 95% CI 0.42-1.25). • Participants presented improvements in reducing anxiety symptoms (t_{29}=1.58; *P*=.13; Cohen *d*=0.28, 95% CI −0.10 to 0.77). • The app was ineffective in reducing alcohol use disorder symptoms (t_{26}=1.55; *P*=.13; Cohen *d*=0.31, 95% CI −0.06 to 0.43), drug use disorder symptoms (t_{26}=1.55; *P*=.13; Cohen *d*=0.31, 95% CI −0.06 to 0.43), and lead dependence (t_{29}=0; *P*>.99; Cohen *d*=0, 95% CI −0.29 to 0.29). • Participants' parents reported that the app was ineffective in improving psychological adjustment (t_3=2.15; *P*=.12; Cohen *d*=1.07, 95% CI −2.03 to 10.53).
Kennedy et al [71], 2021	The uMARS[c] survey comprises 26 questions and 5-point Likert scales	• Calculate descriptive statistics and mean and SD for continuous variables	Multibehavioral change app "MAMA-EMPOWER"	• Participants (n=16) reported acceptable perceived impact (mean 3.55, SD 1.06).
Tighe et al [84], 2020	Record usage of the app and results from psychological instruments: DSI-SS, K-10, and PHQ-9	• Regression analyses	iBobbly program	

XSL•FO
RenderX

Evidence type and study (author, year)	Data collection method	Data analysis method	Digital mental health service type	Major findings
				• The iBobbly app was ineffective for the primary outcome, suicidal ideation, which was measured with the DSI-SS. For every minute spent on the app, DSI-SS scores reduced by 0.013 points (R^2=0.29). • The iBobbly app was ineffective in reducing psychological distress that was measured with the K-10. For every minute spent on the app, K-10 scores reduced by 0.007 points (R^2=0.35). • The iBobbly app was ineffective in reducing depression that was measured using the PHQ-9. For every minute spent on the app, PHQ-9 scores reduced by 0.001 points (R^2=0.268). • According to the authors, the low validity could be caused by the small sample size.
Routledge et al [81], 2022	Paper-and-pen test on classes or an online questionnaire	• Analysis of descriptive data (method unspecified)	Web-based lesson package, Strong & Deadly Futures	• Among First Nations students (n=15), more than half (53.3%) reported that they were likely to use the information and skills taught by the course in their own lives. Nearly half (46.7%) of First Nations students were unsure, and 0% of First Nations students believed they were unlikely to use the information and skills taught by the course. • First Nations students generally thought this program was effective in handling problems related to substance use (73.3% of students supported this idea), stress (66.7%), and peer pressure (80%).

Targeted Mental Health Conditions

Five studies did not specify the mental health conditions targeted by DMH services [66,67,70,77-80]. Three studies focused on psychological assessment and diagnosis [82,86,87], and 5 studies addressed the management of distress, depression, and anxiety disorders [71,75-85,86]. Additionally, 5 studies examined the management of substance use [71,72,75,76,83], and another 5 studies were related to the management of suicide or self-harm behaviors [67,73,75,84,85]. See Table 2 for detailed information about the settings of the included studies.

XSL•FO

[c]TMMSE: telehealth version of the MMSE.

[d]TKICA-screen: telehealth version of the KICA-screen.

Quality Assessment Results

According to the results from the Aboriginal and Torres Strait Islander Quality Appraisal Tool, the included studies presented an acceptable connection to First Nations values and principles, with at least 16 studies having "Yes" or "Partially" (provided sufficient information) answers to 11 out of 14 questions. However, most studies (n=14-18) did not properly negotiate a formal agreement with First Nations people to access and protect their knowledge. Moreover, some studies were deemed less culturally engaging for First Nations people, such as a study that researched DMH services designed for the general population [73], and some studies applied quantitative methods that resulted in lower participation in First Nations communities [82,86,87].

In terms of the results from the MMAT, all studies were considered to have high-quality research designs. For example, all qualitative studies, except for 1 study [71], completely matched all MMAT criteria. Moreover, all included studies had at least 82% of the criteria marked as "Yes."

Effectiveness

Twelve studies [68,71,72,74,75,80-82,84-87] reported the effectiveness of DMH services in managing mental health conditions among First Nations people in Australia (Table 1). Their results are summarized in the following paragraphs based on their study designs.

Qualitative Evidence

Six studies used a qualitative study design to explore the perceived effectiveness of DMH services in managing mental health conditions among First Nations people [68,74,75,80,81,85]. Three studies [68,74,75] assessed the youth version, custodial version, or standard version of the Aboriginal and Islander Mental Health Initiative (AIMhi) Stay Strong app for First Nations people. The AIMhi Stay Strong app helped participants achieve mental health improvements, guided positive thinking, and supported participants in overcoming difficulties [68,74,75]. Participants perceived the AIMhi Stay Strong app and general DMH services to be effective for improving their mental health outcomes [80]. Moreover, "Strong and Deadly Futures" online courses were examined among First Nations people to prevent alcohol and tobacco use and reduce stress and peer pressure [81]. Both clients and practitioners reported that the app enhanced clients' self-insight, self-reflection, positive thinking, confidence, and overall self-perception. However, in the study by Povey et al [75], while both the AIMhi Stay Strong and iBobbly apps were viewed as helpful for managing minor mental health difficulties, participants considered them less suitable for addressing severe conditions or preventing suicide. Participants agreed that the efficacy of the iBobbly app was limited for "vulnerable people with strong emotions" [84].

Quantitative Evidence

Eight studies reported quantitatively measured effectiveness [68,71,72,82,84-87], with mental health outcomes measured through self-reported instruments and scales.

Quantitative Evidence Without Comparison

Four studies reported the effectiveness of DMH services in managing mental health conditions among First Nations people without comparing them to typical services or other control groups [68,71,81,84]. Kennedy et al [71] found that the multibehavioral change app "MAMA-EMPOWER" was effective in managing substance use and psychological distress and was acceptable (average score of 3.55 on a 5-point Likert scale) for First Nations mothers. Meanwhile, Routledge et al [81] found that Strong & Deadly Futures (a web-based lesson package aiming to improve mental well-being and substance use prevention) was effective in 53.3% of First Nations students, who were likely to use the knowledge they obtained from the course, and no participants reported that they were unlikely to apply that knowledge. Moreover, 73.3%, 66.7%, and 80.0% of First Nations students thought that this program was helpful in managing substance use, stress, and peer pressure, respectively. However, Dingwall et al [68] found mixed therapeutic outcomes for the AIMhi-Y general mental health support app among First Nations youth. More specifically, the app was found to be effective in reducing psychological distress and depressive symptoms (Cohen d=0.85 and 0.75, respectively) and reducing anxiety symptoms (without statistical significance), but was not effective in managing substance use disorders or improving psychological adjustment. Furthermore, Tighe et al [84] found that the iBobbly app was not effective in managing suicidal ideation and reducing psychological distress or depression.

XSL•FO
RenderX

However, all indicators presented a trend of improvement. See Table 1 and Multimedia Appendix 3 for detailed information.

Quantitative Evidence With Comparison

Five studies examined the effectiveness of DMH services in managing [85,86] and assessing [72,82,87] mental health conditions by comparing the effectiveness of DMH services with that of typical mental health services [72,82,87] or waitlist control groups [85], or comparing the effectiveness of DMH services between First Nations people and non-First Nations people [86].

The Grog Survey app [72], which was developed for assessing substance abuse among First Nations people, was found to be effective in detecting the alcohol consumption level (94.7% overall agreement between the app and clinical interviews). The app was also found to be more sensitive than a clinical interview for the number of drinks, the greatest number of drinks, the median of reported drinking, and the daily consumption of standard drinks per drinking occasion (mean difference=1.6, 0.8, 3, and 0.4, respectively). Higher sensitivity was found among those classified as risky drinkers (2.3% and 4.5% more detection among males and females, respectively), as well as in the reporting (17.0% vs 7.2%) and prediction (P=.02 vs P=.44) of tremors. See Table 1 and Multimedia Appendix 3 for detailed information.

A previous study compared the telehealth versions of the Mini-Mental State Examination (TMMSE) and Kimberly Indigenous Cognitive Examination-short form (TKICA-screen), which were used for cognitive screening, with their typical versions [87]. The study found that the median TMMSE scores were slightly lower than the Mini-Mental State Examination (MMSE) scores (median difference=4.5), and the agreement measured by correlation was moderate (r_s=0.33; P=.20) but with unacceptable limits of agreement (the effectiveness may not significantly reduce in the TMMSE). On the other hand, the TKICA-screen showed a significant effectiveness loss compared with the Kimberly Indigenous Cognitive Examination-short form (KICA-screen). For instance, there was a significant mean difference of 2.17, with a tendency for poorer agreement at the lower end of the performance. See Table 1 and Multimedia Appendix 3 for evidence of proportional bias. Russel et al [82] found that the KICA-screen delivered through digital platforms was as effective as the face-to-face version, with a statistically significant correlation (Pearson r=0.851; P<.01) and agreement (intraclass correlation coefficient=0.85; P<.01) between the versions.

Titov et al [86] found that the MindSpot service, aiming to provide general mental health support, was effective in managing psychological distress, depression, and anxiety, with statistically significant decreases in the Kessler Psychological Distress Scale-10, Patient Health Questionnaire-9, and Generalized Anxiety Disorder Scale-7 scores (χ^2=5933.1, 5938.8, and 5658.8, respectively). As a DMH service designed for all Australians, there were no statistically significant differences in treatment outcomes between First Nations patients and non-First Nations patients or between First Nations patients who chose the general well-being course and those who chose the First Nations well-being course.

Tighe et al [85] evaluated the iBobbly app that was designed for suicide prevention. The results suggested that there were no statistically significant differences between the iBobbly app group and the waitlist control group in suicide prevention ($t_{58.1}$=2.40; P>.05). However, it was effective in managing depression when compared with a waitlist control group and preintervention baseline scores (P<.05). Similarly, the DMH service was found to be effective in managing psychological distress ($t_{57.5}$=2.44). See Table 1 and Multimedia Appendix 3 for P values and effect sizes. The iBobbly app was found to not be effective in managing impulsivity.

Determinants of DMH Service Implementation

Overview

Overall, this review identified the determinants of facilitators and barriers that influence the implementation of DMH services. See Table 3 for the extracted themes.

Table 3 presents 9 themes and 26 subthemes that describe the facilitators and barriers influencing the implementation of DMH services for First Nations people. There were 4 subthemes under *organizational factors*, 4 subthemes under *cultural appropriateness*, 6 subthemes under *accessibility*, 1 subtheme under *engagement*, 2 subthemes under *coverage*, 6 subthemes under *acceptability*, 1 subtheme under *integration of DMH services with existing context*, 4 subthemes under *digital literacy*, and 1 subtheme under *efficiency of DMH services*.

XSL•FO
RenderX

Table . Themes and subthemes of the identified studies.

Theme and subtheme	Supporting evidence
Theme 1: Organizational factors within DMH[a] service providers	
Supportive structure and managers within DMH service provider organizations facilitate DMH service uptake	• Supportive structures or working culture within organizations facilitated resource allocation or staff training for DMH service uptake [78-80]. • Enthusiastic managers provided direct support, which increased the willingness of staff and the organization itself for DMH service uptake [66,80].
Policy and structural obstacles and a lack of resources in DMH service provider organizations create barriers for DMH service uptake	• Procedural and administrative obstacles and obstructive IT policies limited the access of staff to technologies and DMH services and created failures in digital resource allocation [66,67,79,80]. • High workloads within the workplace and a lack of digital resources resulted in a lack of DMH training for DMH service providers [66,79,80].
Theme 2: Cultural appropriateness of DMH services	
DMH services could be culturally appropriate owing to cultural safety designs and culturally relevant content in DMH services and empowerment, which can increase the willingness of First Nations people to use DMH services	• Overall cultural safety reported by participants [74]. • DMH services empowered clients to record their own information and interact with service providers [78,80]. • Cultural safety designs were applied in DMH services, which created a safe environment or directly increased the acceptability and interest of clients [69,70,75,76,83,84].
Lack of cultural appropriateness creates barriers for First Nations users to overcome existing negative perceptions and accept DMH services	• Negative perception toward the health system created barriers for First Nations people to use DMH services [67]. • Problematic use of English within DMH services and lack of First Nations languages may cause difficulties in using DMH services [75,83].
Theme 3: Accessibility of First Nations people to DMH services	
First Nations people have mixed perceptions of their accessibility to DMH services	• First Nations clients generally appraised the high accessibility of DMH services, such as reporting that the DMH services they received were accessible [83,86]. • However, general accessibility-related concerns, such as a lack of services and resources, and long response times, were also expressed [67].
Portability and flexibility of DMH services, as well as existing digital infrastructure coverage among First Nations communities, could facilitate the implementation of DMH services	• DMH services were available on multiple digital platforms [75]. • A high coverage of digital infrastructure among communities was presented, which facilitated the uptake of DMH services [67,77]. • DMH services can be operated on portable devices, which can create unique advantages in accessibility [78,84].

XSL•FO
RenderX

Theme and subtheme	Supporting evidence
Many First Nations people report limited access to appropriate digital infrastructure, resulting in low accessibility to DMH services	• In some First Nations communities, a lack of digital infrastructure and devices resulted in difficulties in the implementation of DMH services [69,77-80]. • Even in special environments, such as prisons, access to digital devices and some specific functions of DMH services, such as access to images, was limited [74]. • In remote areas, a lack of digital infrastructure created barriers for First Nations residents to implement DMH services [75,78].
Free DMH apps are highly accessible, while those with download fees limit client access	• Apps with high accessibility were preferred, such as free-to-download apps that can operate on different platforms [76]. • The cost of e-mental health apps negatively influenced their accessibility [75].
DMH services that do not have First Nations language versions create accessibility barriers for First Nations people whose first language is not English	• A lack of DMH services in First Nations languages created accessibility barriers [69,75,78].
Theme 4: Ability of DMH services to promote engagement	
DMH services can promote engagement between clients and service providers by breaking the power imbalance and then creating facilitating effects	• DMH services could help establish positive relationships between health care providers and clients, eventually creating positive experiences for clients or increasing First Nations clients' willingness to use these services [69,74,78].
Theme 5: Ability of DMH services to cover a wide range of settings and First Nations population groups	
DMH services could cover different types of clients, topics, and reference periods	• High applicability across different age groups and mental health conditions [69]. • DMH services could cover sensitive topics due to their nature of indirect engagement [69,78]. • Compared to typical face-to-face mental health services, DMH services could cover longer reference periods on substance use topics [72].
DMH services fail to cover some severe mental health conditions, which is considered a barrier	• DMH services may not be able to cover severe mental health conditions, such as suicide [75,78].
Theme 6: Acceptability of First Nations people to DMH services	

XSL•FO
RenderX

Theme and subtheme	Supporting evidence
Acceptability of First Nations people to DMH services is perceived as high	• Satisfaction and optimism regarding DMH services and willingness to use DMH services to seek help were presented by First Nations clients, indicating high acceptability [68,69,71,74,75,77,81,84,86]. • First Nations people also expressed their idea of not expecting to receive help from DMH services [73].
Good visual design can facilitate participants' acceptance of DMH services, while visual design problems are considered barriers	• Clients reported that the DMH services they received had an attractive or engaging visual design, which increased their acceptability of DMH services [68,69,71,74,78]. • Some visual design problems also raised the attention of clients, such as high text density [70].
The unique nature of DMH services has high acceptability among First Nations people	• First Nations clients preferred the web-based, client-led, and clinician-supported nature of DMH services [74,75,83].
Attractive and useful content included in DMH services facilitates First Nations people to accept DMH services	• First Nations clients perceived that mental health resources in DMH services were generally interactive and useful [71,80]. • Embedded media forms, such as games, videos, and animations, were especially preferred by First Nations clients [68,75]. • Tailored content for First Nations students was welcomed [83].
Inadequate, repetitive, and less engaging content included in DMH services is considered a barrier	• Inadequate and repetitive content in DMH services reduced the acceptability of DMH services [68,71,84].
The unique functions of DMH services increase their acceptability among First Nations clients	• The unique functions of DMH services, such as text messages sent as reminders or data capture functions, were acceptable for First Nations clients and prompted clients to use those services [68,69,74,78].
Some functions are not attractive enough or are difficult to use, resulting in lower acceptability of DMH services	• However, some functions of DMH services were ignored, could hardly be used, or could not fit in special contexts, such as in prison [68,71,74,75].
DMH services with data safety have high acceptability, but the concern about data safety is perceived as a barrier	• DMH service apps with high privacy and data safety were preferred [76]. • Some service providers and clients also considered data unsafety as a potential risk and barrier [67,78].
Theme 7: Ability of DMH services to integrate with existing contexts	
Some DMH services are hard to integrate with existing contexts	• Some service providers felt that it was challenging to integrate DMH services into their routine care because DMH services may not easily fit group clients, pre-existing practices, and local community status [79,80].
Theme 8: Digital literacy of clients and service providers	

XSL•FO
RenderX

Theme and subtheme	Supporting evidence
Clients and service providers who have high digital literacy facilitate the uptake of DMH services	• Young clients presented especially high digital literacy and willingness to receive DMH services [67,80]. • Based on their own enthusiasm for using DMH services or specific DMH training, some service providers obtained high DMH literacy [66,67].
Clients who do not have high digital literacy may face challenges when operating DMH services	• Some clients reported that the DMH app is difficult to operate [70,75,78]. • Relatively lower digital literacy resulted in lower awareness of DMH services [68,75,80].
Service providers who do not have high digital literacy may face challenges when operating or providing DMH services	• Low digital literacy of service providers led to negative perceptions, including overestimating the complexity of technology or thinking DMH services will distract them from their current job [66,67,78]. • Inadequate digital literacy among service providers created challenges in maintaining and using DMH services [67,79,80]. • Overall, the digital literacy level among service providers was highly heterogeneous [78,79].
Theme 9: Efficiency of DMH services	
DMH services have high efficiency and are considered time-saving	• Service providers believed that DMH services could reduce the time cost of recording client notes and waiting for data transmission, and these had advantages for data recording and management compared to typical paper format services [78,80].

[a]DMH: digital mental health.

Organizational Factors

Organizational factors related to the administration and management of the organization (usually service providers) could either facilitate or create barriers to implementing DMH services.

Four studies asked stakeholders and service providers to generally comment on DMH services [66,78-80]. The supportive structure within the organizations was a significant facilitator, which included the regular supervision and review of DMH service utilization [78]; being supportive of allocating resources, time, and training [79]; and building the work culture that welcomes DMH services within the workforce [80]. Direct support from managers was also considered to facilitate the uptake of DMH services [80] by increasing the opportunity and interest of staff in adopting DMH services [66].

Four studies asked mental health service providers about their general perspectives on DMH services [66,79,80] and on using DMH services in suicide prevention [67]. Service providers reported that organizational factors created barriers for the uptake of DMH services. These included a lack of organizational support [80], administrative obstacles, obstructive IT policies within the workplace [66,79], work restrictions [67], a lack of training resources within organizations [79], and time allocated to cope with the extra workload brought on by the implementation of DMH services [66,79,80].

Cultural Appropriateness

Cultural appropriateness was perceived as a critical determinant of the uptake of DMH services within First Nations people in Australia, with high cultural appropriateness facilitating uptake and low cultural appropriateness impeding uptake.

Ten studies reported high culturally appropriate DMH services [69-71,74-76,78,81,83,84]. The users of the AIMhi Stay Strong app [69] and its custodial version [74] reported satisfaction with cultural safety. Similarly, participants in programs, such as the "SMS4dads" mobile app program, "Stayin' on Track" website program [70], AIMhi-Y app program [76], and iBobbly suicide prevention program [84], valued the culturally appropriate visual and content design [76] as well as the private space these tools provide to reduce shame and stigma [75,84]. Stakeholders also highlighted the empowering nature of DMH services that allowed users to record personal information and engage with culturally meaningful content [71,78].

The "Strong & Deadly Futures" web-based substance use prevention program, though designed for the general population, was also praised for its cultural appropriateness owing to its inclusion of First Nations characters and an equitable learning

XSL•FO
RenderX

environment for both First Nations and non-First Nations students [81,83].

Three studies reported a lack of cultural safety within DMH services [67,75,83]. Some First Nations health workers perceived digital suicide prevention tools as culturally inappropriate, reflecting broader concerns about cultural unsafety in the mental health system [67]. Users of the AIMhi Stay Strong app and the iBobbly suicide prevention app expressed uncertainty about whether these tools could address trauma linked to colonization [75], and "Strong & Deadly Futures" participants provided mixed responses for the use of "Aboriginal English" [83].

Accessibility

Accessibility was another key determinant of DMH service implementation among First Nations people. Two studies generally evaluated accessibility [83,86], noting that MindSpot could deliver care when local face-to-face mental health services were unavailable [86], and Strong & Deadly Futures was accessible to users with varying abilities [83]. However, concerns remained about poor communication systems, limited resources, slow response times, and service gaps in digital suicide prevention tools [67].

Five studies reported that improved digital infrastructure supported access to DMH services [67,75,77,78,84]. Apps, such as AIMhi and iBobbly, were considered accessible due to their compatibility with multiple devices and their portability [67,75,77,78,84], which enabled use across locations and levels of remoteness. Nevertheless, limited availability of devices and internet connectivity reduced access [78-80], particularly in remote communities and custodial settings [74,75].

Cost was another barrier, with participants preferring free-to-download apps, and the fees for the AIMhi Stay Strong and iBobbly apps were seen as deterrents [75,76].

Finally, language barriers restricted access, as most apps lacked First Nations language options, making it difficult for some users to understand key terms such as "resilience" [69,75,78].

Integration

The difficulty in integrating DMH services with existing practices was generally perceived as a barrier in the included studies. More specifically, some service providers in 2 studies commented on applying DMH services in general mental health areas [79,80] and reported difficulties in integrating DMH services into usual practices when facing non-one-to-one settings, such as facing a group of clients [79], or the need to fit existing practices and the local community status [80].

Engagement (Between Service Providers and Clients)

Three studies highlighted that DMH services promoting engagement between clients and service providers were well received in general mental health care [69,74,78]. The AIMhi app was reported by health providers to reduce barriers, such as power imbalance, and foster positive relationships between health care providers and clients [69]. Moreover, stakeholders expanded this result to other DMH tools that could provide indirect engagements when solving sensitive issues and supported the building of positive relationships [78]. Improved rapport was also observed in custodial settings through the custodial version of the Stay Strong app [74].

Coverage

Coverage refers to the ability of DMH services to cover different types of clients and various mental health conditions. Three studies found that broader coverage facilitated implementation [69,72,78]. The AIMhi app was reported to reach clients across age groups and symptom profiles, including those who were otherwise difficult to engage [69]. Moreover, clients of the AIMhi app [69] and service providers providing general opinions on DMH services [78] noted that DMH services could address sensitive mental health topics. Furthermore, the Grog Survey app, which aimed to investigate the alcohol dependence status, enabled coverage of longer reporting periods than typical clinical interviews [72].

However, 2 studies reported that clients and service providers felt DMH services, including the AIMhi and iBobbly apps, may be unsuitable for addressing severe mental health conditions such as suicide [75,78].

Acceptability

Acceptability refers to the extent to which DMH services are acceptable to First Nations Australians. Ten studies mentioned overall positive acceptability [68,69,71,73-75,77,81,84,86]. Except for Lifeline Australia, which was rated low due to participants' limited expectations of receiving suicide prevention support [73], all other services, including the AIMhi Stay Strong app and its custodial and youth versions [68,69,74], "MAMA-EMPOWER" [71], AIMhi, iBobbly [75,84], "Strong & Deadly Futures" [81], and MindSpot [86], were generally well received, showing high satisfaction, usability, and acceptability [77].

The nature of DMH services was reported as acceptable by 3 studies [74,75,83]. The custodial version of the AIMhi app was appraised for its client-led nature [74], and the AIMhi app and iBobbly suicide prevention app were praised for their clinician-supported nature that could overcome mental health literacy barriers [75]. The web-based nature of "Strong & Deadly Futures" was preferred by students of web lessons [83].

Two studies emphasized relevance and noted that MAMA-EMPOWER was meaningful to users facing relevant issues, although substance use content was viewed as less relevant by nonusers or younger students [71,81].

Four studies discussed digital functions, identifying useful features, such as text messaging in AIMhi [68], service consistency functions in AIMhi [69], goal-setting in the custodial Stay Strong app [74], and data capture features [78]. However, some functions were ineffective or difficult to use, such as the "stories" page in AIMhi-Y [68], and had limited avatar customization [74] and hard-to-use designs [71,75].

Five studies described content as a major contributor to acceptability [68,71,75,80,83]. Participants valued engaging and informative material, including media components (games, videos, and graphics) and culturally tailored content for First

XSL•FO
RenderX

Nations users [83]. Conversely, inadequate or repetitive content reduced engagement [68,71,84].

Six studies addressed visual design [68-71,74,78]. Most participants praised the cultural appropriateness, color, and user-friendly layout of AIMhi and MAMA-EMPOWER, while some found SMS4dads and Stayin' on Track overly text-heavy [70]

Finally, 3 studies discussed data safety and privacy as concerns [67,76,78]. Youth participants preferred DMH tools with secure data handling [76], but general apprehension about data security, particularly in suicide prevention contexts, was reported as a barrier [67,78].

Digital Literacy

Digital literacy was identified as a key determinant of the implementation of DMH services. Three studies reported that high digital literacy facilitated the use and acceptability of DMH services [66,67,80]. Young First Nations clients with higher digital literacy demonstrated greater acceptance of DMH tools [67,80], and some suicide prevention gatekeepers preferred digital platforms, such as Facebook, for service delivery [67]. Training also improved providers' digital literacy, enhancing DMH adoption [66].

However, low digital literacy hindered engagement for both clients [68,70,75,78,80] and service providers [66,67,78-80]. Clients reported difficulty operating apps, such as SMS4dads, Stayin' on Track, AIMhi, and iBobbly [70,75,78], with some forgetting or being unaware of DMH tools [75]. Among providers, digital competency varied widely, with some describing themselves as "less technologically competent" and struggling with basic functions like downloading apps [67,79,80].

Efficiency

Efficiency was another determinant of the implementation of DMH services. Two studies [78,80] reported that service providers perceived DMH services as improving efficiency. More specifically, DMH services could reduce the time cost of recording client notes and waiting for data transmission [78], offering advantages in data recording and management compared with traditional paper-based systems [80].

Discussion

Principal Findings

This is the first review to synthesize evidence on the effectiveness of DMH services and the determinants of the facilitators and barriers of DMH services for First Nations people in Australia. Our review found that DMH services were effective in assessing mental health conditions, monitoring mental health status, and delivering mental health education, and had the potential to improve mental health conditions among First Nations Australians. However, the effectiveness of these services for severe mental health conditions remains limited. Additionally, this review identified determinants that could facilitate or inhibit the uptake of DMH services among First Nations people in Australia.

Effectiveness of DMH Services

The effectiveness of DMH services for First Nations Australians varied across different mental health outcomes and intervention types. Consistent with a previous government report [88] and similar studies [89-91], qualitative studies included in this review suggested that DMH interventions can support mental health improvement, increase self-reflection, and enhance self-confidence and empowerment [68,74,75,80,81,84].

Considering that most included DMH services applied culturally adapted designs, these findings align with broader evidence that culturally adapted DMH tools can provide valuable support for the mental health of First Nations people [3,10,92]. However, concerns remain about the adequacy of digital interventions for severe mental health conditions, particularly suicide prevention, where some participants expressed doubts about their effectiveness beyond mild to moderate distress [75,84,85]. This highlights the ongoing challenge of delivering digital suicide prevention interventions effectively in First Nations communities, as also noted in previous research [55].

Moreover, evidence supports the effectiveness of DMH interventions for substance use. The Grog Survey app accurately identified at-risk drinkers with high sensitivity and reliability [72], and it was as effective as the web-based lesson package Strong & Deadly Futures in preventing substance use [81]. However, the AIMhi-Y app was ineffective in reducing alcohol and drug use symptoms [68], indicating that while DMH tools could be valuable for monitoring and performing early intervention, they might not have sufficient therapeutic impact for substance use disorders without additional face-to-face support. This aligns with previous research on First Nations people in the United States, who had insignificant therapeutic outcomes [93]. The use of DMH interventions for cognitive assessment has also yielded mixed results [82,87]. These findings highlight the need for careful adaptation of cognitive assessments for telehealth delivery, as the telehealth version of the test reduced the visual cues of the test [87] and resulted in insignificant results, but the same test that was delivered through video conferencing obtained acceptable effectiveness compared with typical in-person services [82]. Finally, our engagement and user perception findings indicated that DMH education and behavioral change interventions can be beneficial but require further refinement. For instance, the Strong & Deadly Futures program was generally acceptable to First Nations students owing to the perceived effectiveness in preventing substance use [81]. However, a substantial proportion of students remained unsure about applying the information in their own lives. This suggests that while digital education programs can improve mental health literacy, their impact on long-term behavioral change may be limited without additional reinforcement, as noted in previous research [94].

This review found that the effectiveness of DMH services for First Nations people in Australia is in line with that for First Nations people from other countries. For example, the effectiveness of DMH services in Australia was found in international evidence, such as a general mental health program that successfully caused positive behavioral change for First Nations people in Canada [95] and a mental health screening

XSL•FO
RenderX

program in New Zealand [96]. This indicates that the experience and knowledge generated from First Nations people can be generalized. Heterogeneity was present in some areas. For example, a program in the United States achieved statistical significance in treating substance use issues for First Nations people [93], while a program with a similar target only obtained insignificant results in Australia [68]. Considering that the situation and historical factors faced by First Nations people in Australia are unique, care should be taken when generalizing the results from this review.

Determinants of the Uptake of DMH Services Among First Nations People in Australia

This review highlights that the implementation of DMH services for First Nations people is shaped by interconnected structural, cultural, and individual factors. Organizational readiness, including leadership support, workforce capacity, and digital infrastructure, remains foundational. Leadership drives the strategic vision, fosters innovation, and ensures resource allocation, which are essential for successful implementation [97,98]. Strong leadership also facilitates stakeholder engagement and addresses resistance to change, which are key factors in digital health uptake [99]. Organizational support further enhances workforce readiness and policy development, sustaining long-term adoption [100]. Without these elements, DMH initiatives risk poor adoption and limited impact [66,67,79,80]. Additionally, cultural appropriateness emerged as a defining determinant of uptake. Culturally safe, co-designed tools enhanced engagement and empowerment, whereas culturally unsafe or linguistically limited designs hindered trust and acceptability. Culturally relevant app designs incorporating First Nations art and metaphors were found to enhance engagement [69,70,75,76,83,84]. This echoes prior research emphasizing the importance of embedding cultural elements to ensure relevance and acceptance within First Nations communities [101].

Accessibility, digital literacy, and efficiency collectively reflect the broader digital divide that continues to shape health equity in Australia. First, inconsistent digital literacy among both clients and practitioners has been previously identified as a key obstacle to effective use of DMH services [66-68,70,75,78-80]. Delivering technology training and ongoing support could improve digital literacy and confidence in using DMH services [102,103], ultimately enhancing their uptake and efficacy among First Nations communities. Second, while improved infrastructure and targeted training enhanced access and usability in some First Nations communities, persistent disparities in internet connectivity, device availability, and digital skills constrained the scalability of DMH interventions, particularly in remote and custodial settings [104]. Despite evidence showing common ownership of digital infrastructure in some First Nations communities [67,77], limited infrastructure and technology access remain significant challenges, particularly in remote communities where access to tablets, Wi-Fi, and reliable technology is often restricted [67,69,75,77-80]. It has been reported that First Nations Australians, especially those living in remote areas, are some of the most digitally excluded populations [105]. This finding highlights the urgent need for targeted investments in digital infrastructure to bridge the technology gap and ensure equitable access to DMH services. To address these challenges, it could be helpful to expand community Wi-Fi programs, provide subsidized digital devices, and implement mobile-based DMH solutions that require minimal bandwidth [88]. The Mob Link initiative by the Institute for Urban Indigenous Health is a strong example [106], as it provides culturally responsive digital health support, including assistance with telehealth and digital access, helping to reduce barriers and improve engagement with health care services. Without sustained investment in digital inclusion and community-based training, DMH services risk reproducing existing inequities rather than closing service gaps [107].

At the service level, DMH tools enhance engagement and communication between clients and providers, supporting self-reflection and rapport. However, limited integration with existing care models, concerns about data privacy, and uncertainty about applicability to severe mental health conditions reduce trust and engagement with DMH services and signal the need for clearer clinical pathways and blended-care frameworks. For instance, privacy concerns and the fear of data misuse have been constantly identified as significant deterrents to the uptake of DMH services [67,78]. It is imperative to address the concerns of First Nations people regarding data sovereignty and the potential misuse of personal health information [108], so that DMH services can be designed with robust privacy protection and transparent data governance frameworks. Furthermore, streamlined data management and integration may be helpful for integrating DMH services and reducing administrative burden, enabling system-level adoption of DMH services for First Nations Australians.

Heterogeneity of DMH Service Types

This review included various DMH service types, which caused differentiation in determinants. For example, the telehealth version of an included cognitive screening tool showed lower effectiveness due to the absence of visual cues in the test [87], while the same test with visual cues obtained acceptable effectiveness [82]. A possible explanation for this difference is that the latter test was delivered through video conferencing and involved a complete version of the assessment containing images and visual cues. Similarly, the visual design and multimedia content of DMH apps [68,69,71,74,75,78,80,83] and the various digital functions in DMH apps [68,69,74,78] were praised for increasing the acceptability of DMH services among First Nations people. However, no similar facilitators were reported by the users of telehealth DMH services, hinting at the potential benefits of designing app- or web-based DMH services compared with telehealth DMH services. Despite such diversities, this review aimed to synthesize all evidence representing technology-assisted mental health services. Therefore, it has provided an integrated understanding of how digital approaches have been applied to support mental health among First Nations people.

Limitations

We acknowledge that this review has several limitations. First, the included studies were highly heterogeneous in terms of intervention types, study designs, and outcome measures. This limited our ability to draw precise or generalizable conclusions

XSL•FO
RenderX

about overall effectiveness. Second, as our search was restricted to academic databases, relevant gray literature may have been missed, potentially contributing to publication bias. Third, many included studies had a moderate to high risk of bias, with small sample sizes and self-reported outcomes, which may reduce the certainty of the evidence.

Conclusion

This review highlights the effectiveness of DMH services in assessing, monitoring, and managing mental health conditions for First Nations Australians. However, information on their impact on severe conditions, including suicide, remains limited. Digital health apps showed promising results in improving general mental health support. Digital health apps and online courses were also perceived to be effective in preventing and assessing substance use, but did not have a significant treatment effect on managing it. For screening mental health conditions, the digital health versions of instruments were comparable to face-to-face versions, while the telehealth versions showed less effectiveness than both the digital health and face-to-face versions, indicating that effectiveness may vary across different types of DMH services.

Long-term funding in DMH services through culturally responsive community services (eg, Institute for Urban Indigenous Health) from the government or organizations should be beneficial, especially for First Nations people facing barriers to accessing in-person mental health services (eg, those who reside in remote areas) and for DMH services that are supported by evidence.

This study also identified key facilitators (eg, strong leadership, culturally relevant designs, clinician-supported tools, and community) and major barriers (eg, digital exclusion, low digital literacy, and privacy concerns). These findings highlight the need for targeted infrastructure investment that can reduce the digital divide for First Nations people, especially in regional and remote communities; digital training for both mental health care providers and First Nations clients; and transparent data governance. However, the evidence should be interpreted with caution, given the heterogeneity of study designs and outcomes, potential publication bias, and moderate to high risk of bias across the included studies. Future research should focus on co-designing DMH services with First Nations communities, rigorously evaluating their effectiveness, and integrating them into existing health care models to ensure accessibility, cultural relevance, and long-term impact.

Abstract

Background: Delayed recognition of patient deterioration in a non–intensive care unit (ICU) setting contributes to serious adverse events. Continuous monitoring devices with alerting systems offer real-time data to support early detection, but their effectiveness depends on usability. While prior reviews focus on clinical outcomes, usability—defined by effectiveness, efficiency, and satisfaction—remains underexplored.

Objective: This study aims to scope the evidence related to the usability of continuous monitoring devices with deterioration alerting in noncritical adult care units.

Methods: A scoping review was conducted following the Joanna Briggs Institute methodology and reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. A comprehensive search of MEDLINE, Embase, Emcare, Web of Science, and IEEE Xplore was performed for studies published up to November 2024. Title and abstract screening, full-text review, and data extraction were independently conducted by 2 reviewers. Studies were included if they (1) evaluated the usability—defined as effectiveness, efficiency, or satisfaction—of continuous monitoring devices; (2) focused on adult patients in non-ICU hospital settings; (3) used primary data; (4) were published in English; and (5) described how clinicians received alerts.

Results: The search identified 1284 papers, with 35 included. Most studies focused on postoperative patients in surgical wards, mainly from the United States and the Netherlands. Only 2 studies used mixed methods, and 10 reported clinician characteristics. While effectiveness (71%) and efficiency (74%) were widely studied, satisfaction (46%) and usability barriers (29%) received less attention.

Conclusions: Continuous monitoring devices with deterioration alerts may reduce rapid response team calls and ICU transfers, save time, and maintain acceptable alarm frequencies with high user satisfaction. However, usability challenges persist, including technical issues, alarm fatigue, patient discomfort, and limited training or workflow integration. This review mapped current use, usability, and barriers, categorized key usability factors for improvement, and identified the need for further research on clinician perspectives and broader health care settings to enhance generalizability.

KEYWORDS

continuous monitoring; monitoring; wearable devices; early warning score; vital sign; alerts; alarms; deterioration

Introduction

In 2022 - 2023, the United Kingdom recorded 16.4 million hospital admissions, compared to 33.7 million in the United States and 12.1 million in Australia [1-3]. Many of these patients may experience severe adverse events (SAEs), such as cardiac arrests or intensive care unit (ICU) admissions, during their hospital stay, with estimates ranging from 5% to 10% [4,5]. According to UK data, 23% of in-hospital SAEs resulting in sudden death are due to failures to recognize or respond to patient deterioration [6]. This issue is particularly concerning in non-ICU environments, where higher nurse-to-patient ratios require nurses to divide their attention among multiple patients, making timely identification of patient deterioration more challenging [7]. As van Galen et al [8] reported, 46% of 49 unplanned ICU transfers were linked to insufficient monitoring by nurses, highlighting the urgent need for enhanced monitoring strategies to support timely identification of at-risk patients in general wards.

The early warning score (EWS) is a widely used tool for early detection of patient deterioration in non-ICU settings [9]. It assigns weighted scores to vital signs (eg, respiratory rate, oxygen saturation, blood pressure, heart rate, temperature, and consciousness) to assess severity and guide interventions [9].

XSL•FO
RenderX

Studies have shown that the EWS can effectively identify patient deterioration, potentially reducing mortality rates in general wards [10,11]. The systematic review by Smith et al [11] of 21 retrospective studies in academic hospitals, primarily involving patients from medical and surgical wards, found that applying EWS was associated with a reduction in hospital mortality rates from nearly 50% to 40% and reduced cardiac arrest rates from 50% to 35%. However, studies also highlight that the effectiveness of the EWS can be compromised by inaccuracies in recorded data and its inability to capture immediate, real-time changes in vital signs [12,13]. In many general wards, nurses measure vital signs infrequently due to high patient-to-nurse ratios (especially compared with ICU settings) and intense workloads, which leave significant gaps during which critical signs of patient deterioration may be missed [12,13]. Incomplete and delayed data are associated with 19% of EWS inaccuracies in the United Kingdom and untimely responses in 75% of high-risk cases [14].

To help nurses improve the accuracy and timeliness of patient monitoring, real-time continuous monitoring systems with deterioration alerts have been proposed. Using wearable sensors or bedside monitors, these systems provide continuous data on key physiological parameters and generate alerts when out-of-range values are detected [15,16]. Multiple reviews have examined the effectiveness of these systems in non-ICU settings. Two reviews highlight positive outcomes: Downey et al [15] reviewed 24 studies involving over 40,000 patients and reported benefits such as reduced ICU transfers, shorter hospital stays, and significant cost savings. Similarly, Sun et al [16], in their meta-analysis of 14 studies, found that patients under continuous monitoring had a 39% lower risk of mortality compared to those with intermittent monitoring. However, other reviews have not found that continuous monitoring improves patient outcomes. Cardona-Morell et al [17] conducted a systematic review and meta-analysis of 22 clinical studies, involving sample sizes ranging from 16 to 64,661, and found no significant differences in the proportion of high-risk patients requiring urgent attention, preventing serious adverse events, cardiac arrests, or reducing ICU transfers. Similarly, the meta-analysis by Areia et al [18] reported potential reductions in ICU admissions and complications but found no differences compared to standard monitoring.

The differences in results across these reviews may be attributed to several factors. First, the design and functionality of continuous monitoring devices and their deterioration alerting systems vary, leading to differences in how alerts are generated and how clinicians interact with the devices. For example, Areia et al [18] focused solely on wearable devices, while Cardona-Morrell et al [17] included both wearable devices and bedside monitors. Second, the sample size and composition differed across studies. Downey et al [15] included 24 studies covering 40,274 patients and 59 ward staff across 9 countries, whereas Sun et al [16] analyzed 14 studies involving only 14,880 patients without including staff perspectives, resulting in a smaller and more limited participant base. Finally, these reviews primarily focused on device effectiveness, with limited attention to factors such as patient satisfaction and clinicians' adoption preferences, while all emphasized the need for future research on usability factors to enhance the devices' adoption and overall effectiveness [15-18]. Collectively, these findings highlight the limited focus on usability in current reviews, underscoring the need for further investigation into usability barriers and their impact on device usage.

Usability is a key factor in the adoption and successful use of health care technology, as it directly influences whether systems can achieve their intended goals, such as improving patient outcomes. Notably, these devices do not function in isolation. While they cannot make decisions, they provide essential information that shapes clinical judgment. Therefore, careful consideration of how these devices are integrated into clinical practice is critical. In this sense, the device's usability reflects both its inherent attributes (eg, battery life, sensor design, and interface clarity) and its application within the broader health care context, where clinicians interpret data, make treatment decisions, and adapt workflows accordingly. Poor usability, such as unclear interfaces, false alarms, or complex workflows, can lead to clinician disengagement, reducing trust and limiting the system's impact on clinical decisions and care processes [19].

According to the International Organization for Standardization (ISO), usability is defined as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" [20]. ISO Standard 9241-11:2018 further breaks usability into 3 dimensions: effectiveness, which refers to the accuracy and completeness with which users achieve their goals; efficiency, the resources required to achieve these goals; and satisfaction, the comfort and acceptability of the system to its users [20]. As highlighted in the previous paragraph, studies on continuous monitoring and alerting systems in non-ICU settings often emphasize effectiveness while neglecting other critical factors, such as satisfaction and efficiency [15-18]. Therefore, this review aimed to map existing evidence on the usability of continuous monitoring devices with deterioration alerting systems.

Methods

The review followed the Joanna Briggs Institute methodology for scoping reviews. A scoping review was chosen because it enables mapping of heterogeneous evidence across varied definitions of "usability," ensuring that all aspects of the concept are covered. The review also adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines for transparent reporting.

The objectives of the review were framed using a Population, Concept, and Context framework as follows:

- Participants: the review includes studies involving clinicians working in non-ICU adult care settings, focusing on those who interact directly with continuous monitoring devices with deterioration alerting capabilities.
- Concept: the concept evaluated is the usability (effectiveness, efficiency, and satisfaction) of continuous monitoring devices that monitor vital signs and trigger

XSL•FO
RenderX

alerts. These devices must demonstrate how they improve clinical outcomes, enhance workflow efficiency, and increase user satisfaction.
- Context: the context includes hospital settings where these devices are applied in real-world non-ICU scenarios. Studies must describe how clinicians receive alerts and interact with these systems to ensure a comprehensive usability assessment.

No published protocol or registration was in place before this study.

Search

The search was conducted in published electronic databases up to November 13, 2024, including MEDLINE, Embase, Evidence-Based Medicine Reviews, Web of Science, and IEEE Xplore databases. Gray literature was searched through Web of Science.

The search strategy, incorporating the Population, Concept, and Context framework and MeSH (Medical Subject Headings) terms, was refined using search keywords from previous reviews on continuous monitoring devices with deterioration alerting systems' capabilities [15-18,21].

A sample search strategy for MEDLINE was as follows:

("adult care unit*" OR "general ward*" OR hospitalization OR inpatient) AND (continuous* OR "real-time" OR remote* OR wearable* OR sensor* OR monitor*) AND ("early warning score*" OR "track and trigger" OR "deterioration alert*" OR "deterioration alarm*" OR "deterioration warn*")

The final search terms and database results are provided in Multimedia Appendix 1.

Eligibility Criteria

The review included studies that evaluated the usability (of continuous monitoring devices with deterioration alerting, operated by clinicians in non-ICU hospital settings. Usability, as defined by ISO 9241-11:2018, consists of 3 key dimensions:

- Effectiveness: the accuracy and completeness with which users achieve their goals (eg, impact on ICU transfers, hospital stays, and patient outcomes).
- Efficiency: the resources required to achieve these goals (eg, alarm burden, false alert rates, and nursing workload).
- Satisfaction: the comfort and acceptability of the system to its users (eg, clinician and patient perceptions of comfort and acceptability).

The review focused on wearable sensors and bedside monitors that automatically track vital signs—including heart rate, blood pressure, respiratory rate, oxygen saturation, and temperature—at intervals of no more than 15 minutes. Studies were included if they described how clinicians received alerts, as this helps assess the impact of alerts and devices on clinical practice. Exclusion criteria omitted studies conducted in ICU settings; those in which clinicians—especially nurses, who are primarily responsible for patient monitoring—were blinded to alerts or not included in the research; studies involving participants under the age of 18 years; non-English publications; and review or protocol papers. The full criteria are provided in Textbox 1.

To ensure consistency in applying the inclusion and exclusion criteria during the study selection process, a dual-reviewer approach was used. The second reviewer independently evaluated 33% of studies at each review stage, including title/abstract screening and full-text review. If discrepancies exceeded 25%, the criteria were revised, and the screening process was repeated until the discrepancy rate fell below this threshold. Conflicts of less than 25% were resolved through consensus or consultation with a third reviewer. Additionally, reference lists of included studies were examined to identify further relevant studies meeting the inclusion criteria.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Studies evaluating the usability (effectiveness, efficiency, and satisfaction) of continuous monitoring devices with deterioration alerting in hospital settings.
- Studies demonstrating the use of continuous monitoring devices with deterioration alerting in patient monitoring: alerts must be triggered by monitoring one or more vital signs such as heart rate, blood pressure, respiratory rate, oxygen saturation, or temperature.
- Studies that describe how clinicians receive alerts.

Exclusion criteria:

- Studies not published in English.
- Studies that did not apply continuous monitoring devices with deterioration alerting in non–intensive care unit (ICU) hospital settings or failed to clearly segregate data from non-ICU and ICU settings.
- Studies in which clinicians do not receive or acknowledge alerts: exclude studies where clinicians are kept unaware of alerts from monitoring devices (ie, clinicians were "blinded" to alerts, or the device did not generate alerts, unless clinicians had another way to receive the alerts, such as from ringing notifications or a central station).
- Studies stating that they involved participants younger than 18 years.
- Review or protocol papers: systematic reviews, meta-analyses, narrative reviews, and research protocols are excluded to focus solely on original research and first-hand data regarding device usability.

RenderX

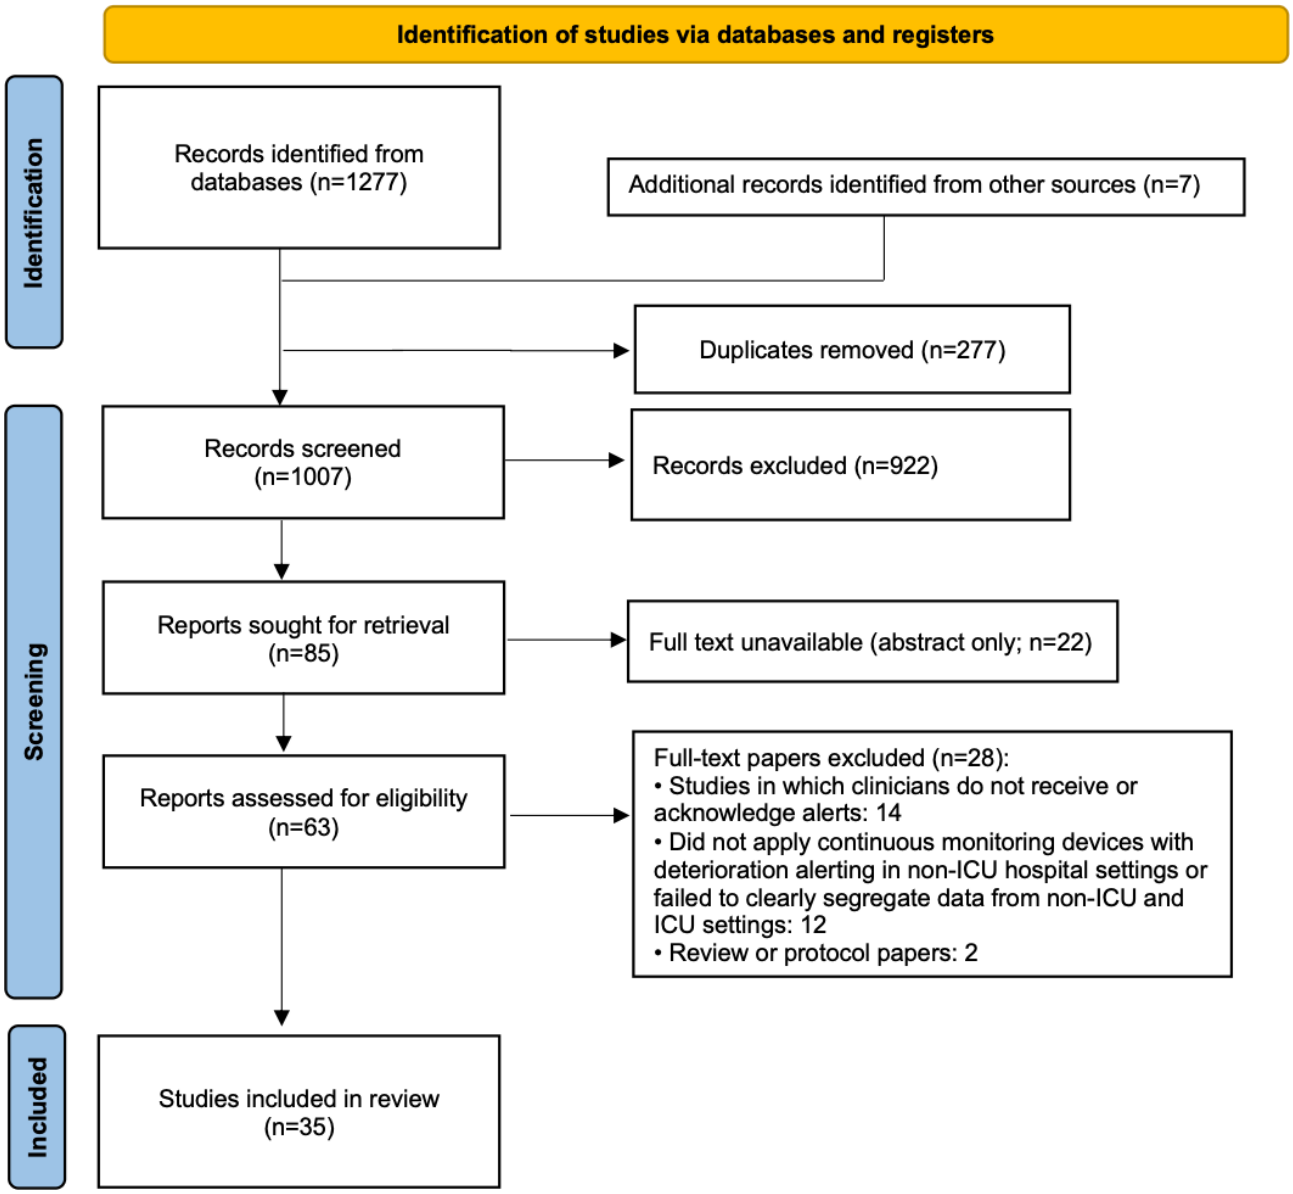
Data Extraction

A structured data extraction form (Multimedia Appendix 2) was used to collect details on citations (author and year), study characteristics (participants, setting, design, methods, and country), device features (type, function, alerts, and application), and usability aspects (effectiveness, efficiency, satisfaction, and barriers).

First, a pilot data extraction phase involved both reviewers independently reviewing 2 included studies. Second, after independent extraction, both reviewers convened to discuss their findings. Discrepancies were resolved through discussion, and any unresolved issues were referred to a third reviewer. Third, following alignment on the pilot studies, the first reviewer extracted data from the remaining studies. The second reviewer then reviewed these extractions to verify consistency with the initial agreement and the standard definitions discussed. Remaining conflicts were resolved through consensus or consultation with a third reviewer.

Synthesis

Studies were summarized and categorized based on key attributes, including publication year, country, study design, and research aim. First, these categorizations mapped the current research landscape and identified the distribution of studies across various contexts. For example, the percentage of studies conducted in different wards was reported to highlight where these devices are most frequently used. Second, the extracted data were categorized by common characteristics, such as device type and alert type. Finally, a narrative synthesis was conducted, thematically categorizing findings to align with the research question and objectives. Studies were grouped by their focus on usability (effectiveness, efficiency, and satisfaction) and barriers to usability, summarizing their findings, such as the accuracy of devices in detecting patient deterioration, categorized under effectiveness.



Results

Search Outcome

The search identified 1284 paper citations. After excluding duplicate records, 1007 records were deemed eligible for screening. A total of 63 studies were selected based on abstracts and underwent full-text review. After applying the inclusion and exclusion criteria, 35 studies were selected for this review. Figure 1 provides the study selection process in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines (the PRISMA checklist is provided in Checklist 1).

Overview of Included Studies

An overview of the included studies, including study design, study devices, interventions, comparison groups, and outcomes measured, is summarized in Table 1. Overall, the 35 studies reported outcomes for a total of 65,029 patients and 323 clinicians in 8 countries. Multimedia Appendix 3 provides a summary of the included studies.

Table . Summary of the included studies.

Author	Study aim type	Study design	Sample size	Alert mechanism type	Device type
Becking-Verhaar et al [22]	Implementation and feasibility of continuous monitoring systems	Cross-sectional survey	58 nurses	Threshold alert	Wearable devices
Bellomo et al [23]	Impact on clinical outcomes and patient safety	Observational study	18,305 patients (9617 before intervention and 8688 after intervention)	EWS[a] base alerts	Bedside monitors
Blankush et al [24]	Technological evaluation and alarm strategies	Observational study	133 patients	EWS base alerts	Bedside monitors
Brown et al [25]	Impact on clinical outcomes and patient safety	Randomized controlled trial	Baseline cohort: 1535 (control) and 1433 (intervention); postimplementation cohort: 2361 (control) and 2314 (intervention)	Threshold alerts	Bedside monitors
Downey et al [26]	Nurses' and patients' perspectives and experiences	Randomized controlled trial	226 patients randomized (140 to continuous monitoring and 86 to intermittent monitoring)	Threshold alerts	Wearable devices
Downey et al [27]	Comparison with episodic monitoring	Observational study	12 patients	Threshold alerts	Wearable devices
Downey et al [28]	Implementation and feasibility of continuous monitoring systems	Randomized controlled trial	136 patients	Threshold alerts	Wearable devices
Eddahchouri et al [29]	Comparison with episodic monitoring	Observational study	Baseline cohort: 2466 admissions and intervention cohort: 2303 admissions	Threshold alerts	Wearable devices
Gazarian [30]	Nurses' and patients' perspectives and experiences	Prospective, descriptive, observational study	57 patients observed, 37 on continuous ECG[b] monitoring; 9 nurses	Threshold alerts	Wearable devices
Hravnak et al [31]	Technological evaluation and alarm strategies	Observational study	629 patients (323 in phase I and 306 in phase III)	AI-based[c] alerts	Bedside monitors
Hravnak et al [32]	Technological evaluation and alarm strategies	Observational study	326 patients	AI-based alerts	Bedside monitors
Joshi et al [33]	Technological evaluation and alarm strategies	Observational study	50 patients	Threshold alerts	Wearable devices
Klumpner et al [34]	Technological evaluation and alarm strategies	Observational study	64 monitored rooms	EWS base alerts	Bedside monitor + wearable devices
Kuznetsova et al [35]	Implementation and feasibility of continuous monitoring systems	Observational study	35 (preimplementation: 13 and postimplementation: 22) clinicians	Threshold alerts	Bedside monitors
Leenen et al [36]	Implementation and feasibility of continuous monitoring systems	Observational study	12 nurses	Threshold alerts	Wearable devices
Leenen et al [37]	Implementation and feasibility of continuous monitoring systems	Observational study	30 patients and 23 nurses	Threshold alerts	Wearable devices

Characteristics of Included Studies

The overview of the studies' characteristics is summarized in Table 2. The aim of the included studies was categorized into 5 main subjects: implementation and feasibility of continuous monitoring systems (n=9, 24%) [22,28,35-37,44,45,50,51], comparison with episodic monitoring (n=5, 14%) [27,29,52,53,55], impact on clinical outcomes and patient safety (n=11, 31%) [23,25,38,39,41,42,47-49,54,56], nurses' and patients' perspectives and experiences (n=4, 11%) [26,30,43,46], and technological evaluation and alarm strategies (n=6, 17%) [24,31-34,40]. The included studies were predominantly from 3 countries: the United States (n=16, 46%) [24,25,30-32,34,35,38-40,44,47,49,53,54,56], the Netherlands (n=10, 29%) [22,29,36,37,41,43,45,51,52,55], and the United Kingdom (n=5, 14%) [26-28,33,48]. The most common study design was observational (n=28, 80%) [23,24,27,29-41,43,44,46-54,56]. Additionally, 20 of the included studies (57%) were categorized as nonrandomized trials [23-25,29,31-33,38,39,41,43,44,47-52,54,56]. Mixed-method studies were the least frequently used, with 2 studies (6%) [22,40]. Seventy-four percent of the included studies had comparison groups (n=26), with before-and-after implementation comparisons (n=11, 31%) [23-25,31,32,35,39,40,49,51,56] and comparisons with intermittent monitoring (n=12, 34%) [26,28,29,34,38,41-43,45,46,48,53] being most commonly used. Sixty-three percent of studies used methods combining electronic health records (EHRs), observations, clinical trials, and experiments (n=22) [23-25,29-34,39,41-43,45,46,48-53,56]. The studies most commonly involved surgical-related wards (n=18, 51%) [22,24-27,29,30,35,36,38-40,42,43,45,49,52,54] and postoperative patients (n=17, 49%) [26-30,33,37-39,41-43,45,49,52-54].

Characteristics of Clinicians

Ten (29%) of the included studies reported clinicians' characteristics involved in using continuous monitoring devices with deterioration alerting [22,30,35-37,47,49,53,54,56] (Multimedia Appendix 4). Seven studies reported incomplete characteristics [22,36,47,49,53,54,56], and 4 studies provided sample size and profession [47,49,54,56]. The available data indicated more female than male clinicians, with mean ages between 27 and 30 years. Most clinicians had 5-10 years of work experience, with nurses being the majority of users (Multimedia Appendix 5).

Overview of Study Devices

The devices used can be classified into wearable devices and bedside monitors. Wearable devices, worn directly by the patient, monitor vital signs continuously while allowing patient mobility. The most commonly used wearable devices were the SensiumVital patch (Sensium Healthcare; n=8, 23%) [26-28,33,36,37,45,52] and ViSi Mobile (Sotera Wireless Inc; n=7, 20%) [22,43,51,53-56]. The SensiumVital patch, applied to the chest, monitors heart rate, respiratory rate, and body temperature, transmitting data every 2 minutes to a central station or mobile device, with visual alerts for deviations from preset vital signs [26]. ViSi Mobile monitors heart rate, blood pressure, respiratory rate, body temperature, and oxygen saturation from the upper arm, chest, and wrist, sending visual alerts to a central monitor and the nurse's Wi-Fi phone [56]. Bedside monitors are stationary devices placed near the patient's bed, offering continuous monitoring within the monitor's vicinity. The IntelliVue Guardian Solution (Philips), used in 4 studies, tracks heart rate, respiratory rate, blood pressure, body temperature, and oxygen saturation, providing visual alerts on central and bedside monitors [23,24,41,48]. It can also be used with wireless monitors on the chest, wrist, and upper arm, ensuring continuous monitoring and timely clinical actions [23,24,41,48].

The alerting mechanisms in the included studies were categorized into 3 groups: threshold alerts, EWS-based alerts, and artificial intelligence (AI)–based alerts. Threshold alerts (n=25, 71%) notify health care providers when a monitored vital sign exceeds predefined limits, typically applied to respiratory rate, oxygen saturation, heart rate, and blood pressure (with temperature less consistently included), although only a minority of studies reported explicit numerical cut-off values or which parameters most commonly triggered alarms [22,25-30,33,35-40,42,44-49,51-53,56]. EWS-based alerts (n=5, 14%) are generated using an aggregated score based on multiple vital signs to identify patients at risk of deterioration [23,24,34,41,55]. AI-based alerts (n=5, 14%) use algorithms to analyze vital signs and predict potential clinical deterioration [31,32,43,50,54]. In terms of delivery methods, 20 studies reported systems that sent alerts directly to clinicians' mobile devices, including phones or pagers [24-28,33,34,36,37,39,40,42,46,48,49,51-53,55,56], while also notifying the central nurse station. The remaining studies indicated that alerts were sent exclusively to the central station, highlighting variability in alert dissemination approaches.

Effectiveness, Efficiency, Satisfaction, and Barriers to Usability

The included studies were analyzed for their reported effectiveness, efficiency, satisfaction, and barriers to usability.

Effectiveness

Twenty-five studies (71% of all included studies) provided relevant data on effectiveness [23,25,26,28,29,31-33,36,37,40-45,47-50,52-56]. Eight of these studies (32%) reported on rapid response team (RRT) calls: 2 studies indicated an increase [23,48], 1 study reported no significant change [53], and 5 studies observed a decrease in RRT calls [29,40,47,49,56]. ICU transfer rates were evaluated in 13 (52%) studies, with 3 studies finding no significant change [25,42,45] and 10 studies reporting a decrease [28,29,31,32,40,47-49,53,56]. Mortality rates were assessed in 12 studies, with 5 studies noting an increase in survival rates [23,31,32,48,49] and 7 studies finding no significant change [26,28,29,41,53,56]. The length of hospital stay was examined in 12 studies; 2 studies did not specify results [37,50], 5 studies found no significant change [29,41,45,49,56], and 5 studies reported a decrease [23,25,26,28,47]. Readmission rates were evaluated in 3 studies, with 1 study [41] finding no significant change and 2 studies [26,28] observing a decrease. Serious adverse events were investigated in 6 studies, with 2 studies identifying adverse events [50,52] and 4 studies reporting a decrease [31,32,48,53]. Notably, 5 studies using AI-based alerting systems demonstrated potential benefits [31,32,43,50,54], including reduced mortality and ICU transfer rates [31,32] and improved identification and reduction of SAEs [31,32,50]. However, no significant tendency was observed across other measured outcomes. Of the 4 studies that combined bedside monitors with wearable devices [31,32,34,48], 3 reported strong effectiveness in reducing mortality, ICU transfers, and SAEs [31,32,48]. However, the effectiveness of bedside monitors alone remains unclear due to the limited number of studies.

Overall, more studies suggested that RRT calls and ICU transfer rates decrease after implementing continuous monitoring devices

XSL•FO
RenderX

with deterioration alerting systems. However, the effects on mortality, length of hospital stay, readmissions, and serious adverse events remain inconclusive.

Efficiency

Twenty-six studies (74%) provided insights into efficiency issues, such as alarm frequency, false alert rate, workload impact, and time saving [22-24,30-40,42-44,46,47,49-52,54-56]. Alarm frequency was reported in 15 studies, with 4 studies indicating excessive alarms (over 4 alarms per patient per day) [24,30,36,56] and 11 studies reporting fewer than 5 alarms per patient per day [34,35,37-40,42,43,49,52,54]. The false alert rate was reported in 12 studies; 7 studies reported a high false alert rate (>40%) [24,30,36,37,43,50,52], while 5 studies reported a low false alert rate [31,34,44,49,56]. The impact on workload was investigated in 15 studies; 5 studies were unsure of the impact [22,39,47,51,56], 3 studies reported an increase in workload [24,36,54], and 7 studies observed a reduction in workload [32,34,35,38,40,46,50]. Time savings were evaluated in 8 studies, with 1 study reporting unclear results [55] and 7 studies reporting time savings [22,35,38,44,46,47,56]. Most current studies suggest that continuous monitoring devices save time, although the impact on workload is less clear. Alarm frequency generally remained below 5 alarms per patient per day, but false alarms were reported as a common and significant issue.

Satisfaction

Satisfaction with the devices was reported in 16 (46%) studies. Comfort was reported in 8 studies, focusing only on patient perspectives. Among these, 88% (n=7) [26-28,37,42,44,47] reported that patients found the devices comfortable, while 1 study reported discomfort [22]. Acceptability was reported in 94% of the studies, with 8 studies reporting patient acceptability [22,26-28,37,39,42,49] and 9 studies reporting clinician acceptability [35,36,38,40,44,47,49,56]. High acceptability was found among both patients and clinicians, with 1 study not clearly stating clinician acceptability [53].

Barriers to Usability

Usability barriers were formally reported in 10 studies (29% of all included studies) [22,26,27,30,35,36,39,44,47,49], while 5 studies mentioned them only in their discussion [24,28,40,42,43]. These barriers included technical issues, alarm management, patient comfort and experience, training and knowledge needs, and workflow integration challenges (Table 3).

Table . Summary of barriers to usability (n=10, 29% of all studies).

Studies	Definition	Studies, n (%)
Technical issues [22,39,44]	Issues with device connectivity, battery life, sensor attachment, internet connectivity, and overall device design, along with technical difficulties and artifactual issues, such as poor lead adherence and interference, as well as the cumbersome nature of device use, including removal and reapplication for showers.	3 (20)
Alarm management [26,30,49]	Frequent and high rates of initial false alarms leading to alarm fatigue and inconvenience, inconsistent practices in managing alarms, and excessive alarms from the system, often due to malfunctioning hardware or baseline tachycardia.	3 (20)
Patient comfort and experience [26,27,36,39]	Discomfort and skin reactions from the patch, concerns about practicalities such as showering, trust issues with technology reliability, patient refusals due to discomfort, confusion, or personal reasons, and discontinued monitoring due to various factors, such as contact allergies or initiation of palliative care.	4 (27)
Training and knowledge needs [22,26,35,36,39]	The need for patient education, ongoing training and coaching for health care providers, and challenges including alarm fatigue, accuracy and trust issues, and insufficient training for secondary users are impacting the patient experience.	5 (33)
Workflow and integration issues [27,36,47,49]	Challenges with integrating the monitoring system into clinical workflows, managing alarm burdens, interpreting vital sign trends, ensuring seamless integration with hospital systems, and the potential reduction in face-to-face nursing contact.	4 (27)

Technical issues were identified in 3 studies and included problems with device connectivity, battery life, sensor attachment, internet connectivity, and overall device design, along with artefactual issues such as poor lead adherence (ie,

XSL•FO
RenderX

leads detaching frequently and affecting continuous monitoring), interference, and the cumbersome nature of device use, including removal and reapplication for showers [22,39,44]. Alarm management was a concern in 3 studies [26,30,49], with frequent and high rates of initial false alarms leading to alarm fatigue and inconvenience, inconsistent practices in managing alarms, and excessive alarms often resulting from malfunctioning hardware or baseline tachycardia. Unlike efficiency measures, which assess the total number of alarms and false alarm rates quantitatively, these studies highlighted usability-related challenges, such as how clinicians respond to alarms, their perceived reliability of alerts, and whether excessive alarms led to desensitization or delayed responses to actual critical alerts. Additionally, alarm issues were often linked to hardware malfunctions or patient baseline conditions (eg, persistent tachycardia triggering unnecessary alerts), which further complicated clinical workflows and increased clinician frustration. Patient comfort and experience were highlighted in 4 studies [26,27,36,39], discussing discomfort and skin reactions from the patch, practical concerns such as showering, trust issues with technology reliability, patient refusals due to discomfort, confusion, or personal reasons, and discontinued monitoring due to contact allergies or the initiation of palliative care. Training and knowledge needs were emphasized in 5 studies [22,26,35,36,39], underscoring the need for patient education, ongoing training, and coaching for health care providers, with challenges including alarm fatigue, accuracy and trust issues, and insufficient training for secondary users impacting the patient experience. Workflow and integration issues were reported in 4 studies [27,36,47,49], noting challenges with integrating the monitoring system into clinical workflows, managing alarm burdens, interpreting vital sign trends, ensuring seamless integration with hospital systems, and the potential reduction in face-to-face nursing contact. Finally, only 6 studies systematically surveyed usability barriers from clinicians' perspectives, collecting data through interviews, surveys, or by directly including clinicians as participants [22,30,35,36,47,49].

Discussion

Principal Findings

This scoping review aimed to map the evidence on the usability of continuous monitoring devices with deterioration alerting in non-ICU settings, according to the ISO standard. It focused on effectiveness, efficiency, satisfaction, and the barriers affecting usability. Current review findings suggest that while most research supports the effectiveness and efficiency of these devices, evidence regarding satisfaction and barriers to usability remains limited, with usability barriers receiving the least attention. Through the limited evidence, 5 key barriers to usability were identified in this review: (1) technical issues (eg, connectivity and battery limitations), (2) alarm management challenges (eg, false alarms and alarm fatigue), (3) patient comfort concerns (eg, skin irritation), (4) training gaps for clinicians, and (5) workflow integration difficulties. Considering the impact of barriers to usability on effectiveness, efficiency, and satisfaction, a critical gap in the literature is highlighted [19]. Future research should prioritize investigating usability barriers by examining patient and clinician experiences and developing interventions to overcome implementation challenges.

The findings of this review suggest that continuous monitoring devices with deterioration alerting are associated with reductions in RRT calls and ICU transfer rates in some studies, supporting previous reviews. Cardona-Morrell et al [17] and Sun et al [16] also reported significant reductions in cardiac arrest calls and rescue events associated with continuous monitoring. However, mortality outcomes remain inconclusive, likely due to variability in study designs, small sample sizes, and differences in patient populations or clinical settings. Similarly, Cardona-Morrell et al [17] and Areia et al [18] found no significant impact on mortality, while Sun et al [16] reported a 39% reduction in mortality risk, making it the only review with a significant finding. Interestingly, previous reviews all reported nonsignificant reductions in ICU transfers, which contrasts with the findings of this review [15-18]. These findings collectively suggest that continuous monitoring devices may improve patient outcomes; however, further research is needed to provide more evidence supporting their comprehensive benefits.

The efficiency of continuous monitoring devices with deterioration alerting is supported by evidence indicating time savings and manageable alarm frequencies. Most studies report fewer than 5 alarms per patient per day, which is generally acceptable to clinicians [56]. However, false alarms remain a significant concern, with some studies reporting rates exceeding 40% following device implementation. This issue has been highlighted in previous systematic reviews, which emphasize the need for improved alert accuracy, as false alarms are consistently identified as a usability barrier requiring further research and refinement [15,16,18]. Additionally, the impact of these devices on workload remains inconclusive, as findings vary across studies—some report a reduction in workload, others an increase, while some remain uncertain. Downey et al [15] noted that nurses who received proper training and felt confident using the technology experienced less workload strain, whereas a lack of familiarity led to disengagement and a perceived increase in workload. Given these inconsistencies, further research is needed to establish clearer trends regarding the workload impact of continuous monitoring devices.

Satisfaction with continuous monitoring devices is notably high, with both patients and clinicians reporting positive experiences. Most studies indicate that patients perceive these devices as comfortable and acceptable. While previous reviews have focused less on satisfaction metrics, Downey et al [15] provide valuable insights, noting that patients and clinicians recognize the clinical benefits of these devices and express willingness to adopt them due to enhanced patient safety. These findings align with the current review's conclusions regarding high satisfaction levels.

The barriers to usability associated with continuous monitoring devices with deterioration alerting systems in non-ICU settings are multifaceted, which prior reviews rarely address. Technical issues found in this review, such as unreliable Wi-Fi connectivity and sensors detaching from patients (triggering nonactionable alarms), align with findings from Leenen et al [21], whose review of 13 wearable devices highlighted design

XSL•FO
RenderX

limitations—including partial wiring in supposedly "wearable" systems that restrict patient mobility and generate clinically irrelevant alerts. In addition, patient discomfort and experience, manifested as skin irritation, mobility restrictions, and distrust in device reliability, have been widely recognized as a barrier in existing literature [15-18]. Furthermore, alarm management challenges, particularly false alarms, exacerbate clinician workload and desensitization, a concern echoed across previous review studies [15-18].

Notably, this review identifies training gaps and workflow integration challenges as critical yet underreported usability barriers that were not emphasized in earlier literature [15-18]. Inadequate education for both patients and clinicians—particularly regarding alarm interpretation, device operation, and troubleshooting—amplifies usability challenges and undermines system effectiveness. These findings align with Chaniaud et al [57], who suggest that even basic, widely adopted home devices (eg, blood pressure monitors and pulse oximeters) require robust user education to achieve their full potential. This highlights the universal importance of training programs tailored to device complexity and user expertise. Similarly, poorly integrated systems disrupt clinical workflows. For example, devices that lack seamless connectivity with existing EHR systems force clinicians to manually reconcile data, increasing staff burden and reducing time for direct patient care [49]. Collectively, these barriers highlight the necessity of holistic solutions that address not only technical performance but also human-centered design (eg, prioritizing patient comfort and clinician workflow efficiency) and system interoperability to maximize the potential of continuous monitoring.

One key aspect of the adoption and use of continuous monitoring systems is the critical role of clinicians who are responsible for implementing and managing these technologies. According to these findings, nurses make up the majority of front-line users, managing continuous monitoring, interpreting alerts, and overseeing these technologies in non-ICU environments. This highlights the need to prioritize nurses' needs in the design and integration of continuous monitoring with deterioration alert systems. However, a significant limitation in the literature is the disproportionate focus on patient experiences compared to clinician-related factors. This imbalance is problematic because clinicians' acceptance and effective use of technology are pivotal to integrating these systems successfully into clinical workflows. Few studies have examined usability barriers from the clinicians' perspective or provided detailed data on factors such as familiarity with devices, willingness to adopt new technologies, and demographic characteristics (eg, age, gender, and experience). In fact, clinicians' attributes can significantly influence usability, user behavior, and overall adoption of these systems [58]. Or et al [58] demonstrate that clinicians who trust and are willing to use technology are more likely to adopt EHR systems in their practice. These findings align with Carayon and Hoonakker [59], who argue that clinicians—as both implementers and end users—are as critical as system designers in determining health IT effectiveness. Their review underscores that neglecting clinician-specific barriers risks poor adoption and suboptimal outcomes. Addressing these gaps is essential for ensuring the long-term viability of continuous monitoring technologies and highlights the urgent need for studies that prioritize clinician-centered usability metrics.

Finally, this review adds several key points compared to previous reviews. First, AI-based alerting systems remain underused and are not yet well tested in these studies, indicating a need for further research to establish their effectiveness for future applications. A systematic review by Muralitharan et al [60] suggests that AI-based alerting methods perform better than threshold alerts and EWS-based alerts; however, this scoping review found limited practical application of AI-based alerting, underlining the necessity for additional clinical trials. Second, most studies on continuous monitoring devices with deterioration alerting are concentrated in the United States and are primarily conducted in surgical units with postoperative patients. This suggests that the application of these devices is currently limited to specific clinical settings, patient populations, and geographic regions. However, continuous monitoring systems have been highlighted as promising remote patient monitoring solutions that can save clinicians time by alleviating staffing burdens and improving patient safety—particularly in light of staffing shortages in both limited-, low-, and middle-income countries [61]. Third, implications for smaller community hospitals and lower-resource wards also warrant consideration. Most of the implementations identified in this review were in larger, well-resourced centers, whereas prior work has highlighted that higher nurse-to-patient ratios in general wards and human-related monitoring failures are important contributors to delayed recognition of deterioration [7,8]. In settings where 1 nurse cares for more patients and technical support is limited, the additional alarms and infrastructure required for continuous monitoring may therefore have different consequences for workload, alarm fatigue, and value for money; although earlier reviews have described potential cost savings in selected high-resource wards, economic outcomes were rarely reported in this review's included studies, underscoring the need for formal economic evaluations—particularly in community and resource-constrained hospitals—before large-scale implementation [15,61]. These gaps highlight the importance of expanding research to assess the generalizability of continuous monitoring technologies by exploring diverse clinical environments and rigorously evaluating emerging AI-based alerting systems.

Limitations

This review is limited to studies published in English, potentially excluding relevant non-English publications and unpublished studies. The focus on usability (effectiveness, efficiency, and satisfaction) excludes studies that did not mention or examine these aspects. Only studies providing primary data were included, potentially omitting those reporting secondary data, such as systematic reviews and meta-analyses, or unpublished studies. Due to significant variations in methodology, objectives, and reported data among the included studies, a meta-analysis was not feasible. The search strategy excluded studies conducted in the ICU or nonhospital services, focusing deliberately on noncritical adult care units to investigate usability in these settings. This may have omitted relevant studies that include both ICU and non-ICU settings. Furthermore, as a scoping

XSL•FO
RenderX

review, this study aimed to include a broad range of studies without excluding any based on quality. Finally, usability was measured with heterogeneous, study-specific items, and no study used a validated instrument (eg, System Usability Scale), precluding cross-system benchmarking or pooled usability scores. Alert parameters and thresholds were inconsistently reported, limiting the comparability of alarm burden across devices and protocols.

Conclusion

Continuous monitoring devices with deterioration alerting systems are increasingly recognized as valuable tools for preventing patient deterioration in non-ICU settings. However, their successful implementation hinges on a comprehensive understanding of usability (encompassing effectiveness, efficiency, and satisfaction) and the barriers influencing real-world adoption. This review indicates that these devices can reduce RRT calls and ICU transfers, save time, and maintain manageable alarm frequencies while achieving high user satisfaction. However, significant usability barriers remain, including technical issues, alarm management challenges, patient discomfort, and insufficient training and workflow integration. Moreover, most existing studies focus on effectiveness and efficiency, leaving satisfaction and broader usability factors understudied. Additionally, research has predominantly focused on patient perspectives, often neglecting clinician insights and has been limited to specific clinical contexts, patient populations, and geographic regions, which raises concerns about the generalizability of these findings. Future studies should prioritize usability factors and expand to the clinicians' usage perspective and diverse health care settings to ensure these technologies deliver equitable, scalable improvements in patient safety and optimize care delivery in non-ICU environments.

Abstract

Background: Accurate monitoring of moderate-to-vigorous physical activity (MVPA) is critical for advancing public health research and personalized interventions. Traditional accelerometry methods, reliant on regression-derived intensity cut points, exhibit significant misclassification errors and poor generalizability to the free-living environment. Recent advancements in machine learning (ML) and deep learning (DL) offer promising alternatives for automated MVPA detection.

Objective: This scoping review synthesizes evidence on ML and DL techniques for MVPA estimation and prediction using accelerometer data, focusing on performance, algorithm bias, sensor configurations, and translational potential.

Methods: Following PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines, we conducted a systematic search across PubMed, IEEE Xplore, and Web of Science (February 1995-April 2025), supplemented by snowball citation tracking. Two independent reviewers screened titles, abstracts, and full texts against predefined inclusion criteria. Data from included studies were charted by one reviewer and verified by the other, extracting details on study characteristics, sensor configuration, ML and DL techniques, validation methods, and performance metrics. A narrative synthesis approach was used, guided by 6 research questions, to collate and summarize the findings. The synthesis process was rigorously reviewed by multiple authors to ensure consistency.

Results: Of 1938 screened studies, 40 met the inclusion criteria, with 4 studies added by follow-up manual searches. While traditional ML models (eg, random forest, support vector machine) achieved strong laboratory performance with F_1-score of 87.4%-100% and accuracy of 87.9%-100%, their real-world performance declined by 8.0%-13.3% in F_1-score and 6.6%-12.2% in accuracy, due to environment noise and device heterogeneity. DL architectures (eg, convolutional neural networks, transformers) achieved robust performance by leveraging raw signal dynamics with an F_1-score of 71.9%-79.8% and an accuracy of 87.9%-100% in free-living settings. Hybrid models (eg, convolutional neural networks and long short-term memory) demonstrated state-of-the-art performance (F_1-score 91.4%-98.4%, accuracy 97.7%-99.0%). Wrist-worn sensors dominated studies (30/40, 75%) and matched hip/thigh placements in lab settings (mean F_1-scores: 86.5%-88.6%), but multisensor configurations (wrist + hip) yielded the highest accuracy (89.7%). Key challenges included algorithmic bias reducing applicability in older adult populations, and impaired reproducibility, with only 42.5% (17/40) of studies sharing code and data. Emerging opportunities are noted for edge computing and hybrid models integrating contextual data.

Conclusions: ML and DL significantly enhance MVPA monitoring by automating feature extraction and improving adaptability to free-living variability. However, persistent gaps in generalizability, inconsistent validation protocols, and transparency deficits hinder translation. The findings support the need for future research to prioritize inclusive model training, standardized reporting frameworks, and open science practices to realize the equitable potential of artificial intelligence–driven physical activity assessment.

KEYWORDS

physical activity intensity; raw accelerometer data; wearable sensors; free-living validation; classification; estimation; sensor placement; machine learning; deep learning

Introduction

Moderate-to-vigorous physical activity (MVPA) is defined as activities requiring specific metabolic equivalent of tasks (METs), such as 3 METs or 4 METs [1,2]. It is critical to preventive health, linked to reduced risks of cardiovascular disease [3,4], diabetes [5], and premature mortality [6]. Current guidelines, such as those from the World Health Organization, emphasize MVPA as a priority; for example, children and adolescents are advised to engage in MVPA with an average of 60 minutes per day across the week to improve health [7,8]. Additionally, accurate measurement of physical activity is critical for identifying the individual, environmental, and sociocultural determinants and evaluating the efficacy of intervention strategies. Accelerometer-based motion sensors, owing to their compact design, durability, and low cost, have emerged as the predominant tool for objective physical activity assessment in diverse populations [9-12].

Traditional accelerometry methods, though widely adopted, have historically been underused in research due to reliance on intensity-based cut points derived from linear regression models or receiver operating curves [13,14]. These approaches establish thresholds by predicting energy expenditure from accelerometer counts. However, proprietary count-based thresholds, such as Freedson's cut points [15], exhibit significant misclassification of activity intensity (eg, sedentary, light, moderate, vigorous intensity) of approximately 50% in adults [16] and 28%-45% in children and adolescents [17-20]. Such methods fail to account for biomechanical nuances (eg, energy expenditure differences between walking on flat terrain vs uphill terrain) or uncontrolled variables in free-living environments, such as nonexercise movements [21,22]. The proliferation of conflicting regression-derived cut points has further complicated cross-study comparisons [23]. While these thresholds remain standard for quantifying activity intensity, their inability to accurately predict intensity across diverse activities is increasingly acknowledged [22].

The advent of machine learning (ML) and deep learning (DL) has revolutionized intensity recognition by enabling feature extraction and classification from raw accelerometer signals [24,25]. Compared with traditional cut point methods, ML models (eg, random forests [RFs] and support vector machines [SVMs]) leverage time- and frequency-domain features from high-resolution triaxial data (eg, 30-100 Hz) to reduce energy expenditure errors by 25%-50% in school-age children [19,26]. More recently, DL architectures, such as a convolutional neural network (CNN) for local temporal pattern detection, a long short-term memory network (LSTM) for modeling activity sequences, Transformers for long-range dependency learning, and hybrid models (eg, convolutional neural network and long short-term memory [CNN-LSTM]), have further advanced the field. These models identify MVPA bouts by modeling temporal dependencies in continuous data streams [27].

Three distinct methodological approaches have emerged for MVPA detection: The first one is based on activity classification, which directly identifies MVPA from activity-specific movement patterns [28,29]. The second one is based on energy expenditure prediction from predefined MET thresholds (eg, ≥3 METs) [19,30]. The third one is based on an end-to-end DL architecture that automates hierarchical feature extraction from raw accelerometer signals to classify activity intensity directly or through energy expenditure estimation [31-33]. Hybrid models, such as CNN-LSTM, further enhance performance by integrating spatial feature extraction (via convolutions) with temporal modeling (via recurrent layers) to identify subtle biomechanical patterns (eg, stride variability during running) and contextual transitions between movements [34]. However, over 60% of models remain inaccessible due to unshared code or validation protocols, perpetuating a "new cut-point conundrum" that undermines cross-study comparability and clinical utility [35].

Other shortcomings further undermine progress in MVPA-specific research. First, lab-based findings fail to be generalized to real-world conditions. For example, RF achieves >90% accuracy in lab settings [36,37], but its free-living performance degrades dramatically to around 66% [38]. However, only 10% of studies validate models in the real world [39], limiting translational relevance. Second, disparities in validation protocols, such as settings (laboratory-controlled vs free-living environments), or device placement (hip vs wrist), complicate cross-study comparisons. For instance, models trained on hip-based ActiGraph data often underperform when applied to wrist-worn devices [40]. Third, ethical and reproducibility challenges, such as algorithmic bias against older adults or clinical cohorts, and limited code or data sharing, hinder the translation.

Several systematic reviews have explored the broader field of activity recognition using accelerometers and artificial intelligence (AI). However, a focused synthesis on AI-driven MVPA detection is lacking. Previous reviews have either focused on physical activity type detection in real-life conditions rather than intensity-specific thresholds [41], provided the general methodologies of human activity recognition using wearable sensors and ML without a systematic analysis of performance and bias in MVPA classification [42-44], examined the validation of accelerometer-based monitors using ML but not within the specific context of MVPA's lab-to-real-world gap [27], or highlighted the critical issue of accessibility and reproducibility of novel analytical models but not connected them to the development of equitable MVPA models [35]. Other reviews have focused on specific aspects, such as calibration techniques [45], sport-specific movements [46], or compared DL architectures like CNN and LSTM [47]. While 2 recent

XSL•FO
RenderX

reviews touch on predicting physical activity intensity from smartphones or smartwatches [48,49], they do not encompass the full spectrum of research-grade and wearable sensors, model architectures, and the critical synthesis of translational challenges presented here.

Therefore, this scoping review is the first to systematically scope and synthesize the literature exclusively on ML and DL techniques for MVPA intensity. We uniquely quantify the performance of MVPA detection methods as a function of the sensors used, sensor placement, target populations, feature extraction strategies, model architectures, lab-to-real-world settings, and look at possible algorithmic bias introduced by the restricted age and health status of the tested participants.

Methods

Overview

This scoping review follows the Arksey and O'Malley framework, which includes 5 key stages: identifying the research question (RQ), identifying relevant studies, selecting studies, charting the data, and collating, summarizing, and reporting the results. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) was also consulted to ensure methodological rigor. EndNote X9 (Clarivate Analytics) was used for reference management, deduplication, and the screening process.

Identify the Research Questions

This paper presents a scoping review that synthesizes advancements in ML- and DL-driven MVPA estimation and prediction from accelerometer data. The review aims to answer the following RQs:

- RQ1: What ML and DL techniques have been and are currently used for MVPA detection from accelerometer data?
- RQ2: How do accelerometer specifications (eg, sensor type, sampling rate), body placement (eg, wrist, hip, and thigh), and multisensor configurations influence model performance and generalizability?
- RQ3: What's the magnitude of the performance gap between laboratory-controlled and free-living environments, and what potential factors contribute to this disparity?
- RQ4: How do validation protocols vary across studies, and how do inconsistencies in these protocols limit cross-study comparability and clinical utility?
- RQ5: To what extent do current models exhibit biased results, preventing generalization to older adult or clinical populations?
- RQ6: What proportion of studies adhere to open science practices, and how do transparency gaps hinder reproducibility, scalability, and equitable deployment?

Identify Relevant Studies

To ensure a comprehensive and focused literature search, we used a multi-step process. The search strategy was developed and refined in discussion with all the authors, who have specialized expertise in systematic review methodologies and database search strategies. Initially, we conducted a preliminary manual search to identify eligible studies and determine relevant databases and query terms. The search strategy included the following keywords and their combinations: "artificial intelligence" (eg, "machine learning" and "deep learning"), "accelerometer" (eg, "wearable device," "smartphone," "smartwatch," and "inertial measurement unit (IMU)"), and "moderate-to-vigorous physical activity" (eg, MVPA, "physical activity intensity," and "energy expenditure").

The comprehensive search was conducted across multiple databases, including PubMed, IEEE Xplore, and Web of Science. The search was conducted on April 4, 2025. To further enhance the comprehensiveness of our search, a manual citation search was conducted using reference lists of relevant studies to identify other potentially eligible studies. The detailed search strategies used to find relevant studies for this scoping review are described in Multimedia Appendix 1.

Selection of Eligible Studies

We followed the steps outlined in the PRISMA (the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension guidelines) flow diagram to select eligible studies. The study selection process involved 2 independent reviewers (YZ and SRBVDV) who screened titles and abstracts, followed by full-text assessment. Any discrepancies were resolved through discussion. This process is illustrated in the PRISMA flow diagram. The inclusion criteria were as follows: (1) studies that applied ML or DL technique; (2) studies that used accelerometry, no matter any location, number of sensors, or any type of devices, such as accelerometers or smartphones or smartwatches; (3) studies that estimated of MVPA as the outcome; (4) studies that focused on human, any age group or any health status; and (5) peer-reviewed studies published in English.

The exclusion criteria were as follows: (1) studies that did not involve ML or DL techniques (2) studies that relied on multimodal sensor systems (eg, integrated heart rate monitors with accelerometers) or nonaccelerometric data (eg, video-based estimation); (3) studies that focused on nonhuman or nonphysical activity contexts, such as only differentiating sedentary behavior from nonsedentary activity; (4) studies that focused on general activity recognition or physical activity intensity classification without MVPA-specific analysis; (5) studies that focused on theoretical models without empirical validation; (6) studies that were not peer reviewed or reported in a non-English language; and (7) studies without full text available.

Data Charting

Duplicates were identified and removed using the automated deduplication feature in EndNote X9, which was configured to define duplicates based on matching author, publication year, and title field. This automated process was followed by a manual check to ensure the thoroughness and accuracy of deduplication. Then, guided by the RQs, the following details were extracted from included studies: study characteristics (eg, author, publication year, population characteristics), sensor configuration (brand and model, placement, sampling rate), ML or DL techniques used to detect MVPA (features choosing

XSL•FO
RenderX

strategy, features selected, MVPA classification technique), ground truth validation of MVPA (via indirect calorimetry [IC] or direct observation [DO]), validating setting (lab or free-living conditions), classification performance metrics (F_1-score and accuracy), and code availability. In this review, only the F_1-score and accuracy for MVPA classification were extracted. In cases where these metrics were not explicitly reported in the primary studies, they were inferred from the provided confusion matrices using the standard functions. Accuracy, representing the proportion of total correct predictions, was calculated as:

The F_1-score, the harmonic mean of precision and recall, was calculated as

Where:

In which, TP is the number of true positives, TN is the number of true negatives, FP is the number of false positives, and FN is the number of false negatives.

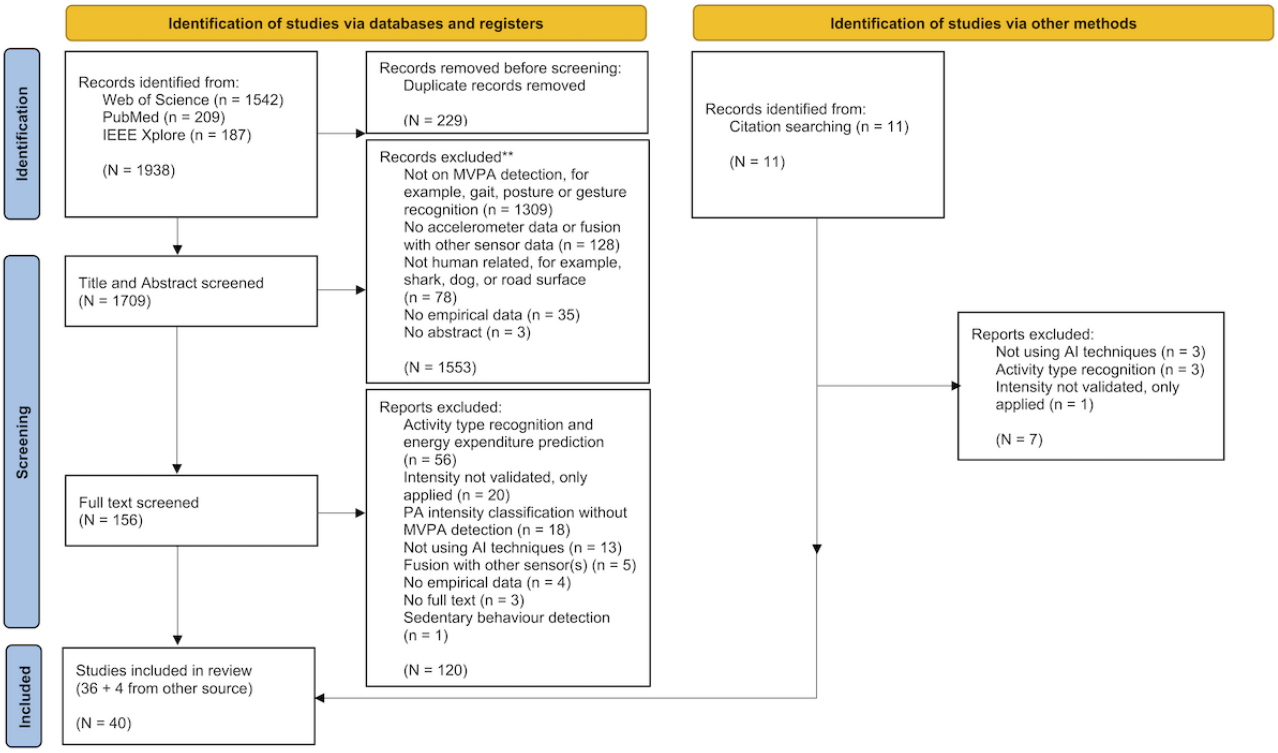
Collating, Summarizing, and Reporting the Results

To answer the RQs, the results are organized into 6 sections: evolution of feature engineering and model architectures, task-specific insights, sensor performance, validation practices, algorithmic bias, and reproducibility crisis.

A narrative synthesis approach was used, guided by the predefined RQs. The extracted data were summarized quantitatively (using frequencies and percentages) and qualitatively (identifying key themes and trends). To ensure rigor and trustworthiness, the data charting and initial synthesis were performed by one author (YZ) and critically reviewed by the others (SRBVDV, EJCDG, and PC) for accuracy and consistency.

Ethical Considerations

This scoping review synthesized findings from previously published research involving human participants. No new participants were recruited, and no new primary data were collected for this review. Consequently, separate ethical approval for this specific synthesis was not required. All original studies included in this review were expected to have obtained appropriate ethical approval from their relevant institutional review boards or ethics committees and informed consent from participants, consistent with ethical standards for human participation research involving sensor data. We noted that the majority of included studies explicitly reported ethical approval within their publications. For studies where an explicit ethics statement was not found in the publication, we acknowledge this limitation in reporting transparency. As this review analyzed results reported in published literature and did not involve direct access to or reanalysis of the raw accelerometer data from the original studies, specific data licenses or permissions beyond the published findings were not required.



Results

Overview

A total of 1938 articles were identified from PubMed (n=209), IEEE Xplore (n=187), and Web of Science (n=1542). After removing 11.8% (229/1938) of duplicates, 88.2% (1709/1938) of the articles were included in the title and abstract screening phase. After this phase, 156 (8.1%) were screened for eligibility in the full-text screening phase. As a result, 36 articles met the inclusion criteria. In addition, 4 studies were included from manual searches. In total, 40 articles were included in this scoping review, shown in Figure 1.

Overview of Included Studies

Table 1 provides a summary of included studies, including the author's name and publication year, mean age of participants (SD), number of participants, sensor brand and specific model, number of sensors tested, the placement of sensors, MVPA classification techniques used, validation setting (lab or free-living), assessment of MVPA ground truth, and code availability. The information on the country where the test was conducted, sampling rate, feature choosing strategy, window length, feature selected, and F_1-score and accuracy of model detecting MVPA was listed in Multimedia Appendix 2 [19,28,29,31,33,34,36-38,50-81].

[a]MVPA: moderate-to-vigorous physical activity.
[b]Not applicable.
[c]RF: random forest.
[d]SVM: support vector machine.
[e]DO: direct observation.
[f]PRE: predefined activity schedule.
[g]IC: indirect calorimetry.
[h]NR: not reported.
[i]k-NN: k-nearest neighbor.
[j]XGBoost: extreme gradient boosting.
[k]1D-CNN-LSTM: one directional CNN-LSTM.
[l]ANN: artificial neural network.
[m]DT: decision tree.
[n]BiLSTM: bidirectional long short-term memory.
[o]NB: naive Bayes.
[p]k-means: k-means cluster analysis.
[q]LASSO: least absolute shrinkage and selection operator.
[r]CNN: convolutional neural network.
[s]QDA: quadratic discriminant analysis.
[t]HMM: hidden Markov model.
[u]ViT-BiLSTM: vision transformer bidirectional long short-term memory.
[v]CNN-BiLSTM: convolutional neural network and bidirectional long short-term memory.
[w]ViT: vision transformer.
[x]35^{CF}: 35 participants with cystic fibrosis.
[y]28^{h}: 28 healthy participants in the study.
[z]20^{T1D}: 20 participants with type 1 diabetes.

A total of 40 studies (2006-2025) met the inclusion criteria, with 62.5% (n=25) published between 2020 and 2025, reflecting the growing interest in AI-driven MVPA estimation.

Most studies (37/40 studies, 92.5%) targeted healthy populations, while only 5% (2/40 studies) addressed clinical cohorts, that is, cystic fibrosis [37] and type 1 diabetes [80], with one study (2.5%) did not specify the characteristics of participants [36].

Eleven studies (27.5%, 11/40) focused on children and adolescents [19,28,29,38,50-52,55,62,63,79], 40% (16/40) were

XSL•FO
RenderX

on adults (18-60 years old) [34,53,55,56,58,59,61,65-68,70,71,73,74], and 17.5% (7/40) were on old adults (60 years or older) [54,64,69,72,77,78], and 2 studies reported on the clinical conditions (ie, cystic fibrosis [37] and type 1 diabetes [80]). The remaining 7 studies (17.5%) tested their models using public datasets in adults, such as Capture-24 and Energy-24 (age range 18-91 years) [31,33,53,57,75,76] and a study with multiple datasets, including UOULU (University of Oulu), OSU (Oregon State University), the PAMAP2 Physical Activity Monitoring dataset (the UCI Machine Learning Repository), and the Daily and Sports Activities (the UCI Machine Learning Repository) [60]. Among these, Chen et al [55] covered the analyses both on children and adults; Andò et al [36], though not reporting participant ages, was contextually aligned with older adult research due to its emphasis on age-associated risks of physical inactivity among older adults and its heavy reliance on references related to older adults; Capture-24 and Energy-24 datasets [31,33,53,57,75,76] were grouped into adult, due to the age distributions: 72% of participants were younger than 53 years, with only 22.5% aged 53 years or older [82]; Farrahi et al [60], which included 4 datasets with an average participant age of about 19 years, was classified under adults.

ActiGraph (30/40, 75%) and GENEActiv (6/40, 15%) were the most common sensors using acceleration sensors to identify MVPA, with limited use of consumer wearables, for example, other brands of accelerometers (eg, Axivity AX3, activPAL; 9/40, 22.5%), inertial measurement units (5/40, 12.5%), smartwatches (2/40, 5%), smartphones (1/40, 2.5%), wristbands (1/40, 2.5%), and armbands (1/40, 2.5%).

Lab-controlled validations predominated (30/45 analyses, 66.7%; some studies had multiple analyses); 33.3% of analyses (15/45) were conducted in free-living conditions, while 4 analyses combined lab and free-living validations.

Evolution of Feature Engineering and Model Architectures

A total of 45 analyses from 40 studies used a range of ML and DL techniques for MVPA detection.

Methodological Evolution

The shift from feature-driven ML to end-to-end DL reflects a broader trend toward scalability and generalizability. While traditional ML models excel in interpretability and low computational cost, their dependence on handcrafted features renders them brittle in free-living contexts. In contrast, DL architectures, though data-hungry and opaque, inherently adapt to signal variability through hierarchical abstraction, a critical advantage for real-world deployment [31].

The progression from manual feature engineering to automated DL underscores a paradigm shift toward scalable, context-aware MVPA monitoring. Table 2 synthesizes this evolution, contrasting supervised, unsupervised, and hybrid paradigms. Supervised DL models, particularly those using transfer learning, now dominate, with all studies adopting pretrained CNN or bidirectional long short-term memory (BiLSTM) to mitigate data scarcity [31,33,34,68,79]. Unsupervised approaches, such as the self-organizing map and k-means cluster analysis, remain nascent but offer potential for leveraging unlabeled free-living data [83,84].

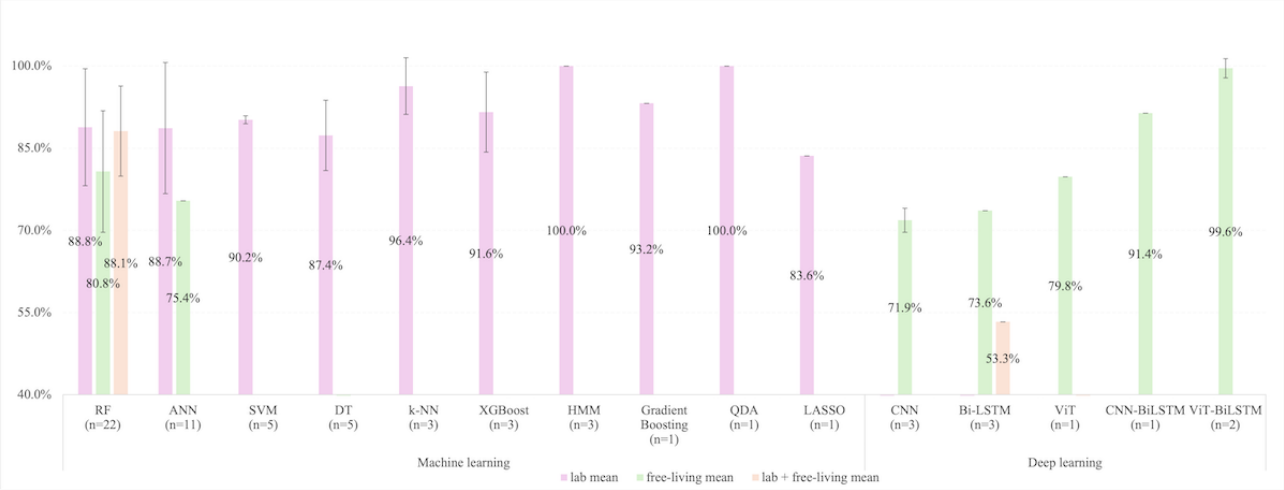
[p]ViT-BiLSTM: vision transformer bidirectional long short-term memory.



Traditional Machine Learning

Traditional ML techniques have dominated accelerometer-based MVPA detection since 2006 [71], relying on handcrafted features derived from time- and frequency-domain analyses.

Among these, RF emerged as the most prevalent algorithm (22/40 studies, 55%) [28,36-38,50-53,56,57,59,64,67,70,72,74-78,80], achieving mean F_1-scores of 86.6% and mean accuracy of 88.6%. RF's ensemble structure, which aggregates predictions from multiple decision trees (DTs) (usually 100-1000), mitigates overfitting and enhances robustness to noise, a critical advantage in heterogeneous accelerometer datasets [67,76]. Artificial neural network (ANN) followed (11/40 studies, 27.5%), with mean F_1-scores of 87.4% and mean accuracy of 89.5% [19,29,31,58,60-62,65,66,70,73]. ANN used a multi-layer perceptron with input, hidden (3-25 nodes), and output layers, nonlinear activation functions model complex feature interactions. Another often-used method was the SVM (5/40 studies, 12.5%), with an F_1-score of 90.2% and accuracy of 86.5% [28,31,50,55,70]. SVM maps features to a high-dimensional space and constructs optimal hyperplanes using kernel functions (eg, radial basis function). The F_1-scores of models using DT (5/40 studies, 12.5%; F_1-score 87.4%) [31,58,62,64,74] underperformed k-nearest neighbor (3/40 studies, 7.5%; F_1-score 96.4%) [36,37,70], extreme gradient boosting (3/40 studies, 7.5%; F_1-score 91.6%) [54,64,80], hidden Markov model (3/40 studies, 7.5%; F_1-score 100%) [71,75,76], Gradient Boosting (1/40 studies, 2.5%; F_1-score 93.2%) [70], and quadratic discriminant analysis (1/40 studies, 2.5%; F_1-score 100%) [71]. Least absolute shrinkage and selection operator achieved the lowest F_1-score (83.6%) in detecting MVPA among all the ML models [64]. The details are illustrated in Figure 2.

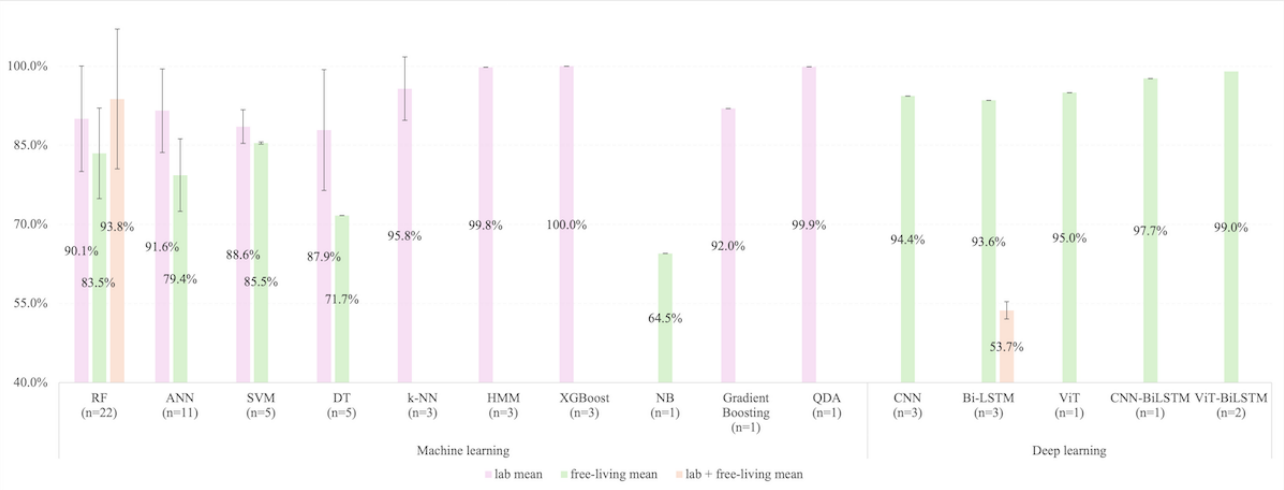

Figure 2. The extracted F1-score for moderate-to-vigorous physical activity from machine learning and deep learning models. Error bars, where applicable, represent SD. "n" means the number of studies using the model. ANN: artificial neural network; BiLSTM: bidirectional long short-term memory; CNN: convolutional neural network; CNN-BiLSTM: convolutional neural network and bidirectional long short-term memory; DT: decision tree; HMM: hidden Markov model; k-NN: k-nearest neighbor; LASSO: least absolute shrinkage and selection operator; QDA: quadratic discriminant analysis; RF: random forest; SVM: support vector machine; ViT: vision transformer; ViT-BiLSTM: vision transformer bidirectional long short-term memory; XGBoost: extreme gradient boosting.

However, performance disparities between lab-controlled and free-living environments underscored inherent limitations. RF models, for instance, exhibited a decline of 8.0% in F_1-score (88.8% lab vs 80.8 free-living) and 6.6% in accuracy (90.1% lab vs 83.5% free-living), attributed to over-reliance on static features (eg, variance, spectral entropy) that fail to generalize to unstructured movement patterns [27]. Similarly, ANN experienced reduced accuracy in free-living contexts (F_1-score 88.7% lab vs 75.4% free-living; accuracy 91.6% lab vs 79.4% free-living), highlighting sensitivity to signal variability introduced by nonexercise movements (eg, gesturing, device placement) [27]. The rest of the algorithms had no free-living validation.

Figures 2 and 3 stratify F_1-score and accuracy by model type, revealing that simpler algorithms like k-nearest neighbor and quadratic discriminant analysis achieved near-perfect lab performance (96.4%-100%) but performed less well in free-living validations.

Figure 3. The extracted accuracy for moderate-to-vigorous physical activity from machine learning and deep learning models. Error bars, where applicable, represent SDs. "n" means the number of studies using the model. ANN: artificial neural network; BiLSTM: bidirectional long short-term memory; CNN: convolutional neural network; CNN-BiLSTM: convolutional neural network and bidirectional long short-term memory; DT: decision tree; HMM: hidden Markov model; k-NN: k-nearest neighbor; NB: naive Bayes; QDA: quadratic discriminant analysis; RF: random forest; SVM: support vector machine; ViT: vision transformer; ViT-BiLSTM: vision transformer bidirectional long short-term memory; XGBoost: extreme gradient boosting.

Deep Learning

DL architectures revolutionized MVPA detection by automating hierarchical feature extraction from raw accelerometer signals, circumventing the manual feature selection bottleneck. CNN was used in 3 studies (3/40 studies, 7.5%), achieving a mean F_1-score of 71.9% (shown in Figure 2) and a mean accuracy of 94.4% (shown in Figure 3) in free-living conditions [33,34,68]. Their layered structure, comprising convolutional filters (64, 128, 256, and 512 filters), pooling layers, and activation functions (such as rectified linear unit), enables granular analysis of signal dynamics.

XSL•FO
RenderX

Recurrent architectures, notably LSTM and BiLSTM, addressed temporal complexity in sustained MVPA bouts (eg, 10 min). BiLSTM, which processes sequences bidirectionally, achieves an average of F_1-score 71.9% and accuracy 80.3% (shown in Figures 2 and 3) in 3 studies (of 40 studies, 7.5%) (2 in free-living settings, and 1 combining both lab and free-living settings) by modeling contextual transitions (eg, walking-to-jogging) [31,33,79]. Transformers, though less prevalent, demonstrated promise in capturing long-range dependencies through self-attention mechanisms. When hybridized with vision, vision transformer (ViT), the accuracy of detecting MVPA is 95.0% (F_1-score 79.8%) in a free-living validating setting in 1 out of 40 studies (2.5%) [33].

Hybrid models (eg, convolutional neural network and bidirectional long short-term memory [CNN-BiLSTM], vision transformer bidirectional long short-term memory), in 2 out of 40 studies (5%), synergized spatial and temporal learning, achieving peak F_1-score (95.5%) [34] and peak accuracy (98.4%) in free-living settings [33].

Task-Specific Insights

Classification

Classification tasks in accelerometer-based MVPA research involve assigning discrete intensity classes, such as sedentary, light, moderate, or vigorous activity. Early methodologies predominantly used traditional ML algorithms, such as RF and SVM, which relied on handcrafted features like signal variance, spectral entropy, and movement counts. For instance, RF achieved robust performance in laboratory settings (F_1-score mean 91.9%, Table 3) by aggregating predictions from DTs trained on bootstrapped subsets of ActiGraph data. However, these models struggled with ambiguity in free-living environments, particularly in distinguishing light-intensity activities (eg, slow walking at 2.5 METs) from MVPA (≥3 METs). SVMs with radial basis function kernels, while effective in lab-annotated running protocols (F_1-score 75.4%) [28], misclassified 9.0% of slow walking (or stroll) bouts as MVPA in unstructured settings due to overlapping signal patterns [50].

Table 3. Taxonomy of machine learning and deep learning technologies for moderate-to-vigorous physical activity (MVPA) detection, categorized by learning paradigm.

Learning paradigm	Key features	Algorithms	Strengths	Limitations	References
Supervised	Require labeled data (activity intensity labels)	RF[a], ANN[b], SVM[c], DT[d], XGBoost[e], HMM[f], QDA[g], LASSO[h], k-NN[i], and gradient boosting	• High accuracy with sufficient labeled data • Interpretable feature importance, Robust to noise and nonlinear patterns	• Dependency on large, labeled datasets • Overfitting risk • Poor generalization to free-living environments	[28,29,33,36-38,50-60, 62,64-67,69-72,74-78,80]
Unsupervised	Work with unlabeled data, focus on clustering or feature learning	k-means, SOM[j], and autoencoders	• No need for labeled data • Identifies hidden patterns in raw signals • Reduces dimensionality	• Limited direct applicability to MVPA classification • Lower accuracy for intensity-specific tasks • Interpretability challenges	[19,29,63]
Hybrid	Combine supervised and unsupervised components, integrates multiple architectures	CNN-BiLSTM[k], ViT-BiLSTM[l], DLEN[m], and multitask learning frameworks	• Capture spatial and temporal dependencies • Improve generalizability • State-of-the-art performance in free-living settings	• High computational complexity • Require large datasets • Synchronization challenges for multisensor data	[29,31,33,34,68,79]

XSL•FO
RenderX

DL architectures, particularly CNN, addressed these limitations by automating hierarchical feature extraction directly from raw accelerometer signals. By applying convolutional filters to sliding windows of raw data, CNN detected local biomechanical patterns (eg, stride frequency during running), achieving parity with traditional hip-based cut point methods in MVPA detection by the wrist-model [68]. Subsequent advancements, such as Transformer architectures, further improved classification accuracy by using self-attention mechanisms to model long-range dependencies, outperforming CNN by 9.5% in free-living scenarios [33].

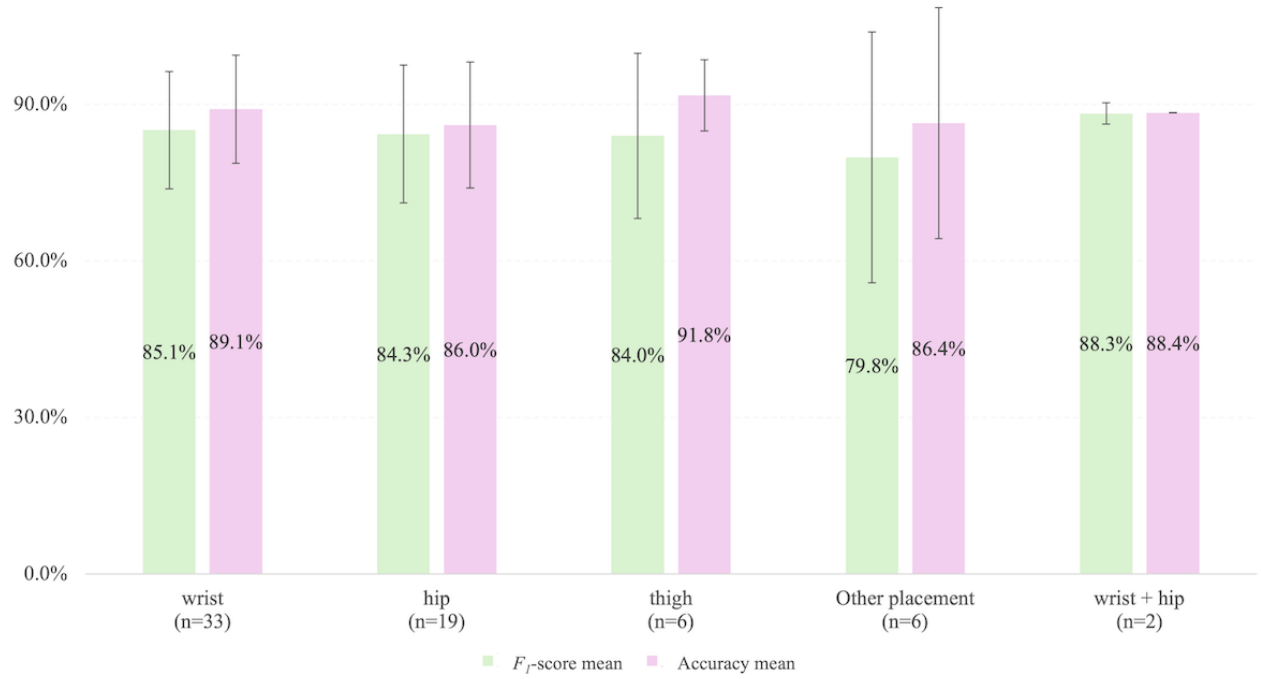
Estimation

Estimation tasks focus on predicting energy expenditure metrics (eg, METs) through regression-based models to map accelerometer signals to continuous outcomes. Conventional approaches, such as linear regression-derived cut points (eg, Freedson equations), exhibited significant limitations due to oversimplified assumptions about the relationship between acceleration signals and MET values, especially for free-living activity [65,81]. ML models, such as an additive regression tree, lowered the standard error of estimation by 0.33-22.11 in lab settings using ActiGraph data [69].

DL architectures, like BiLSTM, elevated estimation accuracy by capturing temporal dependencies in accelerometer signals (eg, MET fluctuations during exercise recovery). BiLSTM achieved a mean absolute error of 0.757, with LSTM as the baseline method [79].

Deep Learning

DL frameworks bridge the gap between classification and estimation by unifying feature extraction and task-specific learning with end-to-end frameworks. Multitask architectures, such as AccNet24, integrate BiLSTM layers for activity intensity with fully connected layers for MET prediction, achieving 97.7% accuracy in MVPA detection in free-living settings [31].



ViTs further optimized task performance via attention mechanisms that dynamically prioritized critical signal regions. For example, ViT allocated closer attention to peak acceleration intervals during jumping, outperforming Bi-LSTM by 6.2% (F_1-score) in free-living MVPA detection [33]. However, these advancements come with trade-offs; hybrid CNN-BiLSTM models require much more training time than traditional RF, limiting real-time deployment on wearables [31].

Sensor Performance

Sensor Placement

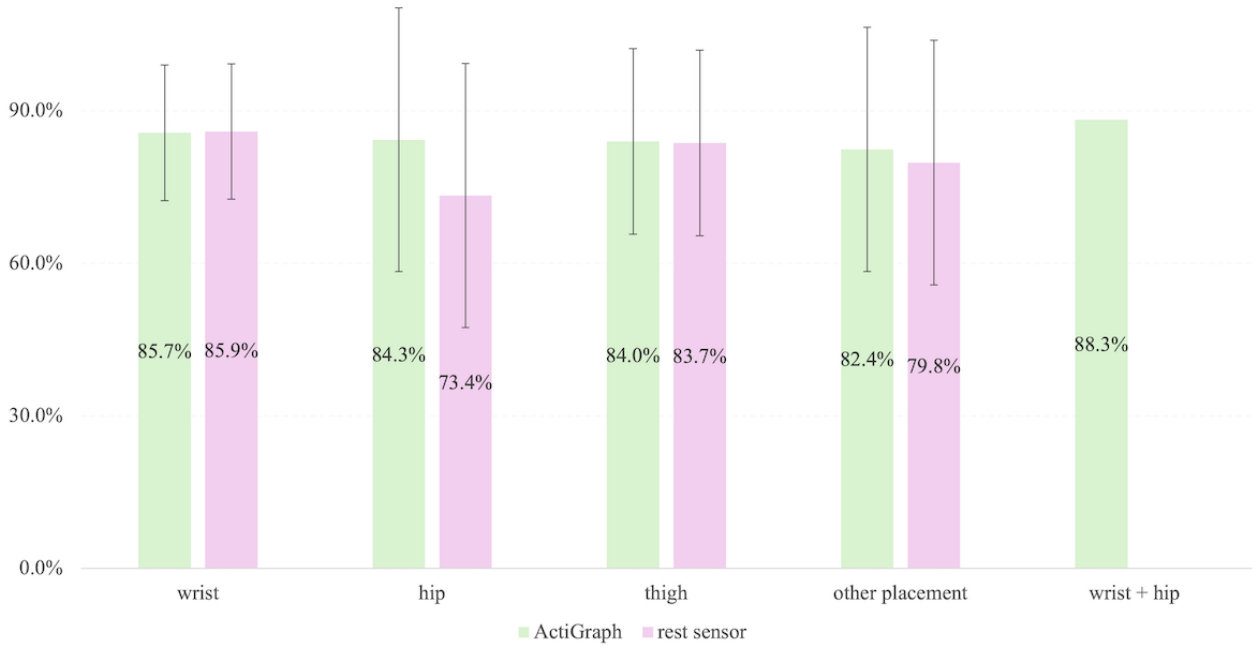
The efficacy of accelerometer-based MVPA estimation is significantly influenced by sensor placement. Figure 4 illustrates the averaged performance metrics (F_1-scores and accuracy) across sensor placements.

Figure 4. Mean value of F1-score and accuracy in relation to sensor placement across all validation settings. Error bars, where applicable, represent SDs. Other placements included chest, lower back, backpack, pocket, hand, and upper arm. “wrist + hip” means the multi-sensor configuration using both wrist and hip placements.

Regarding sensors placement, wrist-worn devices dominated in 75% of studies (30/40 studies), followed by hip (19/40, 47.5%), thigh (6/40, 15%), chest (1/40, 2.5%), lower back (1/40, 2.5%), backpack (1/40, 2.5%), pocket (1/40, 2.5%), hand (1/40, 2.5%), upper arm (1/40, 2.5%). Multisensor configurations (eg, wrist + hip) were applied in only 5% (2/40) of studies [28,51]; only the combination of wrist and hip was applied.

Comparative analyses on MVPA revealed that wrist-, hip-, and thigh-worn sensors exhibited comparable mean performance metrics across all validation settings (mean F_1-scores 85.1% vs 84.3% vs 84%, accuracy mean 89.1% vs 86% vs 91.8%) as well

XSL•FO
RenderX



as in laboratory-controlled settings (F_1-score mean 88.6% vs 86.6% vs 86.5%, accuracy mean 91.7% vs 89.6% vs 97.3%). However, disparities emerged in free-living environments. While wrist- and hip-worn sensors demonstrated similar F_1-scores (80.3% vs 79.0%), wrist-worn devices achieved superior accuracy (86.3% vs 70.8%). This discrepancy may stem from the wrist's ability to capture a broader range of upper-body movements associated with MVPA in unstructured environments, such as arm swings during brisk walking or lifting activities, which are less pronounced in hip-worn sensors.

Notably, multisensor configurations (eg, wrist + hip) achieved the highest performance (F_1-score 88.3%, with 89.7% in lab and 86.8% in free-living; accuracy 88.4%, with 88.4% in lab but nonreports in free-living), bridging the gap between controlled and free-living settings. However, practical challenges, including increased participant burden due to multiple devices and synchronization complexities between heterogeneous sensors, limit their widespread adoption.

Sensor Type and Performance Heterogeneity

Device specifications and sensor type further influenced model generalizability. Figure 5 shows the F_1-scores in relation to sensor type (ActiGraph and other types) and sensor placement. While models trained on ActiGraph data achieved a higher mean F_1-score (84.9% vs 83.1%), models using consumer-grade wearables surprisingly achieved a higher mean accuracy (91.8% vs 87.8%). This disparity may arise from the inherent class imbalance in free-living data, where MVPA represents a minority of activities. Accuracy can be inflated by correctly classifying the predominant sedentary and light activities, whereas the F_1-score provides a more balanced measure of performance specifically for the MVPA class. The higher F_1-score associated with ActiGraph models suggests they may be more adept at correctly identifying true MVPA bouts, which is critical for public health monitoring.

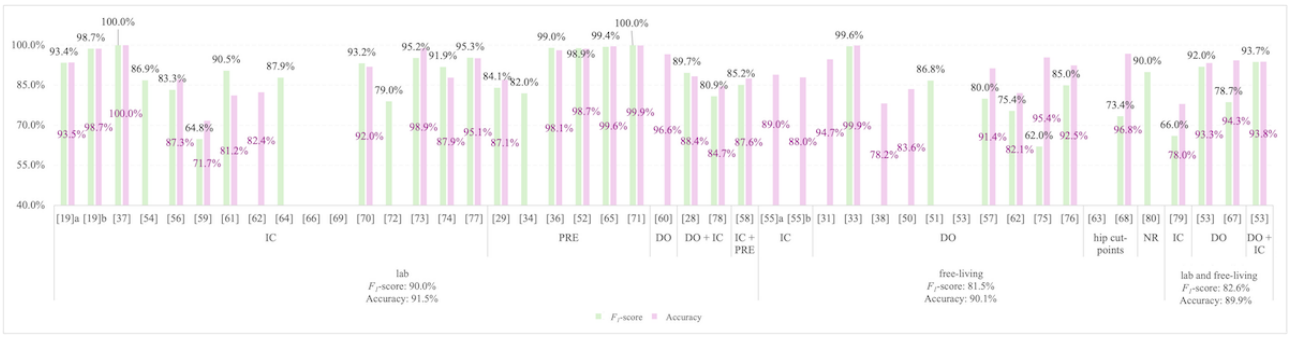
Figure 5. Mean value of F1-score in relation to sensor type and placement across all validation settings. Error bars, where applicable, represent SDs.

Validation Practices

Ground Truth Methodologies and Their Implications

Validation of ML and DL models for MVPA detection relies heavily on the specification of ground truth, with IC and DO predominating. IC (21/40 studies, 52.5%), considered the gold standard for energy expenditure measurement, provides MET values through oxygen consumption analysis, enabling precise alignment of accelerometer signals with intensity thresholds (eg, ≥3 METs) [19,28,37,53-56,58,59,61,62,64,66,69,70,72-74,77-79]. However, its laboratory-bound nature limits ecological validity, as structured protocols often fail to replicate free-living movement variability.

In contrast, DO (16/45 analyses, 35.6%) offers real-world applicability by annotating activities in a naturalistic setting but introduces subjectivity, particularly in distinguishing borderline intensities with 2 stages. At the first stage, participant movements were categorized into activity type (eg, sedentary, standing utilitarian tasks, walking, and running) using recordings [28,38,50,51,60,62,65,67,78] and time-stamped images from wearable cameras (eg, combining the usage of a diary in Capture-24) [31,33,53,57,75,76]. At the second stage, physical intensity was coded using references, mainly the Compendium of Physical Activities (sedentary, light, moderate, and vigorous) and Children's Activity Rating Scale (5 categories from stationary/motionless to fast translocation).



Additionally, reliance on hip-reference cut points as proxies for ground truth (2/45 analyses, 4.4%) perpetuates circular validation, wherein models trained on threshold-based labels inherit the biases of traditional regression methods [63,68]. A total of 15.6% (7/45) of analyses used a predefined activity

XSL•FO
RenderX

schedule in the validation process to define the ground truth [29,36,52,58,71]. Only 11.1% (5/45) of analyses used combined ground truth approaches (eg, IC + DO) [28,53,78], despite evidence that combined methods improve F_1-score by 8.3%-27.7% in free-living compared with IC or DO [53].

Figure 6 illustrates the distribution of ground truth methods across studies, stratified by validation setting. Lab-based studies disproportionately favored IC (19/26 analyses, 73%), while free-living validations leaned on DO (10/15 analyses, 66.7%), with lab validations outperforming free-living (F_1-score mean difference: 8.5%, accuracy mean difference: 1.4%).

Figure 6. F1-score and accuracy metrics for moderate-to-vigorous physical activity (MVPA) classification across studies, stratified by ground truth methods and validation settings. [19]a represents the MVPA classification conducted based on the 10s and 60s window lengths, while [19]b only on the 60s window length. [55]a represents the MVPA classification conducted among the children and adolescents with a mean age of 12.3 (SD 1.0) years, while [55]b represents the MVPA classification conducted among adults aged 24.9 (SD 2.6) years. The mean value of F1-score and accuracy in each group (lab, free-living, and lab and free-living) was shown underneath their names [19,28,29,31,33,34,36-38,50-80]. DO: direct observation; hip: hip reference cut-points; IC: indirect calorimetry; NR: not reported; PRE: predefine activity schedule.

Cross-Validation Protocols and Performance Metrics

The trained models typically undergo rigorous evaluation during the model evaluation and validation phase to verify their generalizability and practical applicability. This process is essential to systematically assess classification accuracy across activity intensities and validate reliability under diverse user scenarios. To mitigate overfitting and ensure model robustness, *k*-fold cross-validation (11/45 analyses, 24.4%) was most commonly implemented. It partitions the dataset into *k* equally sized subsets, iteratively designating one subset as the validation set and the remaining *k*-1 subsets for training. The process is repeated *k* times to ensure all data points contribute to both training and validation. Common configurations include 10-fold and *5*-fold cross-validation, which enhance model generalizability by reducing sensitivity to specific training instances. By systematically evaluating performance across varied data partitions, this method strengthens the activity intensity classification system's reliability and mitigates overfitting, a phenomenon where models memorize training data artifacts rather than learning generalizable patterns.

Leave-one-out cross-validation, which iteratively holds out each individual data point as a test set to evaluate model performance, was also used in 13.3% of analyses (6/45 analyses). Leave-one-subject-out cross-validation, an extension of leave-one-out cross-validation designed for datasets with multiple subjects, iteratively holds out all data from one subject as the test set while training on the remaining participants. This method, used in 24.4% of analyses (11/45), was critical for assessing interindividual generalizability. Its variant, leave-10-subject-out cross-validation, appeared less frequently (1/45 analysis). In contrast, nested cross-validation, which separates hyperparameter tuning from final performance evaluation to prevent data leakage, was sparingly adopted (3/45 analyses, 6.7%) in studies.

Model efficacy was quantified using precision, recall, accuracy, and F_1-score, with metrics calculated iteratively to ensure objective assessment. F_1-score (33/45 analyses, 73.3%) and accuracy (35/45 analyses, 77.8%) were emphasized in this review, though their interpretation varied widely. Notably, studies reporting accuracy exceeding 90.0% often excluded transitional activities (eg, sit-to-stand) [19,37,65,70] or used imbalanced datasets [28,71,80], potentially inflating scores. Conversely, F_1-scores below 75.0% typically correlated with free-living validations, where non-MVPA movements confounded detection [62,68,75].

In the studies not reporting the metrics of MVPA detection, but including a confusion matrix, we calculated F_1-scores and accuracy values from the confusion matrix [28,29,33,36,52,53,57,58,61,62,67,68,70,71,73-78]. Two studies reported the F_1-scores of moderate physical activity (MPA) and vigorous physical activity (VPA) separately without a confusion matrix, so they averaged MPA and VPA to get MVPA [72,79].

Four studies omitted both F_1-score and accuracy [53,63,66,69]. For instance, Li et al [63] reported only the overall accuracy of physical activity intensity classification, while Montoye et al [66] quantified MVPA error (+1.8 min) relative to IC. Ahmadi et al [53] only provided sensitivity (MPA: 80.0%, VPA: 90.0%) and precision (MPA≈75.0%, VPA≈99.0%), and Nnamoko et al [69] reported only the standard error for estimation of personalized cut points.

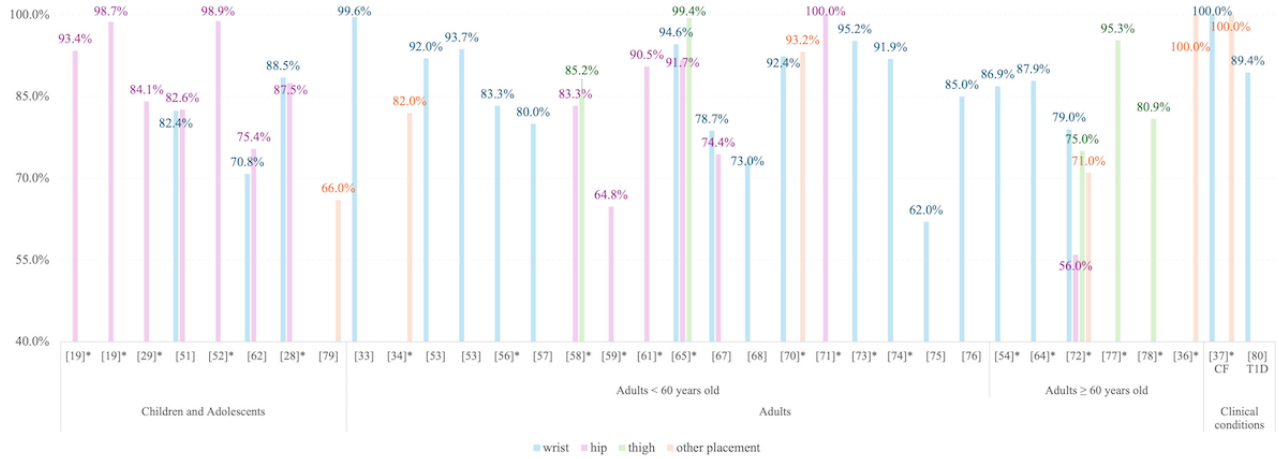
Algorithmic Bias

The performance of machine and DL models for MVPA detection is inherently tied to the physiological characteristics of the training populations. These have been mostly young, healthy adults. Persistent algorithmic bias induced by using this group can undermine the generalizability of models across the older adult and clinical cohorts.

XSL•FO
RenderX

Figures 7 and 8 stratified MVPA detection performance (F_1-scores and accuracy) by age group (children and adolescents, adults younger than 60 years, adults aged 60 years or older, and clinical populations) and sensor placement (wrist, hip, thigh, other). Among children and adolescents (11/40 studies, 27.5%), both F_1-scores (53.5%-98.9%) and accuracy (52.1%-98.7%) varied widely [19,28,29,38,50-52,55,62,63,79]. Adults under 60 years (20/40 studies, 50%) exhibited consistently high performance (F_1-score mean 85.8%, accuracy mean 91.7%) [31,33,34,53,55-59,61,65-68,70,71,73-76], while older adults (60 years or older) in 15% of studies (6 out of 40 studies) showed relatively reduced score (F_1-score mean 72.3%, accuracy mean 89.9%) [54,64,69,72,77,78]. Clinical populations (2/40 studies, 5%), on the other hand, achieved near-perfect scores (F_1-score 97.6%-100%, accuracy 87.9%-100%), though limited studies (n=2, one in mild cystic fibrosis, and one in type 1 diabetes) necessitate cautious interpretation [37,80].

Figure 7. F1-scores for moderate-to-vigorous physical activity detection across age groups and sensor placements. Brackets ("[]") represent the reference numbers; asterisks ("*") indicate lab-validated results [19,28,29,33,34,36,37,51-54,56-59,61,62,64,65,67,68,70-80]. CF: cystic fibrosis; T1D: type 1 diabetes.



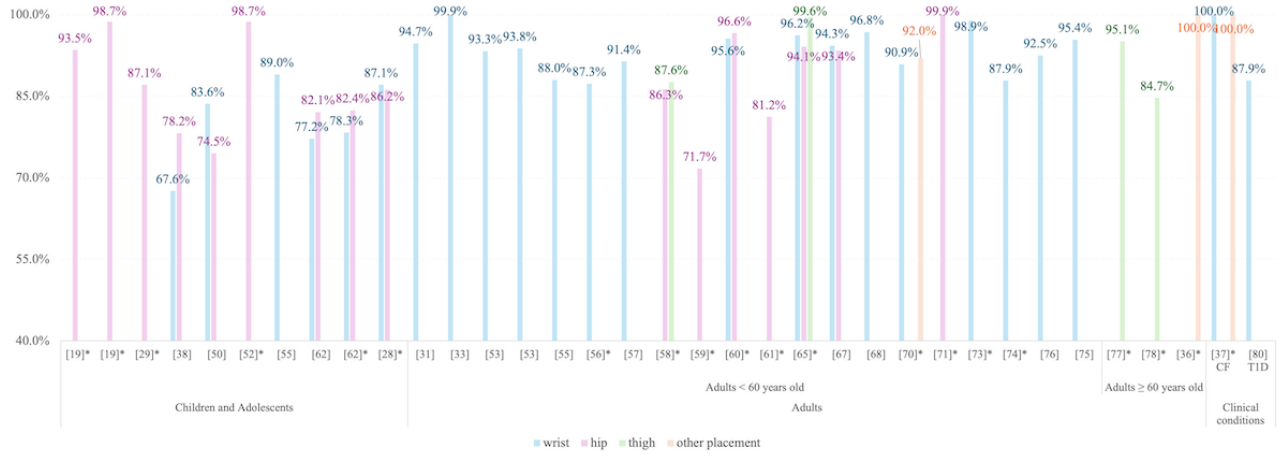


Figure 8. Accuracy metrics for moderate-to-vigorous physical activity detection across age groups and sensor placements. Brackets ("[]") represent the reference numbers; asterisks ("*") indicate lab-validated results [19,28,29,31,33,36-38,50,52,53,55-62,65,67,68,70,71,73-78,80]. CF: cystic fibrosis; T1D: type 1 diabetes.

Reproducibility and Transparency Gaps

Notwithstanding the performance advancement reported, 57.5% of the studies (23/40 studies) failed to disclose code or datasets, and 60% (3/5 studies) of DL studies lacked hyperparameter specifications (eg, learning rates, batch sizes) [34,68,79]. This "black box" methodological opacity mirrors the reproducibility crisis in traditional cut point research, where proprietary algorithms replace opaque thresholds, compromising interpretability. Only 20.0% of studies (8/40) adhered to open science practices by publicly sharing the code of models [38,51,52,58,67,68,72,76], with one study providing only sample code availability [67].

The absence of standardized reporting frameworks exacerbates methodological inconsistencies. For example, window lengths for signal segmentation ranged from 1s to 60s, complicating cross-study comparisons (details shown in Table 1). While 5 studies evaluated multiple window lengths [19,29,33,51,56], optimal performance diverged across populations: 15s or 16s were preferred for adults [33,56] and preschoolers [51], whereas 60s windows were superior to 10s and 30s among preschoolers [29]. Notably, Trost et al [19] found no difference between 10s and 60s among children (mean 11, SD 2.7 years). Similarly, MET thresholds for MVPA classification varied, such as 2.8 METs [38], 3 METs [34,37,59,60,65-67,70,71,74,76,77,79], and 3.9 METs [19,29]. This variability introduces heterogeneity

XSL•FO
RenderX

in intensity categorization, undermining cross-study generalizability.

On the positive side, the proliferation of public datasets (accounting to 25%, 10/40 studies), including Capture-24 [31,33,53,57,75,76], Energy-24 [57], UOULU (University of Oulu) [60], OSU (Oregon State University) [60], the PAMAP2 Physical Activity Monitoring dataset (University of California, Irvine, UCI) [60], and the Daily and Sports Activities (the UCI Machine Learning Repository) [60] has partially mitigated by enabling benchmarking and reducing data dependency.

Discussion

Principal Findings

This systematic scoping review synthesizes advancements in ML and DL techniques for estimating and predicting MVPA from accelerometer data. Traditional ML models (eg, RF, ANN) demonstrated robust lab-based accuracy (F_1-score mean 83.6%-100%) while real-world performance declined by 8.0%-13.3% due to environmental noise and device heterogeneity. DL architectures (eg, CNN, Transformer) achieved superior performance by leveraging raw signal dynamics (F_1-score mean 73.6%-98.4%) in free-living settings, especially with hybrid models (CNN-BILSTM, ViT-LSTM). Wrist-worn devices were most often tested (30/40, 75.0% of studies) and performed comparably to hip/thigh placements in a lab setting (F_1-score mean 84.0%-84.3%, accuracy mean 86.0%-91.8%). Multiaccelerometer configurations (eg, hip + wrist) achieved the best performance (accuracy mean 88.4%) but face practical limitations. Algorithmic bias was seen to disfavor older adult participants, but not clinical populations. However, only a few studies have tested patients, limited to cystic fibrosis and type 1 diabetes.

Methodological Advancements and Challenges

From Feature Engineering to End-to-End Learning

The evolution of MVPA detection methodologies reveals a clear paradigm shift from manual feature engineering to automated DL. Historically, ML models relied on handcrafted features (eg, spectral entropy, variance) derived from time-and frequency-domain analyses. In contrast, DL architectures, such as CNN and Transformers, automate hierarchical feature extraction from raw accelerometer signals, capturing biomechanical nuances (eg, stride variability during running) through convolutional filters and attention mechanisms [33,68]. For instance, hybrid models like CNN-BiLSTM synergized spatial and temporal learning, achieving state-of-the-art accuracy (F_1-score 98.4%-99.6%, accuracy 97.7%-99.0%) in free-living settings [33]. The effectiveness of this architecture is further corroborated by its successful application in related biomechanical modeling tasks, such as predicting ligament fatigue failure risk from complex signal data, highlighting its robust capability to capture critical spatiotemporal patterns [85]. Nevertheless, DL's computational intensity and reliance on high-resolution data (≥100Hz) limited deployment on resource-constrained wearables [33]. Furthermore, while DL reduced manual feature engineering burden, nearly 60.0% of models remained inaccessible due to unshared code, perpetuating reproducibility challenges (section "Reproducibility and Transparency Gaps").

Three key advancements define this evolution: (1) Static to dynamic features, unlike the fixed features of traditional ML, DL architectures dynamically extract nuanced biomechanical patterns from raw signals (section "Traditional Machine Learning" and "Deep Learning") [31,33,34,68,79]. (2) Early studies treated classification and estimation as separate tasks, but modern frameworks like AccNet24 unify these through shared neural pathways, improving efficiency (section "Task-Specific Insights") [33]. (3) Self-supervised learning, pretraining on unlabeled data, reduced annotation costs while maintaining high performance, addressing scarcity of free-living settings (section "Methodological Evolution and Comparative Insights") [33,68].

Lab-to-Real-World Performance Comparison

Although lab-validated models achieved high performance (eg, 87.9%-100% accuracy across ML techniques, section "Evolution of Feature Engineering and Model Architectures"), free-living performance experienced unstructured movement patterns and environment noise. For example, RF accuracy dropped from 90.1% (lab) to 83.5% (free-living), while wrist-based models exhibited superior adaptability to upper-body movements (eg, arm swings) in unstructured settings (section "Sensor Placement"). Notably, only 42.2% of studies validated models in real-world environments (most after 2020), highlighting a critical translational gap.

Two key insights emerge from a lab-to-real-world comparison. (1) There is a 3.1%-16.2% accuracy decline when using ML techniques (section "Evolution of Feature Engineering and Model Architectures"). Context-aware architecture, DL architectures, such as transformers, partially mitigated performance declines by leveraging context-aware attention to movement sequences (eg, detecting walking interruptions), achieving accuracy of 95.0% in free-living scenarios [33]. (2) There is an algorithmic bias across age groups that hinders real-world deployment (section "Algorithmic Bias").

Validation and Reproducibility

A key challenge lies in inconsistent validation protocols. While IC provided precise MET-based thresholds, its lab-bound nature limited ecological validity [58]. Conversely, DO offered real-world applicability but introduced subjectivity in intensity classification [86,87]. Moreover, disparities in metrics reporting (eg, exclusion of transitional activities) [19,37,65,70] and variable parameters (eg, MET threshold: 2.8-3.9, window lengths 1-60s) hindered cross-study comparability (section "Reproducibility and Transparency Gaps"). Compounding these issues, 42.5% of studies adhered to open science practices, perpetuating a "new cut-point conundrum" akin to proprietary regression thresholds.

Our synthesis reveals a vicious cycle underpinning the translational challenges in AI-driven MVPA monitoring. The foundational issue is the lack of standardized validation protocols. Inconsistent MET thresholds and variable data window lengths mean that models are trained and evaluated on

XSL•FO
RenderX

fundamentally different definitions of MVPA. This directly contributes to the lab-to-real-world performance gap, as a model calibrated with one protocol fails to generalize to data collected under another. Furthermore, this inconsistency, when combined with the prevalent lack of code sharing, makes it impossible to audit, replicate, or fairly compare models. Consequently, this opacity hinders the identification and correction of algorithmic bias against underrepresented populations, as the root cause of poor performance, a flawed model versus an incompatible validation method, cannot be discerned. Thus, these challenges are not isolated but are synergistic barriers that collectively impede the development of truly generalizable and equitable models.

Sensor Performance and Device Bias

Device placement and type emerged as critical determinants of model performance, as evidenced in the section "Sensor Performance." For instance, while ActiGraph-trained models achieved high lab accuracy (F_1-score 79.9%, accuracy 90.5%), they underperformed on consumer wearables (eg, Samsung smartwatch, F_1-score mean difference 3.2%) due to differences in sensor calibration and sampling rates (Table 1 and Figure 5) [56]. Additionally, interdevice variability across brands (eg, Axivity vs GENEActiv) exacerbated performance inconsistencies, particularly in free-living settings. Notably, optimal sensor placement (eg, wrist vs hip) influenced adaptability to movement patterns, with wrist-worn devices showing superior capture of upper-body dynamics (eg, arm swings) but struggling with lower-body activities [40,88]. These findings highlight the need for device-agnostic training pipelines to mitigate performance variability across brands and placements.

Translational Opportunities and Challenges

Public Health and Clinical Integration

Wrist-worn devices demonstrated comparable accuracy to hip/thigh placements in lab settings (F_1-score 84.0%-84.3%, accuracy 86.0%-91.8%) and superior adaptability to free-living upper-body movements (Figure 4), supporting their feasibility for scalable monitoring. However, ActiGraph's dominance (n=30, 75.0% of studies) and limited validation on consumer wearables (eg, smartwatches) hinder real-world applicability. Clinically, models achieved high accuracy in controlled settings for cystic fibrosis and type 1 diabetes, but small sample sizes and structured protocols limit ecological validity [37,80]. Expanding validation studies to more diverse clinical populations (eg, mobility impairments) is critical.

Age and Population Disparities

Results revealed systemic biases across the age range (section "Algorithmic Bias"). For instance, models trained on adults misclassified MVPA in children (F_1-score mean difference: –5.7%) due to developmental differences in stride length and metabolic variability [19]. Studies involving preschoolers reported accuracy fluctuations between 53.7% and 88.4%, reflecting challenges in modeling erratic movement patterns typical of young children [28,29,38,50,52,63,79]. Conversely, older adults (60 years or older) exhibited reduced accuracy (F_1-score mean 77.9%) due to slower gait speeds, postural instability, and comorbidities that alter movement signatures [54,64,69,72,77,78]. Wrist-based model, for example, underestimated MVPA in this cohort by 6.0%-16.6% compared with thigh-worn sensors, highlighting the need for age-specific calibration [78].

Emerging Innovations

Hybrid DL models have emerged as a powerful approach. For instance, integrating LSTM with CNN (CNN-LSTM) or ViTs (vision transformer bidirectional long short-term memory) enables the capture of spatial-temporal patterns in accelerometry data [33,34]. Building on this, BiLSTM layers further enhance temporal dependency modeling by analyzing sequences in both forward and backward directions [31].

In parallel, image-based feature extraction methods, such as converting raw accelerometer signals into Gramian angular field images, have improved feature learning by transforming time-series data into visual representations [33]. Additionally, multisensor fusion strategies—combining data from hip, wrist, and thigh placements—address variability in sensor positioning, boosting model robustness [28,34]. Furthermore, transfer learning leverages pretrained architectures like ResNet101, adapting them for accelerometer classification tasks [31].

Another key innovation lies in advanced feature engineering. Autonomous feature extraction via CNN reduces reliance on handcrafted features [68], while time-frequency domain fusion (eg, spectral power) enhances activity discrimination [52]. Notably, real-time and edge computing advancements explore lightweight models through pruning and quantization, enabling deployment on wearable devices [33].

However, significant challenges remain. First, models trained in controlled lab settings often generalize poorly to free-living environments due to uncontrolled variability [52]. Moreover, short and heterogeneous activity bouts, common in populations like preschoolers, result in mixed-activity windows that complicate classification [29]. Another critical challenge is sensor placement variability, as signal patterns differ across body positions [37]. Compounding this, class imbalance from overrepresented sedentary/light activities skews model performance [75]. Additionally, computational complexity limits real-time use, as seen in resource-heavy models like AccNet24 [31]. Finally, distinguishing biomechanically similar activities (eg, climbing vs walking) remains problematic [29].

Future Directions

To address existing gaps, 4 interconnected priorities emerge. First, resolving inconsistencies in ground truth methods, such as variable MET thresholds (2.8-3.9 METs) and window lengths (1-60s), is critical. This requires standardized validation frameworks, including consensus guidelines and open datasets (eg, Capture-24), to harmonize protocols and reduce discrepancies in intensity classification [64].

Second, prioritizing free-living validation is essential to bridge the lab-to-real-world performance gap. For instance, RF models exhibit accuracy declines from 90.1% in lab settings to 83.5% in free-living environments. Concurrently, diversifying training

XSL•FO
RenderX

data to include underrepresented groups, such as the older adult, pediatric, and clinical populations, will improve generalizability and mitigate age-related biases [62,72].

Third, advancing algorithmic fairness through regulatory frameworks and bias audits is imperative. This includes expanding datasets to encompass more and diverse clinical cohorts while addressing disparities in model performance across the age range. Additionally, mandating open science practices, such as code/data sharing and hyperparameter transparency, will enhance reproducibility and resolve the "new cut-point conundrum" plaguing activity intensity thresholds.

Finally, optimizing DL architectures, such as quantized models or hybrid CNN-BiLSTM frameworks, for low-power wearables will enable real-world deployment while maintaining computational efficiency [31,33].

Looking ahead, these priorities align with broader calls for standardization and interpretability. For example, improving the "black-box" nature of DL models [68] and harmonizing evaluation metrics will foster clinical trust. Moreover, lightweight, edge-compatible architectures and multimodal data integration represent promising pathways to overcome current limitations in real-world MVPA monitoring.

Limitations and Methodological Considerations

The strengths of this review include the rigorous adherence to PRISMA-ScR guidelines, a comprehensive search strategy across 3 electronic databases (PubMed, IEEE Xplore, Web of Science, and others via manual citation tracking), and systematic screening of 1938 records. The methodology prioritized transparency through dual-reviewer full-text screening to resolve discrepancies and consultation to ensure methodological rigor. By focusing on peer-reviewed studies, we aimed to synthesize evidence grounded in empirical validation, thereby minimizing inclusion of speculative or opinion-based articles.

However, several limitations warrant consideration. First, the exclusion of gray literature (eg, unpublished trials, industry reports, or conference proceedings) may have omitted insights from ongoing or unsuccessful implementation efforts, particularly those led by technology developers or health care providers. This introduces potential publication bias, as negative results or pragmatic challenges in real-world deployment are often underrepresented in peer-reviewed journals. Second, our decision to exclude non–peer-reviewed studies and prioritize articles reporting empirical implementation in clinical or free-living settings risks overlooking formative research, such as feasibility studies or pilot trials, which could offer valuable lessons for scalable AI integration.

A further limitation arises from our emphasis on the highest reported performance metrics (eg, F_1-scores, accuracy) across studies. While this approach highlights peak algorithmic capabilities, it may overestimate real-world applicability, as optimal configurations (eg, 15-second windows for adults, multisensor placements) often lack generalizability to diverse populations or unstructured environments. For instance, models achieving 99.0% accuracy in lab settings may exhibit significant performance degradation in free-living contexts due to uncontrolled variables like device heterogeneity or nonexercise movements.

Methodologically, while the Arksey and O'Malley framework does not mandate quality appraisal, the inclusion of studies with heterogeneous validation protocols (eg, variable MET thresholds, ground-truth methodologies) complicates cross-study comparisons. Future reviews could strengthen synthesis by incorporating quality assessment tools to evaluate bias risk and methodological consistency. Last, the predominance of studies using young, healthy cohorts limits insights into algorithmic fairness and generalizability for older adult or clinical populations, underscoring the need for more inclusive training datasets.

These considerations do not diminish the review's contributions but highlight critical gaps, such as reproducibility challenges and translational biases, that must be addressed to advance equitable, real-world deployment of AI-driven MVPA monitoring tools.

Conclusions

This systematic scoping review highlights that ML and DL have significantly advanced in the detection of MVPA by using accelerometer data, yet persistent gaps in generalizability and transparency hinder real-world impact. To bridge the lab-to-real-world divide, collaborative efforts across public health and computer science must prioritize reproducibility, inclusive design, and robust validation. By addressing these challenges, AI-driven tools can fulfill their potential as scalable, equitable solutions for advancing global physical activity research and intervention.

Acknowledgments

During the preparation of this work, the authors used DeepSeek to improve the readability and language of the manuscript. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the published article.

Abstract

Background: Social isolation and loneliness have considerable health implications. Research indicates that older men are generally more susceptible to social isolation compared with women, highlighting the need to integrate gender-responsive approaches in the development and implementation of interventions for mitigating social isolation and loneliness in later life.

Objective: This study aimed to conduct a review of intervention programs targeting social isolation and loneliness, focusing on gender-specific considerations. Specifically, it aims to examine the gender composition (male-to-female ratio) of participants in intervention programs and identify and analyze intervention strategies that demonstrate gender-sensitive effectiveness.

Methods: A scoping review was conducted as per the Joanna Briggs Institute manual for evidence synthesis. A comprehensive literature search, including hand searching, was conducted across 6 English-language databases, PubMed, MEDLINE, Cochrane, CINAHL, ScienceDirect, and Web of Science, for papers and reports published in 2013-2023. The authors, country, subjects, research design, intervention method, results, and mentions of gender for each included document were presented.

Results: The study identified 1282 papers and reports, of which 10 were selected for analysis. Only 1 study reported a higher number of male participants compared with female ones; in contrast, all other studies included predominantly female samples. The studies assessed outcomes based on 2 indicators of social isolation, 4 indicators of loneliness, and 29 other indicators. Exercise and workshops proved effective for social isolation and loneliness, while meditation and laughter therapy were effective for loneliness. The intervention with the highest percentage of male participants (264/323, 82%) was a customized meditation program. Conversely, physical activities, social support, and community-based group health classes drew more female participants. In total, 8 studies did not mention gender in the discussion section, and none considered gender-specific issues in formulating research objectives and outcomes.

Conclusions: Research on social isolation and loneliness has generally ignored the influence of gender. The review also indicated a gender bias in participant selection, with women markedly overrepresented in study samples. The study found that women tend to prefer interventions emphasizing conversations, shared experiences, and emotional exchange. In contrast, men showed the highest participation in a meditation program focused on self-dialogue, which required minimal interaction. Importantly, interventions aimed at promoting social interaction or participation are unlikely to succeed without consideration of gender-specific issues. Therefore, systematically identifying conditions necessary for effective interventions that target older men is crucial for guiding future research and program development.

Introduction

Background

Social isolation is defined as "the objective lack or paucity of social contacts and interactions with family members, friends, or the wider community" [1]. Factors associated with social isolation include advanced age, male gender, presence of depressive symptoms, and low socioeconomic status [2]. The concept of social isolation is closely related to loneliness. According to Valtorta and Hanratty [1], loneliness is "a subjective negative feeling associated with a perceived lack of a wider social network (social loneliness) or the absence of a specific desired companion (emotional loneliness)." Scholars have defined social isolation as a lack of interaction with others and distinguished loneliness from subjective loneliness [3]. Although social isolation and loneliness are considered closely related, their definitions differ. Some studies have found only a weak correlation [4,5]; socially isolated individuals are not necessarily lonely, and vice versa. Despite these distinct definitions and realities, social isolation and loneliness are often studied together as overlapping concepts. Newall [6] also proposed that they should be examined in conjunction.

A growing body of evidence indicates that gender is a crucial factor influencing older adults' experiences of social isolation and loneliness. For example, older men (ie, those aged 65 years and older) in Japan are more likely to experience social isolation compared with their female counterparts [7,8]. In a cross-sectional study, Nomura and Kobayashi [9] discovered that gender can influence the isolation-prevention strategies used by community-dwelling older people in Japan. The authors found that satisfaction with social activities (ie, the degree of satisfaction with activities involving participation in groups and organizations and interpersonal activities with others) and strategies for interactions helped older Japanese women maintain relationships with others. However, for older Japanese men, only satisfaction with social activities contributed to maintaining social relationships. Some studies also identify the need to focus intervention efforts on men [10]. Men are more likely to feel lonely compared with women for one reason: when confronted with challenges or distressing situations, women tend to respond emotionally and engage in conversation with others, whereas men tend to avoid stressors and neglect talking to others about them [11]. These findings underscore the importance of considering gender in the development of interventions targeting social isolation. Nevertheless, few intervention programs have appropriately accounted for gender. Furthermore, a comprehensive overview of findings on the salience of gender in social isolation research is lacking. Moreover, the treatment of gender in research on social isolation is inconsistent, given that researchers adopt different approaches to this issue.

Barreto et al [12] argued that research on loneliness has failed to address gender beyond the binary categories of male and female, thereby obscuring important influences. Other meta-analyses have also indicated a correlation between loneliness and gender. For example, Pollak et al [13] identified gender as a predictor and risk factor for loneliness and functional decline, while Haihambo et al [14] suggested that gender differences exist in both loneliness and social adaptability. However, these studies represent only one dimension of the analysis and fail to specifically focus on gender. Although gender is a critical determinant in understanding social isolation and loneliness, the prevalence of gender-focused interventions remains underexplored.

Several studies have examined intervention programs designed to address social isolation and loneliness. For example, Milligan [15] conducted a scoping review of Men's Sheds and gender interventions to assess their impact on the health and well-being of older men. Men's Sheds are community-based, mutual self-help groups established primarily in Australia and the United Kingdom, among other countries. These initiatives were intended to alleviate social isolation and loneliness among retired men by fostering purpose, companionship, and shared activities [16]. The review identified limited evidence supporting the impact of Men's Sheds and other gender-focused social activities on the mental health and well-being of older men. However, this paper was published in March 2015; therefore, it does not cover research published after 2014. Fakoya et al [17] conducted a scoping review of studies on loneliness and social isolation interventions targeting older adults to identify effective interventions. The sample comprised 33 papers published until 2018. Findings indicated that the individual nature of experiences of social isolation and loneliness may impede the development and implementation of standardized interventions. The study concluded that no universal approach exists for addressing social isolation and loneliness, and interventions must be tailored to specific individuals and groups, as well as the severity of loneliness. Although existing studies encompass diverse interventions, a key limitation is that none explicitly considered gender as an influencing variable. Although a few studies address the potential impact of gender on interventions targeting the alleviation of social isolation and loneliness, the actual prevalence of such gender-focused interventions remains unclear.

Objective

This study aims to comprehensively map intervention programs targeting social isolation and loneliness among older adults, with a particular emphasis on the integration of gender considerations in these programs. Specifically, it intends to (1) identify the male-to-female ratio of participants across studies and (2) determine effective intervention strategies that are responsive to gender differences. The results are expected to

XSL•FO
RenderX

facilitate the development and implementation of new gender-focused intervention programs.

Methods

Research Design

A scoping review was conducted in accordance with the Joanna Briggs Institute (JBI) manual for evidence synthesis (hereafter, JBI framework) [18]. The JBI framework defines the purpose of a scoping review as identifying and analyzing knowledge gaps and examining how research is conducted within a given field [18]. The decision to conduct a scoping review was aimed at mapping the existing evidence and identifying areas that require further exploration rather than synthesizing findings, as customary in a systematic review. The review protocol was registered with the Center for Open Science Framework. No deviations were observed between the registered protocol and the content presented in this study. The inclusion criteria were based on the following definitions of participants, concept, context, and types of sources of evidence.

Participants

The participants were older men and women residing in a community, regardless of whether they reported being socially isolated. The review also focused on older adults but did not strictly define the participants' ages. Thus, age was excluded as an eligibility criterion given the diverse definitions of "elderly" across countries and studies.

Concept

This study focused on the implementation of strategies for addressing social isolation and loneliness. However, studies examining the correlation of social isolation and loneliness with curfew restrictions during the COVID-19 pandemic were excluded. This study focused on cases of social isolation and loneliness in which underlying causes remained unclear and included gender as a variable. The present-day concept of gender is multifaceted; nevertheless, it is often reduced to a binary model that assigns specific biological and behavioral traits to men and women.

Context

Social isolation and loneliness are influenced by various social factors, including geographic location, religious affiliation, and racial identity. This study does not impose any specific limitations regarding such factors; instead, it encompasses diverse community-based interventions.

Types of Sources

This review covered various intervention studies, such as randomized controlled trials, nonrandomized controlled trials, and before-and-after studies. Quantifying the effectiveness of interventions targeting social isolation and loneliness is challenging. Therefore, the review also included websites, reports, and research papers while excluding observational studies, qualitative studies, reviews, and conference abstracts. The rationale for incorporating websites was twofold. First, a significant number of interventions that target social isolation and loneliness have not been disseminated through academic journals. Second, existing research on social isolation and loneliness has predominantly focused on academic publications, with nonacademic sources receiving minimal representation.

Literature Search Strategy

The literature search strategy in this study was developed in consultation with a librarian at Mejiro University. A search was conducted on 6 databases (PubMed, MEDLINE, Cochrane, CINAHL, ScienceDirect, and Web of Science) on May 30, 2023, to identify relevant papers published within an 11-year period (2013-2023). The following terms were searched in combination: intervention, social isolation, loneliness, elderly, older adults, older people, older peoples, sex characteristics, sex, gender, and difference (Textbox 1). In addition to database searches, hand searches were conducted on the websites of 3 journals that frequently publish research on social isolation and loneliness: *Health and Social Care in the Community*, *Journal of Aging and Health*, and *Ageing & Society*. Furthermore, a hand search for gray literature was conducted on 2 websites, the Social Care Institute for Excellence and Connect2Affect, for the terms "social isolation" or "loneliness," with the publication period limited to 2013-2023 (Multimedia Appendix 1).

Textbox 1. Search strategy.

"(intervention)

and (((((social isolation)or(loneliness))

and (((aged)or(elderly))or((""older people"")or(""older peoples""))))

and((sex characteristics)or(((sex)or(gender))and(difference)))))"

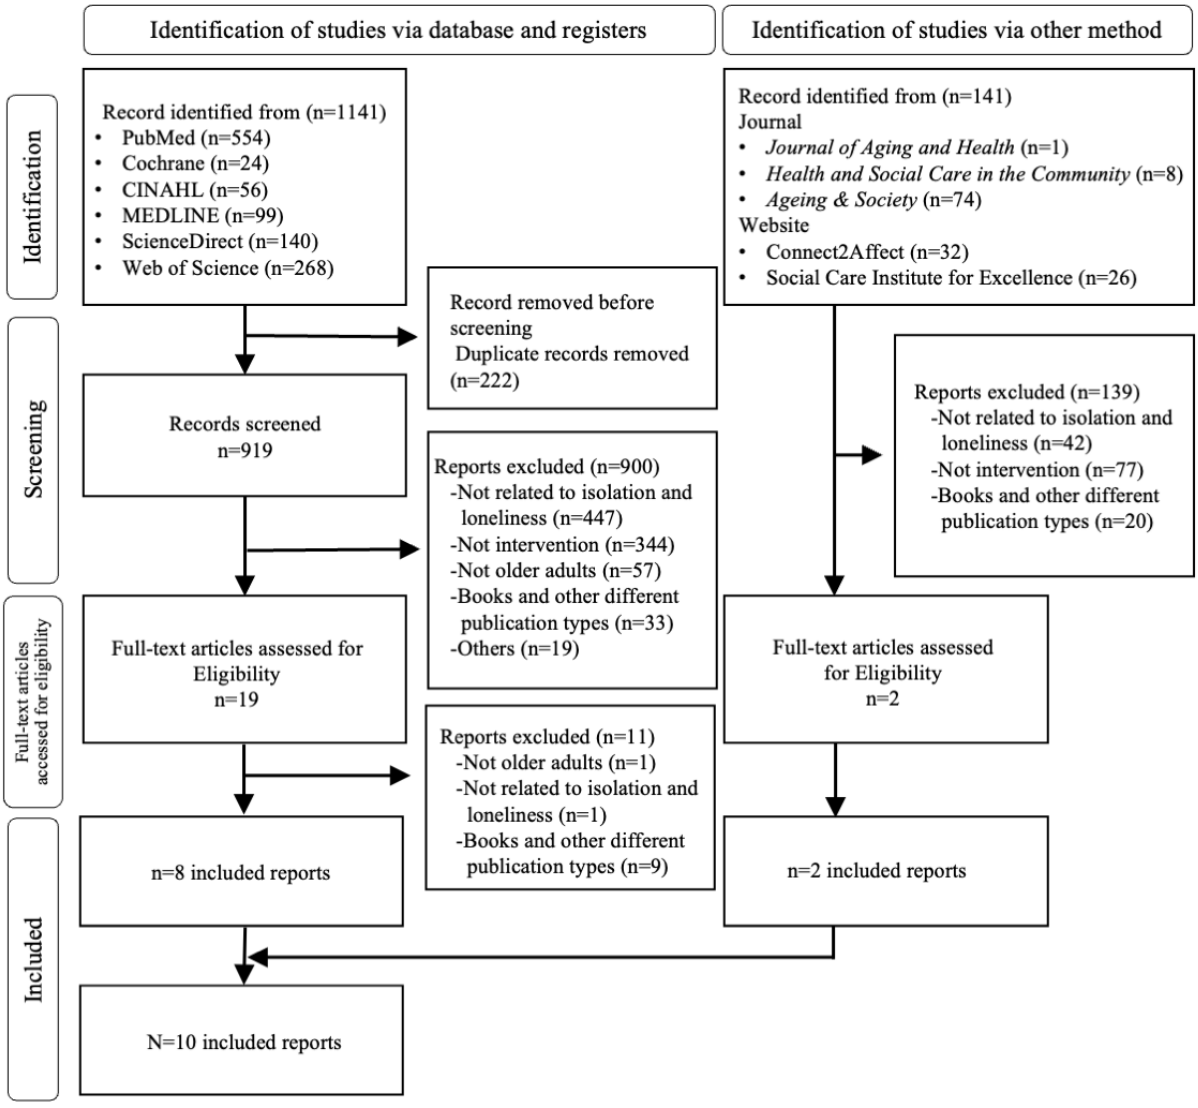
Literature Selection

Data extraction was performed by KN. All identified academic studies and relevant texts were uploaded to Rayyan [19]. Duplicate papers were omitted, followed by a screening. KN and EI conducted the initial and full-text screening of the literature, while NK was consulted in cases of disagreement. The sample included English-language papers featuring intervention programs for social isolation and loneliness. The following texts were excluded: conference abstracts; studies without mention of social isolation or loneliness in their objectives, methods, results, or discussion; and studies that focused on COVID-19 countermeasures.

Data Analysis

The selected studies were presented in the form of a table that included the following information for each study: author, country of origin, participants, intervention method, outcome, and gender. An additional table was constructed to illustrate the male-to-female participant ratio per study and to classify the

XSL•FO
RenderX



type of intervention (remote or in-person, group-based or individual, or a combination of these formats). Furthermore, the measures and outcome indicators used to evaluate the interventions were presented in tabular form. To enhance clarity and comparability, the primary outcome concepts were systematically categorized and organized according to their thematic relevance.

Results

Characteristics of the Selected Studies

The literature selection process was visualized as a flowchart in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist (Figure 1; Multimedia Appendix 2) [20]. The database search yielded 1141 studies, of which 222 were duplicates and were therefore excluded. The screening process yielded 19 studies, 8 [21-28] of which were included in the analysis. Of the 900 studies that were excluded during the screening process, 447 were unrelated to social isolation and loneliness, while 344 were not intervention studies. The hand search yielded 141 studies, of which 2 were included (Table 1). A total of 10 studies [21-30] were included in the final analysis. These studies described detailed interventions conducted in the United States (n=3 [23,27,28]), the United Kingdom (n=2 [29,30]), Singapore (n=1 [26]), Turkey (n=1 [25]), Spain (n=1 [21]), Ireland (n=1 [23]), and India (n=1 [22]; Table 1).

Table 1. Summary of included studies.

First author, date, and country	Participants (final analyzed individuals)	Intervention description	Result	Gender references
Ngiam et al, 2022 [26], Singapore	Older adults who resided in the southeast region of Singapore, aged >55 years, belonging to a lower socioeconomic status. 138 were included for analysis (59 male and 79 female).	Project Wire Up was a volunteer-led, one-on-one, goal-directed, and home-based digital literacy program: (1) equipped with smartphones and internet connection; (2) trained by volunteers for 6 sessions (1 to 2 hours per session) over 3 months that were held in the older adults' homes; and (3) digitally connected to existing social networks.	There were significant improvements in digital literacy scores in the intervention group as compared to controls (mean difference 2.28, 95% CI 1.37-3.20; *P*<.001). There was no statistically significant difference in the University of California, Los Angeles 3-item loneliness scale, Lubben Social Network Scale-6, Personal Wellbeing Score, or EQ-5D Utility and visual analog scale score.	No mention
Santos-Olmo et al, 2022 [21], Spain	The sample (N=68: 18 male, 50 female) was 65 years of age or older; lived alone or lived with other people older than 65 years; had uncovered social and/or health needs; have little or no social support network; refused the assistance offered to cover their needs from the normalized social and/or health services.	The Psychological Support Service for Socially Isolated Elderly People (PSIE) facilitates contact between the elderly person and social and health services (both primary and specialized care) in their area, so that they can receive the care they need on each occasion.	Concerning the total score of the Health and Psychosocial Functioning (Total HoNOS65+, *t*=10.12, *P*<.001, Cohen *d*=1.49) and the Spanish adaptation of the Camberwell Needs Assessment Questionnaire for the Elderly (CANE; average number of unmet needs, *t*=19.99, *P*<.001, Cohen *d*=2.31), significant differences were also observed between pre- and posttreatment. Statistically significant changes were obtained in Global Assessment of Functioning (GAF; *t*=4.06, *P*<.001, Cohen *d*= 0.6) and the Spanish adaptation of the WHO Disability Assessment Short Scale (WHO-DAS-S; A. personal care and survival, *t*=8.82, *P*<.001, Cohen *d*=1.3).	The gender variable does not seem to have an influence on any of the outcome measures studied, except for alcohol use. PSIE has achieved positive results in both men and women, without gender appearing to be a relevant variable in these results.
Dodge et al, 2022 [27], United States	Participants with normal cognition or mild cognitive impairment were recruited from Portland, OR, and Detroit, MI. Key inclusion criteria included (1) age 75 years or older, (2) socially isolated. One hundred eighty-six participants (86 with normal cognition and 100 (52.8%) with mild cognitive impairment) were randomized into the experimental (n=94) or the control group (n=92).	The intervention group had video chats with trained study staff for 30 minutes per day, 4 times per week for 6 months (high dose), and then twice per week for an additional 6 months (maintenance dose). Both intervention and control groups received a phone call once per week (approximately 10 minutes duration) to assess changes in health and social activities.	After the induction period, the experimental group had higher global cognitive test scores (Montreal Cognitive Assessment [primary outcome]; 1.75 points [*P*=.03]). After induction, participants in the experimental group with normal cognition had higher language-based executive function (semantic fluency test [secondary outcome]; 2.56 points [*P*=.03]). At the end of the maintenance period, participants in the experimental group with mild cognitive impairment had higher encoding function (Craft Story immediate recall test [secondary outcome]; 2.19 points [*P*=.04]).	No mention
Pandya et al, 2021 [22], India	Intervention group older adults (IN_2=166, 136 males, 30 females), the control group (CN_2=157, 128 males, 29 females), who underwent no intervention	The key features of the meditation program were (1) postures interspersed with relaxation, (2) slowness in movements, and (3) inner watchful awareness.	There were significant mean differences in the posttest scores on loneliness, well-being, life satisfaction, and contentment outcomes of the intervention group, with high observed effect sizes (Cohen *d* range=2.43-8.78; *P*≤.01). The intervention group older adults reported that they were less lonely and experienced greater well-being, life satisfaction, and contentment posttest (ηp^2 =0.71-0.78; *P*≤.01).	Men, middle class, married, and cohabitating participants, who also comprised a majority of the sample, were less lonely at the pretest phase as compared to women, upper class, single, and living alone. Gender was an important factor, and results showed that retired South Asian men were less lonely and more satisfied pretest as well as posttest.

Mays et al, 2021 [23], United States	Participants (n=382, 63 male, 315 female) were offered enrollment based on the following inclusion criteria: aged 50 years or older, community-dwelling, able to complete questionnaires, able to consent to participate in the study, and able to communicate in English.	Participants met with the program coordinator and selected from 1 of the 4 evidence-based programs: Tai Chi for Arthritis, Enhance Fitness, the Arthritis Foundation Exercise Program, and the Healthier Living Workshop. Group health class lasted 6 to 8 weeks.	Older adults who met with a health coach and participated in a single session of community health programs reported decreased loneliness (ER[a] 0.931, 95% CI 0.895-0.968; *P*<.001) and social isolation (ER 1.033, 95% CI 1.016-1.050; *P*<.001) at 6 months post participation, compared to their baseline scores.	No mention
Zamir et al, 2020 [29], United Kingdom	Twenty-two residents aged ≥65 years (5 male, 17 female) across 3 British care homes	Twenty-two residents engaged with each other using "Skype quiz" sessions with the support of staff once a month over an 8-month trial. Residents met other residents from the 3 care homes to build new friendships and participate in a 30-minute quiz session facilitated by 8 staff members.	Analysis of the field notes revealed 5 themes of: residents with dementia remember faces, not technology, inter- and intraconnectedness, regaining sense of self and purpose, situational loneliness overcome, and organizational issues create barriers to long-term implementation.	No mention
Lawlor et al, 2019 [24], Ireland	Participants (n=40) from older (aged≥50 years) women's groups from 4 different community centers	Intervention consisted of 3 face-to-face group education sessions, encouragement to enlist the support of a buddy (eg, spouse, partner, friend, or a group member), an information pack, and the option of weekly telephone contact. Each education session lasted approximately 20 minutes.	87% (40/46) of women consented to participate, and 78% (31/40) attended all education sessions. Few participants provided valid accelerometer data, but 63% (25/40) completed the HADS[b] questionnaire at all time points. 85% of participants (34/40) were somewhat or very satisfied with their involvement in the study.	No mention
Alıcı et al, 2018 [25], Turkey	The study participants were older adults living in 2 nursing homes set up by foundations located in the capital of Turkey. Their ages were more than 65 years. A total of 50 older adults formed the intervention group (n=20; 9 males, 11 females) and control group (n=30; 14 males, 16 females).	Laughter therapy was conducted by the principal investigator 2 days a week, with one application during each session. The program involved performing yoga, breathing, and physical exercises, as well as laughter therapy. The program continued for 5 weeks for a total of 10 applications. The control group received no intervention.	A statistically significant difference (*P*<.001) between mean De Jong Gierveld Scale scores of the intervention (mean 7.15, SD 1.755) and control groups (mean 15.63, SD 5.027) was observed after the intervention. Median De Jong Gierveld Scale scores were significantly lower in the intervention group than in the control group. After therapy, the social loneliness score was significantly lower in the intervention group (mean 3.10, SD 1.553; *P*<.001) than in the control group (mean 6.90, SD 3.100). Post therapy, the emotional loneliness score was significantly lower (*P*<.001) in the intervention group (mean 4.05, SD 1.538) than in the control group (mean 8.73, SD 2.599).	No mention
Dodge et al, 2015 [28], United States	Eighty-three individuals participated (41 in the intervention group and 42 in the control group). Participants aged 70 years or older were included.	Daily 30-minute face-to-face communications were conducted during a 6-week trial period in the intervention group. The control group received only a weekly telephone interview.	Among the cognitively intact participants, the intervention group improved more than the control group on a semantic fluency test (*P*=.003) at the posttrial assessment and a phonemic fluency test (*P*=.004) at the 18-week assessments. Among those with mild cognitive impairment, a trend (*P*=.04) toward improved psychomotor speed was observed in the intervention group. No difference was found between intervention and control groups in the pre- to posttrial changes in the loneliness score, the secondary outcome.	No mention

Hind et al, 2014 [30], United Kingdom	The eligibility criteria included being aged ≥ 75 years, living independently, and having reasonable cognition. Fifty-six participants (control n=30, intervention n=26) were included in the intention-to-treat analysis group.	Manualized the telephone friendship (TF) with standardized training: (1) one-to-one befriending: 10- to 20-minute calls once per week for up to 6 weeks made by a volunteer befriender, followed by (2) TF groups of 6 participants: 1-hour teleconferences once per week for 12 weeks facilitated by the same volunteer. Control: usual health and social care provision.	The 2 groups were reasonably well matched with respect to baseline demographic characteristics. At 6 months post randomization, the SF-36 mental health mean (SD) scores were 77.5 (18.4) in the intervention group and 70.7 (21.2) in the control group, with a mean difference of 6.5 (95% CI –3.0 to 16.0); after adjusting for age, sex, and baseline scores, the mean difference was 9.5 (95% CI 4.5-14.5). In summary, over the 6-month follow-up period, there was no change in the SF-36 mental health scores in the intervention group, but there was a decline or deterioration in scores in the control group.	No mention

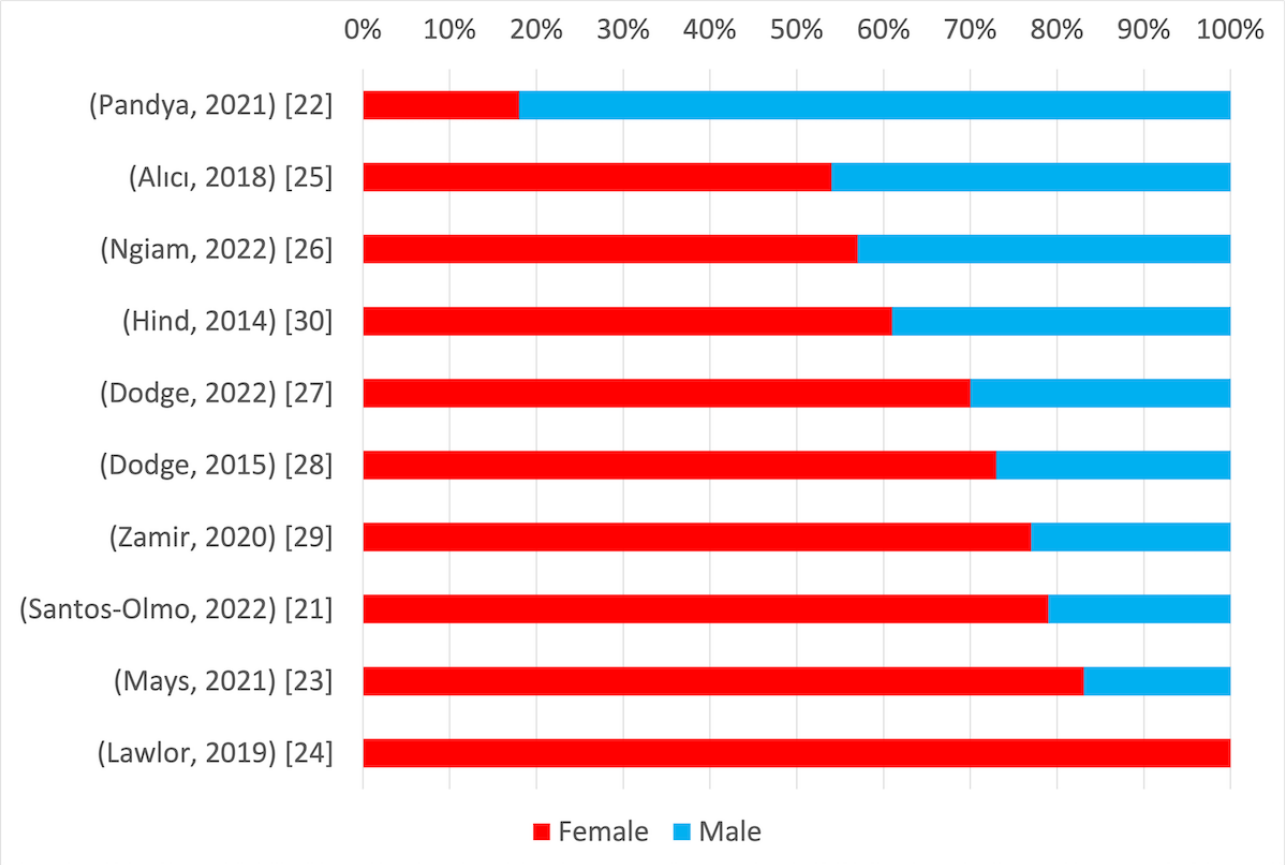
[a]ER: estimated ratio.

[b]HADS: Hospital Anxiety and Depression Scale.

The literature search was conducted using 2 complementary approaches: database and hand searches. Database searches were performed across the 6 abovementioned databases, yielding 1141 records, of which 8 studies [21-28] met the inclusion criteria. Hand searches were conducted across 3 journals and 2 websites, identifying 141 records, of which 2 [29,30] studies were eligible for inclusion.

In total, 10 studies [21-30] were included in the final analysis.

Table 1 presents a summary of the 10 papers included in the final analysis. All studies were published between 2013 and 2023. The United States and the United Kingdom were the countries with the highest representation in terms of intervention programs. Participants were generally older adults aged ≥50 years, with the majority being ≥65 years and predominantly female.



Characteristics of Participants

The 10 included studies [21-30] involved 1343 older adult participants, with sample sizes ranging from 22 to 382 (mean 134.3, SD 119.2; median 73, IQR 51.5-174). The proportion of female participants varied per study: approximately 10%-20%, 50%-60%, 60%-70%, 70%-80%, 80%-90%, and 100% women participated in 1 [26], 2 [21,27], 1 [22], 4 [23-25,29], 1 [28], and 1 [30] study, respectively (Figure 2 [21-30]). Overall, 8 documents incorporated the term “social isolation” or “loneliness” in their objectives, methods, or results. However, these documents did not explicitly address gender in the discussion section. In contrast, a few documents incorporated gender-related content in the discussion section. Studies referencing gender examined its impact on intervention effectiveness [21] and loneliness levels [22]. Among the included studies, the most common intervention method for those with the highest proportion of male participants (82%) was a personalized meditation program [22]. Conversely, studies involving women used different methods, including community-based group health classes [23] and physical activity and social support [24].

Only 1 [22] study reported a higher number of male participants compared with female ones; the remaining studies had a majority of female participants. One study [24] exclusively targeted older women, whereas no study focused solely on older men.

XSL•FO
RenderX

Figure 2. Gender ratio of participants [21-24, 26-30].

Intervention Methods and Means

The studies used 4 types of study designs: randomized controlled trials (n=5), nonrandomized control trials (n=1), pre-post outcome studies (n=3), and action research (n=1). They assessed 5 types of in-group programs: a program intended to enhance access to social and health services [21], a meditation program [22], an exercise and workshop [23], a physical activity program [24], and a laughter therapy program [25]. Overall, 3 studies discussed individualized remote programs, including a digital literacy program [25], a video chatting program [27], and a face-to-face communication program [28]. Another study assessed a remote group program that used a Skype (Microsoft) quiz format [29]. Furthermore, 1 study evaluated a remote individual program and a remote group program based on telephone friendship [30] (Table 2). The exercise workshop [23] effectively alleviated social isolation and loneliness indicators; meanwhile, the meditation [22] and laughter therapy programs [25] effectively mitigated loneliness (Table 1).

The interventions were nearly evenly divided between “remote” (n=5) and “in-person” (n=5) formats. Notably, no individual in-person programs were reported; instead, group-based in-person interventions were the most common. In-person programs typically involved strategies such as facilitating access to social resources, meditation, exercise, and workshops. Remote programs included activities such as digital literacy training, video-based communication, and online conversational sessions.

Measurement of Effectiveness

The 10 studies [21-30] assessed outcomes based on 2 indicators of social isolation, 4 indicators of loneliness, and 29 other indicators (Table 3). Among these, outcomes with positive effects were observed for the Duke Social Support Index [23] for social isolation, the 3-item loneliness scale of the University of California, Los Angeles [23], the De Jong Gierveld Loneliness Scale [25], and the 6-item De Jong Gierveld Loneliness Scale [22].

The selected studies presented relatively few measures for assessing social isolation and loneliness; however, they used a broad range of indicators to evaluate cognitive function, well-being, satisfaction, and other psychosocial domains. For outcomes related to social isolation or loneliness and cognitive function, the number of studies that reported significant effects was approximately equal to those reporting no effects.

Discussion

Principal Findings

In this review, a total of 1282 papers were identified, of which only 10 [21-30] were eligible for analysis. Studies were excluded primarily because they did not specifically examine social isolation or loneliness or were merely cross-sectional investigations that emphasized the need for interventions. Of the included studies, East Asia was represented only by Singapore; notably, no research was included from Japan despite its status as a super-aged society.

Regarding the interventions, the methods were evenly distributed between remote and in-person methods. In total, 5 [26-30] of the 10 (50%) studies [21-30] used remote interventions (eg, digital literacy and video chats), while the other 5 studies [21-25] used in-person interventions (eg, exercise, meditation, and

XSL•FO
RenderX

laughter therapy). However, none of them combined remote and in-person approaches.

A significant gender bias was observed; in 9 studies [21-24,26-30], most participants were women. Among studies in which women accounted for ≥80% or more of the participants, interventions frequently emphasized communication, shared emotional expression, and group-based activities. Conversely, the study with the highest proportion of male participants (82%) featured a meditation program characterized by self-dialogue and individual reflection.

Importantly, only 2 [21,22] of the 10 studies [21-30] discussed the impact of gender on intervention outcomes, whereas no study focused on gender-specific issues as a primary research objective. Furthermore, the use of specific indicators for social isolation and loneliness was limited; indicators were typically substituted by measures of cognitive function or quality of life, depending on the study's specific objectives.

Comparison With Prior Work

The finding that 50% of the studies used remote interventions represents a significant increase compared with the result of a previous scoping review conducted by Fakoya et al [17]. The authors found that only 15% (5 of 33) of interventions cited in papers published between 1984 and 2018 were remote. This trend aligns with the growing efficacy and development of remote tools [31,32], likely accelerated by the global COVID-19 pandemic. However, while Sen et al [32] recommended the use of online and offline resources to enhance efficacy, this review found no studies adopting such a hybrid approach.

The predominance of female participants is consistent with previous literature emphasizing that research on social isolation and loneliness is biased toward women [33,34]. This finding contradicts evidence suggesting that older men are more prone to social isolation compared with women [7,8].

Regarding intervention preferences, the findings support existing theories on gender differences. Female participants' preference for exchanging experiences in supportive settings mirrors the findings of Venter et al [35]. In contrast, the male preference for the meditation program aligns with research proposing that men gravitate toward task-oriented activities, autonomy, and less intimate social networks, as seeking help or emotional disclosure can be perceived as vulnerability [36].

The lack of gender-specific analysis in the included studies is in contrast with the recommendations of Santos-Olmo et al [21] and Wen et al [10], who argued that future research needs to prioritize gender as a variable for predicting the effectiveness of interventions. The absence of studies conducted in Japan is also a concern, given the cultural specificity of isolation [13,37], thus highlighting a gap between Japan's urgent policy needs [38] and the available evidence base.

Strengths and Limitations

Strengths

The primary strength of this study is its explicit focus on gender. To the best of our knowledge, this is the first literature review on social isolation and loneliness that considers gender as a central variable. Additionally, relevant studies were identified using a rigorous methodology based on multidisciplinary databases.

Limitations

First, the review may not have captured all relevant studies, partially because the study period overlapped with the COVID-19 pandemic, potentially causing delays in publication. Second, the literature search concluded in May 2023, excluding subsequent studies. Third, despite manual searches, some high-quality sources or community-based practices that indirectly address isolation (eg, neighborhood association activities) may have been missed. Finally, as a scoping review, no quality assessment of the included papers was conducted; thus, the quality of evidence may vary.

Future Directions

Gender-specific interventions: a clear need exists to develop and implement new gender-focused intervention programs.

For older women: interventions should prioritize group-based activities that foster dialogue, mutual understanding, and emotional connection.

For older men, future efforts must rigorously identify criteria for interventions targeting men. Programs should incorporate activities that enable self-expression without overt emotional disclosure, such as those emphasizing skill use, personal autonomy, and a sense of contribution.

Research design: future studies must move beyond merely reporting gender demographics. Studies should include gender as the primary variable in order to analyze its impact on intervention outcomes. A reexamination of previous studies that failed to show significant effects could reveal whether the lack of gender consideration was a contributing factor.

Hybrid approaches: given the increased popularity of remote interventions and the established value of in-person interaction, future interventions should aim to combine remote and in-person methods. Leveraging the experience of online-based interventions to create hybrid models could enhance the precision and efficacy of countermeasures against social isolation and loneliness.

Conclusions

This scoping review, which aimed to examine the composition of participants by gender and gender-sensitive strategies, confirms that research on social isolation generally underestimates gender. This finding reveals a bias in which women are markedly overrepresented in study samples, contradicting evidence that older men are more susceptible to isolation. Critically, no study considered gender-specific issues in its objectives, undermining the efficacy of general interventions. We found gender-based differences in preferences: women favored conversation and emotional exchange, while men exhibited the highest proportion of participation in self-dialogue meditation programs. Therefore, a clear need exists to develop new gender-focused intervention programs and systematically identify conditions for effective interventions that specifically target older men.

Abstract

Background: Self-rated health (SRH) is a robust predictor of morbidity, functional decline, and mortality in later life. As internet use becomes increasingly embedded in older adults' daily routines, clarifying its association with SRH and the pathways through which it may operate is important for research, practice, and policy.

Objective: This scoping review aimed to map and characterize the international evidence on the association between internet use and SRH among older adults, synthesize how potential mediators and moderators have been examined, and identify key methodological, theoretical, and population gaps in the literature.

Methods: Guided by the Joanna Briggs Institute methodology and PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) reporting standards, we conducted a scoping review and searched 5 databases: PubMed, CINAHL, AgeLine, PsycINFO, and Web of Science. The final search was performed on February 5, 2024. Reference lists were screened, and Google Scholar searches were conducted as supplementary search methods.

Results: Database searches identified 4294 records; after removing 615 duplicates, 3679 records were screened, and 77 full texts were assessed, resulting in 27 included studies. All included studies were quantitative, and the evidence base was predominantly cross-sectional (25/27). Explicit theoretical frameworks were used in 6 out of 27 studies. Most studies were published between 2019 and 2024 (22/27) and were conducted most frequently in China (11/27) and the United States (7/27). All studies were conducted in high-income countries. SRH was typically assessed using a single-item measure, while internet use was operationalized as access/use (yes/no), frequency, and/or purpose/domain-specific measures. Most studies reported a statistically significant positive association between internet use and better SRH (24/27), with socially oriented uses (eg, communication and social participation) showing the most consistent associations. Mediating pathways were examined in 6 out of 27 studies, and most often suggested social mechanisms such as greater social support, higher social engagement, and lower loneliness. Subgroup heterogeneity was reported in 10 out of 27 studies, including differences by age, gender, residence, and marital status.

Conclusions: Overall, internet use, particularly socially oriented use, was most consistently associated with better SRH among older adults. Policy efforts should support digital inclusion by improving access, skills, and ongoing assistance that enable meaningful use for social connection and service access. At the same time, nondigital options are essential to avoid excluding older adults who do not use the internet. In addition, evidence gaps, including limited use of theoretical frameworks and scarce data from low- and middle-income countries, underscore the need for theory-informed longitudinal and intervention studies to strengthen causal inference, expand knowledge on mediating and moderating factors, and assess generalizability across diverse contexts.

Introduction

Self-rated health (SRH) is a measure of individuals' subjective assessments of their general health, encompassing physical, mental, social, and cultural aspects [1-3]. Usually, SRH is assessed using a single item, often phrased as: "Would you say your general health is excellent, very good, good, fair, or poor?" [4]. This scale is widely used to assess health status among older adults, as it is considered valid, reliable, quick, and easy to administer [5,6]. Indeed, SRH is regarded as an important predictor of healthy aging, future morbidity, functional capacity, hospitalization, health care consumption, and mortality [7-11]. The literature indicates that a variety of factors may play an important role in good SRH among older adults, including background characteristics (eg, younger age, higher education, and male gender), social support networks, good mental and physical health, the ability to care for oneself, and healthy behaviors (eg, sufficient physical activity) [1,12-17].

An additional factor that may be related to older adults' SRH is internet use. The internet offers **a range of opportunities** to promote independent living among older adults and to improve their quality of life and overall well-being [18-21]. It facilitates communication and helps older adults maintain relationships with family and friends, as well as establish new social connections [19,21]. In addition, the internet enables participation in online leisure activities [22,23]. Furthermore, older adults can use the internet to seek information, including health-related information, potentially increasing health literacy, and supporting better health-related decision-making [24-26]. However, extensive internet use also entails potential risks. For instance, frequent internet use for nonsocial purposes, such as information seeking and entertainment, may reduce social interactions and weaken existing social networks, thereby increasing social exclusion [27-29]. There is also a risk of internet addiction among older adults [30], along with exposure to privacy invasion and data theft [31,32]. These opportunities and risks may, in turn, influence older adults' SRH.

In recent years, a growing body of research has examined the association between internet use and SRH among older adults; however, this literature has not yet been comprehensively synthesized and organized. Conducting a scoping review is therefore warranted, given the increasing integration of the internet into later life and the expansion of online services, especially in health and social domains [33-35]. In addition, digital technologies have been suggested as potentially contributing to responses to population aging and to alleviating pressures on health systems [36,37].

Therefore, the aim of this scoping review is to map and synthesize the existing international literature on internet use and SRH in later life by (1) describing how internet use and SRH have been conceptualized, operationalized, and examined across studies, as well as mapping the reported patterns of findings regarding the direction and nature of the association between internet use and SRH; (2) mapping how the literature addresses potential pathways linking internet use and SRH, including mediating and moderating factors, where mediators are defined as variables that explain the mechanisms through which one variable influences another, and moderators are defined as variables that affect the strength or direction of this relationship [38]; and (3) identifying methodological and theoretical gaps, as well as underrepresented populations within the existing evidence base. Identifying these elements is essential for informing the development of evidence-based interventions aimed at promoting SRH and well-being in later life through the use of digital technologies, as well as for supporting the design and advancement of policies in the fields of aging and digital health.

Methods

Overview

This scoping review was conducted in accordance with the Joanna Briggs Institute (JBI) methodology for scoping reviews and is reported following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [39]. In line with scoping review methodology, no formal appraisal of methodological quality was conducted [39]. An overview of adherence to the PRISMA-ScR reporting criteria is presented in Multimedia Appendix 1.

Search Strategy

The search strategy was reported in accordance with the PRISMA-S (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Searching) guideline to enhance transparency and reproducibility [40]. An overview of adherence to the PRISMA-S reporting criteria is provided in Multimedia Appendix 2. The search strategy was developed by the first author, who has expertise in aging and technology, and reviewed by the second author. It was developed iteratively, guided by the review objectives, key concepts identified in the literature, and preliminary exploratory searches. The search was conducted across 5 databases relevant to the research topic: PubMed, CINAHL, AgeLine, PsycINFO, and Web of Science. Searches were limited to peer-reviewed journal articles published in English. The final search was performed on February 5, 2024, and included all publications available up to that date. The search strategy combined keywords and Boolean operators representing 3 core concepts: internet use ("Internet" or "web" or "online" or "digital" or "technology" or "information and communication technology" or "social media" or "computer" or "smartphone" or "tablet"), SRH ("self-rated health" or "self-reported health" or "self-assessed health" or "perceived health" or "subjective health"), and older adults ("older adults" or "aging" or "aged" or "older people" or "elderly" or "seniors"). Full search strategies for each database are presented in Multimedia Appendix 3. To enhance the comprehensiveness of the search, reference lists of all included articles were screened, and Google Scholar was used as a supplementary search tool, consistent with recommendations to use Google Scholar as a complementary resource in systematic and scoping reviews rather than as a stand-alone database [41]. No additional eligible studies were identified through these supplementary searches. Duplicates were removed manually by the first author by comparing titles, authors, and

XSL•FO
RenderX

publication details across records, and the deduplication was verified by the second author.

Inclusion and Exclusion Criteria

Studies were eligible for inclusion if they met the following criteria: (1) the study reported original empirical findings derived from quantitative, qualitative, or mixed methods research, based on either primary data collection or secondary data analysis; (2) the study explicitly addressed the conceptualization and/or operationalization of the key constructs and examined the relationship between internet use and SRH; (3) the study population consisted primarily of older adults, defined as individuals aged 60 years and older, or was explicitly described by the original authors as comprising older adults, in line with commonly used definitions in previous systematic and scoping reviews (Huang et al [42]). Studies with broader age ranges were also eligible if results for older adults were reported separately; (4) the article was published in English; and (5) the article appeared in a peer-reviewed journal. Studies were excluded if they were opinion pieces, conference abstracts, book reviews, book chapters, theses, or doctoral dissertations. In addition, studies in which internet use was modeled as the outcome variable and SRH as the independent variable were excluded. This decision ensured methodological consistency by maintaining a uniform analytical direction, as is common in systematic and scoping reviews [43,44], thereby facilitating more coherent evidence mapping and synthesis across studies.

Data Charting

Data charting was guided by a structured framework informed by the JBI data extraction template for scoping reviews and adapted to the objectives of this review [45]. Data were charted from each included article at the individual-study level, including bibliographic details, study aims, study design, stated theoretical framework, sample characteristics, and the measures used to assess internet use and SRH. Key findings were also charted, including the reported association between internet use and SRH and mediators or moderators explicitly examined or discussed by the study authors. The first author conducted the data charting manually by reviewing each included article in full. To enhance reliability, the second author reviewed the charted data and the data charting framework for accuracy and consistency, and uncertainties were resolved through discussion and consensus.

Data Analysis and Synthesis

Prior to finalizing the approach for analysis and presentation, the authors conducted a preliminary review of 5 randomly selected included articles to inform the structure and focus of the subsequent analysis. Building on the charted data, study characteristics were organized descriptively to map the evidence base and to support a systematic presentation of study characteristics in the Results section (Table 1). Subsequently, a narrative synthesis of the reported findings was conducted to identify recurring patterns across studies. The synthesis summarized the direction of the association between internet use and SRH and organized results according to key dimensions aligned with the review objectives, including the type of internet use and variation across population subgroups. Findings related to mediating pathways and between-study variation were integrated where reported, to support a coherent presentation of results in the Results section, while Table 2 provided a concise overview of the synthesized evidence. To ensure the reliability of the analytical process, both authors jointly reviewed the organization and presentation of the synthesized findings, and any discrepancies were resolved through discussion and consensus.

Table 1. Characteristics of included studies.

Authors (country)	Aims	Study design/theoretical framework	Sample characteristics	Measure of SRH[a]	Measure of internet use
Chen et al 2022 [46] (China)	To examine the association between internet use and health outcomes, including the mediating role of cultural engagement	Cross-sectional; Chinese General Social Survey (2015 and 2017 waves) Activity theory (Fernández-Ballesteros et al 2021 [47])	N=6066 older adults aged ≥60 years; mean age 69.19 (SD 7.27) years; 52% women; mean education 1.5492 (SD 0.6378); range 1 (“primary school”) to 3 (“college or above”)	Single item (unhealthy/healthy)	Internet use (yes/no)
Chopik 2016 [48] (United States)	To examine the association between socially oriented technology use and health-related outcomes	Cross-sectional; Health and Retirement Study (2012 wave)	N=591 older adults; mean age 68.18 (SD 10.75) years; 55.5% women; mean education 13.28 (SD 2.70) years; 73.9% White, 19.9% Black/African American, 6.1% Hispanic	Single item (5-point scale: 1 “poor” to 5 “excellent”)	Social technology use was measured using 5 modalities (email, social networking sites, online video/phone calls, online chat/instant messaging, smartphone); summed index (0-5)
Ding et al 2023 [49] (China)	To examine the association between internet access and health-related outcomes	Cross-sectional; China Health and Retirement Longitudinal Study (2011, 2013, 2015, and 2018 waves)	N=57,960 older adults; mean age 58.7 (SD 8.09) years; 50% women; mean education 1.712 (SD 1.304)	Single item (poor health/good health)	Internet access (yes/no)
Duplaga et al 2021 [50] (Poland)	To examine the association between internet use and health-related outcomes	Cross-sectional; telephone survey	N=1000 adults aged ≥50 years; 39.3% aged 50-59 years, 28.5% aged 60-69 years, 29.7% aged ≥70 years; 55.8% women; education: 27.8% below secondary, 45.9% secondary/postsecondary, 26.3% university	Single item (“unsatisfactory”/”at least satisfactory”)	Frequency of internet use (4-point scale: 0 “no use,” 1 “a few times a month or less,” 2 “a few times a week,” 3 “every day”)
Falk Erhag et al 2019 [51] (Sweden)	To examine the association between internet use and SRH	Cross-sectional; Gothenburg H70 Birth Cohort Study (2014-2016 wave); personal interview and self-administered questionnaire	N=1136 older adults aged 70 years; 69.3% men; 82.9% had >9 years of education; 28.5% had a university degree	Single item (5-point scale: “excellent” to “poor”)	Frequency of internet use (7-point scale: “never” to “daily or several times a day”)
Fjell et al 2020 [52] (Norway)	To examine the association between SRH and factors related to demographics, lifestyle, health conditions, and medical diagnoses	Cross-sectional; face-to-face interview	N=233 older adults participating in a preventive home visit program; mean age 77 (range 75-79) years; 50% women; education: 25% >7 years, 75% ≤7 years	Single item (5-point scale: 1 “poor” to 5 “excellent”)	Internet use (yes/no)
Gracia and Herrero 2009 [53] (Spain)	To examine the association between internet use and SRH	Cross-sectional; telephone/online survey (Digital divide and quality of life among older people)	N=709 adults aged ≥55 years; 56.7% aged 55-64 years, 43.3% aged 65-74 years; 52.2% women; social class: 8.1% high, 9.2% medium-high, 26.3% medium, 35.3% medium-low, 21% low	Single item (good health/poor health)	Internet use (user/nonuser)
Jeon and Choi 2024 [54] (Korea)	To examine the association between internet use and physical and psychological health outcomes	Cross-sectional; Living Profiles of Older People Survey (2020 wave); face-to-face interviews	N=5094 older adults aged ≥65 years; mean age 70.71 (SD 2.8) years; 54.1% women; education: 9.7% college+, 42.6% high school, 25.3% middle school, 19.3% elementary school, 3.1% no formal education	Single item (5-point scale: 1 “very good” to 5 “very poor”)	Internet use: Interpersonal communication: 3 yes/no items; summed index (0-3) Instrumental use: 8 yes/no items; summed index (0-8)
Kim et al 2020 [55] (United States)	To examine the association between ICT[b] use and health-related outcomes	Cross-sectional; National Health and Aging Trends Study (2010 wave)	N=4976 older adults aged ≥65 years; mean age 73.7 (SD 0.09) years; 54.3% women; mean education 2.8 (SD 0.4); range 1 (“less than 12th grade”) to 5 (“graduate degree”); 83.5% White, 7.6% Black, 2.9% other	Single item (5-point scale: 1 “poor health” to 5 “excellent health”)	ICT: IT (6 items; yes/no): 3 items for personal tasks >3 items for health-related information. Communication technology (1 item; frequency): sending messages by email or texting (rarely/some days/most days).

Authors (country)	Aims	Study design/theoretical framework	Sample characteristics	Measure of SRH[a]	Measure of internet use
Koopman-Boyden and Reid 2009 [56] (New Zealand)	To examine the association between internet use and well-being	Cross-sectional; phone/online survey	N=1680 older adults aged 65-84 years; 31% aged 65-69 years, 28% aged 70-74 years, 25% aged 75-79 years, 16% aged 80-84 years	Single item (satisfied/dissatisfied with health)	Internet use (yes/no)
Lee and Jang 2022 [57] (Korea)	To examine the association between changes in internet use during the COVID-19 pandemic and SRH, comparing young-old (65-74) and old-old (≥75) adults	Cross-sectional; Digital Divide Survey (2020 wave); face-to-face interviews	N=1150 older adults aged ≥65 years: young-old (n=670; mean age 69.18 (SD 2.8) years; 52.5% women; 23.4% <middle school, 76.6% ≥high school) and old-old (n=480; mean age 79.93 (SD) 3.6 years; 62.9% women; 44.8% <high school, 55.2% ≥high school)	Single item (4-point scale: 1 “not satisfied at all” to 4 “very satisfied”)	Internet use: 4 domains (each rated on a 5-point scale from 1 “significantly decreased” to 5 “significantly increased”): (1) social networking and information-sharing services; (2) social participation services; (3) daily services; and (4) search, email, and content services
Lee et al 2018 [58] (United States)	To examine the association between ICT use and health-related outcomes among older cancer survivors	Cross-sectional; National Health and Aging Trends Study (2011 wave)	N=1411 community-dwelling cancer survivors aged ≥65; 53.6% aged 65-74 years, 36.2% aged 75-84 years, 10.2% aged ≥85 years; 48% women; mean education 2.9 (SD 0.22); range 1 (“less than 12th grade”) to 5 (“graduate degree”); 90% White, non-Hispanic	Single item (5-point scale: 1 “poor” to 5 “excellent”)	ICT use: Communication technology: Frequency of emailing/texting (no or rarely/some days/most days) Information technology: 6 yes/no items, summarized as 2 indices: personal tasks (3 items) and health-related internet use (3 items)
Li et al 2023 [59] (China)	To examine the association between online and offline social activities and health-related outcomes	Cross-sectional; World Values Survey (wave 7, China sample) and China Health and Retirement Longitudinal Study (2018 wave)	Sample 1: N=598 older adults aged ≥60 years; mean age 64.76 (SD 2.97) years; 52.7% women; education: 53.8% primary school or below, 26.4% middle school, 15.6% high school/vocational, 3.8% bachelor’s, 0.3% master’s or above. Sample 2: N=9434 older adults; mean age 68.53 (SD 6.44) years; 50% women; education: 73.7% primary school or below, 16.3% middle school, 8.5% high school/vocational, 0.7% associate degree, 0.6% bachelor’s, 0.03% master’s or above	Single item (5-point scale: 1 “very poor” to 5 “very good”) in both samples	Sample 1: Frequency of internet use (5-point scale: 1 “never” to 5 “daily”). Sample 2: Frequency of internet use (0-3 scale: 0 “no participation” to 3 “almost daily”; past month)
Liu et al 2023 [60] (China)	To examine the association between internet use and SRH, including the mediating role of social engagement and heterogeneity by living arrangements	Cross-sectional; China Health and Retirement Longitudinal Study (2018 wave)	N=14,587 middle-aged and older adults aged ≥45 years; mean age 61 (SD 9.248) years; 52% men; education: 62% elementary school or below, 23% junior high, 13% high school or above	Single item (5-point scale: 1 “very poor” to 5 “very good”)	Two measures: Internet use (yes/no) Frequency of internet use (4-point scale: 0 “never” to 3 “almost every day”)
Liu et al 2022 [61] (China)	To examine the association between internet use and SRH, including the mediating role of social support	Cross-sectional; Chinese General Social Survey (2017 wave)	N=4234 older adults aged ≥60 years; mean age 69.34 (SD 7.37) years; 48% men; mean education 6.65 (SD 4.61) years	Single item (5-point scale: 1 “very unhealthy” to 5 “very healthy”)	Internet access (yes/no)
Lyu and Sun 2021 [62] (China)	To examine the association between internet use and SRH, including the mediating role of social capital	Cross-sectional; China Family Panel Studies (2018 wave)	N=7193 older adults aged ≥60 years; age distribution: 64.83% aged 60-69 years, 28.69% aged 70-79 years, 6.48% aged ≥80 years; 51.01% men; education: 88.39% had 0-9 years, 10.86% had 10-15 years, 0.75% had ≥16 years	Single item (unhealthy/healthy)	Internet use (yes/no)

Authors (country)	Aims	Study design/theoretical framework	Sample characteristics	Measure of SRH[a]	Measure of internet use
Millar et al 2020 [63] (United States)	To examine the association between problem-solving in technology-rich environments and SRH, focusing on age differences	Cross-sectional; Program for the International Assessment of Adult Competencies (2012-2014 wave) Paasche-Orlow and Wolf's [64] model (2007) and Gewald and Rockmann's [65] model (2016)	N=3260 adults aged ≥35 years; age: 26.65% 35-44 years, 28.71% 45-54 years, 27.12% 55-65 years, 16.58% ≥66 years; 54.82% women; education: 60.74% high school or less, 39.25% college or higher	Single item (good health/poor health)	Internet use for health information seeking (yes/no)
Nakagomi et al 2022 [66] (Japan)	To examine the association between internet use and subsequent health and well-being	Longitudinal; Japan Gerontological Evaluation Study (3 waves: 2013, 2016, 2019); self-administered questionnaires	N=3903 older adults aged ≥65; mean age 71.34 (SD 4.65) years; 62.97% women; education: 68.07% had ≥10 years, 31.92% had ≤9 years	Single item (excellent/good vs others)	Frequency of internet use (4-point scale: not at all/a few times a month/a few times a week/almost every day)
Sims et al 2016 [67] (United States)	To examine the association between ICT use and well-being among the oldest-old	Cross-sectional; online/telephone survey Socioemotional selectivity theory and biological models of aging	N=445 older adults aged ≥80 years; mean age 84 (SD 3) years; 64% women; 45% had more than high school education; 26% non-White	Single item (5-point scale: 1 "excellent" to 5 "poor")	ICT use: number of ICT devices/applications used (3-point scale: 0 "none," 1 "one," 2 "two or more"); motivation for ICT use: 2 items (connect with family/friends; learn new information/skills), each rated on a 5-point scale (1 "strongly disagree" to 5 "strongly agree")
Swed et al 2020 [68] (United States)	To examine the association between internet use and SRH among older military veterans	Cross-sectional; National Survey of Veterans (2010 wave); mail questionnaire	N=8539 older adults aged ≥60 years; mean age 61.02 (SD 0.02) years; 91.5% men; education: 5.4% <high school, 26% high school, 30% some college, 27% college degree, 11.7% professional degree; 80.6% White, 10.9% Black, 4.8% Hispanic, 3.7% other	Single item (3-point scale: "fair/poor," "good/very good," "excellent")	Frequency of internet use (4-point scale: daily/once a week, not daily/once a month-once per year/does not use the internet)
Tavares 2020 [69] (17 European countries and Israel)	To examine the association between internet use and SRH, and whether this association varies across countries with different levels of eHealth policy development	Cross-sectional; Survey of Health, Ageing and Retirement in Europe (SHARE), wave 6 Social ecological model (Dahlgren and Whitehead 1991 [70])	N=66,279 adults aged ≥50 years from 18 countries; mean age 67.93 years; 46.8% men; mean education 10.83 years	Single item (5-point scale: 1 "poor health" to 5 "excellent health")	Internet use in the past 7 days (yes/no)
Wang et al 2020 [71] (China)	To examine the association between internet use and health-related outcomes and whether individual cognitive ability moderates this association	Longitudinal; Chinese General Social Survey (2012 and 2015 waves)	2012 wave: N=2821 older adults aged ≥60 years; mean age 69.10 (SD 7.20) years; 56% men; mean education 2.40 (SD 1.27); range 1 ("no education") to 7 ("graduate and above"). 2015 wave: N=3185 older adults aged ≥60 years; mean age 69.39 (SD 7.46) years; 49% men; mean education 2.39 (SD 1.26); range 1 ("no education") to 7 ("graduate and above")	Single item (5-point scale: 1 "relatively poor" to 5 "very healthy")	Frequency of internet use (5-point scale: 1 "never" to 5 "very frequently")

Table 2. Main results of included studies on internet use and self-rated health (SRH).

Authors (country)	Level of SRH	Level of internet usage	The impact of internet use on SRH	
			Positive/negative/NS[a]	Mediators, moderators, and heterogeneity across groups
Chen et al 2022 [46] (China)	39% reported being healthy	22% used the internet	Positive	Mediated by cultural engagement
Chopik 2016 [48] (USA)	Moderate-high level; mean 3.26, SD 1.05	Low level (social technology use for social connection); mean 1.37, SD 1.42	Positive	Mediated by reduced loneliness
Ding et al 2023 [49] (China)	74% reported good health	24% had internet access	Positive	Stronger among vulnerable groups (eg, difficulties in ADL[b], no social participation, or no spouse)
Duplaga 2021 [50] (Poland)	67.9% reported at least satisfactory health	51.1% did not use the internet, 7.9% used the internet a few times a month or less, 14.8% used the internet a few times a week, and 26.2% used the internet every day	Negative	N/A[c]
Falk Erhag et al 2019 [51] (Sweden)	11.97% excellent; 36.18% very good; 35.56% good; 14.35% moderate; 1.94% poor	66.10% reported using the internet daily	Positive (minor effect compared to health-related variables)	N/A
Fjell et al 2020 [52] (Norway)	Moderate level; mean 2.84, SD 0.88	44% used the internet	Positive	N/A
Gracia and Herrero 2009 [53] (Spain)	83.2% reported good health	17.3% used the internet	Positive (the relationship between internet use and SRH disappeared once social class was considered)	N/A
Jeon and Choi 2024 [54] (Korea)	Moderate level; mean 2.44, SD 0.81	Internet use for interpersonal communication: high level; mean 2.24, SD 0.74 Internet use for instrumental purposes: moderate level; mean 3.22, SD 2.22	Positive (the impact of internet use for instrumental purposes was stronger than the impact of internet use for communication purposes on SRH)	N/A
Kim et al 2020 [55] (USA)	Moderate-high; mean 3.4, SD 0.02	Information technology—personal tasks: 32% used the internet for personal tasks; 44% shopped groceries/personal items; 44.2% paid bills/banking; 17.6% ordered/refilled prescriptions Information technology—health-related information: 15.9% contacted medical providers; 11.8% handled medical/health insurance matters; 36.2% gathered information about health conditions Communication technology: 65.5% emailed/texted most days; 28.4% some days; 15.1% rarely	Positive for overall ICT[d]; NS for information technology only; NS for communication technology only.	N/A
Koopman-Boyden and Reid 2009 [56] (New Zealand)	N/A	51% used the internet	Positive	N/A

Authors (country)	Level of SRH	Level of internet usage	The impact of internet use on SRH	
			Positive/negative/NS[a]	Mediators, moderators, and heterogeneity across groups
Lee and Jang 2022 [57] (Korea)	Young-old: moderate-high level; mean 2.61, SD 0.80 Old-old: moderate-high level; mean 2.44, SD 0.70	Young-old: moderate to moderate-high level of increase in internet use: social networking and information-sharing services (mean 3.24, SD 0.58), social participation (mean 2.89, SD 0.59), daily services (mean 3.20, SD 0.59), search/email/content services (mean 3.26, SD 0.57) Old-old: moderate level of increase in internet use: social networking and information-sharing services (mean 2.98, SD 0.44), social participation (mean 2.87, SD 0.51), daily services (mean 2.98, SD 0.42), search/email/content services (mean 3.01, SD 0.42)	Positive	Age differences: positive association between SRH and social networking/information-sharing services and online daily services in both groups; social participation services and search/email/content services were positively associated with SRH only among the old-old group
Lee et al 2018 [58] (United States)	Moderate-high level; mean 3.2, SD 0.03	Communication technology: 15.7% emailed/texted some days; 26.8% most days Information technology (personal tasks): 31.7% used the internet for personal tasks Health matters: 26.5% used the internet for health matters	Positive for communication technology (significant only when used most days); NS for information technology and health matters	N/A
Li et al 2023 [59] (China)	N/A	Sample 1: moderate level of frequency of internet use; mean 3.03, SD 1.87 Sample 2: mean 0.19, SD 0.71; 6.7% used the internet in the last month	Positive among both samples	N/A
Liu et al 2023 [60] (China)	Moderate-high level; mean 3.079, SD 1.021	14% used the internet Low frequency of internet usage; mean 0.387, SD 0.982	Positive	Mediated by social engagement; stronger contribution among those with children (vs without children)
Liu et al 2022 [61] (China)	Moderate level; mean 2.97, SD 1.07	23.1% had access to the internet	Positive	Mediated by social support (relatives and friends); stronger among male older adults, younger older adults, and rural older adults
Lyu and Sun 2021 [62] (China)	53.47% reported that they were healthy	12.87% used the internet	Positive	Mediated by social capital
Millar et al 2020 [63] (United States)	85.2% reported good health	69.96% used the internet to seek health information	NS	N/A
Nakagomi et al 2022 [66] (Japan)	87.8% reported excellent/good health	47.7% not at all; 14.7% a few times a month; 13.5% a few times a week; 24.2% almost every day	Positive (modest link; significant only for almost every day internet use); NS for a few times a month/a few times a week	N/A
Sims et al 2016 [67] (United States)	Moderate level; mean 2.87, SD 0.87	Mean number of devices/applications used 1.23, SD 0.83 Moderate-high level of using technology to connect with family and friends; mean 3.66, SD 1.28 Moderate level of using technology to learn new information and skills; mean 2.61, SD 1.44	Positive	Mediated by using technology to learn new information; not mediated by using technology to connect with family and friends
Swed et al 2020 [68] (United States)	72.4% had good/very good/excellent health	48.7% used the internet daily; 16.6% used it once a week (not daily); 5.6% used it once a month-once per year; 29.1% did not use the internet	Positive	N/A

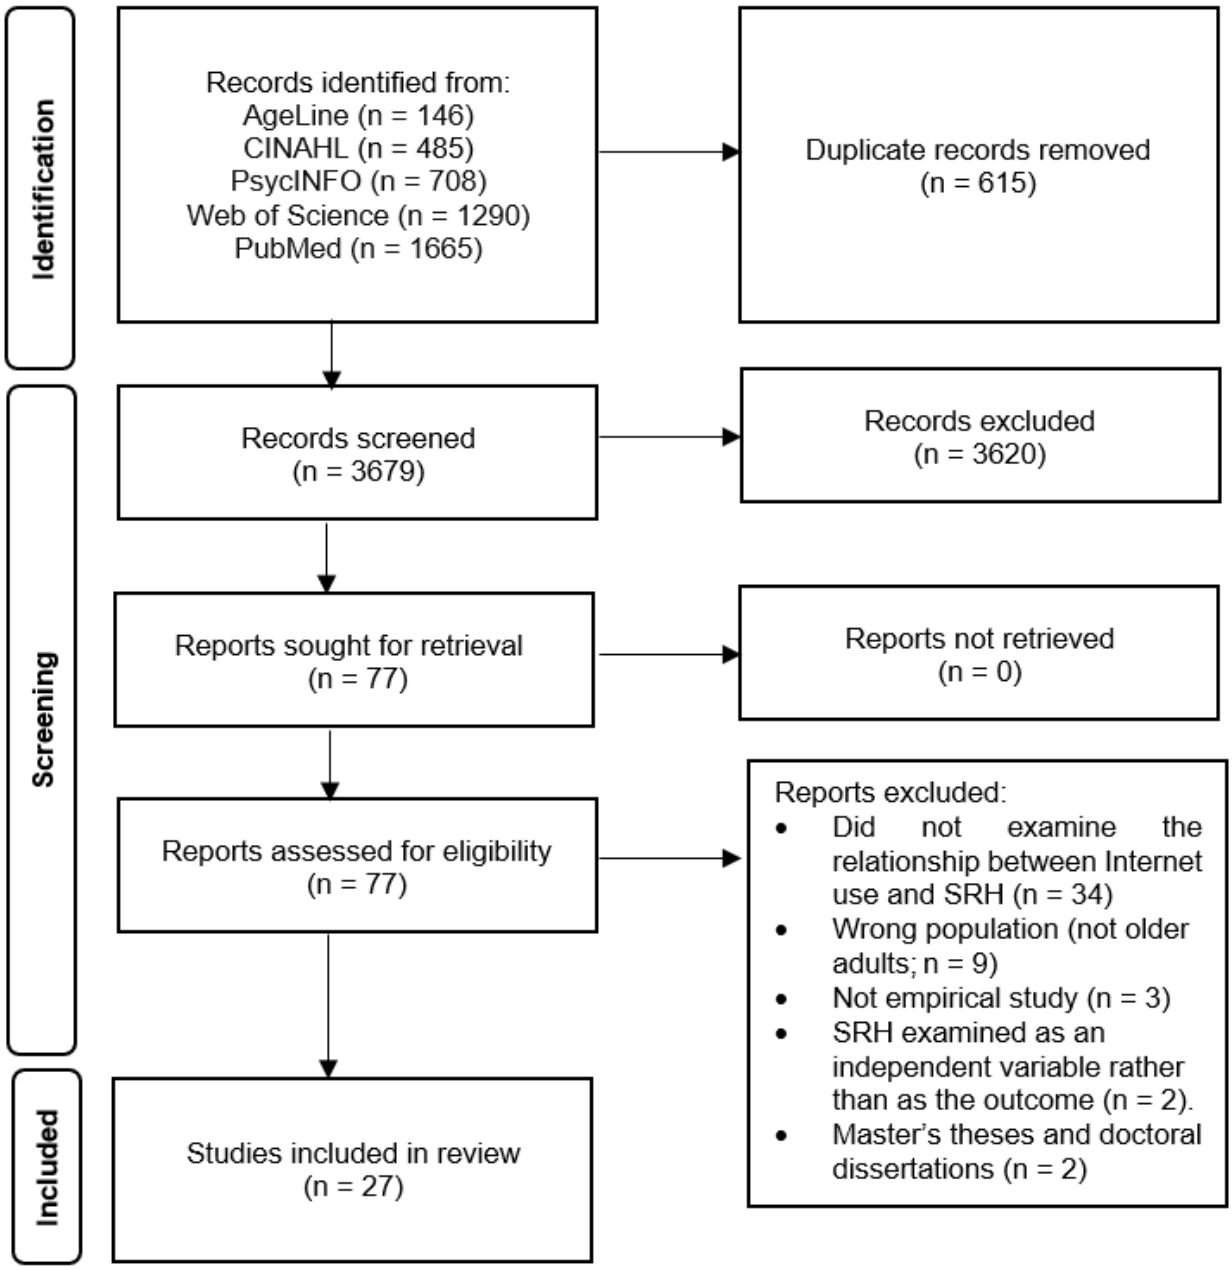
Authors (country)	Level of SRH	Level of internet usage	The impact of internet use on SRH	
			Positive/negative/NS[a]	Mediators, moderators, and heterogeneity across groups
Tavares 2020 [69] (17 European countries and Israel)	11.42% poor; 28.56% fair; 35.61% good; 17.62% very good; 6.78% excellent	48.4% used the internet in the previous 7 days	Positive	Stronger in less eHealth-developed countries; not beneficial for older adults with low levels of health
Wang et al 2020 [71] (China)	Moderate-high level in both waves; mean 3.01, 3.18, SD 1.05, 1.06 (2012 and 2015, respectively)	Low level in both waves; mean 1.20, SD 0.78 and mean 1.35, SD 0.93 (2012 and 2015, respectively)	NS	Not moderated by individual cognitive ability
Wei and Guo 2023 [72] (China)	Moderate-high level; mean 2.377, SD 0.760	57% used a smartphone	Positive	Stronger among urban residents and among adults aged >75 years; mediated by performance expectations and individualized needs
Wei et al 2022 [73] (China)	Moderate-high level; mean 3.12, SD 1.04	5% used WeChat	Positive	Stronger among younger-older adults (<70 years); positive effects among both older men and women
Wen et al 2023 [75] (China)	23.85% positive health; 49.49% general health; 26.65% negative health	24.32% used the internet	Positive	Significant among older adults living in both rural and urban settings
Xiaobing and Meng 2022 [76] (China)	8.34% very unhealthy; 39.08% relatively unhealthy; 34.16% average; 14.72% relatively healthy; 3.69% very healthy	Internet use: 88.91% did not use the internet; internet use frequency: 83.68% never; 4.98% rarely; 4.93% sometimes; 4.43% often; 1.98% always**;** internet as an information source: 4.53% used the internet as a source of information	Positive for frequent internet use, and for using the internet as a source of information	SRH mediated the relationship between internet use and community engagement
Yang et al 2020 [77] (USA)	Young and middle-aged: 26.8% excellent; 37.9% very good; 25.0% good; 8.2% fair; 2.1% poor Older adults: 16.1% excellent; 33.3% very good; 33.4% good; 13.6% fair; 3.8% poor	Young and middle-aged: 85.6% daily; 6.1% use but not daily; 8.3% never Older adults: 43.5% daily; 12.4% use but not daily; 44.1% never	Positive	Stronger among older adults than among young and middle-aged adults

[a]NS: not significant.

[b]ADL: activities of daily living.

[c]N/A: not applicable.

[d]ICT: information and communication technology.



Results

Overview

The study selection process is shown in Figure 1. Searches of 5 databases identified 4294 records (PubMed, n=1665; Web of Science, n=1290; PsycINFO, n=708; CINAHL, n=485; AgeLine, n=146). After removing 615 duplicates, 3679 records were screened by title and abstract, and 77 full-text reports were assessed for eligibility. A total of 27 studies were included. The 50 excluded full-text reports were primarily excluded because they did not examine the internet use-SRH relationship (n=34), involved an ineligible population (n=9), were not empirical studies (n=3), treated SRH as an independent variable (n=2), or were theses/dissertations (n=2).

RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram of study selection. SRH: self-rated health.

Characteristics of Included Studies

Overview

Table 1 provides an overview of the included studies and summarizes the following elements: study aims; publication year and country; study design and theoretical framework (where applicable); sample characteristics; and measures of SRH and internet use. Overall, the evidence base comprised predominantly cross-sectional, quantitative survey studies and included relatively limited use of explicit theoretical frameworks. Across studies, SRH was consistently assessed using a single-item measure (with varying response scales), whereas internet use was operationalized across multiple dimensions, including access/use (yes/no), frequency of use, and purpose-specific or domain-based measures.

Aims of the Studies

Across nearly all included studies (26/27), internet use was examined as the independent variable and SRH as the outcome. In 1 study, SRH was examined as a mediator in the association between internet use and community participation [76].

Publication Years and Geographical Distribution

Most included studies (n=22) were published between 2019 and 2024. Three studies were published between 2016 and 2018 (2016: n=2; 2018: n=1), and 2 studies were published in 2009. Studies were most frequently conducted in China (n=11) and the United States (n=7). Two studies were conducted in Korea, and 1 study each was conducted in Poland, Sweden, Norway, Spain, New Zealand, and Japan. One cross-national study analyzed data from 17 European countries and Israel [69].

XSL•FO
RenderX

Study Designs and Data Collation

All included studies were quantitative and relied on survey or structured questionnaire data. **Notably,** no qualitative or mixed methods studies met the inclusion criteria. Several studies drew on the same underlying survey datasets: 3 studies used the Chinese General Social Survey (CGSS) [46,61,71], 5 studies used the China Health and Retirement Longitudinal Study (CHARLS) [49,59,60,75,76] (including 1 study that combined CHARLS with an additional dataset [59]), and 2 studies used the National Health and Aging Trends Study [55,58]. Two studies used longitudinal designs [66,71], while the remainder were cross-sectional. Specifically, Nakagomi et al [66] (2022) analyzed 3 waves of the Japan Gerontological Evaluation Study (2013, 2016, and 2019), and Wang et al [71] (2020) analyzed 2 waves of the CGSS (2012 and 2015).

Sample Characteristics

Most included studies focused on community-dwelling populations. Although the review targeted older adults, 4 studies drew on datasets that included younger age groups in addition to older adults (eg, samples defined as ≥45, ≥50, or ≥35 years), while still reporting results specifically for older adults as a separate group [50,60,63,69]. In 1 study, older adults were explicitly compared with a younger group (18-64 years vs ≥65 years) [77]. One study focused on older cancer survivors [58], and 1 examined older military veterans [68].

Sample sizes varied widely. Four studies included fewer than 1000 participants (range 233-709) [48,52,53,67]. Most studies (n=18) used large samples of 1000-10,000 participants (range 1000-9434), including 1 study that analyzed 2 samples (n=598 and n=9434) [59]. Five studies used very large samples of >10,000 participants (range 13,474-82,014) [49,60,69,75,77].

Theoretical Framework

Most included studies (21/27) did not report an explicit theoretical framework. Six studies referenced a theory or conceptual model: Chen et al [46] drew on activity theory; Wei et al [73] drew on social participation theory; Sims et al [67] referenced socioemotional selectivity theory and biological models of aging; Tavares [69] used a social ecological model; Millar et al [63] drew on Paasche-Orlow and Wolf's model and Gewald and Rockmann's model; and Xiaobing and Meng [76] drew on displacement theory. Overall, these findings indicate that the association between internet use and SRH has largely been examined in an atheoretical manner.

Measurements

Overall, SRH was measured consistently across studies using a single-item indicator, although response scales varied. In contrast, internet use was assessed across 3 main dimensions: access/use (yes/no), frequency (ordinal scales), and purpose or domain of use (eg, social, instrumental, or health-related).

SRH Measurements

All included studies assessed SRH using a single item, typically phrased as a global self-assessment of health. Response scales varied: 8 studies used dichotomous response options (eg, unhealthy/healthy; poor/good health; or satisfied/dissatisfied with health) [46,49,50,53,56-63,66]. Three studies used 3-point scales [68,72,75], 1 study used a 4-point scale [57], and 15 studies used 5-point scales [48,51,52,54,55,58-61,67,69,71,73,76,77].

Internet Use Measurements

Measures of internet use varied substantially across studies. Nine studies measured internet use/access using a single binary indicator (eg, yes/no; user/nonuser; or use in the past 7 days) [46,49,52,53,56,61,62,69,75]. Nine studies assessed frequency of internet use using ordinal response scales ranging from 3-point to 7-point measures (including 3-point [77], 4-point [50,66,68], 5-point [71], and 7-point [51]). In addition, 3 studies used more than 1 internet-use measure [59,60,76]: Liu et al [60] included both a binary internet use indicator (yes/no) and a frequency measure (4-point scale); Xiaobing and Meng [76] included multiple internet-use indicators, including indicators of access/use, a measure of use frequency, and the internet as a primary source of information, and Li et al [59] used different frequency measures across samples (a 5-point scale in sample 1 and a 4-point scale in sample 2).

Several studies operationalized internet use in more specific ways, including socially oriented technology use [48], interpersonal communication and instrumental internet use [54], changes in internet use across multiple online domains [57], and internet use for health information seeking [63]. Finally, some studies assessed broader information and communication technology (ICT) use rather than internet use alone, including ICT indicators or indices and counts of devices or applications and related motivations [55,58,67]. Some studies also used platform- or device-specific measures, such as smartphone use or WeChat use [72,73].

Main Results of Included Studies on Internet Use and SRH

Overview

Table 2 summarizes the main findings of the included studies. It reports levels of SRH and internet use, the direction and significance of the association between internet use and SRH, and, where available, mediators and heterogeneity across subgroups. Overall, Table 2 indicates that most studies report a positive association between internet use and SRH. However, the magnitude and robustness of this association vary depending on the type of internet use examined and the characteristics of the study population.

Levels of SRH

Across studies, SRH levels were reported either as mean scale scores or as proportions. In 12 studies reporting mean SRH scores, the average level of SRH was generally moderate to moderately high [48,52,54,55,57,58,60,61,67,71-73]. In studies reporting proportions, the share of participants reporting good to excellent health was often high (approximately 75% to the mid-80% range) [49,51,53,63,68], with an even higher proportion reported by Nakagomi et al [66] (87.8%). Lower proportions were also reported in some studies, including 53.47% reporting healthy status in the study by Lyu and Sun [62] and 39% reporting healthy status in the study by Chen et al [46].

Levels of Internet Use

Overall, reported levels of internet use varied widely across studies, partly because internet use was operationalized in different ways (eg, binary use, frequency categories, or mean/index scores). Seven studies reported a relatively low prevalence of internet use, generally around 11%-24% [46,49,60-62,75,76]. In contrast, 4 studies reported substantially higher prevalence, with around 44%-57% of participants using the internet (or using a smart device) [52,56,69,72]. In studies reporting frequency-based measures, daily or near-daily use also varied considerably: 2 studies reported that roughly 25% of participants used the internet daily or almost every day [50,66], whereas 2 other studies reported higher daily-use rates including 48.7% [68] and 66.1% [51].

Several studies also reported purpose- or domain-specific levels of internet use. Social or communication-oriented use was reported as a low mean level of socially oriented technology use (mean 1.37, SD 1.42) [48], moderate to high engagement in communication technology in some samples (eg, emailing/texting most days, 65.5%) [55], and lower engagement in others (eg, emailing/texting some days, 15.7%, and most days, 26.8%) [58]. In 1 study assessing online purposes, interpersonal communication use was reported (mean 2.24, SD 0.74), alongside instrumental use (mean 3.22, SD 2.22) [54], and another study reported moderate to moderately high levels of change across multiple online domains (approximate means 2.87-3.26 across domains) [57]. Health-related internet use also varied: in 1 study, specific health-related online activities ranged from 11.8% to 36.2% [55], whereas another study reported 69.96% using the internet for health information seeking [63]. Finally, platform- or device-specific use was generally low for WeChat (5%) [73] and higher for smartphone use (57%) [72].

The Association Between Internet Use and SRH

The majority of included studies (24/27) reported a positive association between internet use and SRH, indicating that older adults who used the internet tended to report better SRH than nonusers [46,48,49,51-62,66-69,72,73,75-77]. Consistent with this pattern, studies assessing frequency-based measures generally suggested that more frequent internet use was associated with better SRH [54,57,59,66-68,76,77]. Purpose-specific measures showed positive associations in several contexts, including socially oriented technology use and communication-related use [48,54,57,58], and instrumental use, such as accessing information and services, in some studies [54,57]. One study also reported that combined ICT use was associated with better SRH [55].

At the same time, findings were not uniform. One study reported a modest association that was significant primarily for near-daily internet use [66], and another found that communication technology was positively associated with SRH only when used most days [58]. One study reported that the contribution of internet use to SRH was minor compared with health-related factors, such as chronic or psychiatric conditions [51], and another found that the association was attenuated after accounting for social class [53]. Two studies reported no significant association between internet use and SRH [63,71], and 1 study reported a negative association [50]. In addition, nonsignificant results were reported for specific types of health-related internet use in some studies [58,63].

Mediating Factors in the Relationship Between Internet Use and SRH

Six of the included studies (6/27) examined mediating pathways linking internet use with SRH. Several of these studies highlighted social pathways: cultural engagement [46], social support from relatives and friends [61], and social engagement [60] were each reported as mediators of the association between internet use and SRH. Loneliness was also identified as a mediator in 1 study, with socially oriented technology use associated with lower loneliness, which in turn was linked to better SRH [48]. In addition, 1 study reported that using technology to learn new information and skills mediated the association between ICT use and SRH, whereas using technology to connect with family and friends did not show a mediating effect [67]. Finally, 1 study identified performance expectations and individualized needs as mediators of the association between smart device use and SRH [72].

Heterogeneity Across Subgroups in the Association Between Internet Use and SRH

Studies examining subgroup differences in the association between internet use and SRH reported heterogeneous findings. With respect to age, 1 study comparing younger and older adults reported a stronger association between smartphone use and SRH among older adults than among younger and middle-aged adults [77]. In addition, age-stratified analyses in 1 study of internet use domains showed that social networking and information sharing and daily services were positively associated with SRH in both the young-old (aged 65-74 years) and old-old (aged ≥75 years) groups, whereas social participation services and search, email, and content services were positively associated with SRH only in the old-old group [57]. Other studies also suggested that the benefits of internet and social media use may be more pronounced among younger-old adults (eg, aged <70 years) [61,73].

Regarding place of residence, findings were mixed: 1 study reported a stronger benefit of internet use among rural older adults [61], whereas another reported a stronger association between smartphone use and SRH among urban older adults [72]. A third study found no differences between urban and rural settings [75]. For gender, 1 study reported a stronger benefit of internet use among older men than older women [61], whereas another study found no gender differences in the association [73]. Evidence of heterogeneity was also reported for other population characteristics. Internet access appeared more beneficial for vulnerable groups (eg, those with difficulties in activities of daily living) and for individuals with lower social participation or without a spouse [49]. In contrast, 1 study reported that internet use was not beneficial among older adults with low levels of health [69], while also indicating a stronger association between internet use and SRH in countries with less developed eHealth contexts [69]. In 1 study, cognitive ability was examined as a moderator, but no significant moderating effect was found [71]. Finally, 1 study reported that the contribution of internet use to SRH was greater among older adults with children than among those without children [60].

Discussion

Principal Findings

The purpose of this scoping review was to map and characterize the existing literature on internet use and SRH among older adults, including how this relationship has been studied, what patterns of association have been reported, and which gaps remain in the evidence. Overall, the review included 27 studies, most of which (24/27) reported a statistically significant positive association between internet use and SRH among older adults. Several studies further suggested that socially oriented uses of the internet, including communication and social participation, were positively associated with SRH [48,57,58]. Evidence on potential mechanisms was more limited; however, the available findings indicate that social factors, including social support and social participation, may help explain the observed association between internet use and SRH [46,60-62]. In addition, some studies suggested that certain vulnerable groups, such as individuals with difficulties in activities of daily living, lower social participation, or without a partner, may derive greater benefit from internet use, although subgroup findings were mixed overall [49]. These findings can be interpreted in light of social participation theory, which posits that active engagement in social activities, whether in-person or virtual, can enhance well-being and contribute to better perceived health in later life. Similarly, social capital theory highlights the importance of social networks and the resources they provide, including emotional and instrumental support [78]; these resources may be expanded or sustained through internet use and, in turn, relate to SRH. Beyond these perspectives, as a possible theoretical interpretation, the findings may also be viewed through the lens of socioemotional selectivity theory [79], which suggests that as individuals age, they increasingly prioritize emotionally meaningful goals and relationships. From this perspective, socially oriented internet use, including communication with family and friends or participation in online social activities, may be particularly relevant to older adults' SRH because it supports emotionally salient connections that are central to well-being in later life.

At first glance, these findings suggest that interventions supporting older adults in acquiring internet skills may be relevant for supporting SRH. However, a closer examination highlights persistent digital gaps. Several studies in this review reported relatively low levels of internet use, particularly in studies that included a binary indicator of internet use (eg, Chen et al [46], Liu et al [60], Lyu and Sun [62], and Xiaobing and Meng [76]). Although internet adoption among older adults has increased over the past decade [33-35], evidence continues to point to a digital divide [80,81]. Digital divide frameworks conceptualize digital inclusion as a cumulative process that involves motivation to use digital technologies, physical access, and digital skills [82]. Consistent with this perspective, the divide reflects not only age-related barriers (ie, "gray" gaps), including negative attitudes toward technology, limited digital skills, lack of interest, and experiences of ageism [33,83,84], but also broader sociodemographic and structural disparities, including lower socioeconomic resources, lower education, poorer health, and disability [34-46,48-63,66-69,71-73,75-89]. As a result, it is important that interventions address access conditions, including infrastructure, devices, and affordability, as well as guidance and support that strengthen digital skills and enable safe and meaningful use. Such a combined approach may help reduce inequalities in opportunities for social connection, access to information and services, and potential health-related benefits.

Indeed, most studies in the review reported a positive association between internet use and SRH; however, 1 study reported a negative association [50], and 2 studies reported no significant relationship [63,71]. Duplaga [50] found that more frequent internet users were more likely to rate their health as poor, possibly reflecting a more critical self-appraisal associated with exposure to health-related content. It is therefore important to acknowledge that internet use may also entail potential risks for older adults. One concern is exposure to online health misinformation, which can lead to confusion, mistrust in health professionals, and potentially harmful health behaviors [90,91]. Additional risks include digital fatigue and information overload, which may contribute to cognitive strain and mental exhaustion [91-93], as well as cybersecurity threats, such as scams, fraud, and privacy violations, which can increase stress and reduce trust in digital technologies [94,95]. Together, these considerations highlight the need for digital literacy programs and supportive interventions to help ensure that internet use promotes, rather than undermines, older adults' health and well-being. Finally, the absence of a positive association between internet use and SRH in some studies may reflect background and contextual factors, such as socioeconomic resources (eg, income and education), cognitive ability, and the inherently subjective and multidimensional nature of SRH, which may be less responsive to behavioral influences such as internet use [63,71].
